There is no dispute that the above-quoted portion of the specification describes the process in claim 1 where the terms "suitable escape character" and "complimentary check character" are used. Rather, Sutton relies on general dictionary definitions and its own expert's testimony to urge broad definitions. Construing terms broadly based entirely on this sort of extrinsic evidence in the face of particular language within the specification is clearly improper under Phillips. Sutton's proposed definitions divorce the claim terms from the context of the patent. For instance, Sutton's definition of "suitable escape character" gives no indication what "special treatment" is indicated by an escape character when the process described above clearly explains the function and purpose of the claim term. Likewise, Sutton's proposed definition of "complimentary check character" generally defines "complementary" without addressing the particular context with which the term is used in the claims. The patent specifically describes, using the terms "TEC" and "second character," a process by which a 7 bit character (the "suitable escape character") is used to flag a transformed 7 bit character (the "complimentary check character") in order to avoid transmitting a prohibited character while retaining the original message. Accordingly, Nokia's proposed definitions are adopted, and "suitable escape character" is defined as "a 7-bit sequence used to indicate that a complimentary check character follows the sequence" and "complimentary check character" is defined as "a 7 bit sequence representing a transformation of a prohibited character."

In analyzing the language of the claim, the Court reiterates that the invention neither requires nor prohibits either internal illumination or dichroic mirrors, because the Court has already construed the lens to require neither a dichroic mirror nor internal illumination. Claim 1 of the '653 patent states that the invention is "comprising: a telecentric lens suitable for imaging said multi-sample plate positioned to collect light from said plate. . . ." ('653 patent, col. 5, In. 4-5). Defendant asserts that suitable may include size but, because the patentee did not specifically assert "size" and instead asserted "suitable," the term cannot refer only to size and, in particular, refers to the necessity for internal illumination and suitable for use without a dichroic mirror and, as such, does not have a plain and ordinary meaning.

In determining whether a claim is indefinite, the Federal Circuit has held, "a claim is not indefinite merely because it poses a difficult issue of claim construction; if the claim is subject to construction, i.e., it is not insolubly ambiguous, it is not invalid for indefiniteness." Bancorp Serv., L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367, 1371 (Fed. Cir. 2004). To be sure, claims need not "be plain on their face in order to avoid condemnation for indefiniteness; rather, what [this court has] asked is that the claims be amenable to construction, however difficult that task may be." Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001). Moreover, "[i]f the meaning of the claim is discernible, even though
the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds." Id. Claims are only found to be indefinite where reasonable efforts at construing the claim are in vain. Id. (stating that courts "protect the inventive contribution of patentees, even when the drafting of their patents has been less than ideal."). As such, "close questions of indefiniteness in litigation involving issued patents are properly resolved in favor of the patentee." Id. at 1380.

In the matter at hand, multi-sample plates describe contents from the vantage point of the samples whereas multi-well plates describe contents from the vantage point of the wells. Since multiple samples go into multiple wells, in this instance, the plate is the mechanism for holding the wells that contain the samples. Therefore, this Court concludes that the interchangeable use of the terms "multi-sample plate" and "multi-well plate" in claims 1-4 of the '653 patent does not preclude the construction of the claims or create indefiniteness.

Turning to the claim construction, the phrase "said multi-sample plate" refers, for example, in claim 1, directly to "a multi-sample plate having at least one sample in a recessed well." '653 patent, col. 21, In. 5-6. Claims 1-4 of the '653 patent specifically apply to a multi-sample plate with at least one recessed well. Although Plaintiff admits that generally the terms would have different meanings, a person skilled in the art would understand that these claims themselves are limited to plates with at least one recessed well. The multi-well feature is read by the Court as a limitation of the multi-sample plate for purposes of these claims. As such, the Court construes the entire disputed term as "can be used for creating an image of a multi-sample plate having at least one sample in a recessed well."

3. "Suitable for transmission"

Liquidnet construes "suitable for transmission" to mean "meeting the filtering criteria established by the traders and/or the electronic marketplace." 101 ITG/Pulse suggests a broader definition, construing the term to mean "appropriate for transmission." 102 I adopt ITG/Pulse's definition because suitable and appropriate are virtual synonyms. 103 As a result, the adopted definition is nothing more than the language of the claim, while Liquidnet's definition attempts to inappropriately narrow the claim.

While it is apparent from the specification that the patented method will often use a filtering module to determine what data is suitable for transmission, 104 it is also apparent that the patented method does not always use such filtering modules. This is disclosed by a portion of the specification which describes two embodiments of the patented method -- one where "all open orders are suitable for transmission" and another where a "filtering module" is used to determine what orders are suitable for transmission. 105 As ITG/Pulse argues, "Liquidnet's construction of 'suitable for transmission' accounts for the second embodiment but ignores the first." 106 Accordingly, it is inappropriate to limit the term "suitable for transmission" to the use of filtering criteria.

While it is apparent from the specification that the patented method will often use a filtering module to determine what data is suitable for transmission, 104 it is also apparent that the patented method does not always use such filtering modules. This is disclosed by a portion of the specification which describes two embodiments of the patented method -- one where "all open orders are suitable for transmission" and another where a "filtering module" is used to determine what orders are suitable for transmission. 105 As ITG/Pulse argues, "Liquidnet's construction of 'suitable for transmission' accounts for the second embodiment but ignores the first." 106 Accordingly, it is inappropriate to limit the term "suitable for transmission" to the use of filtering criteria.

104 See, e.g., Patent '834 col. 3 ll. 61-65 ("The OIM also preferably includes a filtering module for filtering out specified orders by security type, security name, order type, order price, order quantity, or other category, so that those orders are not
transmitted to the ETM."); id. col. 11, lines 22-27 ("In other embodiments of the present invention, the OIM, through the filtering module, makes the determination of suitable orders based on other criteria, such as the security type (e.g., stock or bond), security name (e.g., IBM or T), order type (e.g., market or limit order), order quantity, and/or order price.").

105 Patent '834 col. 11 ll. 18-27.106 ITG/Pulse Resp. at 20.

Instead, I adopt ITG/Pulse's broader construction of the term. While substituting the word appropriate for the word suitable does little to clarify the meaning of this term, the evidence does not permit a more exacting definition. The patented claim encompasses any means for determining whether a non-binding indication is appropriate for transmission -- including the use of a filtering module or simply allowing all non-binding indications generated from records of open orders to be transmitted.

4311

B. "Super Block"

One element of independent claims one and ten of the '918 Patent, and the remainder of the Asserted Claims (all of which depend upon those claims) is the formation of "super blocks." This is the only element of the Asserted Claims at issue here.

The Court construed "super block" to mean "two or more blocks that are used to store data, the two or more blocks having addresses that are correlated with a group of logical block addresses that is determined by the number of sectors in a block."

6 The parties do not seem to disagree that when the high-speed erase mode of the Fuji AIMS System is used, four physical blocks in four different physical chips are always erased together. (Niwano Decl., P 11; McAlexander Decl., Exh. A at 111 ("[w]hile the Fuji AIMS card can erase four blocks in parallel...") The parties do, however, dispute whether the four blocks are correlated with a group of logical block addresses ("LBAs").

6 A "block" is "erasable storage for a plurality of sectors."

GO BACK

4312

V. "super-block" -- '918 patent

The claim term "super-block" appears in only one of Lexar's patents-in-suit: the '918 patent, in independent claims 1 (and dependent claims 3, 4, 5, 7, and 9), 10 (and dependent claims 13, 14, and 15), and 17. Lexar and Toshiba respectively propose that "super block" be construed as follows:

Lexar's proposed construction: Two or more blocks that are used to store data, the two or more blocks having addresses that are correlated with a group of logical block addresses that is determined by the number of sectors in the blocks.

Toshiba's proposed construction: 11 A number of blocks that are in like locations of the different nonvolatile memory devices and residing in parallel with respect to each other.

- 4581 -
11 Pretec offers no proposed construction here. Pretec only proposes constructions for disputed terms in the '638 and '051 patents.

In the Preferred Embodiment section of the '918 patent, a particular embodiment of the invention is described and then the following language appears:

In this respect, a 'super' block is defined by a number of blocks that are in like locations of the different nonvolatile memory devices and residing in-parallel with respect to each other.

('918 patent, 9:11-15.) Toshiba contends that this language is an expression of the patentee's intention to act as his own lexicographer regarding "super block" and that it should serve as the construction of the term throughout the patent. Indeed, where an inventor defines a claim term "with reasonable clarity, deliberateness, and precision," that definition is understood to control the construction of the claim term. Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002). Here, however, the language relied upon by Toshiba, at column 9, lines 12-15 of the patent, is not such a definition. The "in this respect" language indicates that what follows is relevant only to a preferred embodiment of the invention and to adopt it as the universal construction of "super block" would be too restrictive as it would improperly import limitations from the preferred embodiment into the construction of the claim term itself. The Court therefore rejects Toshiba's proposed construction of "super block." The Court also notes that, as Lexar points out, to adopt Toshiba's construction would exclude a preferred embodiment, represented in Figure 5, which shows blocks positioned vertically, not "in parallel" with one another. This the Court declines to do.

The Court finds that Lexar's proposed construction here is the correct one. The Court therefore construes the term "super-block" as follows: two or more blocks that are used to store data, the two or more blocks having addresses that are correlated with a group of logical block addresses that is determined by the number of sectors in the blocks.

1. Super scaler cache

Both parties seek to define this phrase by incorporating specific elements of the claims into the definition of the term itself. However, the elements comprising the structure vary among the claims. Compare '003 patent at 7:35-55, with id. at 8:18-43. Thus, the Court cannot accept this construction approach and looks to the Patent Office examiner's characterization in the prosecution history. The Court construes "super scaler cache" as a cache capable of holding multiple instructions for issuing and executing in parallel. See Intel's Claim Construction Brief, Exhibit D, tab. 18, p. 3.

2. Super scaler storage

Intergraph contends no construction is required for this term, but that it should be given its ordinary meaning to one skilled in the art. Intergraph identifies this ordinary meaning as "storage such as a cache line, a register or other mechanism for holding one group of the groups of software-scheduled instructions, each software-scheduled instruction within the one group having embedded therein an instruction pipeline identifier of a plurality of instruction pipeline identifiers."

Incorporating its proposed definition of other terms, Intel similarly defines "super scaler storage" as a memory device adapted to hold one group of instructions where each instruction has a pipeline identifier embedded inside. The Court construes "super scaler storage" as a cache line, register, or other memory device capable of holding multiple instructions for issuing and executing in parallel. '003 patent 5:32-35.
B. Supervisory Signals

Similarly, the Court finds that "supervisory signals" must be given its ordinary meaning. The term commonly means signals that control the operation of a telephone system and indicate such information as whether the phone is on or off the hook. Def's. Ex. B; Def's. Ex. C at 23. Furthermore, the 848 patent does not define the term. It does, however, specify that such signals are produced by a telephone set and transmitted through a telephone line. Def's. Ex. A, col. 4, ll. 19-21. Thus, the Plaintiffs cannot now define the term to include "signals used to indicate the identity of a key actuation on a keypad." Paper 53 at 11. See Senmed, Inc. v. Richard-Allan Medical Indus., Inc., 888 F.2d 815, 819 n. 8 (Fed. Cir. 1989) (when term given its ordinary meaning in specification, self-serving testimony giving it a different meaning is of little or no significance). Accordingly, the Court finds that this term means "signals which are produced by a telephone set and sent through a telephone line."

1. "Supplemental display" is construed to mean a "display used to supplement the main display."

3. Claim 19 - supplemental voltage

Claim 19 of the patent depends from claim 17. Claim 19 recites:

19. The method of claim 17 wherein the primary voltage is V and each of the secondary voltage sources generates a supplemental voltage lower than V, further comprising passing the supplemental voltage to the voltage-controlled oscillator. ('876 patent, col. 9, ll. 48-52).

The only term requiring construction in claim 19 is the term "supplemental voltage." Fairchild contends that "supplemental voltage" means "voltage other than the primary or secondary voltage." Fairchild contends that each claim term must have meaning and therefore, the supplemental voltage must be a third voltage which is distinct from the primary and secondary voltages. (D.I. 156 at 37).

In response, Power Integrations contends that the term "supplemental voltage" does not require construction. Power Integrations contends that Fairchild's construction is inconsistent with the language of claim 17 and 19, because according to the plain language of claim 17, "one or more secondary voltage sources, together, generate a secondary voltage." (D.I. 152 at 14) (emphasis in original). Power Integrations also contends that the plain language of claim 19 indicates that each secondary source itself generates a supplemental voltage whose magnitude is lower than V, the magnitude of the primary voltage. Thus, the secondary voltage is the total of the supplemental voltages, each generated by one secondary voltage source. In this regard, Power Integrations contends that it is incorrect to construe supplemental voltage as something other than secondary voltage, as Fairchild contends. To the extent construction of this phrase is required, Power Integrations contends that the phrase should be construed as "a voltage in addition to the primary voltage." (D.I. 152 at 14).

Reviewing the disputed term in the context of the claim language and the specification, the Court agrees with the construction proposed by Power Integrations. Reading claim 17 and 19 together, the Court is persuaded that the secondary voltage is the total of the supplemental voltages which are each generated by one secondary voltage source. Thus, the Court construes the term "supplemental voltage" to mean "a voltage in addition to the primary voltage."
2. "supplied with a potential of"

Claims 7 and 15 contain the term "supplied with a potential of." Toshiba contends that the ordinary meaning of the phrase should apply. Jt Cl Const, Ex B at 20. Alternatively, Toshiba proposes that the phrase means "applied with a voltage of." Id. Hynix construes this term as "directly supplied with the potential of." Id (emphasis added). Again, Hynix seeks to read a limitation into the claim term, requiring that the potential be directly supplied.

Hynix's construction relies on a statement that the patentees made during prosecution of the related '267 patent. See supra "bit line" construction. The patentees distinguished prior art in which the potential of a certain transistor was less than the potential of a bit line by claiming that the '267 patent disclosed circuits supplying the same transistor with the same potential as the bit line. Doc # 14, Ex E at 2. Hence, Hynix argues the distinguishing and necessary feature of the '994 patent, which is virtually identical to the '267 patent, is that the transistor is "directly" supplied with the same potential as the bit line.

But a plain reading of the patent prosecution statement does not yield Hynix's construction. The patentees merely distinguished the prior art by stating that the '994 patent transistor is "supplied with the potential of the bit line" instead of the lower potential available under the prior art. Id. The patentees never said whether the potential is supplied directly or indirectly. Hence, the prosecution history cited by Hynix does not warrant an additional limitation that the "bit line" potential be supplied directly.

Because Hynix has not provided any reason why "supplied with a potential of" should be construed and Toshiba's proposed construction appears nearly identical to the term itself, the court declines to construe this term.

4. "Supporting the housing of the microprocessor in position relative to said docking connection means so that the single connector on the housing is coupled with said additional connection provided in the docking connection means"

Independent claim 17 is a method claim directed at interfacing a microprocessor with a plurality of peripheral devices. Subpart (e) of independent claim 17 recites the step of "supporting the housing of the microprocessor in position relative to said docking connection means so that the single connector on the housing is coupled with said additional connector provided in the docking connection means." '645 pat., col. 10, Ins. 35-39. Plaintiff argues that this phrase should be construed according to the ordinary meaning of the words used: the housing is supported and the single connector on the housing couples or mates with the connector on the docking module. Plt.'s Opening Br., dkt. # 84, at 15.

Defendants contend that claim 17 should be construed to require that the docking connection means holds the portable computer in a vertical position. They argue that subpart (e) of claim 17 should be construed as "supporting the housing of the microprocessor in a vertical position relative to the docking connector." Dfts.' Opening Br., dkt. # 86, at 18. In support of their construction defendants turn again to the prosecution history. They contend that the applicants waived any claim to a physical orientation of the housing other than vertical in order to obtain the '645 patent. Plaintiff contends that this construction is inappropriate because it ignores the plain language of claim 17 and violates the doctrine of claim differentiation. Plaintiff notes that independent claims 1 and 14 contain a vertical orientation limitation but independent claim 17 does not. Defendants contend that claim differentiation is inapplicable because claim 17 has a different scope from claims 1 and 14 because claim 17 is a method claim whereas claims 1 and 14 are apparatus claims.

I start with the language of the claims. Subpart (e) of claim 17 requires that the housing of the microprocessor be supported such that the single connector on the housing couples with the connector on the docking connection means. As defendants concede, there is no explicit language in claim 17 requiring the housing to be held in a vertical position relative to the docking connection means. In contrast, claims 1 and 14 require "a support holding the housing in a vertical position." '645 pat., col. 8, In. 55; col. 9, In. 65.
Turning to the prosecution history, defendants note correctly that, in the June 15, 1992 response to the patent examiner, the applicants distinguished their system from the patent issued to Herron in part by emphasizing that

the microprocessor housing drops into the docking module in such a manner as to permit the two connectors to mate. The docking module also has a support which holds the housing in a vertical or upright position to keep the connectors mated. It is simply the weight of the housing pressing down on the docking module which maintains the connection.

Aff. of Vito Canuso, dkt. # 87, exh. F, at 14. The applicants trumpeted the vertical orientation of the housing as an advantage because it reduced "the footprint of the system on the desk top." Id. at 15. In contrast, the Herron patent disclosed a docking module "which is latched to the rear of a laptop computer. The computer and docking module both rest on a desk top." Id. at 16. Thus, "the computer in Herron is not oriented vertically as in the Applicants' system." Id. at 17.

It is clear that the vertical orientation of the housing when resting in the docking module was one of the novel features of the applicants' system. However, as I noted in discussing the laptop exclusion, the applicants made it clear in the June 15 response that they were not incorporating all of the novel features of their invention into every independent claim in the patent. Instead, they stated only that each independent claim contained at least one point of novelty. Id. at 16. In the case of the laptop exclusion, it is not obvious which of the independent claims contain the exclusion because none of the independent claims contain language explicitly excluding laptop computers. Therefore, the only way to incorporate the limitation into the patent is to infer that it is inherent in the terms "portable computer" and "portable computer microprocessing system."

The situation is different with respect to the vertical orientation limitation, however. I need not infer that that limitation is inherent in all of the independent claims because the applicants indicated clearly which of the independent claims contain this novel feature. Claims 1 and 14 require "a support holding the housing in a vertical position." Claims 17 and 20 do not contain this limitation. Therefore, defendants are not persuasive when they argue that of the prosecution history supports the importation of a vertical orientation limitation into claim 17.

Defendants do not concede the point easily. They argue that where an applicant makes statements during the course of prosecution that limit the scope of his invention as opposed to specific embodiments thereof or claims in his patent, those statements apply to all of the claims in the patent. For support, they cite Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1312, 1318 (Fed. Cir. 1998). That case concerned a patented method for capturing, storing and displaying fingerprint images. At issue in that case was the claim term "slice data." The defendant argued that this term should be construed to mean data with an "active area" while the plaintiff argued that a "slice" encompassed more than an "active area." Id. at 1346. The court of appeals adopted the defendant's construction. It noted that the word "slice" was used "synonymously with 'active area' in two instances in the written description." Id. Also, the court looked to the prosecution history. In response to a rejection by the patent examiner, the applicants in Digital Biometrics added the word "slice" to one of their claims and distinguished their invention from prior art by Ruell with the following remarks:

Unlike the applicants' claimed invention, there is no provision for generating the composite array as a function of overlapping image portions of the finger. Similarly, Ruell does not teach a system which identifies active portions of the image which are representative of the fingerprint features as a mathematical function of the stored data, and generates the composite array as a mathematical function of the data representative of the identified active portions.

Id. at 1347 (emphasis in original). Instead of limiting these remarks to the claims in which the term "active area" appeared, the applicants had made them with respect to all of the claims that had been rejected. Accordingly, the court of appeals held that the limiting construction in the remarks applied to all of the claims that had been rejected. Id.; see also Honeywell International, Inc. v. ITT Industries, Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006)(limiting term "fuel injection system component" to fuel filter in part because patentees had referred to "invention" as fuel filter at four points in specification).

At the claims construction hearing in this case, defendants argued that the present case was analogous to Digital Biometrics because in both cases the applicants discussed distinguishing characteristics of their inventions, not specific claims or embodiments thereof. This is true up to a point. Although the applicants for the '645 patent discussed their "system" as having a docking module that held the housing in a vertical position in the June 15 response, they also made it clear that all of the points of novelty highlighted in the response were not present in all of the independent claims. The prosecution history is useful in determining how the applicants and the patent examiner understood the claims, Phillips, 415 F.3d at
1317, but it is inappropriate to import a limitation from the prosecution history into a claim whose language will not support that limitation. Sofamor Danek Group v. Depuy-Motech, 74 F.3d 1216, 1220 (Fed. Cir. 1996).

Accordingly, I will adopt plaintiff's proposed construction of the phrase "supporting the housing of the microprocessor in position relative to said docking connection means so that the single connector on the housing is coupled with said additional connection provided in the docking connection means." That phrase will be construed to mean that the housing is supported and the single connector on the housing couples or mates with the connector on the docking module.

4320

b. "Suppressing"

Murata argues that "suppressing" as used in claim 1 of the '641 Patent means "limiting, attenuating, claiming, shunting, or bypassing." Murata's Opening Brief, at 25. Bel Fuse argues that it means "eliminating or attenuating." Bel Fuse's Responsive Brief, at 18. Claim 1 recites "a printed board containing an electronic element for suppressing noise." The court construed "electronic element" above as "an electronic component," and the parties agree that "noise" is properly construed as "undesired electrical signals." Thus, Murata argues that "electronic element for suppressing noise" means "an electronic component which serves to limit, attenuate, clamp, shunt, or bypass undesired electrical signals." But Bel Fuse argues that it means "an electronic component for eliminating or attenuating undesired electrical signals."

Bel Fuse argues that Murata's construction of "suppressing" is overly broad. According to Bel Fuse, the specification of the '641 Patent does not teach noise suppression that occurs by shunting, bypassing, clamping, or limiting. The specification of the '641 Patent, Bel Fuse argues, teaches eliminating and attenuating noise. For example, when describing the first embodiment, the specification states:

In the modular jack with this structure, noise is suppressed by the common mode choke coils 24 built into the coil array 20. Specifically, common mode noise received through the contactors 35 is eliminated in the common mode choke coils 24, and thereby outgoing noise through the terminals 36 is suppressed.

Murata argues that "suppressing" as used in claim 1 of the '641 Patent is entitled to its entire ordinary meaning which includes: "limit, attenuate, clamp, shunt, or bypass." Murata relies on Dr. Hughes' expert report in which he opined that these terms are included within the ordinary meaning of "suppress." To reach this construction, Dr. Hughes relied on two dictionary definitions: one contained in Webster's New World Dictionary of American English 1346 ("suppress" means "keep back"; "restrain, check"; "eliminate or weaken") n9 and one contained in the Modern Dictionary of Electrocs ("suppress" means "elimination of unwanted signals or interference by means of shielding, filtering, grounding, component relocation, or sometimes redesign"; "the reduction to an acceptable level of a certain frequency or frequencies"). Hughes' Report, at 4-5. Dr. Hughes thus concludes that a noise suppressing electronic element in the context of the '641 patent is "an electronic component which serves to limit, attenuate, clamp, shunt, or bypass undesired signals (i.e., noise), and all equivalents thereof." Id. at 5. What is troubling about Dr. Hughes' construction is its conclusory nature. Phillips, 415 F.3d at 1318 ("[C]onclusory, unsupported assertions by experts as to the definition of a claim term are not useful to a court."). The terms "limit, attenuate, clamp, shunt, or bypass" do not appear in the dictionary definitions cited by Dr. Hughes, and he gives no explanation as to how he transformed the dictionary definitions into his proposed construction.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n9 While Murata provided the court with definitions of other terms from this dictionary, Ex. 30 to Murata's Opening Brief, at least in the copy provided to the court, it neglected to include the definition of this term. The court is therefore unable to review this definition in its original source or other entries for this term in this dictionary.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

In eliminating these terms from its proposed construction, Bel Fuse relies only on the preferred embodiments disclosed in
the '641 Patent which it states describe only "eliminating" and "attenuating" noise. Bel Fuse argues that the court should not include "shunt" or "bypass" because these operations would require additional circuitry not disclosed in the '641 Patent. Bel Fuse also argues that, since the patent does not discuss "clamping" or "limiting" noise, it is unclear what those terms would mean in the context of the patent. Because Bel Fuse relies only on the specification with no other supporting evidence, Murata argues that Bel Fuse's construction is "attorney argument." Murata's Reply, at 13.

However, because Dr. Hughes' report is conclusory and it appears that Bel Fuse is correct that the specification does not disclose shunting, bypassing, clamping, or limiting, the court adopts Bel Fuse's proposed construction of "eliminating or attenuating." \[n10\]

--- Footnotes ---

n10 The court notes its role in claim construction is to determine the meaning of the claim term from the viewpoint of a person of ordinary skill in the art. Because the parties' briefing on "suppressing" has been scant, and neither party has made clear the meanings of "shunting," "bypassing," "clamping," or "limiting," the court has been limited in its ability to construe the meaning of this term.

--- End Footnotes ---

4321

Surface mount light elements/ Surface mount semiconductor light elements

The term "surface mount light elements" appears in the '823 patent; "surface mount semiconductor light elements" appears in the '302 patent. Because of the "semiconductor" limitation in the '302 patent, Litepanels contends that two separate constructions are needed for each term. Gekko proposes the following construction for both terms: "light component designed to be soldered to a surface of a circuit board."

Regarding the '823 patent, the specification states that an advantage of the "surface mount" is the heat dissipation capabilities, "particularly as compared to non-surface mount LEDs which tend to dissipate heat typically through their leads." '823 patent, Col. 24:34-36. It teaches that using surface mount light elements provides a "larger and more direct heat conduction path to the mounting surface." Id. at Col. 24:37-38. While the specification describes the advantages of surface mounts, it does not provide a clear definition of the term.

Because the specification lacks clear guidance on the meaning of "surface mount," both Gekko and Litepanels based their proposed constructions on the Wiley Electrical and Electronics Engineering Dictionary's ("Wiley Dictionary") definition of "surface mount." The Wiley Dictionary defines surface mount as "a technology for mounting components and devices in which the connections are soldered to a surface, as opposed to having leads which pass through said surface." Wiley Electrical and Electronics Engineering Dictionary (2004).

When reading the advantages described in the specification together with the definition of "surface mount," Gekko's proposal is too broad. Gekko's construction excludes a key portion of the definition: "as opposed to having leads which pass through said surface." Gekko argues that the Wiley Dictionary's definition does not require the substrate to appear without holes; however, the specification contemplates otherwise. As discussed above, one of the main advantages of surface mounts are the increased heat dissipation because of the increased contact to the mounting surface. '823 patent, Col. 24:34-36. These advantages would be greatly diminished, and possibly nullified, if holes were drilled into the surface. Therefore, reading the claim in light of the specification of which it is a part, Gekko's proposed construction is improper.

Litepanels proposes the phrase means "a light emitting element where the electrical leads are designed to be soldered to a surface of a circuit board, rather than mounted through a hole in the circuit board." The first part of Litepanels's proposed construction tracks the Wiley Dictionary's definition. The second part of Litepanels's construction ties the specification in with the definition by excluding through-hole mounts.
Because the specification teaches the advantage of surface mounting is the lack of holes, the construction needs to include that limitation. Thus, the Court construes "surface mount light elements" to mean "a light emitting element where the electrical leads are designed to be soldered to a surface of a circuit board, rather than mounted through a hole in the circuit board."

The '302 patent claims contain a "semiconductor" limitation. As a continuation of the '823 patent, the '302 patent contains the same discussion of "surface mount" advantages. Gekko's universal construction removes the "semiconductor" limitation present in the '302 patent claims, which impermissibly broadens the claim language. Therefore, the Court construes "surface mount semiconductor light elements" to mean "a semiconductor light emitting element where the electrical leads are designed to be soldered to a surface of a circuit board, rather than mounted through a hole in the circuit board."

4322

B

The question on which the indefiniteness issue in this case turns is easily stated. All of the independent claims in the '792 patent refer to "surrender value protected investment credits for the life insurance policy." Hartford argues that the term "surrender value protected investment credits" is indefinite because the patent does not expressly define the term; because the meaning of the term cannot be inferred from anything in the patent; and because the term does not have a commonly understood meaning to persons of skill in the pertinent fields of art. Bancorp responds that the patent makes clear that the term "surrender value protected investment credits" means the same thing as "stable value protected investment credits," a term that is used throughout the patent, and that persons of skill in the pertinent art would so understand it. Both Bancorp and Hartford agree that the acronym "SVP," which is used throughout the patent, refers to "stable value protected investments." Bancorp argues that the acronym "SVP" also should be understood to refer to "surrender value protected investments," and that the terms "SVP," "stable value protected investments," and "surrender value protected investments" should all be understood to refer to the same concept.

We agree with Bancorp that the meaning of the term "surrender value protected investment credits" is reasonably discernible and that the asserted claims of the '792 patent are therefore not invalid for indefiniteness. It is true that the entire term "surrender value protected investment credits" is not defined in the patent, and Bancorp has not pointed us to any industry publication that defines the term. Nonetheless, the components of the term have well-recognized meanings, which allow the reader to infer the meaning of the entire phrase with reasonable confidence.

First, the term "surrender value" has a clear meaning to one of ordinary skill in the relevant art. Namely, as the district court noted, "surrender value" is generally interpreted to mean the value of all of the components of a life insurance policy minus any surrender charges and/or outstanding debt. See Bancorp Servs. v. Hartford Life Ins. Co., 2002 U.S. Dist. LEXIS 27200, No. 4:00-CV-70, slip op. at 15 (E.D. Mo. Feb. 13, 2002) (citing Barron's Dictionary of Insurance Terms 76-77 (4th ed. 2000)). Second, the specification of the '792 patent and the extrinsic evidence make it clear that the term "protected investment" refers to the underlying investment components of an insurance policy or policies whose return is stabilized over time in return for a fee. See '792 patent, col. 2, l. 59 to col. 3, l. 4. Finally, the specification makes clear the meaning of the word "credits." The specification explains that the invention "calculates credits due to the targeted return and a present daily investment value." Id. at col. 13, ll. 23-24. A "credit," therefore, is the difference between the actual value of an investment and the smoothed out or targeted return value of that investment. Viewing these components of the claim term together, it is reasonably clear that "surrender value protected investment credits" means the difference between the actual value of a protected investment and the targeted return value of that investment at the time the protected life insurance policy is surrendered. From this analysis, we conclude that the term "surrender value protected investment" is not indefinite, but instead has essentially the same meaning as the term "stable value protected investment," which the parties agree has a well-understood meaning as used in the '792 patent and in the field of stable-value investments.

In support of its argument that the patent makes clear the meaning of the term "surrender value protected investment credits," Bancorp points to dependent claims 4, 12, 23, and 32, and the portion of the specification that corresponds to those claims. Each of those claims recites "notifying a surrender value protected investment writer of the investment value and the value of the underlying securities for the current day." The portion of the specification that corresponds to that claim language states: "In step 1218, the system notifies the SVP writer of the current day's investment value and the value of the
underlying securities." '792 patent, col. 13, ll. 28-10. The correspondence between the claim language and the quoted language from the specification is so close, Bancorp argues, that the inference is inescapable that the term "SVP" is intended to be equivalent to the term "surrender value protected investment." Because it is undisputed that "SVP," as used in the '792 patent, refers at least to "stable value protected" investments, Bancorp argues that the correspondence between the claim language ("surrender value protected investment writer") and the language of the specification ("SVP writer") indicates that the terms "surrender value protected investment," "stable value protected investment," and "SVP" all mean the same thing as those terms are used in the patent.

We agree with Bancorp that the correspondence between the reference to "surrender value protected investment writer" in the specified claims and the reference to "SVP writer" in the portion of the specification relating to those claims provides substantial support for Bancorp's contention that, as used in the patent, the terms "stable value protected investment," "surrender value protected investment," and "SVP" are equivalent. Indeed, Hartford offers no satisfactory alternative explanation for the apparent correspondence between the term "surrender value protected investment" and the acronym "SVP" in claims 4, 12, 23, and 32, and the portion of the specification dealing with the subject matter of those claims.

Instead, Hartford seeks to counter that inference from the text of the patent by pointing out that the term "surrender value protected investment credits" is not defined, or even used, anywhere in the specification, and that each of the independent claims uses both the term "stable value protected investment" and the term "surrender value protected investment." The failure to define the term is, of course, not fatal, for if the meaning of the term is fairly inferable from the patent, an express definition is not necessary (although of course the inclusion of a definition would have avoided the need for this time-consuming and difficult inquiry into indefiniteness). See All Dental Prodx, LLC v. Advantage Dental Prods., Inc., 309 F.3d 774, 780 (Fed. Cir. 2002). The question therefore is whether, even in the absence of any express definitions, it is reasonably clear that the term "surrender value protected investment credit" means the same thing as "stable value protected investment credit."

With respect to that question, Hartford is correct that the use of both terms in close proximity in the same claim gives rise to an inference that a different meaning should be assigned to each. See Ethicon Endo-Surgery, Inc. v. U.S. Surgical Corp., 93 F.3d 1572, 1579 (Fed. Cir. 1996) (stating that if two terms described a single element, "one would expect the claim to consistently refer to this element [with one or the other of the two terms], but not both, especially within the same clause"). That inference, however, is not conclusive; it is not unknown for different words to be used to express similar concepts, even though it may be poor drafting practice.

In this case, moreover, the patent uses the two terms in slightly different ways, which may account for the choice of different language. Each of the independent claims refers to a "stable value protected investment" and then refers to "surrender value protected investment credits." Under Bancorp's interpretation of the claims, "stable value protected investment" refers to investments in which a guarantor, or SVP writer, would ensure a smooth rate of return by promising to make up any difference between the market value of the investments and the agreed-upon smoothed rate of return. The term "surrender value protected investment credits," on the other hand, refers to the credits necessary to make up any shortfall between the actual value of a particular investment at a particular time and the amount the SVP writer had promised to pay on that investment if the policy were surrendered at any particular time. Because of the difference in context, it may be that when referring to the investment the claim drafter intended to emphasize the stability feature (and thus used the term "stable value protected investment").

Addressing the use of the term "surrender value" in light of the meaning of that term in the insurance industry, Hartford argues that "surrender value" normally refers to the value of an entire policy, while a "stable value protected investment" refers only to the account within the policy that is subject to a stable value protected guarantee. Thus, Hartford contends that the two terms necessarily convey different meanings. Again, however, the difference in the way the two terms are used in the patent undercuts Hartford's argument. The reference to "surrender value protected investment credits" is plainly not a reference to the surrender value of the entire policy, but only to the credits allocable to the portion of the investment whose surrender value is protected--something that can easily refer to investments making up less than the entire surrender value of the policy. We therefore do not agree with Hartford that the text of the patent is at odds with Bancorp's argument that the
terms "stable value protected investment" and "surrender value protected investment" are synonymous. To the contrary, the evidence summarized above affords substantial support to Bancorp's interpretation of the claim language; and under that interpretation, the asserted claims are not invalid for indefiniteness.

GO BACK

4323

1. Substantially all of the blocks surrounding a point in the terrain seen from the current viewpoint within a predetermined distance range

The parties dispute two elements of this phrase: first, the meaning of "surrounding" and whether this word implies a three-dimensional sphere and a uniform distance from a point, and, second, whether the original viewpoint is included in the set of "points" referred to in Claim 9. Google proposes a construction of "substantially all of the excess data blocks describing three-dimensional terrain on all sides (in all directions) out to a pre-established distance from a point in the terrain that is seen from the current viewpoint," while Skyline suggests "substantially all of the blocks which include data covering terrain which is within a predetermined distance range in one or more directions from either the viewpoint or a point in the terrain visible from the current viewpoint."

a. Surrounding

To define "surrounding," Google suggests that the plain meaning of the word is to "enclose on all sides." The ambiguity latent in the term in this context is that the rendered display is somewhere between a two-dimensional and a three-dimensional object, so it is unclear whether a circle or a sphere would "surround" a point in the terrain. As Skyline correctly points out, Google's construction would imply that underground blocks of data would have to be downloaded for the "surrounding" data blocks to be considered gathered. It seems unlikely that this result was intended by the claim, because the '189 patent is primarily concerned with the rendering of surfaces with a minimal vertical dimension, not true three-dimensional terrain. Consequently, I find that "surrounding" does not imply a sphere surrounding a point on all sides, but a circle surrounding a point in two dimensions.

The next disputed issue with respect to "surrounding" is whether the area of excess blocks to be downloaded must necessarily be uniform in all directions (or whether a wider area of blocks could be pre-selected in the direction of travel, potentially creating an ellipse around a reference point, rather than a circle). n18 "Surrounding" is customarily read as encircling in a uniform manner, n19 and numerous references in the '189 patent support this reading. n20 At several points, the '189 patent mentions that the user can control the direction of view and look around in all directions, which necessitates downloading blocks in all directions. n21 Based on the common understanding of "surrounding," the specific use of the term and concept in the '189 patent, and the broader context of the claimed method and apparatus, I construe "surrounding" to mean all of the blocks within a uniform distance from the point in question.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

n18 I also note that the points in the terrain selected as the starting points in Claim 9 could be preferentially chosen based on the direction of travel. Although the blocks surrounding each point would be downloaded to a uniform distance, the points chosen could be weighted towards the direction of travel.

n19 See, e.g., Webster's Third New Int'l Dictionary (Unabridged) (1986) (listing as synonyms "encircle," "circle," "ring," and "encompass").

n20 See, e.g., col. 12, 11. 23-25 ("blocks, which are most preferably organized in a square centered directly below the location of the viewpoint"); col. 16, 11. 4-6 ("cache manager first downloads the eight blocks surrounding the block which is directly below the current viewpoint").

n21 See, e.g., col. 2, 11. 3-5 ("allowing the pilot to see the view seen at any point along the flight course at substantially any desired angle"); col. 2, 11. 19-21 ("A user may select at substantially each point along the route the direction of view and may change the direction dynamically"); col. 7, 11. 6-7 ("Preferably, the viewpoint is controlled by a user of the processor"); col. 11, 11. 9-10 ("there is no compulsory correlation between the flight direction and the view direction"); col. 15, 11. 63-
("if the queue is empty, cache manager fills cache memory with the blocks within the range of the current viewpoint, so that, for any direction of view from the current viewpoint, there is no need to download further blocks from the server") (emphasis supplied).

b. Point in the terrain

The next dispute in the construction of this phrase is whether the "current viewpoint" is a "point in the terrain seen from the current viewpoint," as Skyline argues. The plain language of the phrase makes clear that it is not. The current viewpoint is the current viewpoint. A point seen from the current viewpoint is inherently different from the viewpoint itself. Consequently, I reject Skyline's argument that the current viewpoint is also a point seen from the current viewpoint.

Finally, Google includes "excess blocks" in its construction. This term is unnecessary, as Claim 9, a dependent claim of Claim 7, only covers the download of excess blocks.

Construction: (substantially all of the blocks surrounding a point in the terrain seen from the current viewpoint within a predetermined distance range) Substantially all of the data blocks covering terrain within a uniform predetermined distance from a point in the terrain that is seen from the current viewpoint.

E-Watch proposes "a server-controlled network device that contains a sensor for monitoring an area and which generates and transmits an IP signal indicating a condition in the monitored area." This is the same construction as "sensor appliance." Defendant does not offer a definition, but suggests that the phrase "surveillance sensor appliance . . . for monitoring . . . and generating . . ." is a means plus function term.

The claim does not include the word "means," which invokes a presumption that 35 U.S.C. § 112 (6) does not apply. See Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004). "This presumption can be overcome if it is demonstrated that 'the claim term failed to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function.'” Id. at 1358 (quoting CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002)).

In the briefing, and at the hearing, March Networks failed to demonstrate that "surveillance sensor appliance" does not recite sufficient structure, or recites function without reciting sufficient structure. March Networks agrees that the term "sensor appliance" is not subject to § 112, P 6. The addition of the term "surveillance" does not suddenly make the term subject to § 112, P 6. The court concludes that this is not a means plus function term.

The court has already defined "sensor appliance." Some such appliances may send signals to the server but receive no return signal or command. But others, "controlled by the server," may react in response to commands. The specification describes steerable cameras. ' 183 patent col. 5, ll. 65-66. Upon detection of an event some devices may be activated. ' 183 patent, col. 6, ll. 59-61.

March Networks argues that a "surveillance sensor appliance" must be different from a "sensor appliance." Normally each word in a claim should have some meaning, and if the patentee uses "surveillance sensor appliance" that should be different than a "sensor appliance." See CAE Screenplates Inc. v. Heinrich Fiedler GmbH & Co. KG, 224 F.3d 1308, 1317 (Fed. Cir. 2000)("in absence of any evidence to the contrary, we must presume that the use of different terms in the claims connotes different meanings."). But the court should also presume the patent is valid and strive to construe the claim in light of the specifications.

When asked at the hearing, March Networks could provide no example in the specifications, nor from the point of view of one skilled in the art, of a sensor appliance that did not perform some type of surveillance of a condition, area, or event. Tr.
pp. 29-31. One might not think of a temperature or fluid level sensor as performing "surveillance" but the ordinary definitions of "surveillance" do not exclude that definition. And, the claim itself states that the "surveillance sensor appliance" in question is for "monitoring an area and generating a signal indicating a condition. . . ." This is among the functions described for "sensor appliances" in the specifications. See '183 patent, col. 35, ll. 29-36.

While it may have been less than perfect drafting, the court concludes that "surveillance sensor appliance" has the same meaning as "sensor appliance," as defined above. The court therefore defines the term as follows:

"Surveillance sensor appliance controlled by the server" means "a sensor appliance (as defined previously) which monitors one or more conditions or events in an area, and which can receive and respond to signals from a server."

(7) Suspending Operation of the Door Operation Commands of a Door Control System

The '628 Patent includes the term "suspending operation of the door operation commands of a door control system." The parties propose the following meanings to the words "suspending operation":

<table>
<thead>
<tr>
<th>Braun's Proposed Construction</th>
<th>VMI's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Rendering the door control system temporarily unresponsive to door operation commands.</td>
<td>Indefinite, as is &quot;selective delay.&quot; The only embodiment disclosed is intercept/transmit/echo.</td>
</tr>
</tbody>
</table>

As with the previous term, VMI fails its burden to establish indefiniteness. Moreover, VMI's proposed definition construes "selectively delay execution" and "suspending operation" to mean the same thing. Such an interpretation is contrary to claim construction rules as it would render another claim superfluous. See Comark Communications, Inc. v. Harris Corp., 156 F3d 1182, 1187 (Fed Cir. 1998) (finding a violation of the doctrine of claim differentiation when a proposed construction would render another claim superfluous). For example, claims 11 and 23 recite: "suspending operation of the door operation commands of a door control system to selectively delay execution of the door operation commands." If the Court were to accept VMI's proposed construction, the inclusion of both terms within the same claim would be redundant. Accordingly, the Court accepts Braun proposed construction: "suspending operation" means rendering the door control system temporarily unresponsive to door operation commands.

Nonetheless, at the last minute, and in an untimely way, Lucent requests the following claim construction of "auxiliary switch":

"Auxiliary switch" is a switch that does not control[] the converter's power flow," that is, power that flows from the primary winding to the secondary winding of the transformer and to the load."

Because Vicor has not challenged the timeliness of this proposed claim construction, the Court construes that term. The Court must begin with the claim language. Claim One requires an "auxiliary switch connected in series with said storage capacitor." Col. 8, lines 59-60. The specification provides:

More particularly, the invention relates to forward converters of the single ended type, in which the power flow from source to load is controlled by a single solid state switch.
The portion of the specification entitled "Summary of Invention" provides:

This invention provides new apparatus for resetting the transformer's core in single-ended forward converters. The apparatus consists of a storage capacitor, an auxiliary solid state switch (distinguished from the primary switch which controls the converter's power flow), and of a switch control circuit.

I construe the term auxiliary switch to mean a single solid state switch connected in series with the storage capacitor, which does not control (gate) power flow from source to load.

The word "switch" is a term understood by those of ordinary skill in the art, which Mr. Kesner defined as "means which provides a contact or provides an in circuit connection . . . between two components." (Tr. Vol. 33, 20-22.)

Mr. Kesner used Mars' definition of "in circuit" -- which the Court has rejected -- to describe the meaning of the word "switch." However, this does not change the fact that "switch" appears to be a common engineering term which would be understood by anybody of ordinary skill in the art. For this same reason, the Court does not construe "switch" as a means-plus-function element.

The parties next dispute the proper construction of the term "switch." NT proposes the following construction:

"A device, including mechanical, electrical, electronic or optical devices, which opens or closes circuits, completes or breaks a path, or selects paths or circuits."

Peerless would add the additional phrase "in 'real time' to set up calls based upon internal call control and service capabilities." NT argues that the term switch is a standard term of art with a well-accepted, ordinary meaning, reflected in NT's definition. Peerless offers nothing in support of its proposed additional elements of the definition, requiring the switch to operate "in real time" and "to set up calls based upon internal call control and service capabilities." Nor is any evidence for Peerless's proposed construction found in the patent itself, including the claims, specifications and prosecution history. Therefore, the Court construes the term "switch" as "a device, including mechanical, electrical, electronic or optical devices, which opens or closes circuits, completes or breaks a path, or selects paths or circuits."
1. "Switch" and "Optical Switch"

For the following reasons, this court construes the claim term "switch" in patent '772 claims 1 and 15, and "optical switch" in claims 2, 3, 5, 6, 7, 9, 10, 14, 17, 19, 20, 23, and 24 to mean:

A device to receive an optical signal from at least one input and route the optical signal to one of at least two outputs, or to receive an optical signal from one of at least two inputs and route the optical signal to at least one output.

In determining the construction of the terms "switch" and "optical switch," the court must consider whether differences among other asserted claims can assist the court's understanding of a term's meaning. Phillips, 415 F.3d at 1314. For example, when a dependent claim adds a limitation to an independent claim, it is presumed that the independent claim does not include the limitation. Id. at 1314-15.

Intrinsic evidence establishes that the term "switch" in claims 1 and 15 refer to an "optical switch," and therefore both "switch" and "optical switch" should be construed the same. Claim 1 in the patent application issued as claim 1 in the '772 patent. See TLIL0001033. (Nov. 29, 2007 Notice of Allowability.) The amendment and response submitted by the patentee, during the prosecution of the '772 patent and which subsequently led to the allowance of claim 1, clearly stated that the switch in claim 1 is an optical switch. Moreover, in overcoming an initial rejection of claim 1, the patentee explained that amended claim 1 is directed toward a system that comprises "an optical switch operable to optically couple the second optical line interface to (a) the first optical line interface through at least the optical demultiplexer, and alternatively (b) the second transponder." TLIL0000998, TLIL0001002. (Sept. 10, 2007 Office Action Resp. at 14, 18.) Thus, the patentee's explanations at each stage of the prosecution process show that "switch" in claim 1 means an "optical switch."

The meaning of the term "switch" in claim 15 is even more straightforward. Claim 15 is dependent on independent claim 14, which refers to an "optical switch." Because claim 14 is antecedent to claim 15 and claim 15 is dependent on claim 14, the "switch" in claim 15 is an "optical switch."

The specification also discusses the operation of various types of optical switches. (See '772 patent, col. 2:60-3:30; Fig. 1.) Specifically, the operation of the 1x2 switch is described as, "[w]hen in the first position, [lambda] 1 is provided to a transponder which transmits [lambda] 1 to a client apparatus via local port. When in the second position [lambda] 1 is provided to a pass-through port to a corresponding pass-through port in a peer OLT." ('772 patent, col. 2:66-3:3.) Similar descriptions are provided for 2x1 switch, 1xN switch and Nx1 switch. (See '772 patent, col. 2:10-34.) An optical switch therefore can receive an input signal and route the signal to one of multiple outputs, or a switch can receive multiple input signals and route the signals to one output.

Examining the scope of 3(C)(e) first, I find that its plain language, when read in light of the specifications, is not limited to a sliding mode selector switch. Claim 3(C)(e) reads that the audio recording and tape measuring system comprises:

a mode selector switch connected to the circuit controlling and processing means and movable between a RECORD and a PLAY mode, enabling the circuit controlling and processing means to establish the desired operation of the recording circuit.

Zircon argues that the language, "movable between a record and a play mode," requires a slide switch to be read into Claim 3(C)(e) because Claim 2(e), which also defines the mode selector switch, uses "selecting" instead of "movable between." I find that the specifications do not limit the term "movable between" exclusively to the action of a slide switch.

In making this determination, I have presumed that different language between claims signifies a difference in their meaning and scope and that I may interpret claims in light of the specifications that led to the patent. Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987). However, I note that I cannot read into a claim a limitation that appears only in a specification since the claim, not the specification, measures the invention. SRI Int'l. v. Matsushita Elec. Corp. of America, 775 F.2d 1107 (Fed. Cir. 1985). Furthermore, two claims which read differently may cover the same subject.
The specifications state that the mode selector's preferred embodiment "comprises a slide switch which is movable… between a PLAY position and a RECORD position." This differs from the antecedent basis for Claim 2(e) which calls for a mode selector button for mode selection. Despite this difference I refuse to read a slide switch requirement into Claim 3(e) because the specifications also state that "various alternate switch configurations can be employed…." This specification language clearly indicates that Claim 3(C)(e)'s "movable between" language does not necessarily require a slide switch, but allows for other types of switches.

These three limitations, considered together because of their interrelatedness, are the heart of the computer system contemplated in the invention, and the parties spent most of their time at the Markman hearing disputing the meaning of the terms "switch," "establishing the path," and "maintaining the path."

IBM's primary argument with regard to these limitations is identical to its argument concerning the message transfer circuit -- it contends that TM's use of the word "switch," which it believes to be amorphous as to structure, converts this part of the claim into a means-plus-function claim that is subject to the strictures of Section 112, para. 6. Again, I disagree, and for the same reasons as outlined above. A switch is a commonly understood to be a structure. It is a device for making, breaking, or changing connections in an electrical circuit. Like the word "brake," "clamp," or "screw," the name of the device connotes what it does. The commonly understood meaning of the word is cast in terms of its function. It is well settled that naming a function-specifying device in a patent claim is not sufficient to bring that claim within the ambit of Section 112, para. 6. See Ethicon Endo-Surgery, 91 F.3d at 1583; Implant Innovations, Inc. v. Nobelpharma AB, 1998 U.S. Dist. LEXIS 15794, No. 93 C 7489, 1998 WL 704188, *4 (N.D. Ill. Oct. 1, 1998).

TM did not patent a better means for making, breaking, or changing connections in an electrical circuit. It patented a computer system that is configured so as to route messages more efficiently. One of that system's component parts is a switch -- a switch that must be able to decode, establish, and maintain a path through the system. The switch is the structure that is used to accomplish a certain result. It is incorporated into the system in a particular way -- by connecting it to the input circuits, which are in turn connected to the communications links. This is more than sufficient for me to reject IBM's argument -- and with it, IBM's contention that the scope of this limitation is no broader than the embodiment disclosed in the patent.

I agree with TM that, in the Examiner's statement about "the router node as currently claimed and in the structure as currently claimed," the word "structure" refers to the computer system. I do not agree with IBM that this phrase indicates any intention on the part of the examiner to construe the limitation as a means-plus-function limitation. I also reject IBM's argument that I should construe "switch" in means-plus-function terms because the specifications do not use the word "switch." IBM cites no authority for that proposition, and as a matter of logic it makes no sense.

The path to be established by the switch must run from the input circuit that received the message to the "identified" output circuit. The switch "identifies" that output circuit by decoding some portion of the address element at the head of the message in order to determine the message's destination. The parties agree that "decoding" means examining and translating, or analyzing.

IBM argues that the switch as disclosed in the claim should be limited to one that decodes exactly one, and no more than one, address element. TM contends that this is one of those instances when "one" means "at least one" or "one or more than one," and points out that the preferred embodiment would be excluded if the limitation IBM urges were read into the claim. As TM notes, claim interpretation that would exclude the preferred embodiment is "rarely, if ever, correct and would require
highly persuasive evidentiary support." Vitronics, 90 F.3d at 1583. TM also argues that a switch that decodes more than one element of an address would necessarily infringe the patent, because it would have to decode "one" in order to decode "more than one."

IBM's evidence for a contrary result is not unpersuasive. First, the literal meaning of "one" is singular, not singular and/or plural. Despite the fact that "a" and "an" can apparently mean either the singular or the plural, at least in the patent context, see North Am. Vaccine v. American Cyanamid Co., 7 F.3d 1571, 1575-76 (Fed. Cir. 1993) (citing Robert C. Faber, Landis on Mechanics of Patent Claim Drafting 531 (3d ed. 1990)); Shell Oil Co. v. IC1 Americas, Inc., 33 F. Supp. 2d 523, 525-26 (E.D. La. 1999); Isogon Corp. v. Amdahl Corp., 47 F. Supp. 2d 436, 1998 WL 901723, *4 (S.D.N.Y. 1998)), there are plenty of ways to phrase something if both the singular and the plural are intended to be encompassed ("one or more," "one or more than one," and "at least one" all come to mind). Especially in light of the Federal Circuit's recent pronouncement on the subject, see WMS Gaming Inc. v. Int'l Game Tech, 184 F.3d 1339, 1999 WL 508800, *7 (Fed. Cir. 1999), the meaning of the word "one" would seem to be a very straightforward proposition.

Assigning a singular meaning of "one" seems all the more reasonable in light of the fact that claims canceled during prosecution of the '773 patent contained the phrase "at least one," while the eventual language of the patent is limited to "one." TM correctly notes that this matters to claim construction only if the particular language focused on is altered in order to escape an examiner's rejection. See York Products, Inc. v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1574 (Fed. Cir. 1996). However, TM's argument for why this particular alteration was of no consequence to overcoming the rejection -- namely, that the patentee "would have known that 'at least one' and 'one' were synonymous" (TM Reply Br. at 36) -- is neither self-evident nor particularly persuasive. Indeed, placing this limitation as originally filed side-by-side with the limitation as eventually allowed, it seems that the only substantive alteration was changing "at least one" to "one." Of course, this particular phrase is only part of the claim, and IBM conceded at argument that there are other differences between the patent as filed and as allowed. (See Tr. of Markman Hearing, Sep. 8-9, 1999, at 346.)

Finally, IBM argues that the claims calling for the decoding of "at least one" address element were rejected over the prior Lawrence '892 patent, and urges that this very phrase was the reason. It cites the Court to the appendix (A 2163-87) in support of its argument. In response, TM, citing the Examiner's Statement of Reasons for Allowance (A 2113), contends that this change was not the reason for the rejection. It points out that the Examiner said that the router node "will establish and maintain, after it receives enough of a message [which TM interprets to mean not just one element of a message] to determine an output circuit over which it will transmit the message, a path from the input circuit to the output circuit until the entire message has been established" (emphasis added).

I have reviewed the cited portions of the Joint Appendix, especially Figure 15 and its corresponding description at A 2183, and I find that they shed little light on the subject. It seems to me, however, that the single most persuasive piece of evidence on this point is the statement of the Patent Examiner himself. If his reason for rejecting the claim as initially filed was TM's use of the phrase "more than one" rather than "one," it is difficult to understand why he would have stated that the router node transmits the message "after it receives enough of a message to determine the output circuit . . ." (emphasis added). The words "enough of a message" are not limited to a single address element, and it would have been easy enough for the Examiner to say what he meant if he intended to so limit the invention. His choice of words seems especially pertinent because both parties agree that the preferred embodiment calls for the switch to decode more than one element. IBM is correct that there are occasions when it is both necessary and appropriate to construe a patent claim in a way that reads the disclosed embodiment out of the patent. See Ultra-Temp v. Advanced Vacuum, 11 F. Supp. 2d 141, 147 (D. Mass. 1998). This, however, does not seem to me to be such a case.

While the question is a close one, and IBM's presentation is impressive, especially as to the file wrapper estoppel point, I do not find the evidence supporting its argument to be "highly persuasive," as required by Vitronics. See Vitronics, 90 F.3d at 1583. I am therefore inclined to interpret "one" as encompassing both the singular and the plural. I confess that I reach this particular conclusion without much confidence (a la Judge Young in the EMC case), and I invite the parties to submit for my consideration anything that they have not already called to my attention that they believe would either buttress my holding or undermine it. It would be infinitely more helpful if the parties could cite me to a single item of correspondence from the Examiner to the patentee articulating the reasons why he disallowed the initial claims. To date, they have not done so.

That the path must run from the input circuit to the very output circuit that was identified in the decoding process is evident from the plain language of the limitation. It admits of no other interpretation. If that identified circuit is busy, then the head
of the message must proceed to a message buffer, which will be discussed later. It cannot be sent to some alternate address.

4332

14. A switch coupled to the data path and programmable to manipulate data received from the data path, the switch providing data streams to the data path.

The plaintiff asserts that this phrase should be construed to mean the following: "a routing device that is: (1) coupled to and receives data from the data path, (2) rearranges the data fields received from the data path in different ways in response to instructions by performing operations such as deals, shuffles, shifts, expands, compresses, swizzles, permutes, and reverses, and (3) provides the rearranged data fields to the data path." The defendants, however, urge that the disputed phrase should be construed more broadly to "hardware and/or software that performs data handling operations on unified media streams." They argue that the plaintiff's proposed construction imports limitations from the specification by requiring that the switch perform operations such as "deals, shuffles, shifts, expands, compresses, swizzles, permutes, and reverses." In the context of these patents, the court construes "a switch coupled to the data path and programmable to manipulate data received from the data path, the switch providing data streams to the data path" to mean "a routing device that is: (1) coupled to and receives data from the data path, (2) rearranges the data fields received from the data path in different ways in response to instructions, and (3) provides the rearranged data fields to the data path."

4333

D. THE MEANING OF "SWITCH MEANS."

The fourth disputed term is "switch means." With this term, there is disagreement between the parties as to whether it is in means-plus-function format. General Creation asserts that although use of the word "means" creates a presumption of means-plus-function format, the presumption is rebutted because there is only structural language in the claim and no indication of function. (Pls.' Br. at 16.) LeapFrog contends that the presumption is not rebutted because the claim language does recite a function and does not describe the structure of the element. (Def.'s Br. at 39.)

I find that this claim limitation is not in means-plus-function format. There is a presumption that § 112, para. 6, applies here given the "means" language and the claim language does recite the function of the "switch means." However, the presumption is rebutted because "switch means" is written with sufficient structural language.

The '213 claims provide the invention with a "switch means having at least a first condition and a second condition." ( '213 patent, col. 4, 11. 63-64.) "Switch means" is again described later in claim 1 in association with the "memory storage means":

(v) a memory storage means for storing electronic data corresponding to the written material on said pages of the book and the supplemental book, which storage means is electronically connected to said switch means and said first and second actuators and produces audio signals including:

(1) a first audio signal upon actuation of said first actuator when said switch means is in said first condition;

(2) a second audio signal upon actuation of said second actuator when said switch means is in said first condition;

(3) a third audio signal upon actuation of said first actuator when said switch means is in said second condition;

(4) a fourth audio signal upon actuation of said second actuator when said switch means is in said second condition;

( '213 patent, col. 4, 11. 65-67 & col. 5, 11. 1-15) (emphasis added.)

If a claim is in means-plus-function format, § 112, para. 6, provides that the claim elements are stated not in terms of
structure, but in terms of the function that the element performs. 35 U.S.C.A. § 112, para. 6. Here, the function of the "switch means" becomes clear by looking at its relationship with the "memory storage means." Specifically, the function of the "switch means" is to determine which audio signal the "memory storage means" produces, depending on which "condition" the "switch means" is in. The "memory storage means" actually produces the audio signal, but the "switch means" directs the "memory storage means" to play a particular signal. For example, if the "first actuator" is activated and the "switch means" is in "first condition," the "memory storage means" is directed to produce the "first audio signal." ( '213 patent, col. 5, 11. 4-6.) This function is further elaborated upon in the specification, where the "switch means" is described as the "control pressure switch" and the "memory storage means" is described as the "control unit":

The control pressure switch 76 is used to program the control unit 64 to play the audio signals of the particular audio response set which corresponds with the particular book being read.

( '213 patent, col. 3, 11. 22-25) (emphasis added.)

If the '213 patent claims described the function of the "switch means" without describing a corresponding structure, "switch means" would be in means-plus-function format and would be construed accordingly. However, "where a claim recites a function, but then goes on to elaborate sufficient structure, material, or acts within the claim itself to perform entirely the recited function, the claim is not in means-plus-function format." Sage Products, 126 F.3d at 1427-28. Here, the claim language recites sufficient structure to rebut the presumption that "switch means" is in means-plus-function format.

First, the term "switch" itself is a structural term. Dictionary definitions make it clear that a "switch" is a type of device that takes its name from the function it performs. See Merriam-Webster's Collegiate Dictionary, 1193 (10th ed. 1996) ("a device for making, breaking, or changing the connections in an electrical circuit"); Webster's II New Riverside University Dictionary, 1171 (2d ed. 1988) ("a device for breaking or opening an electrical circuit and for diverting current from one conductor to another"). Indeed, "many devices take their names from the functions they perform. The examples are innumerable, such as 'filter,' 'break,' 'clamp,' 'screwdriver,' or 'lock.'" Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1583 (Fed. Cir. 1996). The fact that "switch" "does not call to mind a single well-defined structure" is not dispositive. See id. What matters is that "the term, as the name for the structure, has a reasonably well understood meaning in the art." Id. Because the term "switch" itself imparts structure, its use rebuts the presumption that § 112, para. 6, applies. See also Cole, 102 F.3d at 531 (holding that "perforation means" is not in means-plus-function format because "perforation" describes the structure that performs the tearing function); Enviro Corp. v. Clestra Cleanroom, Inc., 209 F.3d 1360, 1365 (Fed. Cir. 2000) (holding that "baffle means" is not in means-plus-function format because "baffle" imparts structure sufficient to rebut the presumption that the term is in means-plus-function format).

While "switch" itself is a structural term, the claims further define the structure of the "switch." The "switch means" is described as "having at least a first condition and a second condition." ( '213 patent, col. 4, 11. 63-64.) The "switch means" is also "electronically connected" to the "memory storage means." ( '213 patent, col. 5, 1. 1.)

Construing "switch means" to be in means-plus-function format would also be inconsistent with the prosecution history of the '213 patent. The inventor's original claims, filed April 22, 1997, contained a "switching means," as it was then called, in claim 11, a dependent claim of claim 1. The claim language provided for a "switching means for designating an active response selected from the group consisting of said first response set and said second response set." (Pls.' Br. Ex. B at 20.) However, the claims were rejected as "being anticipated by [the] Weiner [patent]." (Id. at 34.) The patent examiner specifically noted that the "switching means" in claims 11 and 20 was met by Wiener. (See id.)

The inventor subsequently amended his claims on January 14, 1998, to overcome the rejection. The original "switching means" was brought into claim 1 and claim 1 provided for "a switch having a first position and a second position." (Id. at 40.) The "switch" was further described in relation to the "signal producing means," what is now known as the "memory storage means." (See id.) Similar to the '213 patent, the "signal producing means" produced a certain signal depending on what position the "switch" was in. Telephone conversations between the patent examiner and the inventor in April of 1998 resulted in the inventor submitting amendments on April 9, 1998. These amendments put the claim language in its present form and the '213 patent was issued. There were many changes made in the supplemental amendments, but there are only two changes relevant here. "Switch" was changed to "switch means" and "position" was changed to "condition." The description of the function of the "switch means" in relation to the "memory storage means" remained the same. There is no indication as to why these particular changes were made.

- 4598 -
This prosecution history does not support a construction of "switch means" as a means-plus-function element. The original claim language was clearly in means-plus-function format. A presumption arose given the "means" language, a function was clearly stated, and no structure was disclosed. However, this claim language was rejected as being anticipated by the Weiner patent. Thus, the inventor, in his first amendment, removed the word "means" and described "switch" in terms of its structure. In the second amendment, "means" was again added to the claim language, but additional description of the structure was also added. The "switch means" has a first and second condition and is electronically connected to the memory storage means. Thus, although "switch means" was originally a means-plus-function element, it did not return to that status again, despite the addition of the word "means." A description of the structure of the "switch" remains in the claim language, preventing a means-plus-function construction.

As "switch means" is not in means-plus-function format, I must construe it accordingly. I must start by analyzing the claim language itself. As described above, the claim language discloses that the "switch means" has a "first condition and a second condition" and is "electronically connected" to the "memory storage means." ( '213 patent, col. 4, 11.63-64.) The claim language does not further describe the form that the "switch means" takes. Thus, I must determine the ordinary meaning of "switch means" as determined by one of "skill in the art." Intellicall, 952 F.2d at 1387. Like "actuator," "switch means" is a broad term, capable of many interpretations. There are likely many toys that employ a switch which, depending on its position, determines the activity that the toy will perform. Thus, the ordinary meaning of "switch means" is "a structure that switches."

As this is the ordinary meaning, I must look to the specification to determine whether the inventor intended to deviate from the ordinary meaning. The specification provides the following description of the "switch means":

The toy may also be provided with a plurality of books and a switching means so that actuators cause the toy to read different stories depending on the particular book being read.

A control pressure switch 76 is located in an ear 78 of the toy 10 and connected by a wire 80 to the control unit 64.

To trigger the control unit 64 to provide audio signals which correspond to the particular book 92 being used, the control pressure switch 76 in the ear 78 is depressed the number of times indicated by the unique numeric code 124 .... The control pressure switch 76 is used to program the control unit 64 to play the audio signals of the particular audio response set which corresponds with the particular book being read. In the case identified in FIG. 1, the control pressure switch 76 would be depressed once to match with the unique numeric code 124 of the book 92.

Once the control pressure switch 76 has been depressed the appropriate number of times, the control unit 64 is thereby programmed to "read" the corresponding pages 130 of the supplemental book 126 as described above.

Similar to "actuator," the specification does not support a finding that "switch means" be construed as a "pressure switch," as LeapFrog contends. (Def.'s Br. at 46-47.) Instead, the specification is consistent with the broad ordinary meaning of "switch means."

First, pressure switches are not the only type of "switch" referenced by the inventor in the specification. The preferred embodiment focuses on pressure switches, but the summary of the invention uses only the general term "switching means." ( '213 patent, col. 1, 1. 61.)

Second, even if pressure switches were the only type of "switch" disclosed, as discussed above, it is the claims and not the specification that measures the invention. See SRI Int'l, 775 F.2d at 1122. Again, the analysis of Gentry Gallery does not...
Accordingly, "switch means" will be construed as "a structure that switches, has at least a first and second condition, and is electronically connected to the memory storage means." 

The Court agrees with Intel that this limitation should be construed as a means-plus-function limitation under 35 U.S.C. § 112, P 6. Mitchell argues that the "first switch means" is not a means-plus-function limitation. Mitchell contends that "switch" is a structural term and argues that claim 1 recites sufficient structure and location to perform the function of the "first switch means."

Mitchell cites Vitronics, 90 F.3d at 1584, for the proposition that the term "switch" is commonly used and understood as a structural element by those skilled in the art. Mitchell also points to the IEEE Dictionary, which provides multiple definitions of the word "switch," one being "a device for making, breaking or changing the connections in an electrical circuit." Mitchell contends that the use of the word "means" in association with the word "switch" does not necessitate the application of § 112, P 6. Mitchell also cites two district court opinions where courts found that "switch means" was not subject to § 112, P 6 because the claim language recited sufficient structure and or location to rebut the presumption of its application. See Gen. Creation v. Leapfrog Enters., Inc., 232 F. Supp. 2d 661,672-73 (W.D. Va. 2002); MediaCom Corp. v. Rates Tech., Inc., 4 F. Supp. 2d 17, 27 (D. Mass. 1998).

Mitchell further argues that the specification supports its contention that the "switch means" is not subject to § 112, P 6. Mitchell cites column 19, lines 38 through 41, which state, "These switches are utilized to connect the address, data and control lines necessary for the proper memory access between the buses," and column 19, line 64 through column 20, line 5, which state that each first through seventh switch means "actually represents a plurality of logical elements, each of which can logically connect or logically disconnect an address, data, or control circuit that is mechanically connected to the switch means. . . ." Finally, Mitchell contends that claim language itself identifies the location of the structure as between the dedicated memory address, data, and control circuits of the path configuring means and the sets of contacts.

Intel argues that the presumption that § 112, P 6 applies has not been overcome because the claim does not identify sufficient structure to perform all of the recited functions of the switch means. The parties do not dispute that the stated function of the "first switch means" is "for connecting said dedicated memory address, data, and control circuits of said path configuring means to each of said first three sets of contacts." Also, the claim provides that the "first switch means" is "comprised of three distinct parts." Therefore, as with "path configuring means," the question becomes whether the claim recites sufficient structure, material, or acts to perform the recited function.

In the context of the '154 patent, the word "switch" itself does not connote sufficient structure to overcome the presumption that § 112, P 6 applies. Unlike the district court cases cited by Mitchell, in Overhead Door Corp. v. Chamberlin Group, Inc., the Federal Circuit held that "second switch means" was subject to § 112, P 6 because "this claim element utilizes the term 'means' and the claim does not specify any structure or material for performing the recited function." 194 F.3d 1261, 1271 (Fed. Cir. 1999). The Federal Circuit did not find that the word "switch" provided sufficient structure to overcome the presumption that § 112, P 6 applied.

Contrary to Mitchell's argument, in deciding whether a particular limitation should be construed as a means-plus-function limitation or not, the issue is not solely whether a dictionary definition can be found for a term, but rather how a claim limitation should be construed in the manner intended by the drafter. Insofar as § 112, P 6 is concerned, an applicant has a choice whether to invoke both the advantages and disadvantages of presenting means-plus-function limitations -- or not. An applicant signals an intent to invoke the advantages and disadvantages of § 112, P 6 by using the word "means." Similarly, an applicant signals an intent not to invoke the advantages and disadvantages of § 112, P 6 by not using the word "means." Although the presence or absence of the word "means" is not necessarily dispositive, the Federal Circuit, drawing on the foregoing rationale, has explained that the presence or absence of the word "means" creates a rebuttable presumption that §
112, P 6 applies, or does not apply, respectively. The Federal Circuit has stressed that "[t]he use of the term 'means' is 'central to the analysis,' . . . because the term 'means,' particularly as used in the phrase 'means for,' is 'part of the classic template for functional claim elements,' . . . and has come to be closely associated with means-plus-function claiming." Lighting World, 382 F.3d at 1358. Accordingly, the Federal Circuit has labeled that presumption "a strong one that is not readily overcome." Id.

Here, the patentee has signaled that he intended to invoke § 112, P 6 by using the word "means." As noted above, there are cases in which it is clear that "means" added nothing to a claim, and that the patent drafter was simply enamored with the word "means." See e.g., Allen Eng'g, 299 F.3d at 1348; Cole, 102 F.3d at 531. As also noted above, here the patentee chose to use the word "means" in connection with limitation [2] "a path configuring means," limitations [9] and [10], i.e., "first" and "second" "switch means," and limitation [13] "means for causing. . . ." Thus, unlike cases such as Allen Engineering and Cole, the intrinsic record suggests that the drafter here chose selectively when to use -- and when not to use -- the word "means."

Thus, during prosecution, the patentee signaled his intention to invoke § 112, P 6 by using the word "means," and in doing so created the aforementioned "strong" presumption. Although that presumption is certainly rebuttable, Mitchell has presented no persuasive reason why the patentee should not be held to that choice, especially given that "switch" has both structural and functional connotations and that the patentee most frequently used "switch" in a functional context.

Mitchell, relying on an IEEE Dictionary definition of "switch," urges that "switch" is defined as "a device for making, breaking or changing the connections in an electrical circuit." But Mitchell does not rely on that definition in urging its proposed claim construction. Rather, Mitchell urges that the "first switch means" and "second switch means" limitations should be construed as:

The first switch means is a mechanism including one first part for connecting those circuits at one end of one path of the path configuring means to one distinct set of contacts and to disconnect those circuits from that one set of contacts. A second part of the mechanism acts by switching to connect those circuits at the end of a second path of the path configuring means to a second distinct set of contacts and to disconnect those circuits from that set. A third part of the mechanism acts by switching to connect those circuits at the end of a third such path of the path configuring means to a third distinct set of contacts and to disconnect those circuits from those contacts. Each part of the switch means connects and disconnects the memory address, data and control circuits of the path configuring means to or from one of the distinct sets of contacts.

The second switch means is a mechanism to connect the dedicated memory address, data, and control lines of the path configuring means to the dedicated memory address, data, and control lines of the CPU respectively, and to disconnect those lines from each other.

Thus, Mitchell proposes an expansive, functional construction having little to do with the proffered definition of "switch."

Claim construction is to resolve the disputed meaning of a term or phrase -- not an invitation for wholesale claim revision. Although it is recognized that Mitchell's functional description is patterned after Judge Illston's explanation of the function served by the "first" and "second" "switch means," the actual limitations of claim 1 simply provide:

[9] first switch means comprised of at least three distinct parts for connecting said dedicated memory address, data, and control circuits of said path configuring means to each of said first three sets of contacts, and

[10] second switch means for connecting said dedicated memory address, data, and control lines of said path configuring means to said dedicated memory address, data, and control lines of said CPU respectively.

That is, if Mitchell's argument that § 112, P 6 should not apply was accepted, elements [9] and [10] would simply be viewed without the word "means."

Second, Mitchell does not address the situation where a term can have both structural and functional connotations and seems to assume that if a term has a structural connotation the presumption should be deemed rebutted because using "means" results in a narrower construction than if "means" is not used. That is not necessarily the case.
In Overhead Door, for example, although the term "switch" had a structural connotation, the Federal Circuit recognized that "switch" also has a functional connotation that potentially prevails when used with "Means." See 194 F.3d at 1271. Moreover, Overhead Door illustrates that although "switch" may have a structural connotation as a noun, "switch" likewise has a functional connotation, and the structural connotation does not trump the patentee's choice to invoke § 112, P 6 by using "switch means," at least where there is no evidence in the intrinsic record to the contrary. Mitchell has pointed to no such evidence.

Third, the Federal Circuit looks to the specification to determine whether a term has been used to define structure. See Lighting World, 382 F.3d at 1361 ("it is clear that the parties in this case have used that term to denote structure. The written description of the [patent-in-suit], for example, uses the term 'connector assembly' as the name for structure."). Here, throughout the specification of the '154 patent, the most frequently used term is "switch means," rather than simply "switch." See Col. 19:53-60. The specification also explains that a "switch means" is a "switching device" under the control of the microcomputer. For example, the specification explains that "[t] he fifth switch means 112 is a switching device, under the control of the BICPU microcomputer, that can logically connect and logically disconnect the circuit between the common junction point and the 'B' bus circuits 128 . . .," Col. 20:44-49; "[t] he sixth switch means 114 is a switching device, under the control of the BICPU microcomputer, that can logically connect and logically disconnect the circuit between common junction point and the 'C' bus circuits 132 . . .," Col. 21:31-38. The specification thus indicates that the patentee did not use "switch" in "switch means" in a structural sense, but rather in a functional sense (i.e., a "means" for providing a "switch" function), and used another term for example "switching device," to refer to structure.

The patentee chose to use the word "means" thus signaling an intent to invoke § 112, P 6. That raises the presumption that § 112, P 6 applies. The term "switch" has both structural and functional connotations. If the patentee had wished to rely on the structural connotation, the patentee could have used "a switch," or a "switching device," or even a generic structural term, but did not. Rather, the patentee used "switch means," as he did throughout the specification, in a context indicating that "switch" was being used functionally, not structurally. Overall, Mitchell has not provided persuasive evidence that the presumption arising from using the term "means" has been rebutted. Compare Interspiro USA Inc. v. Figgie Int'l Inc., 815 F. Supp. 1488, 1504 (D. Del. 1993), aff'd, 18 F.3d 927,930-31 (Fed. Cir. 1994)(agreeing with the district court's construction of "detent means . . . for . . ." as a means-plus-function limitation), with Greenberg, 91 F.3d at 1584 (construing "detent mechanism" as defining structure, reasoning "[w] hile the language in the Interspiro case was in classic 'means-plus-function' format, the language in Dr. Greenberg's patent was not.").

Having concluded that the "first switch means" is a means-plus-function limitation governed by § 112, P 6, the Court construes the function of the "first switch means" as "connecting said dedicated memory address, data, and control circuits of said path configured means to each of said first three sets of contacts." See Micro Chem. II, 194 F.3d at 1258.

Judge Illston "construed" the function of the "first switch means" apparently due to a disagreement of the parties in which Mitchell was proposing a construction that did not differentiate between the "first" and "second" "switch means." Maurice Mitchell v. Samsung Elecs. Co., Ltd., slip op. at 19-20. Intel has now proposed a construction of the "function" of the "first switch means" that is identical to Judge Illston's construction, but with an addition that Mitchell opposes. Mitchell, while contending that "first switch means" should not be construed under § 112, P 6, has nevertheless proposed a construction that also substantively tracks Judge Illston's construction with minor changes, for example using "mechanism" rather than "means." To the extent that there was any previous disagreement as to the "three distinct parts," that disagreement no longer exists.

Both Mitchell's and Intel's proposed constructions use the identical language.

Claim construction is intended to resolve disputes between the parties on the meaning of claim terms and phrases. See Vivid Techs., Inc. v. Am Sci. & Eng'g, Inc., 200 F.3d 795, 803 (Fed. Cir. 1999) (" [O] nly those [claim] terms need be construed that are in controversy, and only to the extent necessary to resolve the controversy."). Because there is no longer any dispute between the parties there is no need for the Court to "construe" the "function" of limitation [9]. For the same reason, the Court rejects Intel's proffered addition to Judge Illston's construction.

Intel urges that the specification discloses no corresponding structure for performing the stated function. Judge Illston held the same. Mitchell, on the other hand, points to several places in the specification as allegedly disclosing such structure.

Intel suggests that this issue should be deferred to summary judgment. The Court agrees. The Federal Circuit has held that whether sufficient structure is disclosed in a specification must be based on the understanding of one skilled in the art, and
asserting that a means-plus-function limitation lacks structural support requires clear and convincing evidence because the consequence is invalidity. See Creo Prods, Inc. v. Presstek, Inc., 305 F.3d 1337, 1347 (Fed. Cir. 2002); Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1376-80 (Fed. Cir. 2001); S3 Inc. v. nVIDIA Corp., 259 F.3d 1364, 1371 (Fed. Cir. 2001); Atmel Corp. v. Info. Storage Devices, Inc., 198 F.3d 1374, 1382 (Fed. Cir. 1999). The Federal Circuit has further held that "corresponding structure" does not require a disclosure of specific circuitry. Intel Corp. v. VIA Techs., Inc., 319 F.3d 1357, 1366-67 (Fed. Cir. 2003).

Accordingly, the issue of whether there is (or is not) "corresponding structure" disclosed in the specification for performing the claimed functions, and if so what that structure may be, is deferred to summary judgment proceedings.

Claim construction is to resolve the disputed meaning of a term or phrase -- not an invitation for wholesale claim revision. Although it is recognized that Mitchell's functional description is patterned after Judge Illston's explanation of the function served by the "first" and "second" "switch means," the actual limitations of claim 1 simply provide:

[9] first switch means comprised of at least three distinct parts for connecting said dedicated memory address, data, and control circuits of said path configuring means to each of said first three sets of contacts, and

[10] second switch means for connecting said dedicated memory address, data, and control lines of said path configuring means to said dedicated memory address, data, and control lines of said CPU respectively.

That is, if Mitchell's argument that § 112, P 6 should not apply was accepted, elements [9] and [10] would simply be viewed without the word "means."

Second, Mitchell does not address the situation where a term can have both structural and functional connotations and seems to assume that if a term has a structural connotation the presumption should be deemed rebutted because using "means" results in a narrower construction than if "means" is not used. That is not necessarily the case.

In Overhead Door, for example, although the term "switch" had a structural connotation, the Federal Circuit recognized that "switch" also has a functional connotation that potentially prevails when used with "means." See 194 F.3d at 1271. Moreover, Overhead Door illustrates that although "switch" may have a structural connotation as a noun, "switch" likewise has a functional connotation, and the structural connotation does not trump the patentee's choice to invoke § 112, P 6 by using "switch means," at least where there is no evidence in the intrinsic record to the contrary. Mitchell has pointed to no such evidence.

Third, the Federal Circuit has looked to the specification to determine whether a term has been used to define structure. See Lighting World, 382 F.3d at 1361 ("it is clear that the parties in this case have used that term to denote structure. The written description of the [patent-in-suit], for example, uses the term 'connector assembly' as the name for structure."). Here, throughout the specification of the '154 patent, the most frequently used term is "switch means," rather than simply "switch." See Col. 19:53-60. The specification also explains that a "switch means" is a "switching device" under the control of the microcomputer. For example, the specification explains that "[t] he fifth switch means 112 is a switching device, under the control of the BICPU microcomputer, that can logically connect and logically disconnect the circuit between the common junction point and the 'B' bus circuits 128 . . .," Col. 20:44-49; "[t] he sixth switch means 114 is a switching device, under the control of the BICPU microcomputer, that can logically connect and logically disconnect the circuit between common junction point and the 'C' bus circuits 132 . . .," Col. 21:31-38. The specification thus indicates that the patentee did not use "switch" in "switch means" in a structural sense, but rather in a functional sense (i.e., a "means" for providing a "switch" function), and used another term, for example "switching device," to refer to structure.

The patentee chose to use the word "means" thus signaling an intent to invoke § 112, P 6. That raises the presumption that § 112, P 6 applies. The term "switch" has both structural and functional connotations. If the patentee had wished to rely on the structural connotation, the patentee could have used "a switch," or a "switching device," or even a generic structural term, but did not. Rather, the patentee used "switch means," as he did throughout the specification, in a context indicating that "switch" was being used functionally, not structurally. Overall, Mitchell has not provided persuasive evidence that the
premise arising from using the term "means" has been rebutted. Compare Interspiro USA Inc. v. Figgie Int'l Inc., 815 F. Supp. 1488, 1504 (D. Del. 1993), aff'd, 18 F.3d 927,930-31 (Fed. Cir. 1994)(agreeing with the district court's construction of "detent means . . . for . . . " as a means-plus-function limitation), with Greenberg, 91 F.3d at 1584 (construing "detent mechanism" as defining structure, reasoning "[w] hile the language in the Interspiro case was in classic 'means-plus-function' format, the language in Dr. Greenberg's patent was not.").

Having concluded that the "first switch means" is a means-plus-function limitation governed by § 112, P 6, the Court construes the function of the "first switch means" as "connecting said dedicated memory address, data, and control circuits of said path configuring means to each of said first three sets of contacts." See Micro Chem. II, 194 F.3d at 1258.

Judge Illston "construed" the function of the "first switch means" apparently due to a disagreement of the parties in which Mitchell was proposing a construction that did not differentiate between the "first" and "second" "switch means." Maurice Mitchell v. Samsung Elecs., Co., Ltd., slip op. at 19-20. Intel has now proposed a construction of the "function" of the "first switch means" that is identical to Judge Illston's construction, but with an addition that Mitchell opposes. Mitchell, while contending that "first switch means" should not be construed under § 112, P 6, has nevertheless proposed a construction that also substantively tracks Judge Illston's construction with minor changes, for example using "mechanism" rather than "means." To the extent that there was any previous disagreement as to the "three distinct parts," that disagreement no longer exists. Both Mitchell's and Intel's proposed constructions use the identical language.

Claim construction is intended to resolve disputes between the parties on the meaning of claim terms and phrases. See Vivid Techs., Inc. v. Am Sci. & Eng'g, Inc., 200 F.3d 795, 803 (Fed. Cir. 1999) ("[O] nly those [claim] terms need be construed that are in controversy, and only to the extent necessary to resolve the controversy."). Because there is no longer any dispute between the parties there is no need for the Court to "construe" the "function" of limitation [9]. For the same reason, the Court rejects Intel's proffered addition to Judge Illston's construction.

Intel urges that the specification discloses no corresponding structure for performing the stated function. Judge Illston held the same. Mitchell, on the other hand, points to several places in the specification as allegedly disclosing such structure.

Intel suggests that this issue should be deferred to summary judgment. The Court agrees. The Federal Circuit has held that whether sufficient structure is disclosed in a specification must be based on the understanding of one skilled in the art, and asserting that a means-plus-function limitation lacks structural support requires clear and convincing evidence because the consequence is invalidity. See Creo Prods, Inc. v. Presstek, Inc., 305 F.3d 1337, 1347 (Fed. Cir. 2002); Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1376-80 (Fed. Cir. 2001); S3 Inc. v. nVIDIA Corp., 259 F.3d 1364, 1371 (Fed. Cir. 2001); Atmel Corp. v. Info. Storage Devices, Inc., 198 F.3d 1374, 1382 (Fed. Cir. 1999). The Federal Circuit has further held that "corresponding structure" does not require a disclosure of specific circuitry. Intel Corp. v. VIA Techs., Inc., 319 F.3d 1357, 1366-67 (Fed. Cir. 2003).

Accordingly, the issue of whether there is (or is not) "corresponding structure" disclosed in the specification for performing the claimed functions, and if so what that structure may be, is deferred to summary judgment proceedings.

"second switch means for connecting said dedicated memory address, data, and control lines of said path configuring means to said dedicated memory address, data and control lines of said CPU respectively"

The Court agrees with Intel that this limitation should be construed as a means-plus-function limitation under 35 U.S.C. § 112, P 6. As with the "first switch means," Mitchell argues that "second switch means" should not be construed as a means-plus-function limitation under § 112, P 6. Mitchell provides essentially the same arguments as it did in reference to "first switch means," except that here, Mitchell argues that the claim language identifies the location of the "second switch means" between the dedicated memory address, data, and control lines of the path configuring means and the dedicated memory address, data and control lines of the CPU. However, for the same reasons discussed above with regard to "first switch means," "second switch means" is construed as a means-plus-function limitation under § 112, P 6.

Similarly, also for the same reasons discussed above, the Court declines to adopt the parties' proposed "constructions" of the stated function, as well as Intel's proposed additional language. The stated function of the "second switch means" is "connecting said dedicated memory address, data, and control lines of said path configuring means to said dedicated memory address, data and control lines of said CPU respectively."
Also for the reasons discussed above, the issue of whether there is (or is not) "corresponding structure" disclosed in the specification for performing the claimed function, and if so, what that structure is, is deferred to summary judgment proceedings.

9. Claim 10: "switched" "Switched" is construed to mean "the mode in which the bypass is on or utilized."

D. Switched Telephone Network

Protus requests that the Court construe the term "switched telephone network" as the circuit switched telephone network." Catch Curve argues that the Court should construe the term as "a system for handling telephone calls."

As discussed above, the Court finds that the asserted claims require the use of facsimile protocol - a digital dialogue over the "switched telephone network." The patents confirm that the term "switched telephone Network" refers to the standard worldwide telephone network, and hot the packet switched network used for sending e-mails. (Roberts Decl. at 12.) "Moreover, the file history indicates that, in trying to overcome "a prior art rejection, the patentee argued that "the present application and invention presumes the existence of a switched telephone network." (Protus Ex. G, at CC_P 124677.)

Protus requests that the Court insert the "switched telephone network" term into the definition of all fax-related claims. However, the Court does not believe this is necessary. When a machine operates using "fax protocol," it necessarily is sending fax messages over the switched telephone network. By including the terra "fax protocol" in the fax-related terms, the Court has already complied with Protus' request.

Furthermore, the Court agrees with Catch Curve that Protus' definition is redundant. However, the Court does not agree that the "switched telephone network" term can have the broad definition that Catch Curve proposes. Thus, the Court finds that the term "switched telephone network" may be understood according to its ordinary and customary meaning and does not require construction.

14. Switched wide area network

The parties do not dispute the meaning of the term "switched." Foundry submits that a "wide area network" is defined as "a communications network designed for large geographic areas." Lucent urges the court to construe "switched wide area network" to mean "a switched data network that covers a large geographic area." After considering the submissions of counsel, the court construes "switched wide area network" to mean "a switched communications network designed for large geographic areas."

During claims construction, the court construed the terms "port," "switching/ transferring," and "session." The parties agreed on the construction of "PPP state," "PPP session" and "dormant/dormant PPP session," and the court adopted the agreed-upon construction of those terms.

The court construed "port" as "a defined physical or logical connection where data enters or leaves a network device."
The court construed "switching" and "transferring" as "shifting or reassociating PPP state to another session associated with the new call set-up message."

The court construed "session" to be "a PPP session."

The parties' agreed upon construction of "PPP Session" is "the time during which a communications device and a network access server are maintaining a negotiated PPP state."

The parties' agreed upon construction of "PPP State" is "a set of parameters negotiated pursuant to PPP sufficient for a PPP session."

Based on the parties' agreement at the claims construction hearing, the court construed "dormant" as "no active data transfer for a predetermined period of time allowing reallocation of resources, but from which active data transfer can resume more efficiently than it could from an inactive state."

Based on the parties' agreement at the claims construction hearing, the court construed "dormant PPP Session" as "a PPP session in a dormant state."

9. User Actuated Switching Means

The Court finds that the term "user actuated switching means" in Claims 1, 8, and 13 invokes a means-plus-function limitation. The presumption of a limitation has not been rebutted by the inclusion of a structure sufficient to perform the function of switching the computer system between the three states described in the claims while preventing the transfer of data between the networks. Therefore, the Court looks to the specifications to determine whether there is some corresponding structure necessary to perform that function.

Citec notes that the Patent provides examples of a switch as a switching means: "A user chooses between the activating of two networks by using a two position switch which activates one of the networks or the reset switch." Col. 2, ll. 10-13. The Patent identifies the type of two position switch more particularly as a "rotary, rocker, or push button." Col. 2, ll. 13-14. The file history contains an Amendment dated January 29, 1998, which adds the limitation "user actuated" to the term "switching means" in Claims 1, 8, and 13. The Remarks to the Amendment indicate clearly that the present invention provides a computer system which employs a user actuated switching means, which may either be a mechanical switch or a password security system/software program, to switch the computer between a first network state, a second network state, and a reset state. The '551 Patent however omits any reference to the use of a password security system or software program to perform the function of switching the computer between states.

Romtec defines the phrase by reference to the specifications as "a rotary, rocker or push button two position switch constructed so that it is impossible to switch between the two networks before first activating the reset switch to prevent data from being transferred between two networks." See Col. 2, ll. 13-18. It notes that in the preferred embodiment, the switching means is coupled to the first and second networks by lines that connect to the interrupt request 31st line and the chip select zero 37th line of the storage means, and to the network cards through activate lines, and that "coupled" in that context is depicted as cuts to lines. See Col. 3, ll. 34-38, 42-44. This structure appears to perform the function of switching the computer between the three states described in the claims. Therefore, the Court adopts Romtec's proposed claim construction and construes the term "user actuated switching means" to mean a rotary, rocker, or push button two position switch (1) actuated by a user, (2) coupled to the first and second networks and to the network cards in the manner described in the specifications (as the term "coupled" is defined below), and (3) constructed so that it is impossible to switch between the two networks before first activating the reset switch to prevent data from being transferred between the networks, and equivalents.
14. "switching means"

The parties dispute whether "switching means" is a means-plus-function limitation governed by 35 U.S.C. § 112 P 6. MOSAID acknowledges, as it must, that the claim term includes the word "means" and, therefore, is presumptively a means-plus-function limitation. CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002). But MOSAID argues that this presumption is rebutted for one of two reasons: 1) the term itself is structural, and 2) even if it is not structural, the claim recites sufficient structure for the identified functions. Defendants on the other hand argue that this term is a means-plus-function limitation because it is not a structural term and fails to recite sufficient structure for each function identified in the claims.

MOSAID argues that the term "switching" is structural in nature. MOSAID asserts that even if "switching" does not call to mind any particular structure to one of ordinary skill in the art, as long as it imparts structure of some fashion it is sufficient to rebut the means-plus-function presumption. (1/5/04 MOSAID Opp. Br. at p. 47). According to MOSAID, a "switching means" is structural because it means a circuit or apparatus that employs switches.

MOSAID cites to three cases where claim terms including the word "means" were found not to be means-plus-function limitations because, in addition to the structure recited for performing the claimed functions, the terms themselves were structural in nature. Cole v. Kimberly-Clark Corp, 102 F.3d 524, 530-31 (Fed. Cir. 1996) (construing the term "perforation means"); Envirco Corp. v. Clestra Cleanroom, Inc., 209 F.3d 1360, 1364-65 (Fed. Cir. 2000) (construing the term "baffle means"); General Creation LLC v. Leapfrog Enters., Inc., 232 F. Supp. 2d 661, 671-73 (W.D. Va. 2002) (construing the term "switch means"). In each of those cases, the court found that the term, e.g., perforation, baffle and switch, possessed an ordinary meaning that imparted structure and thus rebutted the presumption that § 112 P 6 applies.

In this case, however, the word "switching" is not structural in nature; it is a verb that expresses action. In fact, one of MOSAID's cases distinguished between "switch means," which it considered structural, and "switching means," which it stated "was clearly in means-plus-function format." Leapfrog Enterprises, 232 F. Supp. 2d at 673; see also Overhead Door Corp. v. Chamberlain Group, Inc., 194 F.3d 1261, 1271 (Fed. Cir. 1999) (finding that "first switch means" and "memory selection second switch means" were properly considered by the district court to be means-plus-function limitations).

Further, MOSAID has failed to carry its burden of showing that the ordinary meaning of the term "switching" is structural in nature. In sharp contrast to the cases that MOSAID cites to, where the parties submitted dictionary definitions to show that the ordinary meaning of the word contained structure, MOSAID fails to submit a dictionary definition showing that the word "switching" is structural. Instead, MOSAID asserts through attorney argument that the ordinary meaning of "switching means" is a circuit or apparatus that employs switches. Accordingly, MOSAID's argument that "switching means" is itself structure is insufficient to overcome the presumption of § 112 P 6.

MOSAID also contends that "switching means" is not a means-plus-function limitation because the claim recites sufficient structure to perform the claimed function. In order to determine the function or functions of the claim term "switching means," the particular claim language must be examined. Claim 1 of the '201 patent, which includes the claim term "switching means," recites in relevant part:

Switching means including a first switch between one level of the voltage supply and the first terminal of the boosting capacitor and a second switch between the first terminal of the boosting capacitor and a capacitive load, the first and second switches being driven by clock signals, the switching means alternately connecting the first terminal of the boosting capacitor to the voltage supply and to the capacitive load while alternating the level of the voltage supply connected to the second terminal of the boosting capacitor to pump the voltage on the capacitive load to a boosted voltage level greater than and of the same polarity as the DC voltage supply to provide a boosted voltage supply. '201 patent, claim 1 (emphasis added).

MOSAID contends that the claimed function is "to pump the voltage on the capacitive load to a boosted voltage level greater than and of the same polarity as the DC voltage supply." 31 MOSAID then relies on this function to argue that sufficient structure is identified in the claim to rebut the means-plus-function presumption.
31 Originally, MOSAID identified the claimed function as including "alternately connecting the first terminal of the boosting capacitor to the voltage supply and to the capacitive load." (7/18/03 MOSAID's Reply Exh. A at p. 15). MOSAID never revealed to this Court why it discarded that function for its current, proposed function.

MOSAID's asserted function misconstrues the plain claim language. MOSAID's identified function is not a function, but a result of the functions that the "switching means" performs. Claim 1 of the '201 patent requires the "switching means" to perform two different functions. First, it "alternately connect[s] the first terminal of the boosting capacitor to the voltage supply and to the capacitive load." '620 patent, claim 1. Second, it "alterna[es] the level of the voltage supply connected to the second terminal of the boosting capacitor." Id. When the switching circuit performs these two functions, the result is that the voltage level in the capacitive load is boosted higher. See, e.g., '201 patent, col. 4, 1.51 - col. 5, 1. 9.

Having identified the claimed functions, the Court must then identify the corresponding structure for each of those functions. Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1376 (Fed. Cir. 2001); Epcon Gas Sys., Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1033 (Fed. Cir. 2002) ("The district court did not err in requiring that 'corresponding structure' include at least that structure necessary to perform each of the functions recited as being performed by the 'control means' in claim 16."). Although the claim does recite structure that corresponds to the first function of "alternately connecting," i.e., the first and second switches, the claim does not recite any structure for the second function of "alternating the [voltage] level." This lack of structure confirms that "switching means" is indeed a means-plus-function limitation, and requires the Court to look to the specification to identify corresponding structure.

"Structure disclosed in the specification is 'corresponding' structure only if the specification or prosecution history clearly links or associates that structure to the function recited in the claim." B. Braun Med., Inc. v. Abbott Labs., 124 F.3d 1419, 1424 (Fed. Cir. 1997). The parties agree that the structure for the first function includes transistors 23 and 24, and the structure for the second function includes 25 and 26. 32 Defendants, however, also contend that the clock signals, e.g., [PHI][1]<+> and [PHI][2]<+>, that drive those transistors are corresponding structure. MOSAID disagrees and argues that clock signals are voltage levels and, therefore, cannot be corresponding structure. MOSAID has the better argument. The clock signals are clearly voltage levels that are applied to the gates of the transistors. See, e.g., '201 patent, col. 4, 11. 8-11. Therefore, the structure identified by the written description corresponding to the first function is transistors 23 and 24, and the structure corresponding to the second function is transistors 25 and 26.

32 The Court agrees that these transistors are corresponding structure as recited by the written description of the '201 patent. '201 patent, Fig. 3 and col. 3, 1.35-col. 5, 1. 49.

Lastly, the Defendants argue that the patentees disclaimed the use of clock sources to charge the boosting capacitor in the "switching means." The disclaimer of clock sources to charge the boosting capacitor was discussed earlier in the context of the '620 patent. See Section 11 supra. Since the '201 patent is related to the '620 patent, having issued from an application that was a continuation of the '620 application, its specification is materially identical to the '620 specification. Applied Materials, Inc. v. Advanced Semiconductor Materials Am., Inc., 98 F.3d 1563, 1579 (Fed. Cir. 1996) (Mayer, J., concurring) ("By definition, a continuation adds no new matter and is akin to an amendment of a pending application."). Accordingly, for the same reasons articulated above that found a disclaimer applies, the same disclaimer "without using clock sources to charge the boosting capacitor" applies to "switching means."
The specification defines the switching member as a transistor. (621 patent, col. 6, ll. 57-58) The court shall apply the ordinary definition of the word "transistor." The term "transistor" means "a solid state electronic device that is used to control the flow of electricity in electronic equipment." 2

The phrase "switching member" shall be construed to mean "a solid state electronic device that is used to control the flow of electricity in electronic equipment."

Footnotes

4343

1. "switching network . . . for establishing a communications link"

The text of claim 14 is set forth below with the key disputed term highlighted in bold type.

A multiprocessor computer system comprising:

a. a plurality of processing units;

b. at least one data storage array system, each having at least one array controller;

c. at least one switching network, coupled to the plurality of processing units and to at least one array controller of at least one data storage array system, for establishing a communications link between at least one selected processing unit and at least one data storage array system.

HP asks the Court to construe this term as: "A component or set of components to which multiple nodes can attach and that selectively enables giving, receiving, or exchanging of information, signals and/or data among attached nodes." EMC proposes: "A circuit switch, not contained within a data storage array system, that is capable of establishing a dedicated path from any input node of the switch to any output node of the switch." The critical dispute between the parties is whether the term "broadly covers both circuit switching' and packet switching" or whether it is limited to "circuit switching." EMC's Response to HP's Opening Claim Construction Brief ("EMC's Response"), p. 12.

The plain language of the claim indicates that a switching network establishes a communications link between the processing units and the data storage array system by coupling to them and that a plurality of processing units is coupled to a switching network. Thus, there must be multiple connection points between the processing units and the switching network. This conclusion is consistent with HP's construction.

Nothing in the claim language limits "switching network" to a particular type of "switch." The switching network only need be coupled to the processing units and the data storage array system by coupling to them and that a plurality of processing units is coupled to a switching network. Thus, there must be multiple connection points between the processing units and the switching network. This conclusion is consistent with HP's construction.

Although the specification does not support importation of the limitation suggested by EMC, it does provide clarification as to the intended meaning of "switching network." That is, a switching network must be capable of coupling any node to any other node. See, e.g., 638:5/25-26 & 5/3840. Dictionary definitions are consistent with this view. For example, "switch" is defined as "a network infrastructure component to which multiple nodes attach," and "network" is defined as "an interconnect that enables communication among a collection of attached nodes." See Landgraff Decl., Separate Appendix, vol. 2, pp. 0324-26 (A Dictionary of Storage Networking Terminology). A person of ordinary skill in the art would
understand a switching network to mean a component or a set of components to which multiple nodes can attach and that selectively enables transferring of information, signals, or data among the attached nodes.

EMC also contends that the switching network must not be located within the data storage array system. However, nothing in the intrinsic evidence supports such a limitation. In the prosecution history cited by EMC, the patentee distinguished the invention from the prior art on the ground that a switching network was used between the processors and the disk storage array system, while the prior art described the use of a switch between the array controller and the storage units. See Landgraff Decl., Separate Appendix, vol. 2, p. 0285. The distinction does not concern the physical location of the switch but rather where the switch is placed logically in the system in relation to each component. Logically, the switching network must be between the processors and the disk storage array system.

Accordingly, the Court construes this term as "a component or set of components to which multiple nodes can attach and that selectively enables transferring of information among attached nodes."

2. "switching network means . . . for establishing a communications link" The text of claim 1 is set forth below, with the key disputed terms highlighted in bold type.

A multiprocessor computer system comprising:

a. a plurality of processing units;

b. at least one data storage array system, each having at least one array controller;

c. switching network means, coupled to the plurality of processing units and to at least one array controller of at least one data storage array system, for establishing a communications link between at least one selected processing unit and at least one data storage array system.

This claim is expressed in means plus function format, and the Court therefore construes it pursuant to 35 U.S.C. § 112, P 6. HP defines the function as "establishing a communications link between at least one selected processing unit and at least one data storage array system." Because HP's proposal is consistent with the plain language of the claim, the Court will adopt it.

HP defines the corresponding structures as found in "Figs. 2, 3A, 3B, 4; Col. 5:1-6:45." See HP's Opening Brief, p. 13. HP thus asks the Court to construe this term as: "A component or set of components to which multiple nodes can attach and that selectively enables giving, receiving, or exchanging of information, signals and/or data among attached nodes, having structures that are the same as or substantially equivalent to those found in Figures 2-4 and described at Columns 5:1-6:45."

EMC defines the structure more narrowly, proposing: "A circuit switch, not contained within a data storage array system, that is either a cross-point or multi-stage switch that is capable of establishing a dedicated path from any input node of the switch to any output node of the switch, as described in Col. 5, 11 4-51 and shown in Figs. 3 A and 3B."

EMC's argument is persuasive in part. The structures described in Figures 3A and 3B and in Column 5, lines 4 through 67 clearly are associated with the function of establishing a communications link between at least one selected processing unit and at least one data storage array system. See Texas Digital Sys., Inc., 308 F.3d at 1208. In contrast, while Figures 2 and 4 show a "switching network," they do not provide the structure of the "switching network," but instead show the "switching network" as part of the overall system configuration. Similarly, the text in the written description corresponding to those figures does not clearly link the function of the switching network means to its structure.

When the patent specification describes multiple embodiments, each of those embodiments may be claimed pursuant to 35 U.S.C. § 112, P 6. Serrano v. Telular Corp., 111 F.3d 1578, 1583 (Fed. Cir. 1997). The structures described in Figures 3A and 3B and in Column 5, lines 4 through 67 generally "may be of any suitable N x N type, capable of directly coupling any node to any other node." The figures and written description also describe specifically "an N x N cross-point switch or an N x N multi-stage switch" as disclosed in Column 5, lines 7 through 51. The written description additionally indicates that the switching network may comprise fiber optic or wired links and is fault -- tolerant and that the switch may be a dual switching network. Accordingly, the structure of the "switching network means for establishing a communications link" is "any suitable N x N type switching network, capable of directly coupling any node to any other node in addition to the
specific embodiments disclosed in Figures 3A and 3B and Column 5, lines 7 through 67."

2 Because it need not determine in the context of claim construction whether Figure 3B (a multi-switch) includes the possibility of "packet switching," the Court will reserve judgment on the issue. The parties may describe the disclosed structure further in the infringement analysis.

--- Footnotes ---

The term "switching structure" appears in Claims 49 and 50 of the '863 patent, and in context reads "switching structure coupled to said interface structure for switching certain select ones of said individual callers at said remote terminals to any one of a plurality of live operators wherein said live operators can enter at least a portion of said caller data relating to said select ones of said individual callers through interface terminals, which is stored in said record structure."

The plaintiffs contend that this term is not subject to means-plus-function analysis because the term "switch" is well known to those experienced in computer telephony and it brings to mind structure to those of skill in the art. The plaintiffs argue that switching structure should be defined as "hardware with associated software used to route calls." (Pls.' Appendix at 164).

The defendants contend that the term "switching structure" is subject to analysis under 35 U.S.C. § 112, ¶ 6 because the term lacks a sufficiently definite structure such that one of skill in the art would not know what structure to build without more information than is provided in the claim. The defendants argue that in the passages that discuss the switching structure, including Column 5, lines 51-55; Column 7, lines 13-17; Column 10, lines 45-52; and Column 11, lines 8-12 of the '863 patent, Katz did not disclose structure to perform the entire function performed by the means, which is switching callers to a live operator, where the live operator enters caller data for storage in the record structure.

During the Markman hearing, all of the experts referred to "switches" in their discussion of computer telephony at the time of the Katz patents. Similarly, the term "switch" was often used in contemporary references and prior art referred to by the parties at the hearing. The Court concludes that, based on these examples of the state of the art and the testimony of the experts, the term "switching structure" does not implicate 35 U.S.C. § 112, ¶ 6. The Court concludes that the term would have connoted a specific set of structures to those of ordinary skill in the art. Thus, based on the claim language and the specification, the Court construes the term "switching structure" to mean: a device including hardware and associated software that can switch or route telephone calls or signals from one location or connection to another.

--- End Footnotes ---

3. "symbol"

The parties dispute the meaning of the term "symbol," which appears throughout most of the claims of the patent. The point of contention is whether a symbol may exist pre-modulation, i.e., in an unmodulated form. (Tr. at 82:13-15). Plaintiff argues that the inventor imparted a particular meaning with respect to "symbol," one that differs from its ordinary meaning. Plaintiff contends that "symbol" should be construed as "the modulated waveform resulting from a single iteration of the modulator." (Chart at 6). Plaintiff relies on the specification for both the '322 Patent and the '447 Patent to support its definition.

Plaintiff refers to the portion of the '322 Patent's specification which states:
By way of example, as part of the initialization process of the system the control unit 36 can control the transmitter 18 to transmit two consecutive symbols the second of which is the negative of the first (i.e. if the first symbol has a waveform of f(t), then the second has a waveform of -f(t)), resetting the transmit symbol counter to a count of zero immediately after the transmission of the second symbol.

'322 Patent, col. 7, ll. 27-34. Plaintiff contends that this language specifies that a symbol must have a waveform. Plaintiff further relies on the disclosure of the '447 Patent, which is incorporated by reference, to support its argument that the waveform must also be modulated. See '322 Patent, col. 1, ll. 11-28. Specifically, the '447 Patent states: "The b[total] bits in each multicarrier symbol are modulated in modulator 16 by N separate carriers with b[j] bits modulated by the i<--th> carrier." '447 Patent, col. 1, ll. 29-31 (emphasis added). In light of both specifications, Plaintiff concludes that a "symbol" must be a modulated waveform. Plaintiff includes the phrase "resulting from a single iteration of the modulator" in its proposed construction based on its understanding that a symbol becomes a modulated waveform as a result of "a corresponding cycle of operation or 'iteration' of the modulator." (Pl.'s Opening Br. at 19).

Defendants assert that Plaintiff's proposed construction is overly restrictive and unsupported by the intrinsic evidence. At the hearing, Defendants explained that the '322 Patent disclosure supports their assertion that a symbol exists prior to modulation. (Tr. at 82:19-84:14). According to Figure 2 of the '322 Patent, which is a functional block diagram of the invention, Defendants assert that the parties do not dispute that modulation occurs at IFFT, D-A, Filter, & Line Interface 34. (Tr. at 83:17-21); see also '447 Patent, col. 1, ll. 32-35 (describing the use of an Inverse Fast Fourier Transform (IFFT) during modulating). Defendants also argue that symbols interact with the trellis coder and the transmit symbol counter. (Tr. at 82:24-83:6). Defendants reason that symbols must exist prior to modulation if they are in fact involved with the transmit symbol counter and the trellis coder, before they even reach the unit 34 which is responsible for modulation.

The Court finds Defendants' reasoning persuasive. The Court agrees that Figure 2 suggests symbols need not be in modulated form. Plaintiff's reliance on the '447 Patent is misplaced for two reasons. First, the excerpt cited by Plaintiff refers to Figure 1 of the disclosure which represents a basic multicarrier transmitter and receiver as known in the prior art, not an embodiment of the invention claimed. See '447 Patent. col. 1, ll. 19-21. Second, the excerpt describes what takes place as the symbols are processed by the modulator. Not surprisingly, the symbols become modulated. This is not sufficient to support the conclusion that symbols are always modulated. Defendants also accurately note that the inventors themselves distinguished between modulated and demodulated symbols in the specification. Focusing on Figure 3 of the '447 Patent, and Column 1, lines 52 to 54 which states: "The general structure of a DMT system is illustrated in Fig. 3 where [X[0], X[1], . . . X[N-1]] are the original, complex, input data symbols, [X[k]] is the modulated data sequence," it is clear that the inventors distinguished between symbols that are modulated and those that are not. '447 Patent, col. 1, ll. 52-54. Therefore, the Court concludes that a symbol does exist prior to modulation, which renders Plaintiff's proposed construction incorrect and overly restrictive. Moreover, the Court finds no basis for imposing the additional restrictive language that the modulated waveform results from "a single iteration of the modulator."

Having concluded that a "symbol" may exist prior to modulation, the Court must now construe the term. There is no competent evidence before the Court that reflects the technical meaning of "symbol," except for the opinion of Defendants' expert. 15 Dr. Williams opines that "symbol" would be understood by a person of ordinary skill in the art as "a finite, pre-selected representation of the information to be conveyed from the transmitter to the receiver." (Williams Report, P 85). Given the lack of other viable choices, the Court will adopt this definition.

15 Defendants do submit a general dictionary definition of "symbol." (Defs.' Reply at 14). That definition is "an object used to represent something abstract." WEBSTER'S NEW WORLD DICTIONARY 598 (1995). However, this general definition does not comport with how that technical term is used in the claim. Defendants also submit a technical dictionary definition for "symbol."Defs.' Opening Br. at 9. That definition, however, cannot be taken into consideration because it was set forth in a dictionary that was not published until three years after the patent issued, and therefore may not reflect the meaning of the term as used in the patent.

Accordingly, the Court construes disputed term [15] "symbol" to mean "a finite, pre-selected representation of the
The main issue presented to the Court concerns the claim limitation "symbol count" which pervades most of the asserted claims in the '322 Patent. The Court construed the term "symbol" as "a finite, pre-selected representation of the information to be conveyed from the transmitter to the receiver." (Markman Op. at 40). Globespan argues that the accused products do not meet the "symbol count" limitation because the counters in the accused products purportedly only count time. Globespan contends that a period of time cannot be a "symbol" in light of the Court's construction because time is not a representation of information. (See Pl.'s Opp'n to Defs.' Mot. for Summ. J. ("Pl.'s Opp'n") at 6 ("The Court did not rule that the terms 'symbol' or 'symbol count' means 'a period of time.'") (emphasis in original)). Thus, Globespan contends that the accused products cannot satisfy the "symbol count" claim limitation.

Defendants disagree and argue that the Court's construction of "symbol" encompasses a period of time or "symbol period." Defendants argue that the accused products meet this limitation based on the undisputed fact that the counters in the products count symbol periods. This dispute presents a claim construction issue, that is, whether the Court's construction of "symbol," which has been defined as "a finite, pre-selected representation of the information to be conveyed from the transmitter to the receiver," includes time. The Court concludes that it does.

At the outset, the Court notes that Globespan failed to raise the argument that the claim term "symbol" should be construed to exclude periods of time in their claim construction briefs and at the Markman hearing. Instead, Globespan argued that the term "symbol" should be construed as "the modulated waveform resulting from a single iteration of the modulator." (Chart at 6; Tr. of Markman Hr'g at 81:18-22, 84:17-86:15). After performing its claim construction analysis, the Court rejected Globespan's proposed construction and adopted Defendants' broader one. (See Markman Op. at 38-40).

Just as Globespan failed to identify any basis upon which to exclude time from the claim construction during the Markman process, Globespan continues in failing to provide the Court with any factual or legal support sufficient to warrant the adoption of a narrower construction for the claim term. Thus, the Court concludes that time falls within the definition of "symbol." There is no indication in the claim language, specification or prosecution history to indicate that a person of ordinary skill in the art would construe the term "symbol" as excluding time. See Phillips v. AWH Corp., 415 F.3d 1303 (Fed. Cir. 2005) (reaffirming the importance of the intrinsic evidence, especially the specification, when construing claim terms).

Plaintiff argues that a preferred embodiment in the specification suggests that counting is limited to symbols that exclude time. Plaintiff cites the portion of the specification which states:

Preferably the counts at the transmitter and receiver are synchronized by the steps of: transmitting symbols in accordance with a predetermined criterion from the transmitter and setting the count at the transmitter to a predetermined state in dependence upon such transmission; and detecting received symbols satisfying the predetermined criterion at the receiver and setting the count at the receiver to the predetermined state in dependence upon such detection.

(Pl.'s Opp'n at 9 (quoting '322 Patent, col. 3, ll. 18-26)). This portion of the specification, however, describes the process of synchronizing counts at the transmitter and receiver and does not provide any indication that time must be excluded from the definition of "symbols." Indeed, the portion of the specification that describes the step of identifying a "symbol" by a "symbol count" similarly bears no indication that time is excluded from the definition. See '322 Patent, col. 2, ll. 61-64 ("Preferably the step of identifying symbols comprises maintaining a count identifying transmitted symbols at the transmitter and maintaining a count identifying received symbols at the receiver.").

Having clarified the construction of the term "symbol" as encompassing time, Globespan's argument that the accused products do not infringe the '322 Patent because they count time, as opposed to "symbols," must fail.
2. Terms Which Depend on the Construction of "symbol count"

Disputed term [14] is "identifying symbols transmitted by the system by a symbol count," and disputed term [16] is "symbol count." Because the construction of both terms depends on how the Court construes "symbol count," the Court will analyze these terms together. The terms are found in Claims 1 to 19 of the '322 Patent. The issue presented is whether the "count" identifying transmitted symbols is limited to a count of individual symbols, or includes a count of groups of symbols.

Plaintiff argues that the language of the patent indicates that the "identifying" step of the claim "requires that a symbol count be associated or linked with each symbol, in a way that individually distinguishes that symbol from other symbols." (Pl.'s Opening Br. at 19). Focusing on the language of Claim 1, Plaintiff notes that in addition to the "identifying" step, the claim recites the step of "communicating . . . information identifying a change in said parameter and a symbol count for implementing said change." (Id. at 20 (emphasis in original)). Plaintiff argues that because the claim uses the term "change" in the singular form, the "identifying" step should be limited to individual "symbols" in order to maintain consistency.

Plaintiff also focuses on language in the specification which states: "Preferably the step of identifying symbols comprises a count identifying transmitted symbols at the transmitter and maintaining a count identifying received symbols at the receiver. Conceivably, however, each symbol could instead or additionally be identified by transmission of the symbol count as part of the symbol itself . . . ." '322 Patent, col. 2, ll. 61-67 (emphasis added). The patentees' use of the word "each," Plaintiff contends, evinces the patentees' intent that the identification of symbols is a process only involving individual symbols. (Pl.'s Opening Br. at 20). Further, Plaintiff offers a dictionary definition for the term "identity." According to Webster's New World Dictionary, "identity" is defined as the "state or fact of being a specific person or thing; individuality." WEBSTER'S NEW WORLD DICTIONARY 292 (1995).

Defendants' proposed construction for "symbol count," namely "a count of symbols, either individually or by groups," is based on the plain language of the claims and the specification. Defendants assert that the claim language does not limit counting by individual symbols. Rather, the language of the claims may be read to allow counting by groups of symbols. Defendants further argue that the specification provides an even stronger basis for their position. Defendants posit that the patentees acted as their own lexicographer by providing a meaning for the term "symbol count" in the specification. The specification reads as follows:

   In addition, the transmit and receive symbol counters need not be incremented once for each symbol, but instead could for example be incremented after every N symbols, where N is an integer greater than one; for example N=68. In this case the implementation of the changes is similarly determined in relation to the counts, for example coincident with the boundaries between groups of N symbols.

'322 Patent, col. 11, ll. 55-62 (emphasis added). Thus, Defendants argue that the patent's disclosure specifically describes counting by groups of symbols, and not only by individual symbols. (Tr. at 77:13-78:16).

The Court finds that the specification supports Defendants' proposed construction for the term "symbol count." Although one portion of the specification describes incrementation by the symbol counter occurring after the transmission or reception of each symbol, a subsequent portion expressly discloses that incrementation may occur after groups of symbols. See '322 Patent, col. 7, 11. 9-13; col. 11, ll. 55:62. The specification also describes the term "symbol count" as a process that identifies or links symbols, not only one symbol, as they are transmitted or received through the symbol counter. '322 Patent, col. 2, 11. 61-64. Furthermore, the plain language of the claims supports this construction. For example, Claim 4 refers to "maintaining a count identifying transmitted symbols at the transmitter and maintaining a count identifying received symbols at the receiver." '322 Patent, col. 12, 11. 18-21. The word "symbols" is plural. Accordingly, the Court concludes that disputed term [16] "symbol count" means "a count of individual or groups of symbols."

As for the remainder of disputed term [14], Plaintiff submitted a dictionary definition for the term "identify." This term is defined as "to connect or associate closely." WEBSTER'S NEW WORLD DICTIONARY 292 (1995). The Court will adopt the ordinary meaning of "identify" in its construction. Therefore, the Court concludes that disputed term [14] "identifying symbols transmitted by the system by a symbol count" means "connecting or associating a symbol count with individual
A. "symbol information for uniquely identifying the symbol" / "symbol information"

In the joint claim construction statement, the parties presented a single construction for the claim terms "symbol information for uniquely identifying the symbol" and "symbol information." Defendants, for the first time at oral argument, argued that these two terms should be construed separately. The Court rejects this new argument and construes these terms together as they were presented in the joint claim construction statement. Cognex argues that these terms should be construed as "information in the data field of the symbol that is different for and unique to each symbol in the nature of an electronic fingerprint." Defendants believe the inclusion of "electronic fingerprint" is not appropriate and proffer "information within a symbol that uniquely identifies the symbol."

The '524 Patent is directed to "an identification symbol system for an object." '524 Patent, claim 1. The language of the claims and of the specification teaches that a symbol, formed on or affixed to substrate associated with the object, can be used to identify the object, and that the rectilinear data matrix design of the symbol system provides flexibility in the number of different and unique symbols available in an application of the symbol identification system. There is no dispute between the parties that the '524 Patent teaches that symbols are unique within a specific application of the symbol identification system, and that the '524 Patent does not teach that symbols must be unique across applications of the symbol identification system. Thus, the Court concludes that there is no need for the inclusion of the term "electronic fingerprint" in the construction of the disputed terms. The Court construes the terms "symbol information for uniquely identifying the symbol" and "symbol information" as "information within a symbol that uniquely identifies the symbol."

8. Symmetrical Power and Ground

All of the power and ground leads on the memory module are positioned in such a way that when the memory module is inserted into the connector backwards, all of the power and ground leads on the module line up with comparable power and ground leads on the connector, thereby avoiding damage to the computer or module.

14. The dictionary defines "symmetrical" and "symmetric" as "1. having, involving" symmetry, which in turn is defined as "1. balanced proportions . . . 2. the property of being symmetrical; esp: correspondence in size, shape, and relative position of parts on opposite sides of a dividing line or median plane or about a center or axis." The preferred hexagonal base arrangement disclosed in the specification exhibits "correspondence in size, shape, and relative position of parts" both "on opposite sides of a dividing line or median plane" and "about a center or axis." Thus, "symmetrically disposed" bases would be understood to be bases arranged to correspond in relative position either on both sides of a dividing line or median plane or about a center or axis. Because the bases defining this three-dimensional material are polygonal, this material also would be polygonal in the same sense described above as to the bases themselves. 8

7 Pertinent to '725 Claims 8 and 24 and '767 Claim 7, discussed later, the Court notes that those claims do not include a "symmetrically disposed" requirement.

8 IXYS contends that "symmetrical spacing requires identical spacing between each side of a particular cell and the corresponding sides of the cells adjacent to that cell." (Gwozdz Rebuttal Report, p. 21.) However, only claims not asserted against IXYS ('725 Claims 7, 17 and 21 and '767 Claim 5) recite that the polygonal bases are "equally spaced," a
requirement not stated in the asserted claims. Thus, equal spacing between bases -- which is a separate requirement expressly recited in only unasserted claims -- should not be included in a narrow definition of "symmetry" in the asserted claims not requiring equal base spacing. Indeed, the specification states that in "FIG. 2 the axis 120 is the axis of symmetry 120 that is shown in FIG. 1 ("725 Col. 5, lines 3-4)." An "axis of symmetry" is "a straight line with respect to which a body or figure is symmetrical", Webster's Ninth Collegiate Dictionary, p. 121 (definition of "axis"), which suggests that "correspondence in size, shape, and relative position of parts on opposite sides of a dividing line" is sufficient "symmetry" for purposes of the claims.

--- End Footnotes ---

4351

15. Synchronization

The parties dispute what is meant by the term "synchronization." Seven's proposed construction is "updating the client and server databases to reflect changes that have happened since the last connection." Visto's construction is "merging data from the client database with the data from the data store." In the context of these claims, "synchronization" means "updating the client and server databases to reflect changes that have happened since the last connection."

4352

P. Synchronization Agent

Visto contends that "synchronization agent" means "software routines or code that send at least a portion of second version information to a general synchronization module for purposes of synchronization." Seven argues that the term means "a computer software module located on a global server outside the firewall-protected corporate LAN that forwards second version information to a general synchronization module within a firewall-protected corporate LAN." Again, Seven has incorporated the "global server" limitation into its definition of the term and has also limited the location of the synchronization agent to a place outside a firewall-protected corporate LAN. These limitations are not warranted. As such, the court defines the term "synchronization agent" to mean "software routines or code that send at least a portion of second version information to a general synchronization module for purposes of synchronization."

4353

B. The '617 Patent

The parties have requested that the Court interpret the meaning of the term "synchronization signal" found in claims 1, 2, and 6 of the '617 patent. The term is used in the same manner in all three claims. Claim 1 is representative:

A scanning apparatus for scanning an object to generate three-dimensional data, comprising a scanner mounted on a multiply-jointed arm for movement by an operator to scan the object to capture data from a plurality of points on the surface of the object, the scanner comprising:

- a light source operable to emit light onto the object surface; and

- a light detector operable to detect light reflected from the object surface by recording reflected light at recording times defined by a synchronization signal;

- a position calculator for calculating the position of the multiply-jointed arm, and outputting position data defining the position in response to a trigger pulse; and

- 4616 -
a trigger pulse generator for receiving the synchronization signal for the light detector defining the recording times thereof, and, in response thereto, generating and outputting trigger pulses to the position calculator to cause the position calculator to output position data for each of at least some of the recordings by the light detector; and

a three dimensional data generator for receiving recorded data output by the light detector and associated position data output from the position calculator, and for processing the data to generate three-dimensional data related to the object.

'617 patent col. 29, ll. 34-60. The parties agree that the terms "light detector" and "camera" are interchangeable.

Metris argues that "synchronization signal" should be construed as a "signal used to synchronize (coordinate in time) events or actions." Faro advances a narrower definition: "a series of electrical timed electrical signals defined by the camera which are generated to define when the scanning device captures the reflected light." The present dispute focuses on the portion of the definition underlined above.

While not contesting that the signals at issue are "electrical," Metris argues that the plain language of the claim does not require that the synchronization signal be "defined by the camera." Claim 1 requires that the light detector record "reflected light at recording times defined by a synchronization signal." '617 patent, col. 29, ll. 44-45. Later in the claim, it also requires that the "trigger pulse generator" receive the "synchronization signal for the light detector defining the recording times thereof." '617 patent, col. 29, ll. 49-50 (emphasis added). There is no claim limitation restricting the origin of the synchronization signal.

Faro contends that Claim 1 requires that the camera (or "light detector") define the recording times of the synchronization signal. With respect to the language relating to the trigger pulse generator, Metris argues that the word "defining" modifies "synchronization signal," so that the synchronization signal defines the recording times for the light detector. As discussed at the Markman hearing, the word "defining," read in isolation, plausibly could be read to modify the term "light detector" which it follows directly. However, if that were the intended meaning, the word "for" would likely not have been used. Moreover, earlier, the claim provides that the recording times of the camera are "defined by a synchronization signal." '617 patent, col. 29, ll. 45. No language in the claim compels Faro's conclusion that the synchronization signal is "defined by the camera," in the sense of emanating from it. When the word "defining" is read in combination with other claim language, Metris' reading is more logical. Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1299 (Fed. Cir. 2003) ("While certain terms may be at the center of the claim construction debate, the context of the surrounding words of the claim also must be considered in determining the ordinary and customary meaning of those terms.").

To the extent that there is any ambiguity (which there is not), the patent specification amply supports Metris' construction. The specification states that "there are many methods" of performing the synch and trigger function. '617 patent, col. 25, ll. 12-13. It goes on to indicate "[o]ne method," in which the synchronization signal comes "from a CCD camera 25." '617 patent, col. 25, ll. 13-14 (emphasis added). Earlier in the specification, however, the synchronization signal "is fed into the high resolution camera 25 and the colour camera 29." '617 patent, col. 10, ll. 61-62 (emphasis added). As illustrated in Figures 6 and 24 of the patent specification, the synchronization signal may come from the camera or go to the camera 3:

GET DRAWING SHEET 6 OF 24
GET DRAWING SHEET 19 OF 24

A claim should almost never be construed to exclude one of the embodiments found in the specification. Vitronics Corp. v. Conceptronic, 90 F.3d 1576, 1583 (Fed. Cir. 1996) ("Such an interpretation is rarely, if ever, correct and would require highly persuasive evidentiary support, which is wholly absent in this case.").

--- Footnotes ---

3 In these images, item 25 represents the camera, and items 61 and 240 are both identified as synchronization signals. In Figure 6, the synchronization signal moves from a synchronization generator to the camera. '617 patent, col. 10, ll. 60-62. In Figure 24, the synchronization signal moves from the camera to electronic circuitry. '617 patent, col. 25, ll. 13-15.

--- End Footnotes ---
To support its construction, Faro resorts to the prosecution history. In the Patent Office's Notice of Allowability, the examiner stated, "[T]he cited prior art fails to teach or suggest the features of receiving the synchronization signal for the camera defining the recording times thereof, and, in response thereto, generating and outputting trigger pulses to the position calculator to cause the position [sic] to output position data for each image recorded by the camera." (P.'s Ex. B. 380.) From this thin bullrush, Faro seeks to build a pyramid, arguing that the language demonstrates that the examiner intended to grant a patent only for a synchronization signal that was generated "by the camera." (P.'s Br. 22.) However, as Metris points out, in the prosecution history quoted above, the examiner merely restated the proposed claim verbatim, as is indicated by the examiner's use of quotation marks. The examiner never uses the words "defined by the camera" in the quoted portion of the prosecution history.

Nothing in the claim language, the specification, or the prosecution history compels the claim construction that the synchronization signal must be defined "by the camera".

**CLAIM CONSTRUCTION**

*The term "synchronization signal" is construed as an electronic signal used to coordinate events or actions.*

**4354**

T. Synchronization-start module

This term is used in various claims of the '192 patent, the '131 patent, and the '708 patent. The court defines synchronization-start module to mean "software routines or code which initiate the synchronization process." The court has previously rejected Seven's attempt to import location limitations into the claim terms when those limitations are otherwise absent from the claims. This term is no different. The intrinsic record reveals that the synchronization-start module includes a group of software routines which instruct the general synchronization module to begin the synchronization process. However, the court does not read the claims or the specification to require, necessarily, that the synchronization-start module be located within a firewall-protected corporate LAN. See, e.g., '131 Patent, Col. 5, ll. 50-55 ("It will be appreciated that communications with the synchronization agent 126 preferably initiate from within the corporate LAN 1135, because the typical corporate firewall prevents in-bound communications and allows out-bound communications.") (emphasis added).

**4355**

1. Synchronizing

The parties ask the Court to construe "synchronizing" as used in Claim One of the '216 Patent, where the inventors claimed "[a] method of synchronizing a mobile radiotelephone in a cellular digital mobile radiotelephone network." '216 Patent at 8:62-64. IPCom proposes that synchronizing means merely "[b]ringing the mobile station's operation in step with the corresponding operation of a base station." Chart at 1. HTC proposes that synchronizing means "[b]ringing a mobile station's operation in step with the corresponding operation of a base station by performing processes that evaluate a continuously running phase angle calculated from burst signals received from the base station." Chart at 1.

While HTC's proposed construction finds support in the specification, see '216 Patent at 3:9-1 ("The synchronization method of the invention is based on the evaluation of a continuously running phase angle . . . ")), it confuse Claim One and Claim Two and therefore cannot be adopted. Phillips, 415 F.3d at 1315. Claim Two of the '216 Patent depends from Claim One and describes the "further steps of: calculating (continuous evaluation of) a phase angle from sequences of pairs of values . . . and thereafter performing a continuous evaluation of said calculated phase angle." '216 Patent at 9:49-54. Given the specificity of Claim Two's disclosed method and the generality of Claim One, HTC's proposed construction erroneously conflates the two.
HTC argues strenuously that the evaluation of phase angles is the only disclosed mechanism for every claimed substep. While this is a slight overstatement, since substep (1.1) does not evaluate phase angles, it remains basically accurate. The point is, however, that Claim One — the only independent claim in the '216 Patent — does not reveal how to accomplish its method. Those particulars are in the dependent claims that follow. Indeed, the prosecution history reflects the understanding of the Patent and Trademark Office (PTO) that the invented method resided in the multiple steps, not in "phase course" analysis. IPCom's Opening Br., Ex. 5, Prosecution History at 1194 ("none of the references teaches or suggests the arrangement of the steps of initial synchronization, normal synchronization and extended synchronization with the substeps of each respective step in order to form a method of synchronization"); see also Tr. 2/16/10 at 43 (IPCom).

HTC additionally argues that the inventors clearly limited the scope of the invention by three statements:

- The synchronization method of the invention is based on the evaluation of a continuously running phase angle, which is calculated again and again from an in-phase component I and a quadrature component Q. '216 Patent at 3:9-12.
- The method of the invention is based on evaluation of phase angle many times per bit interval. Id. at 3:48-49.
- For taking best advantage of evaluating phase angles by I, Q samples, it is important to utilize the various different transmitted synchronization bursts in accordance with the various steps that usefully make up the various aspects of the invention. Id. at 8:47-52.

An inventor may disclaim or disavow the scope of a claim in the specification. Phillips, 415 F.3d at 1316. To limit the scope of his own patent, a patentee must have had "a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction." Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (6th Cir. 2004). "In that instance . . . the inventor has dictated the correct claim scope, and the inventor's intention, as expressed in the specification is regarded as dispositive." Phillips, 415 F.3d at 1316.

While the specification in the '216 Patent describes evaluation of phase angles, no expressly limiting language is used in Claim One. The focus of Claim One is the method of sequential steps and substeps, not the precise contours of how one practices the invention. Claim One is not bounded by the limitations of relying on evaluating phase angles, as these limitations appear in dependent claims and not in Claim One. Given the structure of the '216 Patent, the Court cannot conclude that Claim One is so limited.

The Court construes "synchronizing" to mean "bringing the mobile station's operation in step with the frame and frequency of a base station." 6

6 While IPCom proposed that synchronizing means "[b]ringing the mobile station's operation in step with the corresponding operation of a base station," see Chart at 1, at the Markman hearing, counsel for IPCom conceded that it is more accurate to define synchronizing as the Court defines it here. See Tr. 2/16/10 at 40 (IPCom).

17. "synchronizing signal"

Power-One proposes "a signal that identifies the start of a communication cycle," while Artesyn proposes "a clock signal that synchronizes the timing of multiple devices with one another for purposes of communication." Claim 1 of the '916 patent requires a POL regulator be adapted "to initiate a communication cycle by providing a synchronizing signal onto a serial data bus followed by a multi-bit data message that includes at least one of an address set, a command set, and a data set." Claim 5, which depends from claim 1, recites that "said synchronizing signal further comprises a clock pulse that pulls said serial data bus to a low state." Thus, from the broad claims in the '916 patent, a "synchronizing signal" "initiate[s] a communication cycle" and is "followed by a multi-bit data message" that includes an address set, a command set and/or a
The "synchronizing signal" of the claims corresponds to the "start sequence" described in the patent specification, as the start sequence in the specification is at the beginning of a communication cycle and is followed by the sets recited in the claims. '916 patent, col. 4:18-25, Fig. 5.

Artesyn uses the term "clock signal" in its proposal. The '916 patent specification describes a "clock signal" that synchronizes the various communicating devices and creates a series of clock cycles, each one including a data bit. '916 patent, col. 4:4-7. This "clock signal" is not described as initiating a communication cycle and it is not followed by a multi-bit message. Artesyn's proposed construction for the "synchronizing signal" of the claims appear to be more descriptive of the "clock signal" described in the specification that is used to transmit the data bits that comprise the address set, the command set and the data set. As the claims recite, these aspects follow the "synchronizing signal."

Power One's proposed construction accurately describes the start sequence described in the specification, which performs the function of the "synchronizing signal" in the claims. Accordingly, the Court construes this term as "a signal that identifies the start of a communication cycle."

2. "packet data" and "synchronous data"

The plaintiff proposes that "packet data" means "variable bit rate data" and "synchronous data" means "constant bit rate data." The defendants propose that "packet data" means "data that is transmitted in packets" and "synchronous data" means "constant bit rate data that is not transmitted in packets." Both parties appear to agree that "synchronous data" refers to constant bit rate data. The dispute is whether "packet data" can also include constant bit rate data.

The specification defines these terms:

The present invention relates to data communications, and more particularly to communications systems that have channelized network access, and may transport both synchronous data and variable-bit-rate data such as frame relay data (hereafter referred to as packet data), in a time-division multiplexed format.

'858 patent, 1:8-11.

Contrary to the defendants' arguments, the patent defines "variable bit rate data" as "packet data," and the court adopts this construction. Moreover, the court defines "synchronous data" as "constant bit rate data."

Synchronous digital network virtual container

The Court does not adopt either party’s proposed construction and construes the term as “an information payload that can be transported across a digital network that uses time-division multiplexing such as SDH or SONET.” Ciena argues that the term should be construed as “SONET or SDH virtual container.” Ciena contends that the specification and prosecution history indicate that a person of ordinary skill in the art would understand synchronous digital network virtual container as a virtual container for only SDH or SONET networks. In support of its construction, Ciena points to the abstract and specification of the patent. The abstract states, “Each port card comprises a conventional frame based data port, a frame switch, a rate adapter means and a mapping means for mapping data frames into a plurality of SDH virtual containers.” See alsoCols. 7:49-51; 7:63-8:2; 10:53-54. Ciena argues that the specification only references SDH virtual containers. However, Ciena concedes that the file history supports a definition of “virtual container” that also includes the SONET standard.

Nortel argues that the term should be construed as “a data channel that can be combined with other such data channels and
transported across a synchronous digital network.” Nortel contends that the term should not be construed to limit “synchronous digital network” to only the SONET and SDH standards. The parties agree that the term “synchronous digital network” should be construed as a “digital network that uses time-division multiplexing such as SDH or SONET.” Nortel argues that this construction of “synchronous digital network” indicates that SONET and SDH are examples of synchronous digital networks but does not limit the term to only SONET and SDH networks. Nortel contends that to construe “synchronous digital network virtual container” as limited to only SONET and SDH data channels would be inconsistent with the agreed construction of “synchronous digital network.” In further support of its argument that the term should not be limited to only the SDH and SONET data channel, Nortel points to Column 7, Lines 11 through 14 of the specification, which state, “A set of STM frames are assembled to contain a plurality of virtual containers which are carried as an STM payload as illustrated in FIG. 4 herein.”

The portion of the specification cited by Nortel indicates that a virtual container is carried as an information payload. Furthermore, the specification does not limit virtual container to a data channel such as SDH or SONET and to construe the term with such a limitation would be inconsistent with the parties agreed construction of “synchronous digital network.” Accordingly, the Court construes the term “synchronous digital network virtual container” as “an information payload that can be transported across a digital network that uses time-division multiplexing such as SDH or SONET.”

3. Synchronous Memory Device

a. Proposed constructions

Hynix argues that "synchronous memory device" should be construed to mean "a memory device in which an external clock is used for timing purposes." Rambus counters that the term should be construed as "a memory device in which address, input data and control signals are recognized and output data signals are transferred in response to an external clock." The parties agree that a "synchronous" memory device is one in which at least some operations are synchronous with respect to an external clock. See, e.g., Hynix's Resp. CC Br. at 12. The parties disagree, however, over whether "synchronous" requires that all operations on the memory device be timed with respect to an external clock, or whether some operations on the memory device can be "asynchronous" while executing other operations as "synchronous." 10

10 Both parties agree that "synchronized" means "having a known timing relationship with respect to." Opp. at 6 n.2.

b. Claim language

11 of the 15 patents in suit have claims reciting the limitation "synchronous memory device." Claim 1 and asserted claim 2 of the '263 patent, for instance, recite:

1. A synchronous semiconductor memory device having at least one memory section which includes a plurality of memory cells, the memory device comprises:

        a programmable register to store a value which is representative of a delay time after which the memory device responds to a read request.

2. The synchronous memory device of claim 1 further including output drivers, coupled to an external bus, to output data on the bus, in response to the read request, synchronously with respect to an external clock.
Although claiming a "synchronous memory device," nothing in the text of claim 1, upon which claim 2 depends, excludes some asynchronous operations. In addition, claim 1 does not explicitly require that address, input data and control signals be provided synchronously. Notably, claim 1 uses the term "comprises" in describing a memory device with a programmable register, thus apparently not closing the claim to asynchronous elements. See Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271 (Fed. Cir. 1986) ("The term comprising' denotes a patent claim as being open,' meaning that the recitation of structure in the claim is open to additional structural elements not explicitly mentioned."); M.P.E.P. § 2173.05(h) (6th Ed. 1996); see also '152 patent, cl. 11.

c. Ordinary meaning

Hynix offers definitions of "synchronous" from two dictionaries. Webster's Ninth New Collegiate Dictionary (2d ed. 1989) defines synchronous as:

1: happening, existing, or arising at precisely the same time; 2: recurring or operating at exactly the same periods; . . . 4a: having the same period; also: having the same period and phase.

The Oxford English Dictionary (2d ed. 1989) defines synchronous as:

1.a. Existing or happening at the same time; coincident in time; belonging to the same period, or occurring at the same moment, of time; contemporary; simultaneous . . .; b. . . . Relating to or treating of different events or things belonging to the same time or period; involving or indicating contemporaneous or simultaneous occurrence. . . .

2.a. Recurring at the same successive instants of time; keeping time with; going on at the same rate and exactly together; having coincident periods, as two sets of vibrations or the like. . . . b. Electr. Applied to alternating currents having coincident periods; also to a machine or motor working in time with the alternations of current. . . . c. Computer and Telecommunications. Of apparatus or methods of working: making use of equally spaced pulses that govern the timing of operations. . . .

The Authoritative Dictionary of IEEE (Institute of Electrical and Electronics Engineering) Standards Terms (5th ed. 1993) ("IEEE Dictionary") defines "synchronous" as:

A mode of transmission in which the sending and receiving terminal equipment are operating continuously at the same rate and are maintained in a desired phase relationship by an appropriate means.

Rambus offers the IEEE Dictionary (4th ed. 1988) definition of "synchronous computer," a "computer in which each event or the performance of each operation, starts as a result of a signal generated by a clock." See also THE AUTHORITATIVE DICTIONARY OF IEEE STANDARDS TERMS 1141 (7th ed. 2000).

In contrast, the IEEE Dictionary (5th ed. 1993) defines "synchronous device" more broadly, as "[a] device whose speed of operation is related to the rest of the system to which the device is connected." See also THE AUTHORITATIVE DICTIONARY OF IEEE STANDARDS TERMS 1141 (7th ed. 2000).

Rambus argues that "synchronous memory device" should be defined in the same way as "synchronous computer." In addition, Rambus argues that articles cited by Hynix's expert, David Taylor, all refer to DRAMs that persons of ordinary skill in the art would refer to as "asynchronous DRAMs." Murphy Reply Decl. P 13. In contrast, the IEEE definition of "synchronous device" does not require that every operation be synchronous, but that the device's "speed of operation" be related to the rest of the system to which it is connected. Hynix also suggests that DRAMs in the late 1980's and early 1990's that timed all inputs and outputs to an external clock were more often referred to as "fully synchronous." 11 Taylor Decl. P 21.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

As discussed supra, the Federal Circuit construed "bus" as having its ordinary meaning, and not limited to a "multiplexed bus." Here, there is no clear statement that a "synchronous memory device" must exclude asynchronous functions. Considering the changing nature of bus architecture, the scope of claims in Rambus's related SDRAM patents covering both memory devices and synchronous memory devices, and the lack of any clear statement defining "synchronous memory device" as requiring that all operations be synchronous, a broader construction of memory device than the one offered by Rambus is warranted.

d. Specification

The specification does not use or define the term "synchronous memory device." Rather, Rambus contends that numerous references in the specification imply a memory device where address, input data and control signals are required to be synchronous. The specification references that Rambus cites, however, in large part discuss a clocking scheme in the context of a multiplexed bus architecture. See, e.g., '263 patent col. 8, 11. 8-32. The specification states, for instance, that "another object of this invention is to provide a method for transferring address, data and control information over a relatively narrow bus and to provide a method of bus arbitration when multiple devices seek to use the bus simultaneously." Id. at col. 3, 11. 25-29. The implication that address, data and control information must be asserted in response to an external clock, however, stems from the multiplexed bus limitation.

Although it appears that address, data and control information must be asserted in response to an external clock in order to work with the described bus architecture, nothing in the specification expressly requires it. As with the term "bus," here "none of Rambus's statements constitute a clear disclaimer or disavowal of claim scope." Infineon II, 318 F.3d at 1095. Without a clear disclaimer in the specification, Rambus's attempt to narrow "synchronous memory device" based on references to a multiplexed bus in the specification is not persuasive.

e. Subsequent briefing

During the claim construction hearing, and in light of the original briefing, the court proposed the construction: "a memory device that receives an external clock to govern the response timing of the memory device's operation(s)." Hynix notes that such a construction would cover devices in which the timing of data input and output is governed by an external clock, and finds the construction acceptable. Pl.'s Supp. Memo re: "Synchronous Memory Device" and "Packet" at 2. Rambus also finds the court's tentative construction acceptable if the words "response timing" are replaced by the phrase "the timing of input and output operations" to clarify that input and output timings must both be governed by an external clock. Def.'s Supp. Memo re: "Synchronous Memory Device" and "Packet" at 1. Although the parties agree that the specification discloses a preferred embodiment in which both inputs and outputs are governed by an external clock, as discussed earlier, it appears from the claims that Rambus's construction is too narrow. The court finds that the language of the claim supports the definition of "synchronous memory device" as "a memory device that receives an external clock signal which governs the timing of the response to a transaction request."

4360

A. "synchronously"

The district court construed the phrase "shifting to a power on state synchronously with a received timing of a beacon signal" to mean "shifting to a power-on state at the same time a beacon signal is to be received." Fujitsu Ltd. v. Netgear, Inc., 576 F. Supp. 2d 964, 976 (W.D. Wis. 2008)(Markman Order). Below, Netgear argued that the claim required that the beacon signal activate the mobile station. The district court rejected this argument based on the plain language of the claim. Id. It held that "synchronously" does not require that the beacon signal control the mobile station, only that the beacon signal and the power on happen "at the same time." Id.

Fujitsu argues that the district court's construction is too narrow. It argues that the term "synchronously" does not mean "at the same time." It argues that the term means that "the shifting to a power-on state has a temporal relationship with the beacon signal so that the beacon signal can be received." It argues that the specification does not support the district court's
construction. Fujitsu points first to figure 18, which shows a first step of "Power-on (Beacon Receiving Timing)" followed by "Receive Power-Saved Station Control Beacon." Further, it points to figure 19 and argues that it shows a power-on timing before the beacon signal, rather than at the same time. Finally, Fujitsu argues that the district court erred because its construction raises possible issues with patentability. It argues that by construing "synchronous" to mean "at the same time," the district court improperly required a physical impossibility because a system cannot cause two things to happen at precisely the same time. It argues that this brings the patentability of the claims into question and that the courts should construe claim terms to avoid this issue.

Netgear responds that the district court was correct, the term "synchronous" must mean "at the same time." According to Netgear, Fujitsu's arguments regarding the figures are not persuasive because, for example, figure 19 shows a short "ramp-up" period that simply allows the mobile station to be at full power at the same time it receives the beacon signal. Netgear also argues that this construction of synchronously does not require a physical impossibility. It argues that we addressed a similar situation in Paragon Solutions, LLC v. Timex Corp., 566 F.3d 1075, 1088 (Fed. Cir. 2009), and held that the term "real-time" necessarily means a "non-zero amount of time." In other words, Fujitsu argues that "synchronously" may mean "at the same time," but that this will not require the physical impossibility of two things happening at the same instant.

We hold that the proper construction of the term is "just before or at the same time." This is the only construction consistent with the specification. For example, the specification shows in figure 19 that the mobile station powers on just before the received timing V1 of the beacon signal:

[SEE FIGURE 18 IN ORIGINAL]

Further, figure 18 includes a flow chart with a first step of "power-on (beacon receive timing)" and a second step of "receive . . . beacon," which further supports that these two events need not happen "at the same time." The district court's construction, urged by Netgear, is too narrow because it requires the term "synchronous" to mean "simultaneous." This would be in direct contradiction to the disclosure of the '642 patent as evidenced by figures 18 and 19. We cannot do as Netgear asks and strue the term "synchronously" to mean "at the same time." Fujitsu's proposal--some temporal relationship between the beacon and the power-on timing--is too broad and amounts to nothing more than a required ordering. It would only require that the mobile station power-on sometime before the beacon is sent. This ignores the power saving purpose of the invention and is not supported by the specification. The object of the invention involves timing the beacon signals and power-on timing "so that an improved . . . power-saving can be realized." '642 patent col. 3 ll.45-46. Fujitsu's proposed construction would allow for any temporal relationship, even if the mobile station powered-on long before the beacon signal thus wasting valuable power resources. Reading the claim language in light of the specification, we construe the term to mean "just before or at the same time." 2

2 We agree with Netgear that the "at the same time" portion of the construction does not require a physical impossibility. As in Paragon, the phrase "at the same time" takes into account technological constraints and necessarily means a "non-zero amount of time." 566 F.3d at 1088.

--- Footnotes ---

--- End Footnotes ---
Defendant contends that in Claim 6 the claim term "the system" is indefinite because it lacks an antecedent basis. However, "[w]hen the meaning of the claim would reasonably be understood by persons of ordinary skill when read in light of the specification, the claim is not subject to invalidity upon departure from the protocol of 'antecedent basis.'" Energizer Holdings v. ITC, 435 F.3d 1366, 1370 (Fed. Cir. 2006). Furthermore, as noted above, in general, Defendant faces a difficult task in establishing by clear and convincing evidence that a claim term is indefinite.

In attempting to make this showing, Defendant notes that the specification appears to disclose multiple embodiments of the ticketing "system" of the invention. For instance, Defendants contend that Figure 1 of the specification discloses a "system" that includes the home computers of ticket buyers, while none of the claims seem to explicitly include this particular component. (D.I. 57 at 18.) In these circumstances, Defendant contends that claim 6 is indefinite because it "gives no indication as to which of these different systems it is supposed to be connected." (D.I. 57 at 19.) Notwithstanding the lack of antecedent basis for the term "system," the Court is unpersuaded that the disclosure of multiple embodiments of the "system" of the invention renders Claim 6 "insolubly ambiguous" such that "no narrowing construction can properly be adopted." Praxair, 543 F.3d at 1319. In this regard, the Court notes that Figure 1 of the specification includes a description of "the system architecture of the preferred embodiment of the present invention," which includes a data center, venues, and terminals. '809 patent at 2:29-39. The specification goes on to describe the makeup and function of these components. See id. at 2:29-3:50. In its Answering Claim Construction Brief, Plaintiff explains that the "system" is the "entire set of computers, databases, and mechanical or optical equipment used to buy and sell tickets and grant or deny access to sports venues." (D.I. 60 at 38.) In the Court's view, this fairly captures the descriptions of the "system" set forth in the specification. Accordingly, the Court will construe the claim term "system" to mean "the entire set of computers, databases, and mechanical or optical equipment used for electronically exchanging paperless tickets for an event in a secondary market from ticket sellers to buyers."
degree of uncertainty and indefiniteness to the construction of the patent. In response to this argument, Intergraph now states that it is willing to accept a modified version of Toshiba's construction: "a bus having multiple masters and through which the primary memory communicates with the cache memory." This is Toshiba's proposed construction replacing the phrase "each system element that accesses primary memory" with "the cache memory." The main dispute, therefore, is whether the term "system bus" must be construed to require that every component communicates with the main memory via the system bus. Under Toshiba's proposed construction, all components that communicate with the main memory must be able to do so via the system bus, though other communication channels may be available. Under Intergraph's proposed construction, only the cache memory must be able to communicate with the main memory via the system bus. The other components need not be able to use the system bus to communicate with the main memory.

In support of its proposed construction, Intergraph raises only two arguments, one based on claim language superfluity and the other based on the prosecution history. First, Intergraph points to Claim 1 of the '846 patent, which includes the element "system bus monitoring means for monitoring I/O requests over the system bus." According to Intergraph, because Toshiba's construction would require all I/O requests to go over the system bus, the phrase "over the system bus" in Claim 1 would be superfluous under Toshiba's construction. In response, Toshiba claims that the phrase "over the system bus" specifies the location where the monitoring takes place, not where the communication occurs.

Additionally, Intergraph argues that the prosecution history does not indicate that Intergraph adopted Toshiba's interpretation of the system bus. In particular, the Examiner initially rejected claims 16-40 of the '835 patent application, claims that recited a "system bus," as obvious based in part on U.S. Patent No. 4,701,844. Pl's Exh. M at 5. The '844 Patent discloses a system bus involved in communications between the CPU and the "Main Memory," but also discloses other paths for communications with the Main Memory. Pl's Exh. F. This, Intergraph asserts, demonstrates that Intergraph's understanding of the term "system bus" during prosecution did not require that all communications with the primary memory take place over the system bus. As Toshiba points out, however, nothing in the prosecution history shows that Intergraph ever advanced the interpretation set forth in the '844 Patent during prosecution. Furthermore, at the time the PTO rejected the claim based on the '844 Patent, the PTO also cited JP Application No. 58-58666, which teaches a system bus as shown in the Intergraph application. Def's Exh. M at 5. Taken together, these two prior art references show not only that Intergraph had no reason to adopt one reference over the other, but also that both types of system bus were present and understood in the prior art. In light of this ambiguity, the court looks to the patent specification for clarification.

Turning to the specification, Toshiba claims that the '846 Patent and the '835 Patent each require the system bus 141 to be the central system artery that provides the pathway for the system elements to access the main memory. '846 Patent at 4:22-25, 4:40-42, 15:17-20; '835 Patent at 1:45-62, 2:1-4. Intergraph's expert, Dr. Wolfe, confirmed this conclusion, stating that the specification has no technical disclosure of alternatives for the system bus. Def's Exh. 2, Wolfe Dep. at 40:21-41:10, 53:23-57:2, 58:3-11, 64:17-20. The diagram denoted Figure 1, which is common to the two patents, clearly shows that all communications between any component and the main memory pass through the system bus.

Additionally, the specifications of the two patents differentiate between different buses, including the I/O bus, the cache/processor instruction bus, and the cache/processor data bus. The claims of the '846 Patent also identify different types of buses, in particular the "processor bus" as opposed to the "system bus." '846 Patent, Claim 17. Toshiba claims that Intergraph's proposed construction would eliminate this distinction between the system bus and other buses which is explicitly drawn in the claims and specification. Dr. Wolfe was unable to identify any language in Intergraph's proposed construction of "system bus" that would not also apply to the processor buses, and acknowledged that the proposed construction does not differentiate between buses based on purpose. Def's Exh. 2, Wolfe Dep. at 101:16-105:17, 111:24-112:18, 122:23-123:2.

Toshiba also points to the context of the claim language in support of its interpretation. Claim 1 of the '846 Patent recites "a system bus coupled to the primary memory," "a first data processing element coupled to the system bus for processing data from the primary memory," and "cache memory management means, coupled to . . . said system bus" including "a cache memory for storing data from said primary memory" (emphasis added). Toshiba asserts that this language comports with the system bus being the sole pathway to the main memory in light of the written description. Additionally, Claims 1 and 9 each recite "data consistency means" that include a system bus monitoring means to monitor I/O requests "over the system bus." Toshiba claims that because the only monitored I/O requests affecting this data consistency are directed to the main memory, they must traverse the system bus. Toshiba additionally claims that Intergraph's statement of the invention confirms Toshiba's construction of "system bus." The stated aim of the invention is to ensure data consistency between the cache and the main memory, and

- 4626 -
this is achieved by a cache controller that monitors the system bus and maintains data consistency. Toshiba claims that monitoring "system bus" transactions would not ensure data consistency if data could flow into and out of the main memory through channels other than the system bus. Def's Exh. 1 P 64. As discussed above, the data consistency function of the invention is important where components other than the cache memory are communicating with the main memory. For example, if an I/O device alters data in the main memory, the system bus monitoring means detects the change and reacts appropriately to ensure data consistency between the cache memory and the main memory. Because the system bus monitoring means monitors the system bus only, if I/O devices could alter data in the main memory through channels other than the system bus, the system bus monitoring means would fail to detect the data modification, and the data consistency operation would not be triggered. Under such circumstances, one of the key aims of the invention--maintaining data consistency between the cache memory and the main memory--would be thwarted.

In response, Intergraph argues that its data consistency mechanism can operate in a computer containing a separate pathway other than the system bus for I/O to access primary memory. According to Intergraph, in such a configuration data consistency could be maintained where an I/O request is sent over the system bus and monitored by the system bus monitoring means. This argument appears wholly irrational. Intergraph appears to confirm that data consistency is attained only where I/O requests are sent over the system bus, which supports Toshiba's argument. In other words, if the goal of the invention is data consistency and data consistency is only maintained for communications passing through the system bus, then the only reasonable interpretation is that all communications must pass through the system bus.

Toshiba further claims that Intergraph's construction would render the patents invalid as non-enabling. In particular, the fact that the specification teaches only a system whereby all main memory communications to go over the system bus would render invalid a claim that covers main memory communications that do not involve the system bus. While this type of invalidity argument is inappropriate at the claim construction stage, the court is mindful of the tenet that claims should be construed to avoid invalidity.

Finally, Toshiba claims that Intergraph knows that its construction is wrong, pointing to previous statements by Intergraph's CEO and an Intergraph expert in a prior litigation indicating that all communication involving the main memory passed through the system bus. Defs' Exhs. 5 & 8. Intergraph responds that these references are irrelevant, and that they express opinions not relied upon by Intergraph. Intergraph further claims that the CEO opinions cited by Toshiba referred to a configuration in which I/O data was not required to go over the system bus to access memory, and that the expert report did not address whether all communication with the main memory took place over the system bus. Because it is not clear that the specific issue at hand here--whether all communications with the primary memory in the claimed system must pass over the system bus--were at issue in the contexts of these previous statements, the court affords this evidence little weight.

Focusing, as the court should, on the intrinsic evidence available, Toshiba's position that the system bus must carry all communications with the primary memory is correct. The cited references support both readings, but the patent itself uniformly treats the system bus as a component carrying all main memory communications. Intergraph does not seem to dispute the treatment of the system bus in the patent itself, or point to anything in the specification suggesting that communications with the main memory can take place via paths not involving the system bus. Furthermore, Intergraph's superfluity argument is unconvincing. Even if the court were to reject Toshiba's argument regarding the meaning of the phrase at issue, the inclusion of this phrase could easily be interpreted as adding clarity to the claim rather than specifying a particular limitation. In any case, superfluity is not so rigid a doctrine as to require the court to disregard the unambiguous teachings of the specification itself. Finally, Toshiba is correct that Intergraph's broad construction would confuse the system bus with other, distinct buses disclosed by the patents.

In sum, the court adopts Toshiba's construction of "system bus": "a bus having multiple masters and through which the primary memory communicates with each system element that accesses primary memory."

4364

3. System Bus

A "system bus" is a plurality of shared signal lines that interconnects more than two agents for transmission of data, address, and control signals. The system bus must be capable of accommodating multiple requesting agents. If multiple requesting agents are present, arbitration determines access to the system bus.
II. System Bus Means

The term "system bus means" appears in Claim 1 of the '835 Patent. The clause at issue is "system bus means, coupled to the primary memory, for communicating data with the primary memory means." The parties disagree as to whether the term is a means-plus-function element.

The use of the word "means" raises a strong presumption that Section 112(6) applies. Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1427 (Fed. Cir. 1997). However, "where a claim recites a function, but then goes on to elaborate sufficient structure, material, or acts within the claim itself to perform entirely the recited function, the claim is not in means-plus-function format." Id. at 1427.

During prosecution, Intergraph canceled certain claims that recited "system bus" and replaced them with claims that recited "system bus means," Pl's Exh. N at 2, lending further support to the contention that "system bus means" is not coterminous with "system bus." In response, Toshiba cites a patent attorney's opinion from an earlier litigation, in which the attorney opined that Section 112(6) did not apply to the term "system bus means." Defs' Exh. 11 at 8 & 15.

In light of the above discussion and construction of the term "system bus," the term "system bus monitoring means" recites sufficient structure to perform the function of "communicating data with the primary memory means." Accordingly, "system bus means" is not a means-plus function term.

7. "system clock" ('002 and '222 patents)

The Special Master found that "the familiar word 'clock' may have the potential to engender some confusion in the mind of a reasonable juror." Rejcting constructions offered by both sides he recommends that "system clock operably connected to the processor to provide a time base" be construed to mean an element, made up of hardware, software, or some combination of the two, that provides electrical signals at a precise frequency to the processor. 107

The Court agrees with the Special Master that the term should be construed for the ordinary juror and that by its plain language the claim requires that a "clock" provides more than interrupts. The Court adopts the claim construction as follows:
the term "system clock operably connected to the processor to provide a time base" is construed to mean an element, made of up hardware, software, or some combination of the two, that provides electrical signals at a precise frequency to the
The plaintiffs propose "a circuit that generates the signal(s) used for timing the operation of the CPU." The defendants contend that the term means "a circuit that is itself responsible for determining the frequency of the signal(s) used for timing the operation of the CPU." The dispute is whether the circuit alone is responsible for determining the frequency of the signal.

A system clock does not generate the signal alone because the timing can be derived from the ring oscillator. '336 patent, 16:63-67. Accordingly, the Court adopts the plaintiffs' proposed construction.

J. "system controller," "comparator," and "classifier" 36

The phrase "system controller" is used in claims 1, 8, 9, 13, 14, 15, 16, 17, 18, 19, 20, 25, 26, 27, 28, 30, 32, 33, 35, 36, 37, 38, 39, 40, 41, and 42 of the '259 patent. The word "comparator" is used in claims 21, 22, and 29 of the '259 patent. The word "classifier" is used in claims 21, 23, and 24 of the '259 patent.

1. ADE's Position

ADE asserts that a plain and ordinary meaning of "system controller" should be adopted by the Court and suggests that the Court construe the phrase to mean "hardware, software or some combination thereof for controlling the system in whole or in part." (D.I. 595 at 29.) ADE says that "comparator" should mean "hardware, software, or some combination thereof, capable of being configured to receive and compare signals." (JCCS at 17.) ADE also argues that "classifier" should be construed to mean "hardware, software, or some combination thereof, capable of being configured to classify defects." (Id.)

2. KLA's Position

KLA does not "believe that a material dispute exists concerning" the meaning of "system controller." (D.I. 615 at 12 n.4.) KLA, however, suggests that "system controller" means "electronic hardware or an electronic hardware/software combination." (D.I. 575 at 8.) KLA asserts that the "comparator" should mean "electronic hardware or an electronic hardware/software combination configured to receive and compare the signals." (JCCS at 17-18.) "Classifier," asserts KLA, should be construed to mean "electronic hardware or an electronic hardware/software combination configured to classify defects as pits or particles based at least in part on the comparison." (Id.)

3. Analysis

The claim term "system controller" is described in the '259 specification. The terms "comparator" and "classifier" are not.

- 4629 -
37 However, "comparator" and "classifier" are plain and ordinary words. In the dictionary, a "comparator" is defined as "a device for comparing something with a similar thing or with a standard measure," and the definition of "classifier" is "a machine for sorting out the constituents of a substance." MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY 211, 233 (10th ed. 2002). Nothing in the specification or intrinsic record dictates a more restrictive definition. The Court, therefore, construes "comparator" to mean a device for comparing something with a similar thing or with a standard measure and "classifier" to mean a machine for sorting out the constituents of a substance.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

37 ADE directs the Court's attention to col. 11 II. 24-36 of the '259 patent specification for a construction of the claim terms "comparator" and "classifier." (JCCS at 17.) KLA points the Court to the same intrinsic evidence it cited for a construction of the claim term "system controller" ('259 Patent at Figures 1, 3, and 7; col. 7 II. 54-60; col. 8 I. 55 to col. 9 I. 10). (Id. at 8, 17.)

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

As to the term "system controller," the inventors specified that "the system controller … operates the inspection system … under the supervision and direction of a human operator, stores and retrieves data generated by the system …, and performs data analysis preferably responsive to predetermined commands." (D.I. 627, '259 Patent Prosecution File History, '259 Patent at col. 8 II. 27-31.) The inventors further specified that "the surface inspection system … as illustrated in FIG. 7, and as understood by those skilled in the art, preferably is formed of a combination of software and hardware which forms these various components, or combinations thereof, of the system …." (Id. at col. 9 II. 5-10.) The Court, therefore, construes "system controller" to mean a combination of software and hardware operated under the direction of a human operator that is capable of storing and retrieving data generated by the system and of performing data analysis on said data, preferably responsive to predetermined commands.

4369

System database

The Court modifies Autobytel's proposed construction and construes the term as "a database in the Data Center system." Dealix argues that the term should be construed as "a collection of related data stored in one or more computerized files in a manner that can be accessed by users or computer programs via a database management system used by the Data Center system." Dealix's proposed construction comes from the IEEE Dictionary's third listed definition of "database." Dealix argues that the "ambiguous and sometimes contradictory way in which the patent specification refers to the system database and the Data Center Programs in relation to the storage medium 106" requires extrinsic evidence to provide a proper construction to the term. Autobytel contends that Dealix's construction is too limiting and proposes that the term should be construed as "a database associated with the Data Center system." Autobytel relies on the specification's discussion of the system database, which is shown as storage medium 106 in Figure 1, see Col. 6:43-54, and particularly the portion that states, "In an alternative embodiment, the database may conform to any database standard, or may even conform to a non-standard, private specification." Col. 6:45-47. Autobytel contends that the specification supports a wide variety of database implementations and is not limited to the use of a database management system.

The Court agrees with Autobytel that there is no need to look to extrinsic evidence such as dictionaries to construe the term. Furthermore, the Court agrees that the specification supports a wide variety of database implementations and is not limited to the use of a database management system. However, the Court does not agree with Autobytel that the database is simply "associated" with the Data Center system. The Court agrees with Dealix that the word "system" is a reference to the Data Center system. Accordingly, the Court construes the term such that the database is "in" the Data Center system.

4370

5. "system for managing financial instruments"
Southwest argues that "system for managing financial instruments" means "a data processing system, software, display, keypad, and printer," whereas 3T argues that it means a "network of devices and employees that interact to manage financial instruments." Southwest and 3T provide little guidance for their proposed constructions.

The Court finds that Southwest's proposed construction lacks specification support and does not follow the language of claim 11. The Court finds that the 3T's proposed construction for the term "system" is more appropriate for the commonly understood meaning of the term if the extraneous term "employees" is eliminated. Thus, the Court construes the term "system for managing financial instruments" to mean "network of devices that interact to manage financial instruments."

4371

a. "System monitor"

The term "system monitor" appears in Claims 22, 24, 25, and 26. In each of these claims, the "test signal generator" from independent Claim 1 comprises a "system monitor." n6 Claim 22 discloses a "system monitor" without qualification. A series of dependent claims that includes Claims 24 through 26 places limitations on the system monitor. The term first appears in the description of the preferred embodiment:

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n6 In its prior order, the court stated that in Claim 22, "the test signal generator' is limited to the system monitor'. . . ." October 25 order at 16 (emphasis added). The court should have stated that "the test signal generator" comprises the system monitor'. . . ."

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

A system monitor mediates the external defibrillator's self-testing functions by watching for scheduled test times and unscheduled power-on events. The system monitor generates test signals periodically at scheduled times and in response to specified events. The system monitor is also responsible for operating a fail-safe defibrillator status indicator or display.

Although the court must look to the preferred embodiment in construing "system monitor," it need not limit the term according to the preferred embodiment. In particular, where claims depending from Claim 22 disclose a limitation on the system monitor, the doctrine of claim differentiation compels a presumption that the term "system monitor" does not contain that limitation. Thus, the "system monitor" presumably need not comprise an application specific integrated circuit as disclosed in Claim 23, need not comprise a separate power supply as disclosed in Claim 24, need not comprise means for generating periodic test signals as disclosed in Claim 25, and need not comprise means for generating test signals in response to specified events or conditions as disclosed in Claim 26.

These disclosures reveal more than what "system monitor" does not mean, they also provide a guide to interpreting "system monitor" in light of the specification. The specification discloses a host of specific capabilities for a system monitor, but when the inventors intended to require the system monitor to perform a specific function, they drafted a dependent claim corresponding to the function. For example, Defibtech insists that the "system monitor" must at least watch for scheduled test times or unscheduled power-on events, as disclosed in the first sentence of the specification describing the element. 374 Patent at 4:60-62. The ability to watch for scheduled test times, however, is necessary only when conducting periodic self-tests. That function is ascribed to the system monitor in dependent Claim 25. Another illustrative example is the "System Watchdog Verify" self-test. 374 Patent at 8:9-17. A defibrillator that ran only this self-test on battery insertion would have no need to monitor for scheduled test times or unscheduled power-on events.

The court thus finds that the bare term "system monitor" refers to a device that performs only the necessary functions that the specification ascribes to the system monitor. Those necessary functions are receiving information from other
components regarding at least one self-test, and operating a fail-safe defibrillator status indicator or display corresponding to that information. As noted in the court's discussion of the term "prior to any attempted use" in its prior order, the 374 Patent does not require any particular self-test or group of tests, but merely requires at least one such test. October 25 order at 17-20. The information that the system monitor receives, and the source within the defibrillator from which it receives that information, necessarily depends on the type of self-test. Thus, absent any suggestion from the parties of information or information sources that are required in any randomly selected self-test, the court declines to impose a more specific limitation. The term "system monitor" thus means "a circuit, component, or device for receiving information regarding at least one self-test and operating a fail-safe defibrillator status indicator or display to correspond to that information."

4372

A. "state" or "system state"

1. The Parties' Proposed Constructions

The plaintiffs say that "state" or "system state" should be construed as "an automated trading procedure that defines the options available to participants and the rules of trading." (D.I. 463 at 3; D.I. 464 at 10.) The defendants' proposed construction is "a condition of a finite state machine embodied in a computer system and used to control an aspect of the system's operation, substantially as described in the '580 patent." (D.I. 463 at 3; D.I. 482 at 6.)

2. The Court's Construction

As discussed, the '580 patent is a business method patent, and not, as the defendants would have it, "a patent on an automated auction protocol processor that implements what could be characterized as a business method." (D.I. 514 at 54:18-21) or "a patent on a computer system that embodies logic…" (id. at 10-12). The defendants' proposed claim construction for "state" or "system state" therefore fails, because it is predicated upon the erroneous conclusion that the invention claimed in the '580 patent is a finite state machine. 8

--- Footnotes ---

8 Furthermore, during prosecution of the '580 patent, the plaintiffs emphasized to the Examiner that a state change referred to changing protocols of trading, and not to the operation of a computer or a computer program. Rather, they said that "change of state refers to the different protocols governing trading securities during different conditions…." (D.I. 463, Ex. E at FN1866-67.)

--- End Footnotes ---

The plaintiffs' proposed claim construction of "state" or "system state" is supported by the intrinsic evidence, specifically, the language of unasserted claim 26, which recites "a plurality of states which define the ability of participants to participate in trading...." ('580 patent, col. 21, II. 24-26.) There is also language in the specification which says that "the workstation "state" determines the options available to [a] trader," (id., col. 5, II. 15-32) and that "as each state is entered, the protocols are shifted and new rules to trading apply" (id., col. 8, II. 55-61). Thus, because the intrinsic evidence clearly supports the plaintiffs' proposed construction of the claim term "state" or "system state", I will construe "state" or "system state" to mean "an automated trading procedure that defines the options available to participants and the rules of trading".

4373

Systems interface

JuxtaComm contends that "systems interface" does not require construction or, if construed, means "an interface to the distribution system." Defendants contend "systems interface" means "a component that enables a user to interact with the system." Defendants argue that "systems interface" is a user interface because the claimed functions performed by the
systems interface are ones that the patent teaches are performed by a user.

Claim 1 does not expressly mention a user. In claim 2, the applicants expressly claimed a user interface. Thus, the applicants claimed a user when they intended a user to be a claim element. The claim 1 systems interface does not inherently require a user as it could be coupled to another computer system rather than a user terminal. See col. 7:19-22. Accordingly, the Court will not add a user limitation to claim 1. The Court construes "systems interface" as "an interface to the distribution system."

TCP/IP protocol data packet

Claim 1 contains the term "TCP/IP protocol data packet." Accolade contends that "TCP/IP protocol data packet" should be given its plain and commonly understood meaning and does not need construction. Alternatively, Accolade argues that the term means "units of data transmitted in compliance with the TCP/IP protocol between computers on a network." Citrix contends that "TCP/IP protocol data packet" means "a data packet constructed, transmitted, and received according to the Transmission Control Protocol/Internet Protocol format."

In light of the intrinsic record, the Court construes "TCP/IP protocol data packet" as "packets of data in compliance with the Transmission Control Protocol/Internet Protocol ("TCP/IP")." The specification refers to TCP/IP protocol data packets, stating, "The construction and use of TCP/IP protocol networks such as the Internet and private Intranets, and the TCP/IP protocol data packets (or simply 'TCP/IP data packets') sent over such networks, is well known to those skilled in the art." Col. 5:13-17. Thus the specification refers to "TCP/IP protocol data packet" as having its ordinary and customary meaning that is well understood by those skilled in the art. Elaborating on the ordinary and customary meaning, the parties agree that the TCP/IP protocol governs the way that TCP/IP protocol data packets are transmitted. Accordingly, transmission of TCP/IP data packets is in compliance with the TCP/IP protocol. Thus, the Court construes "TCP/IP data packets" as "packets of data in compliance with the Transmission Control Protocol/Internet Protocol ("TCP/IP")."

9 The parties do not dispute that "TCP/IP" is an acronym for Transmission Control Protocol/Internet Protocol.

V. "TV quality"

The phrase "TV quality" appears in dependent claims of the '547 patent, and is used to indicate the quality of video images displayed by the claimed invention. See, e.g., '547 patent at 45:48-49 ("reproducing the video images . . . at TV quality"). The parties disagree as to whether the Specification defines TV quality as a particular resolution in pixels, color depth, and number of frames per second, "30 frames per second at 640*480 pixels per frame and the equivalent of 24 bits of color per pixel with accompanying high-fidelity audio (typically between 7 and 15 KHz)," or whether the phrase should be read more broadly as "generally of the same quality as television (at the time the patent was filed)."

The portion of the Specification cited by Tandberg states that

[i]n the preferred embodiment, it has been found particularly advantageous to provide the above-described video at standard NTSC-quality TV performance (i.e., 30 frames per second at 640*480 pixels per frame and the equivalent of 24 bits of color per pixel) with accompanying high-fidelity audio (typically between 7 and 15 KHz).

Spec. at 6:48-53. The problem with Tandberg's reliance on this passage, however, is that it expressly limits its applicability to the preferred embodiment. It would be erroneous to limit the claim language as Tandberg suggests.
Tandberg also offers excerpts from the file history to show that CPI disclaimed other levels of image and audio quality during prosecution. The excerpts, however, are either taken from the prosecution of different claims from those at issue here or do not support Tandberg's proposed standard. For example, Tandberg's excerpt from the prosecution of U.S. Patent No. 6,898,620 recites a standard of 25 Hz rather than 30 Hz, and mentions several alternate standards for TV quality—NTSC, PAL, and SECAM. Tandberg does not argue that all of these standards conform to its proposed limitation. Moreover, CPI points out that the "TV quality" limitation was added as part of a broadening amendment, replacing the language "greater than 20 frames per second." It would be anomalous to construe the claim more narrowly than it was drafted prior to being broadened.

Finally, Tandberg once again argues that CPI's construction is too vague, and would result in rejection under section 112. Tandberg must raise its validity argument in a motion for summary judgment or at trial.

The court therefore adopts CPI's construction. "TV quality" is construed to mean "generally of the same quality as television (at the time the patent was filed)."

An example of the use of the term is seen in claim 1 of the '691 patent, stating in part, with the disputed term in bold:

1. **A method for inventory management, comprising the steps of:** . . .

(b) generating a table of one or more inventory items that most closely correspond to the customer request using a price forecasting system. . .

Grantley proposed, "a graphically arranged collection of data." Clear Channel proposed, "a single visually viewable grid in a single window from which a computer-implemented selection can be made." Clear Channel agreed that the use of the indefinite article "a" did not in itself indicate there could be only one table. Tr. p. 60, ll. 12-17. As a matter of common patent parlance "a" denotes "one or more that one." Norian Corp. v. Stryker Corp., 432 F.3d 1356, 1359 (Fed. Cir. 2005).

"Table" is used in the first sentence of the Abstract and in the first sentence of the "Summary of the Invention" at col. 3, l. 27. In both places, the full phrase is "a table or menu of one or more inventory items that most closely correspond to the customer request . . . ." After the table of inventory items is generated, a selection of one or more items is made by the customer or salesperson. '691 patent, col. 16, ll. 40-42, col. 3, ll. 34.

One possible layout of the computer screens displayed is shown in Figures 9 and 10 and described in the '691 patent at col. 14, ll.15-31. If there are many stations in the network, and a large and varied inventory of advertising spots are available, one skilled in the art would know that the table or menu may comprise several successive windows. For example, the first window could show stations which may meet the customer's criteria, while successive windows would show more precise information as the customer's choice is refined.

A common example of such a hierarchical organization of information is seen in word processing programs, where the user selects a file, and then may have a choice of several sub-files, and then a choice of several documents. The '691 patent states that such a "hierarchy of screens which become progressively more specific as shown is most preferred." See '691 patent, col. 14, ll. 27-31. A claim construction that excludes a preferred embodiment is "rarely, if ever, correct." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996). Here, there is no basis to accept Defendants' invitation to define "table" so as to exclude the preferred embodiment. The court will define this term as follows:

"Table" means: "an arrangement of items of information that assists in choosing one or more of the items."
A. LaserDynamics contends that the term "table of contents" means a concise list or guide. It refers the Court to Merriam Webster's Collegiate Dictionary, Tenth Edition for the "ordinary" meaning of the term. In the specification, LaserDynamics used the term "total of contents," yet, in the claims that term is not used. Thus, the acronym "TOC" and the term "Total of Contents" do not appear in the claims. LaserDynamics argues that the acronym and term are examples found only in the specification, therefore, the Court should interpret the term in the claims more broadly than used in the specification.

Mediamatics argues that the inventor coined "total of contents" and uses the acronym "TOC" to refer to "total of contents." They argue that the term is a technical terms and, therefore, "table contents" as used in the claims must be construed in reference to the "coined" term used in the specification. Given this approach to interpretation, Mediamatics contends that these terms, "table of contents" and "total of contents," when construed together, mean that "table contents" is not a term that is susceptible to its ordinary meaning.

In construing a claim, courts first look to the intrinsic evidence, the claims themselves, the patent specification, and the patent's prosecution history. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). However, within the intrinsic evidence, the actual words of the claims are the focus of the analytical exercise. Digital Biometrics, Inc. v. Indentix, Inc., 149 F.3d 1335, 1344 (Fed. Cir. 1998). Thus, the claims are the text and, therefore, the beginning point for understanding the inventor's intent. In this construct, the specification may be used to explain, discuss or illustrate a proper use of a term in a claim. But, the specification cannot be used to limit the meaning of a term in a claim. Teleflex Inc. v. Ficosa North Am. Corp., 299 F. 3d 1313 (Fed. Cir. 2002). This is so because words used in a claim are presumed to have their ordinary meaning. Id. at 1324. And, a departure is not warranted unless the specification or prosecution history expresses a "manifest exclusion" or restriction that is a clear disavowal of the claim scope.

In the case at bar, the evidence and the specification fail to demonstrate that the use of the term "total of contents" was meant to be a "manifest exclusion or restriction" on the term "table of contents" as used in the claims. The same construction applies to the acronym "TOC." The Court need not address whether the terms are synonymous or whether the term "total of contents" and the acronym "TOC" are a class or collection within the term "table of contents." It is enough to say that the use of the term "table of contents" in the claim is not limited by the use of the term "total of contents" or the
acronym in the specification. Indeed, no internal conflict is revealed by the use of these terms as presented. Finally, the fact that the inventor used both, the term "total of contents" and the acronym "TOC," is of no moment because the term and acronym are not defined contrary to the ordinary meaning given the term "table of contents." Moreover, the manner of use, i.e., in the specification or figures, defines only the parameters of the examples not the claims.

Mediamatics also challenges LaserDynamics' reliance on the "ordinary meaning" definition of "table of contents" because LaserDynamics resorted to a dictionary for the definition of the term. This challenge is groundless since the use of dictionaries, encyclopedias and treatises are permitted in determining the ordinary and customary meanings of terms. Texas Digital Systems, Inc. v. Telegenix, Inc., 308 F.3d 1193, 1205 (Fed. Cir. 2002). Thus, dictionaries and the like are not extrinsic evidence but instead are original sources from which the legal presumption of ordinary meaning finds residence.

4380

6. "tail slots"

| Wi-LAN's Proposed Construction | Defendants' Proposed Construction |
| "groups of frequencies that act as guard bands to reduce power outside of the frequency band" | "divisions within a frame that act as a guard band" |

The construction of this term relates to the construction for the term "points." Claim 7 of the '222 patent expressly states that "the frequency band is formed from … a pair of tail slots each having K2 points." The specification states that the "two tail slots act as guard bands to ensure that the out-of-band signal is below a certain power level." '222 patent, 5:36-38. Both parties agree that the tail slots act as a guard band, but disagree as to the remainder of the proposed constructions. Based upon Figure 2 and the corresponding specification, it is clear that K1 points are located in the frame and K2 points, corresponding to the two tail slots, are located outside the frame but still in the available bandwidth or frequency band. See '222 patent, 5:26-40, FIG. 2. Thus, the Court rejects Defendants' proposed construction that tail slots are necessarily "divisions within a frame." The Court does not find that Wi-LAN's proposal to include the phrase "reduce power outside of the frequency band" is necessary or is entirely based upon the specification. Thus, the Court construes the term "tail slots" as "divisions within the frequency band that act as guard bands."

GO BACK

4381

I. "Profile tailoring the concentration of transition metal atoms in the substrate relative to the surface of the substrate" (claim 2)

The construction of this claim involves a number of peculiarities, not least of all the fact that APT's explanation of profile tailoring in the background section of its brief provides a clearer and more obvious explication of the term than either of the parties' proposed constructions, the specifications, or the claim itself. In its opening brief, APT wrote that "at least part of the platinum diffusion has a tailored profile, that is, the concentration of platinum with respect to the substrate surface changes as a function of distance from that surface, as shown in Figure 3." APT Opening Br., at 4. This explanation comports well with an intuitive understanding of "profile tailoring," namely the structuring and adjusting of (in this case) transition metal atoms in order to achieve a particular layout or pattern. Nevertheless, since this explanation is offered only in the background section to APT's Brief, the court will turn to the claim and specifications for elucidation.

6 Interestingly, in the section of its brief discussed here, APT cites to the same portion of the specifications that it employs in its argument regarding the construction of this claim language.
Both sides agree that only one portion of the specifications discusses profile-tailoring, and even then somewhat obliquely. The specifications teach that "this technique can also be used to profile-tailor the lifetime control dopant with multiple temperature cycles." '202 patent, 24:1-3. The specifications that succeed this sentence describe a process for diffusing metal atoms into the substrate in a series of steps. In particular, it discusses a particular alignment of metal atoms within the substrate: "Low lifetime control doping in the bulk of the epitaxial layers combined with a higher concentration near the substrate surface adjacent the PN junction can provide the best effect. This doping profile can be obtained...." '202 patent, 24:8-12. This leads to the conclusion that a "profile" is indeed a particular pattern or alignment of transition metal atoms within the substrate. Drawing upon the sentence of the specifications that mentions a technique to "profile-tailor," it would appear that "tailoring" is being used in typical fashion in this context to mean "fashioning, adapting, structuring, or adjusting for a particular purpose." This understanding is congruent with claim 7 of the '202 patent, which discusses tailoring a transition metal to have a "relatively shallow profile." '202 patent, claim 7. In that case the "profile" or pattern of metal concentrations is being adjusted in order to achieve the desired "shallow" pattern.

Strangely, both parties propose a number of limitations that do not appear to be compelled by either the claim language or the specifications. Ixys wishes to add the requirement that the profile of metal atoms must be adjusted in at least two places in the substrate based upon only a preferred embodiment which itself is explicitly non-exclusive. 7 Furthermore, there is no support whatsoever within the specifications or the claims for Ixys' assertion that a tailored profile involves metal atom concentrations that are higher in one place and lower in another than "would be achieved by a single application and diffusion of transition metal atoms at a time and temperature." Ixys' Opp. Br., at 17. Ixys attacks APT's proposed construction because it would not exclude the possibility of a "flat profile," namely one in which the concentration of metal atoms is constant with respect to depth in the substrate. However, the only reliable indication that a "flat profile" must be excluded comes from the Background section of APT's memorandum, which describes a concentration that varies with respect to depth.

7 The specifications refer to "the best effect" and "This doping profile," implying straightforwardly that this is only one of many potential profiles that may be achieved through different tailoring algorithms. '202 patent, 24:11-12.

APT's proposed construction seems both under- and over-inclusive. On one hand, there is no reason to limit the claim language to a process that places metal atoms near the surface of the substrate in a gradient band; the claim language (and the specifications, which describe only briefly a preferred embodiment) is broad enough to encompass types of tailoring that might involve deposition of transition metal deep into the substrate. However, APT's language fails to capture what appears to be the nucleus of the meaning of "profile tailoring," namely that metal atoms are being deposited in certain areas or layers precisely in order to create a particular pattern or "profile."

Finally, neither side has discussed the phrase "relative to the surface of the substrate" in any real "depth." However, the use of this phrase within a semi-conductor patent (a field in which devices are created in stacked layers) and the manner in which it is employed lead the court to believe that a person skilled in the art would reasonably understand it to mean "as a function of depth."

In light of these factors, the court construes this claim term as follows: "Fashioning or adjusting the concentration of transition metal atoms as a function of depth within the substrate in order to create a particular pattern or layout of depth-wise concentrations."

G. "The transition metal is tailored to have a relatively shallow profile compared to a completed diffusion throughout the entire substrate" (claim 7)

Ixys has revised its proposed construction of this language from Claim 7 to read: "Diffusing the transition metal atoms in
the substrate in such a way that there is a higher concentration of transition metal atoms near the surface of the substrate, and a lower concentration of transition metal atoms in the substrate, than there would be with a completed diffusion 'throughout the substrate.'" Ixys' Opp. Br., at 19. APT states that it will accept Ixys' construction as long as the phrase "lower concentration" is understood to be inclusive of zero. APT's Reply Br., at 15. Ixys gives no indication that a "lower concentration" could not include zero, and indeed there is no basis for Ixys to argue such. In the context of this particular phrase of claim language, then, there appears to be no meaningful disagreement. The question of whether (in claim 7) transition metal atoms must exist in all parts of the substrate hinges not on the comparison at issue in this claim term, but on the construction of the word "throughout" in claim 2, which is addressed below.

Since the meaning of "throughout the substrate" is disputed, whereas the meaning of the original term ("throughout the entire substrate") is not (see (H)(1), infra), it seems prudent to make that substitution within Ixys' proposed phrase. The court construes this claim language to mean: "Diffusing the transition metal atoms in the substrate in such a way that there is a higher concentration of transition metal atoms near the surface of the substrate, and a lower concentration of transition metal atoms in the substrate, than there would be with a completed diffusion throughout the entire substrate [construed infra]."

LifeScan also appeals the district court's construction of the claim terms: a) "specified time interval"; b) "upon detecting a predetermined drop in reflectance sufficient to indicate that sample reached said first surface"; and c) "calculating said glucose concentration in said sample from one of said reflectance readings." Because the district court read those terms as limited to predetermined timing methods, those claim terms as well require revision based on the full scope of the claim language as understood by those of skill in the art at the time of invention.

Specifically, the district court erred in construing "specified time interval" to mean "times set in advance" because it limited claim 4 of the '162 patent to a preferred embodiment. Claim Construction Order, 2002 U.S. Dist. LEXIS 27575 at *9. Again consulting dictionaries within the context of this field of technology at the time of invention, "interval" is "a space of time between two events or points of time." Webster's Third New International Dictionary at 1183. This definition does not carry any hint of predetermined time calculations or intervals. Because LifeScan does not clearly disavow this customary meaning of the claim term, "specified time interval" means "a space of time between two events." In this instance, the interval refers to the space of time between reflectance readings from the testing surface of the matrix.

The district court ruled that the '124 patent did not clearly define "telephone emulation," and adopted the Orr definition: The replication of the electrical and functional characteristics of a specific telephone set by another device, including the "electrical signature," a critical component of which is the presence, as distinguished from the utilization, of a voice or talk path.

We agree with VMC that this definition and the underlying definition of "voice or talk path" are contrary to the specification. The distinctions are critical to the outcome of this case.

Oshima explains in his declaration that the term "talk path" in the specification refers to the transmission of voice sounds:
12. Although it is not essential that the talk-path be in analog form, that is a typical mode with PBX systems. Newer models actually are on the market that replace the analog voice path system with digital communications, that is, electrical impulses translatable into binary code, i.e., ones and zeroes. Whether the PBX transmits voice in analog form or translates it into digital form, it is the transmission of the sounds—including the human voice—in a telephone call that we refer to in the patent as the talk path. We say this clearly in column 2, line 66 of the '124 patent:

The present invention does not contain, nor utilize any voice detection circuitry and thus cannot establish a direct talk path with the PBX system. The present invention connects with the data pair of the line card only. Since the establishment of a direct talk path is a necessary function of a telephone set, the present invention cannot perform telephone emulation.

Oshima explains that Orr's affirmations are correct only if "voice or talk path" is defined as voice pair wires supplying electrical power to a telephone set device or PBX communications device, in a situation where the device otherwise would not receive power:

22. Where Orr and Fritzinger confuse the issue is in using the term "voice pair" as a synonym for "talk path," contrary to the above-quoted portion of the specification, and contrary to the way the term "voice path" or "talk path" is commonly used in the industry, in my ten years experience in it. The way in which they use the term talk path apparently includes the use of the voice path as a source of electric power, not as a path for voices. Thus, Orr says that the "accepted definition of 'telephone emulation' in the art, requires the presence of a voice or talk path, whether utilized or otherwise . . . " (emphasis added). She therefore concedes that the talk path does not have to be used in order to complete the "handshake."

* * *

26. The definition that Orr draws for telephone emulation from the erroneous definition of voice path, is also necessarily wrong, in the sense that it is inconsistent with what the patent actually says. To paraphrase Orr, she is correct from a technical standpoint, if [sic] when she says that the VMC device will not work without connection to the voice path, only if what she means is "the VMC device won't work unless it is attached to a power source." She is right that the device will not work without power; she is wrong if she uses the correct definition of voice path as it is defined in the patent specification.

(Citations omitted.) Oshima states that Orr misleadingly implies, and conspicuously avoids stating, that the "electronic signature" confirmation or "handshaking" required for operability is accomplished over the voice pair. Oshima states, and the specification requires, that the required handshaking between the PBX and the communications device takes place exclusively over the data pair:

19. . . . There are no polling messages or handshaking messages sent over the voice pair.

* * *

23. On careful reading of the Orr Affirmation, she does not say that the "handshake" is accomplished over the voice pair. In fact, it is not necessary to complete the handshake over the voice pair at all, in our device. As Figure 4 shows, and as the videocassette demonstration shows, the handshake is completed entirely digitally, over the data pair, and there is no need for the voice pair to be connected to anything, if a separate power source is available. To anyone familiar with the operation of telephones, what Ms. Orr is saying ultimately is nothing more than that the system will not work if it is not plugged in. It is obvious to anyone with skill in the art that the best mode diagram and the accompanying text (column 5, lines 4-5) show the voice pair "is used only for reference ground and power."

See also Col. 6, lines 40-42 ("Polling messages can take many forms, but is normally a predefined data packet addressing a specific device or component.")

Thus Oshima explains that Orr's affirmations merely state that the handshaking between the PBX and the attached device can not take place if the attached device, whether it be a telephone set or a PBX communications device, does not receive power. In the case of a telephone set, the voice pair typically supplies power. If the voice pair is severed, the telephone set will not handshake -- not because there is no voice pair, but because there is no power. On the other hand, in one embodiment of the '124 patent, the voice pair is used for reference ground and power, terminating in a transformer that
draws direct power and reference ground from standard AC power lines, i.e., a standard wall outlet. Even if the voice pair is severed, the PBX communications device will continue to handshake and to operate, because the transformer continues to supply power to the PBX communications device. The demonstrative video shows such an embodiment of the '124 patent. The PBX communications device performs various operations, notwithstanding that the voice pair from the line card hangs in space.

Thus Oshima states that Orr merely affirms that neither a telephone set device nor a communications device is capable of handshaking when power is not supplied to the device. According to Oshima, Orr's analysis is premised on a definition of "direct talk path" contrary to the '124 specification.

The declaration of Oshima exposes ambiguities in the Orr and Fritzinger analyses, and their distortion of the '124 invention. We express concern that this court's Markman decision may have led the district court to exclude the Oshima declaration and video demonstration during claim construction. Although in Markman this court stated that "the subjective intent of the inventor when he used a particular term is of little or no probative weight in determining the scope of a claim," this statement does not disqualify the inventor as a witness, or overrule the large body of precedent that recognizes the value of the inventor's testimony. See Hoechst Celanese Corp. v. BP Chemicals Ltd., 78 F.3d 1575, 1580, 38 U.S.P.Q.2D (BNA) 1126, 1130 (Fed. Cir. 1996) (inventor's testimony considered as "enlarging [Federal Circuit's] understanding of the technology and the usage of the disputed terms"). This court in Markman did not hold that the inventor cannot explain the technology and what was invented and claimed; the Federal Circuit held only that the inventor cannot by later testimony change the invention and the claims from their meaning at the time the patent was drafted and granted.

Patents are written not for laymen, but for and by persons experienced in the field of the invention. An inventor is a competent witness to explain the invention and what was intended to be conveyed by the specification and covered by the claims. The testimony of the inventor may also provide background information, including explanation of the problems that existed at the time the invention was made and the inventor's solution to these problems. See, e.g., Hoechst Celanese, 78 F.3d at 1580, 38 U.S.P.Q.2D (BNA) at 1130. Although Markman and other precedent caution the court against creative reconstruction of an invention by interested persons, courts are not novices in receiving and weighing expertise on both sides of an issue. The Supreme Court in Daubert v. Merrell Dow Pharmaceuticals, Inc., 509 U.S. 579, 125 L. Ed. 2d 469, 113 S. Ct. 2786 (1993) instructed trial judges to exclude scientifically unqualified witnesses, not those with superior qualifications.

The district court's definitions of "telephone emulation" and "direct talk path" are contrary to the clear meanings provided in the '124 specification and therefore must be rejected. See Multiform, 133 F.3d at 1477, 45 U.S.P.Q.2D (BNA) at 1432; Lear Siegler, 733 F.2d at 889, 221 U.S.P.Q. (BNA) at 1031. Although Voice Technologies' expert witness Orr characterized Figure 2 as "ambiguous" and "unclear," stating that "the only way the invention described in the specification, including the drawings, would successfully operate is if the voice pair 14 was properly terminated at transformer 15 such that the PBX could be satisfied that a voice path has been established" this statement contradicts the statements in the '124 patent that the invention does not establish a "direct talk path." Orr's definitions, resulting in a specification that describes an inoperable invention, were not supported by any evidence and were impugned by the videotape showing the invention in operation. Orr's definitions were also contradicted by Voice Technologies' own employees.

We conclude that it is not necessary to establish a voice or talk path in order for the '124 invention to operate as described in the specification. Although the absence of a direct talk path comports with the absence of telephone emulation, and is the correct criterion for construction of the claims, the district court did not properly define "direct talk path." A "direct talk path" requires a voice pair or a data pair used to carry voice sounds and connected to voice detection circuitry, and "telephone emulation" is impossible without "direct talk path."
"At least two remote switches within a metropolitan area, which each have switching intelligence enabling local switching among carriers interconnected at said switches without the need to transport or backhaul 4 traffic to a main switching center to make such connections."

Footnotes
4 The term "backhaul" is generally used to describe a situation wherein traffic is "hauled" (i.e., transported) in a manner that might be considered to provide a less-than-preferred level of efficiency.

NT argues that its straightforward construction of tandem access points can be found in the language of claim 1: "a plurality of tandem access points for connection to switches of a plurality of said public and private wireline and wireless carrier networks." Peerless looks to the specification for its proposed construction. Peerless notes that the '708 Patent states "the NTN 40 provides Tandem access points 41 for all carriers in the region." Thus, Peerless argues, descriptions of element 41 are "inextricably tied" to the construction to tandem access points. Peerless then notes that the '708 Patent states "[e]ach gateway or remote module 41 on the NTN metropolitan network 40 will have switching intelligence, thus enabling local switching among carriers interconnected at the remote site without the need to transport or backhaul traffic to the main switching center to make such connections."

NT counters that Peerless's proposed construction improperly excludes many of the explicit examples of tandem access points in the specification and limits the term to a preferred embodiment. And, further, that Figures 15 and 17, from which Peerless draws the "switching intelligence" and "backhaul" language, depict embodiments of the '708 Patent, not requirements. Moreover, that the part of the specification Peerless relies on speaks of a "gateway or remote module," not tandem access points. Had the language been intended to limit the meaning of tandem access points, that term would have been used.

NT's arguments are persuasive. The construction of a tandem access point as the point at which a carrier's network is connected to the claimed network is drawn directly from the language of the claims. By contrast, Peerless's construction includes terms that appear only in the specifications and are not clearly required elements of the term. See Kara Tech. Inc. v. Stamps.com Inc., 582 F.3d 1341, (Fed. Cir. 2009) ("The claims, not specification embodiments, define the scope of patent protection. The patentee is entitled to the full scope of his claims, and we will not limit him to his preferred embodiment or import a limitation from the specification into the claims.").

Peerless further argues that NT's proposed construction of tandem access points is unworkable because it leads to an unending circular analysis: NT's proposed construction of tandem access points refers to "the claimed network," but a determination of what the claimed network is cannot be made until tandem access points are defined. This argument is not persuasive. It is not logically inconsistent for a tandem access point to be considered both part of the claimed network and the point at which that network connects to a carrier's network. A definition of tandem access points would reasonably refer to the network, and a definition of the network would likewise include tandem access points as a component. That the two terms are necessarily and obviously related to one another does not make the analysis impermissibly circular.

Therefore, the Court construes "tandem access points" as "a point at which a carrier's network is connected to the claimed network."

The Court adopts Ciena's proposed construction and construes the term as “an intermediate switch other than the originating and destination switches.” Nortel argues that the term should be construed as "any path-oriented switch that is intermediate to a destination switch and an originating switch on a path." Nortel presents the same arguments with regard to "path-oriented switch" as it did above in its proposed construction of "destination switch." For the same reasons discussed above, the term “path-oriented switch” should not be included in the construction of the term “tandem switch.” Accordingly, the
Court adopts Ciena’s proposed construction of the term.

D. Ref. No. 9 "Portable tangible medium."

This phrase is recited in Claims 1, 94, and 96.

In the patent specification, the patentee expresses concern over the nature of election records "which are intangible and can be changed without leaving any evidence thereof." (Col. 1, ll. 46-48.) Intangible electronic magnetic records may be altered intentionally or accidentally without any evidence of such alteration. (Col. 2, ll. 16-21.) Concerns about such alterations repeated throughout the prosecution history. (Pl. Exs. F, G.) The same prosecution history provides that the tangible medium includes a "portable non-volatile electronic memory [e.g., a smart card] or a portable printed memory [e.g., a printed receipt] as well as other tangible medium that become independent of the means that stores information for one voting session therein." (Defs. Ex. 4b at 22.) The term "portable tangible medium" as used in Claims 1, 94, and 96 refers to the storage of the voting record and the voting session identifier in the medium, separate from the memory. This, in turn, will accomplish the goals set out above -- a tamper-proof voting record.

For the foregoing reasons, the Court construes the term "portable tangible medium" in Ref. No. 9 as follows:

A non-volatile storage medium (e.g., printed receipt and/or a smart card) separate from the memory of the voting machine (and thus portable) in which the records stored and contained therein if changed would leave evidence of that change.

C. Ref. No. 5 "Tangible Receipt"

The term "tangible receipt" is recited in Claim 49 of the '209 Patent. Plaintiff provides the following construction of the term: "A non-intangible storage medium separate from the memory of the voting machine (and thus portable), in which the records stored or contained therein if changed would leave evidence of that change. Here, the non-intangible medium is printed by a printer." Defendants' construction is: "A reviewable printout of the voters' voting selections or choices or a corresponding voting session identifier that is retained by the voter." The relevant Claim includes "a printer providing for each voting session a tangible receipt . . . ."

Plaintiff directs the Court to its discussion about the voting session identifier contained in its brief and described herein. The Court adopts its reasoning for the construction of the term "voting session identifier" discussed above. Additionally, as noted by Plaintiff, the language of Claim 57 would be in direct conflict with the construction proposed by Defendants. Claim 57 provides that the receipt is taken by the voter, retained by the electronic voting machine and printer, retained by the voting machine and printer if not taken within a reasonable time, or retained by the smart card. (Defs. Ex. 2, Col. 46, ll.36-42.) Therefore, the receipt can be taken or not by the voter.

Accordingly, the Court construes the term "tangible receipt" as follows:

A reviewable printout of the voter's voting selections or choices that can be retained by the voter.
M. Ref. No. 27 "Tangible receipt" or "printed receipt" or "printed paper."

These terms are recited or referred to in Claims 21, 49, 54, 55, 72, 77, 82, 83, 84, 85, 102, and 103.

The dispute as to these terms is whether, as argued by Plaintiff, "printed receipt" has one definition and "tangible receipt" and "printed paper" have another or, as argued by Defendants, all three terms have the same definition. Additionally, as discussed above, there is an underlying dispute whether the voters retain the receipt.

Again, the Court must begin with the inventor's goal to provide a tamper-proof voting system encompassing a verification system. (Col. 1, ll. 35-49; Col. 2, ll. 6-21.) Voter confidence is maintained because a voter can compare his or her individual printed receipt with the unique voting session identifier to the Internet election website listing the votes, voting record, and voting results. (Col. 18, ll. 37-53.) The patent teaches that there are three separate and independent identical records of the voters' vote: one in the stored memory of the voting machine, one in the memory of the smart card, and one printed on the voting receipt. (Col. 6, ll. 27-31.) "Each voter deposits his smart card SC into a secure collection box . . . retains the printed voting receipt," Col. 6, ll. 47-51, provided to the voter at the conclusion of the voting session by the "local printer," Col. 7, ll. 9-14. The voting session identifier is printed on that receipt. (Col. 7, ll. 19-21.) The patent teaches that the local printer is of the type that retains no record of the printed data. (Col. 11, ll. 28-37.) The patent later states that "[t]he tangible receipt device provides a tangible receipt such as a printed receipt." (Col. 17, ll. 54-55.) Therefore a tangible receipt and printed receipt, according to the instructions of the patent, are the same item.

Claim 67 provides that the voting records, including "the voting selections of a particular voter and that voter's random voting identifier, are published or posted on the Internet, thereby allowing the voter to compare his or her voting session identifier with the posted result. With the exception of Claim 55, each of the Claims listed in this section provide that the tangible receipt, the printed receipt, and the printed paper include the voting record and the voting session identifier. All three items are treated the same in the Claim language.

The term "printed paper" appears only once in the specification, when modifying "receipt" in Column 10, line 15. (Col. 10, l. 15.) The term reappears in the contested Claims 102 and 103 in the context of directions for "collecting" the printed paper in those Claims. This is inconsistent with other references to the printed receipt and the tangible receipt.

Defendants argue, without contradiction, that Claims 102 and 103 were added three years after the original application for the '730 Patent in a preliminary amendment dated November 17, 2003. (Defs. Response Brief at 25.) As noted above, when the patent applicant adds a Claim after the original filing date, the new Claim must find support in the original specification. Turbocare, 264 F.3d at 1118. Plaintiff refers the Court to no such support. Moreover, the term "printed paper" is used in the specification to modify "receipt." There is sufficient evidence in the specification and the patent Claim to convince the Court that the receipt is provided to the voter at the conclusion of the voting session. There is no evidence from Plaintiff to the contrary.

In support of its argument to the contrary, Plaintiff cites In re Wright, 866 F.2d 422 (Fed. Cir. 1989), discussing the "description requirement" of 35 U.S.C. § 112, P 1. Id. at 424-25. That paragraph "opens with the words: 'The specification shall contain a written description of the invention . . . .'" Id. at 424 (quoting § 112, P 1.) An issue in that case was whether the phrase "not permanently fixed," a phrase that did not appear in the specification as originally filed, was properly rejected under § 112. Id. at 423-25. The court framed the question as follows: "When the scope of a claim has been changed by amendment in such a way as to justify an assertion that it is directed to a different invention than was the original claim, is it proper to inquire whether the newly claimed subject matter was described in the patent application when filed as the invention of the applicant." Id. at 424. The exact words, i.e., "not permanently fixed," need not be used in the specification if the specification, read "in the light of which all that the claims say must be construed" and considered "against the background of the prior art," convinces the court "that the process of the claims, containing the words 'not permanently fixed,' is described in the specification." Id. at 425. Although "the claimed subject matter need not be described in haec verba in the specification," the specification as originally filed nonetheless "must convey clearly to those skilled in the art the information that the applicant has invented the specific subject matter later claimed." Id. at 424, 425 (interim quotations..."
In the instant case, the specification in the '730 Patent does not satisfy this description requirement as it relates to the "printed paper"; therefore, the Court finds the term to be consistent with other references to the printed receipt and the tangible receipt. Additionally, the Court disagrees with Plaintiff's argument relating to Plaintiff's Group Exhibit I. As stated above, there are numerous references to the receipt being retained by the voter in the inventor's description of his invention.

For the reasons set forth herein the Court construes "tangible receipt," "printed receipt," and "printed paper" as follows:

Tangible receipt, printed receipt, and printed paper mean a reviewable printout of the voters' voting selections or choices or a corresponding voting session identifier that is retained by the voter.

B. Tapping Points

The term "tapping points" appears in Claim 1 of the '130 patent, which claims, in pertinent part:

A radio-frequency phase shift assembly coupled to a feedline, comprising: . . . at least two different pairs of antenna radiating elements coupled to the at least two stripline sections and driven with different phase angles (Φ) at mutually offset tapping points . . . .

('130 Patent, Claim 1, Col. 5, ll. 61-67 (emphasis added).) RYMSA argues that the proper definition is "locations on the stripline sections or the center tap where electrical signals are transferred to or from the tapping element." (Defs.' Claim Construction Br. at 17.) Kathrein argues that the proper construction is "points where a signal is transferred from one circuit or system to another circuit or system." (Pl.'s Claim Construction Br. at 9.)

RYMSA contends that tapping points are necessarily associated with a tapping element, either where the tapping element transfers signals to or from the stripline sections or to or from the center tap. To determine the ordinary and customary meaning, again, the Court must first look to the intrinsic evidence, which includes the claims, specification and prosecution history. See Phillips, 415 F.3d at 1316-17. The Court agrees with RYMSA that "tapping points" may be associated with a tapping element. The specification of the '130 patent states "tapping element 25 forms a coupled tapping section or tapping point 27 in the respective area in which it overlaps an associated stripline segment 21." (See '130 Patent, Col. 4, ll.15-18.) The specification states that "two tapping points 27a, 27b are provided, in this example which are offset in the longitudinal direction of the tapping element 25." (Id., Col. 4, ll. 18-20.) It is clear from the specification that the "tapping points" labeled as 27a and 27b in Figure 2 of the '130 Patent are associated with the tapping element. (Id.) The prosecution history also provides that the center tap 29 depicted in Figure 2 is also a "tapping point." (Defs.' Claim Construction Br., Ex. 2, at 46.)

However, that "tapping points" may be associated with the tapping element does not mean that they must always be associated with the tapping element. The prosecution history makes it clear that "tapping points" mean more than merely the locations at which the tapping element overlaps the associated stripline sections or segments. Claim 1 of the '130 Patent claims, in pertinent part:

A radio-frequency phase shift assembly for coupling to a feed line, comprising:

at least first and second stripline sections which are arranged concentrically, said at least first and second stripline sections for coupling to at least two different pairs of antenna radiating elements driven with different phase angles (Φ) at mutually offset tapping points . . . .

(Ids., Claim 1, Col. 1, ll. 61-67.) The prosecution history of Claim 1 (the amended German specification) shows that the inventors stated that the tapping points also include 39a and 39b in Figure 2, which are not associated with the tapping element in such a way that they are located where the tapping element overlaps the stripline sections or segments. (Pl.'s Claim Construction Br., Ex. C, June 7, 2001 Translation of '130 Patent, at 13.) The inventors stated: "on the at least two
stripline sections (21a, 21b, 21c, 21d), at least two different pairs of antenna radiating elements (1a, 1b, 1c, 1d, 1e, 1f) can be driven with different phase angles (Φ) at mutually offset tapping points (39a, 39b). . . . " (Id.)

RYMSA argues that the German translation of '130 Patent is faulty and that "Abgriffstellen" is more properly translated to "tapping positions" rather than "tapping points." (Defs.' Ex., Wardell Decl. PP 9-10.) This argument is not persuasive because it does not explain why the inventors used the term "tapping" at all to describe 39a and 30b. RYMSA also does not attempt to explain the difference between the terms "points" and "positions." (Defs.' Claim Construction Br. at 18.) The only explanation is that the term "tapping" is not limited to RYMSA's crabbed reading because "tapping points" 39a and 39b in Figure 2 of the '130 Patent are not located where the tapping element overlaps the associated stripline sections or segments.

Lastly, the Court agrees with RYMSA that Kathrein's use of two additional undefined words, "circuit" and "system," as well as the word "points" in its proffered construction of the term "tapping points" creates unnecessary ambiguity. Rather, the Court prefers the term "locations" over the term "points." In addition, in construing the term "tapping points," the Court uses terms already defined by the parties or by this Court herein. The Court interprets the term "tapping points" to mean "locations where electrical signals are transferred between, meaning to or from: (1) the tapping element and the stripline sections, segments or elements, (2) the tapping element and the center tap, or (3) the antenna radiating elements and the stripline sections, segments or elements."

4392

12. "[T]ask assistant:" 12 "A feature that displays a list of tasks to be performed on a claim." This construction is consistent with Figure 13 and col. 105:9-12 of the specification.

11. "[T]ask library:" 11 "A feature that stores the rules with which tasks are established." Plaintiffs submit that the task library stores, in addition to rules, templates that can be used to create rules. However, neither the specification nor the claims speak to the added feature of storing templates. The court's construction is consistent with claim 1, which requires simply "a task library database for storing rules." col. 107:38-39.

11 '284 patent, claim 1 (and dependent claims).
The term in question appears either directly or by reference in all claims of both the '653 and '690 patents. Plaintiffs assert that the term should be construed as "a special lens that collects parallel rays." Plaintiffs rely on the specification of the '690 patent which states, for example, that "a telecentric lens collects parallel rays." Defendant asserts that the term reflects an express disavowal to the use of dichroic mirrors and a limitation as to internal illumination.

Beginning with the claims in the '653 and '690 patents, there is no mention or reference in any of the claims to either dichroic mirrors or internal illumination. Claim 4 of the '690 patent, for example, expressly refers to collecting light from a multi-sample plate without noting the light source. Similarly, claim 1 of the '653 patent expressly refers to the lens collecting light and identifies the source as "light incident thereon [the multi-sample plate] or originating from a sample." ('653 patent, col. 21, In. 7-9).

Moving to the specifications, the '653 patent points to a description of "a telecentric lens." "A telecentric lens is free of parallax error." ('653 patent, col. 12, In. 39-40). n1 "A telecentric lens collects parallel rays, over the entire area of a well plate." ('653 patent, col. 12, In. 45-46). n2 In addition, the '653 and '690 specifications point directly to the two items raised by defendant. "A unique property of the present invention is that no dichroic is necessary. The telecentric lens is large, so there is room to install an illumination assembly within its body." ('653 patent, col. 12 In. 11-13). n3

In general, when a term implicitly suggests a broader meaning, there is no express disavowal. See Varco, L.P. v. Pason Sys. USA Corp., 436 F.3d 1368, 1375 (Fed. Cir. 2006). In Varco, the court noted that "the applicant could have used terminology such as 'relays are pneumatically operated valves' that expressly disavows alternative structures. As written, however, the specification contemplates that other structures may 'operate as relays' in addition to the preferred pneumatically operated valves." Id.

In the case at bar, the Court finds that because the patentee made note that "there is room to install an illumination assembly," the Court finds no express disavowal. The term is written in open form and the patent neither requires or excludes the use of an illumination device. Similarly, the phrase "no dichroic is necessary" is not a disavowal of its use and the patent does not require or exclude use of a dichroic mirror. In both situations and as described in Varco, the drafter could have used terminology to expressly disavow dichroic mirrors or require internal (or external) illumination but left the text in open form.

Defendant also bases its assertion, in part, on a letter written by the inventor indicating the inventor's intent. However, such a letter is not within the patents or their prosecution history and is therefore extrinsic evidence. See Phillips, 415 F.3d at 1319. "[U]ndue reliance on extrinsic evidence poses the risk that it will be used to change the meaning of claims in derogation of the 'indisputable public records consisting of the claims, the specification and the prosecution history,' thereby undermining the public notice function of patents." Id. (quoting Southwall Techs. Inc. v. Cardinal IG Co., 54 F.3d 1570, 1578 (Fed. Cir.), cert. denied, 516 U.S. 987, 116 S. Ct. 1387, 133 L. Ed. 2d 424 (1995)). However, despite what the inventor's intentions may have been, the patent itself serves the public notice function and is a part of the intrinsic evidence, as contrasted with the inventor's letter, which does not serve the public notice function and is extrinsic, and the term itself can
be construed absent the extrinsic evidence. As such, the inventor's letter is not relevant to claim construction here.

As such, the Court finds that the term "a telecentric lens" is construed simply as "a special lens which collects parallel rays."

4396

(4) "telecentric lens means for peering into the well"

The term in question appears in claim 5 of the '653 patent. Plaintiffs assert that the term should be construed to not limit the claim to the reference of a telecentric lens. Plaintiffs assert that because the structural component, the telecentric lens, is expressly recited in the claim, it is not appropriate to treat the phrase as a means-plus-function limitation per 35 U.S.C. § 112, P6. In contrast, Defendant asserts that because (1) the phrase's express statement is in means-plus-function format, together with (2) the patentee's assertion of applying 35 U.S.C. § 112, P6 during the prosecution history, the Court should treat "telecentric lens" as a limitation to the claim.

"An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112 P6. "Whether certain claim language invokes 35 U.S.C. § 112, [P]6 is an exercise in claim construction and is therefore a question of law." Personalized Media Commc'n's., L.L.C. v. ITC, 161 F.3d 696, 702 (Fed. Cir. 1998).

The use of the word "means" in the claim invokes a presumption that the patentee invokes the statutory mandate for means-plus-function clause. Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999), cert. denied, 528 U.S. 1115, 120 S. Ct. 933, 145 L. Ed. 2d 812 (2000).

Two specific rules, however, overcome this presumption. First, a claim element that uses the word 'means' but recites no function corresponding to the means does not invoke § 112, [P]6. Second, even if the claim element specifies a function, if it also recites sufficient structure or material for performing that function, § 112, [P]6 does not apply.

Id. (internal citation omitted). The Court begins its construction by adopting the presumption that the patentee invoked the means-plus-function format. However, moving directly to the second exception, the claim element does specify a function ("peering into the well") but also recites a sufficient structure for performing that function (the "telecentric lens"). Although Defendant asserts that such function is insufficient without illumination, the specification does recognize that such illumination can be from the sample within the well and, as such, external illumination is not necessary and the telecentric lens alone represents sufficient structure.

Defendant also asserts that through the prosecution history, Plaintiffs invoked 35 U.S.C. § 112 P6 and, as a result, prosecution history estoppel requires the Court to construe the telecentric lens as a limitation. To begin with, the prosecution history directs the examiner that the claim should be considered as structure under § 112 P6. n4 However, once the applicant directs the examiner to view the telecentric lens as a structure, the applicant directs the examiner toward the second rule to overcoming the means-plus-function presumption of § 112 P6. The claim was subsequently accepted unchanged by the examiner. In addition, the prosecution history makes no explicit mention of this claim relative to means-plus-function, nor does the examiner explicitly accept it as such. Because the prosecution history points directly at the second rule to overcoming the means-plus-function presumption, the prosecution history supports that the "telecentric lens" is not a limitation to the claim.

As a matter of law, this Court construes that the term "telecentric lens" is a sufficient structure to support the function of
"peering into the well." The Court does not accept Defendant's argument of construing the telecentric lens as a limitation stemming from construing the phrase in means-plus-function format of 35 U.S.C. § 112 P6.

17. Telecommunication services

The parties dispute the meaning of the term "telecommunication services." Foundry proposes that "telecommunication services" should be construed to mean "the transmission of information from one point to another." Lucent, for its part, urges the court to construe "telecommunication services" to mean "services typically provided on telecommunication networks, including voice communications, private branch exchange services, multimedia messaging, and information services." The court adopts Lucent's definition of "telecommunication services" and construes the term accordingly.

F. "Telecommunication Switches"

Claim 5 of the '429 patent and claim 7 of the '064 patent recite the claim terms "telecommunication switches." Sprint contends that these claim terms should be construed to mean devices that set up calls and relay voice and/or data information from one connection to another. In Vonage's response to Sprint's trial brief regarding claim construction, Vonage states that it does not dispute Sprint's proposed construction of these claim terms. Accordingly, the court construes them to mean devices that set up calls and relay voice and/or data information from one connection to another.

6. "[T]elecommunications cable" 8 "Cable capable of transmitting high frequency data." Construing the preamble in this manner comports with the specification, which repeatedly identifies the invention of the '491 patent as a "high frequency cable." (Abstract; col. 1:7-23; col. 2:4-6) The specification further recites that the invention of the '491 patent seeks to rectify nominal characteristic impedance problems for "telecommunications cable[s] . . . designed to operate at high frequencies, perhaps up to 100 megabytes." (col. 3:67-4:5; col. 4:39-44)

8 '491 patent.

Plaintiffs define "telecommunications channel access connector," the next disputed term, as "a device providing a connection such as a plug or a wireless connector," in contrast to defendant's definition of "a physical device providing a connection, such as an outlet, receptacle, or plug." (Pls.' Mem. on Claim Construction 17; Def.'s Rebuttal Claim Construction Br. 24). The specification language cited by both parties states that "[t]he customer selects which utilities or services they require, typically by just connecting to the appropriate connector (also know [sic] as outlet, receptacle, or plug) either through physical means or through wireless connections such as infrared." (400 Patent 2:61-65). This language describes a vending machine device that accepts a customer's means of connection, be it a plug or a wireless connector, and both parties' proposals reflect this description.
Accordingly, I construe the disputed claim language as follows:

<table>
<thead>
<tr>

4401

F. Terms which include "Telecommunications Line(s)"

Sightsound asserts that the term "telecommunications line," which is used throughout the claims in suit, should be interpreted in all instances to mean "a medium for the transmission of information from one location to another." Defendants respond that this could refer to, among other things, the Pony Express.

Defendants, on the other hand, wish to focus the inquiry upon the use of the term "connecting" in relation to "telecommunications lines," as in the following examples from the various patent claims: "connecting electronically via a telecommunications line," "forming a connection through telecommunications lines," "telecommunications lines connected," "connecting electronically via the telecommunications lines," and "connecting electronically via telecommunications lines." Defendants assert that each of these formulations of the terms "connection" and "telecommunications lines" entails the following construction:

Establishing a continuous point-to-point conduction path using a telephone service providers' circuit-switched network for the transfer of information. These terms do not include a packet-switched network link, such as a TCP/IP link.

The TCP/IP reference is, of course, addressed to the Internet. Defendants take the position that the use of the terms "connection" and "telecommunications line(s)" bespeak the use of telephone lines and telephone switching services only. A connection over the Internet (which would, in most cases, involve at least some use of telephone lines and the telephone switching system), would not be covered.

The expert testimony in this case was most helpful in describing the distinction between the telephone system and a TCP/IP system such as the Internet. What becomes clear from a review of the testimony and the sources relied upon by the experts, however, is that the distinction which defendants wish to make is not drawn from the claim language, or from the specification.

It is helpful, first, to note that both sides agree that a modem-to-modem connection between two computers over telephone lines would clearly be covered by the claim language. Defendants, however, wish to differentiate from this the process by which an Internet transfer occurs. A common form of such a transaction, and one which was known in 1988, would involve the second party (or buyer) connecting to an internet service provider (ISP) through a modem and over a telephone line. The next part of the process occurs between "nodes" on the packet-switch network (the Internet), until the transmission, in the form of information "packets," reaches another ISP connected to the first party (the seller) by telephone lines. Thus, in each instance, the transmission is ultimately accomplished, at each end, by a traditional telephone communication over telephone lines and through a telephone switching system.

The difference between the two methods of exchanging data occurs in the manner in which the information is sent between the nodes of the packet-switch system, and the manner in which data is sent through a telephone company switching system. However, while a transfer over the Internet differs in some respects from a transfer made directly between two computers over modems and through telephone lines, there is simply no way of reading the plain language of the claims in suit explicitly or implicitly to exclude any means of transferring information so long as it can occur over telecommunications lines.

Defendants, for example, rely upon Figure 1 from the specification of each patent which shows the respective equipment of the first party and second party connected to a "box" entitled "Telephone Lines 30." Even if the use of the phrase "telephone lines" limited the invention, it is not clear that it would do so to omit the Internet, which is normally connected to individual users by telephone lines in any event. Also, Figure 1 is a representation of the preferred embodiment only. It is improper to read into the patent claims limitations from the specification. Comark Communications, 156 F.3d at 1186 ("fine line" exists
between "reading a claim in light of the specification" and impermissible practice of "reading a limitation into the claim from the specification.").

Likewise, defendants' asserted definition of the term "connection" to differentiate telephone communications and an Internet session is not persuasive. Dr. Larky explained in detail how a telephone communication establishes a "continuous point-to-point conduction path," regardless of the use of time division multiplexing (TDM), which results in several different telephone connections sharing the same line. This is so, in his view, because TDM still results in the telephone user having the right to a specific and consistent pathway through which his or her entire conversation is put through to the other party. Resort to the claims and the specification, however, does not yield any basis for making a distinction between the "connection" made in an Internet session, which produces "end-to-end" connectivity, but not a continuous conduction path, and a telephone connection which produces both end-to-end connectivity and a continuous conduction path.

Defendants resort to the prosecution history and note that the term "telecommunications lines" did not become part of the patent until 1992. The manner in which this was accomplished, in defendants' view, should inform the court's interpretation of that term. The original specification and claims disclosed "electronically transferred via telephone lines" (Docket # 70, Tab 4 at 6). This was altered in December, 1988, to "connecting electronically the first memory with the second memory" (Id., Tab 7 at 1). In December, 1991, the first use of the term "telecommunications link" is proposed, and rejected by the examiner as not being well-connected in the system (Id., Tabs 34 and 35). Ultimately, in June, 1992, the term "telecommunications line" was added throughout the claims (Id., Tab 36).

First, defendants assert that, if the term "telecommunications line" is read to reach anything more than a "continuous telephone-circuit network path" this would violate the "written description requirement" which requires a patentee in the initial disclosure to provide an adequate description of what is being patented. See, Purdue Pharma L.P. v. Faulding Inc., 230 F.3d 1320 (Fed.Cir. 2000). This, however, is a validity issue which the court should not reach at this point. And, in any event, the use of the term "telephone lines" in the initial disclosure does not, in light of the fact that the Internet is normally accessed through telephone lines on each end of a transaction between parties, provide support for limiting the definition of "telecommunications lines" to exclude Internet transactions. 15

15 Defendants also assert that "telecommunications lines" is "new matter" which was improperly added to the patent in the years following the initial application. Again, however, defendants seek to introduce a matter normally addressed during the validity stage into the construction phase, and, in any event, it does not serve to raise the distinction which defendants desire.

Defendants also seek to limit the reach of the term "telecommunications line" in light of the changes made during the prosecution of the patents from "link" to "line," a small portion of which the court has already described above. A more complete description of the prosecution history is now necessary.

The original term in the application for the '573 patent was "telephone line." Then, in December, 1988, the term "electronically connecting" was proffered and rejected. This rejection was premised upon the Lightner patent (Docket # 70, Tab 11). The next attempt was simply to recite "connecting" the first and second memories, but this was also rejected over Lightner and the Hughes patent (Id., Tabs 12 and 13). "Connecting electronically" was added (Id., Tab 16), but again a rejection over Hughes resulted because "Hughes . . . shows that the first and second memory are connected electronically . . . such that information can pass therethrough." (Id., tab 30). Claim 11 was amended to state "connecting electronically via a telecommunications link" (Id., Tab 34). The examiner found the term "telecommunications link" to be "not well connected in the system" (Id., Tab 35 at 6). This resulted in the inclusion of the term "telecommunications line" in the next amendment, which was approved (Id., Tab 38 at 6).

Defendants assert that, in view of the prior art, "link" is a broad term, and "line" is a narrower term. Specifically, defendants point to the Hughes patent which discloses "transmitting and recording stations" which are "linked by telephone lines or other signal transmission means" (Defendants' Exhibit 4 at Column 8, lines 39-42). Lightner disclosed a "signal transmission link" with examples thereof including telephone lines, a microwave transmission link and CATV cable.
Lockwood discloses "any suitable remote links . . . such as phone line data communication links" and an indirect link "via a computerized telecommunication network service such as TELENET." (Defendants' Exhibit 7, Column 4, lines 1-16). TELENET is described in Newton's Telecomm Dictionary, 7th Ed., p. 686, as a "private, commercially available network providing both packet-switched and circuit-switched service to subscribers in North America, Europe and some parts of Asia." 16

16 Defendants also point to Freeny (Defendants Exhibit 5) and Elkins (Defendants' Exhibit 6) as examples of prior art which use the term "communications link" as a broad term.

Thus, defendants argue that anything defined in the prior art as a "link" was given up when the Mr. Hair amended his claim from "telecommunications link" to "telecommunications line." This, in defendants' view, includes claiming a packet-switched network, such as that offered by TELENET.

A patentee may limit the definition of a claim term through "altering claim language to escape an examiner rejection" or by "clearly disavowing claim coverage." York Products, Inc. v. Central Tractor Farm & Family Center, 99 F.3d at 1575. Here, in offering the amendment, the patentee gave the following explanation:

The Examiner has also stated that "telecommunication link" is not well connected in the system. Accordingly, "link" has been amended to the more familiar term "line" and "via telephone line" has been added to the connecting step in Claims 11 and 15.

(Docket # 70, Tab 38 at 15).

Here, the examiner did not reject the term "link" on the basis that it was taught by the prior art. Rather, the examiner indicated that a term more closely connected with the disclosed invention was required. Thus, the applicant indicated during the amendment not that he was giving up coverage, but that he was amending to include a "more familiar term" in the patent. Hence, this is not a situation where coverage was expressly conceded, nor would a person skilled in the art believe that any specific coverage had been conceded through this amendment. In fact, neither the examiner nor the patentee ever indicated that there was any difference beyond familiarity between the terms "link" and "line."

Once again, this review of the prosecution history was an attempt by defendants to establish that Sightsound cannot claim coverage of package-switch networks such as the Internet. The court is not convinced that this is so. Thus, the terms "telecommunications line," even when used in the context of "connecting," should not be interpreted as excluding the Internet.

Further, with respect to Sightsound's construction, it is true that "a medium for the transmission of information from one location to another" is much too broad in the context of these patents. This does not mean, however, that Sightsound is attempting to claim coverage of the Pony Express or notes sent by carrier pigeon. Reading the term in context, "telecommunications lines" is used most often in conjunction with the terms "connecting" and "electronically." Where this is done, the coverage claimed is both narrow and clear. Sightsound is claiming an electronic medium of communicating between computers, which requires end-to-end connectivity. The court has not located any language in the patents which would permit any other reading, in context, of the term "telecommunication line(s)".

G. "Telecommunications Link"

In Claim 14, the patent claims "[t]he method of claim 1 wherein said source storage medium is in the domain of a first central processing unit and the destination storage medium is in the domain of a second central processing unit." '776 Patent, col. 18, lns. 20-23. Claim 16, in turn, claims "[t]he method of claim 14 wherein said first and second central
processing units communicate over a telecommunications link and wherein said digital data is sent over said link." Id., Ins. 29-32. The parties agree that a telecommunications link is a "line or channel for sending data." JCCS, Appx. A, at 14 (term 55). Defendant would leave the term at that, while plaintiff adds that the line or channel is for sending data "over a distance." Id.

Plaintiff is correct that the ordinary dictionary definition of "telecommunications" encompasses communication, usually through electronic or electric means, over long distances. See OXFORD ENGLISH DICTIONARY (2d ed. 1989) (online edition available at dictionary.oed.com/cgi/entry/50248394?single=1&query_type=word&queryword=telecommunication); MERRIAM-WEBSTER ONLINE (online edition available at www.m-w.com/cgi-bin/dictionary?book=Dictionary&va=telecommunication). This makes sense in the ordinary course of everyday life: for instance, there is no need to use the telephone to talk to someone sitting in the same room as you; ordinary "communication" suffices. This common sense "over a distance" definition of telecommunications does not necessarily hold when referring to data transmission between individual computer systems. Indeed, other dictionaries, both lay and technical, refer to telecommunications as any data transmission, without any distance limitation. See COMPUTERUSER.COM HIGH TECH DICTIONARY (available online at computeruser.com/resources/dictionary/definition.html?look-up=7078) ("transmission of information over a communications line."); WEBOPEDIA (available online at www.pcwebopedia.com/TERM/T/telecommunications.html) (telecommunications "refers to all types of data transmission."); ENCARTA WORLD ENGLISH DICTIONARY (available online at encarta.msn.com/encnet/features/dictionary/DictionaryResults.aspx?refid=1861718821); CAMBRIDGE DICTIONARY OF AMERICAN ENGLISH (available online at dictionary.cambridge.org/define.asp?key=telecommunication* 1+0&dict=A). Thus, the dictionary definition is of little help in determining how the term would have been understood by persons skilled in the art in 1990.

Nothing in claim 16 or the specification, however, suggests that there is some minimum distance requirement over which the transfer must occur. Further, the "over a distance" limitation is either meaningless or impermissibly vague. Either it really means over any distance, in which case it is meaningless because any transfer over a line or channel will involve some distance, no matter how slight, or it means over some minimum distance, in which case it is irreparably vague because there is nothing either within the patent or in common usage to indicate how far is far enough. See H C Prods. Co. v. Air Vent, Inc., 468 F. Supp. 750, 755 (C.D. Ill. 1979) ("A court must construe a claim in such manner as will render the same not vague and indefinite."). Accordingly, the Court adopts defendant's proposed construction.
CAT contends that the term "telecommunications means" is not in means-plus-function format. According to CAT, the distance within the claim language between the first use of the disputed term and the element that recites the function of the telecommunications means is inconsistent with means-plus-function claim drafting. (D.I. 60 at 104) However, CAT cites no authority for this proposition.

Relying on its expert and a technical dictionary, CAT next asserts that the word "telecommunications" itself imparts sufficient structure to a person having ordinary skill in the art and thereby overcomes the presumption by calling to mind the structure of a modem. (D.I. 44 at 12-13 Ex. 5 (Grimes Decl.) PP 11-12, 20, 22, 24-31, 34-35) CAT also points to a related case, Card Activation Technologies, Inc. v. Walgreen Co., Case No. 06-C-5578 (N.D. Ill.), in which Magistrate Judge Valdez recommended that the Court construe the term "telecommunications means," as used in the '859 patent, as not being in a means-plus-function format. (D.I. 44 Ex. 6 at 10) Judge Valdez relied primarily on Mr. Grimes' unchallenged declarations that the term connoted a particular structure to one skilled in the art. (See id.) However, as both parties note, the related case settled before Judge Valdez's Report and Recommendation could be adopted and this Court is not required to agree with it. (D.I. 44 at 4; D.I. 47 at 13) Having reviewed all of CAT's extrinsic evidence, I have concluded that the presumption is not overcome.

Having determined that the term "telecommunications means" is in means-plus-function format, it becomes necessary to identify the corresponding function and structure. According to SVS, the function of the "telecommunications means" as used in claims 1 and 20 is "for requesting a response of approval or disapproval from the host data processor," and the function as the term is used in claims 10 and 29 is "for requesting authorization of the debit purchase transaction." (D.I. 43 at 8-9) CAT, on the other hand, proposes that the function of the "telecommunications means" as used in all four claims is "communicating with a host data processor." (D.I. 44 at 13) Claims 10 and 29 recite "communicating with a host data processor through the telecommunications means" ('859 patent, col. 8 lines 51-67 to col. 9 lines 1-7); claims 1 and 20 recite "transmitting a transaction request to the host data processor" and "receiving a response from the host computer" (id. col. 7 lines 46-67 to col. 8 lines 1-4). CAT's construction -- "communicating with a host data processor" -- encompasses the "communicating," "transmitting," and "receiving" functions of the telecommunications means as recited in the claims. SVS's construction, on the other hand, identifies not the function of the "telecommunications means," but the purpose of the communications conducted by the "telecommunications means."

Turning to the structure, SVS proposes "a modem that dials an electronic debit processor via a telephone line." (D.I. 43 at 9) CAT contends the structure is instead "a modem or its equivalent." (D.I. 44 at 18) While the parties generally agree that the structure includes a modem, SVS would limit the modem to one that communicates using a standard telephone line. SVS finds support for its position in several passages of the specification that describe how the terminal "is connected via a modem line to a host computer" and "calls" and "dials" a host. (D.I. 43 at 9-10) The parties appear to be in agreement that at the time the patent was drafted, modems operated almost exclusively on standard "dial-up" phone lines. (D.I. 43 at 11; D.I. 44 at 17) 2 However, Federal Circuit "case law allows for after-arising technology to be captured within the literal scope of valid claims that are drafted broadly enough." Innogenetics N. V. v. Abbott Labs., 512 F.3d 1363, 1371-72 (Fed. Cir. 2008). Here, the claim term "telecommunications means" is sufficiently broad to encompass modern equivalents of modems that formerly relied on standard telephone lines. Nothing in the record suggests that the patentee disclaimed those equivalents.

2 Counsel for SVS emphasized this point by playing for the Court a recording of the now "old-fashioned" set of tones that were once associated with a "dial-up" modem establishing a connection to, for example, the internet, over a standard phone line. (D.I. 60 at 14)
1. "telecommunications ('telecom') stage"

NICE's Construction: The stage that serves to capture and pre-process signals from two or more communication channels and interfaces with the recorder stage.

Witness's Construction: Device that receives input passively, and is not part of the communications system.

The parties dispute the meaning of "telecommunications ('telecom') stage," as used in claim 1 of the '372 patent. NICE contends that the specification clearly supports its construction, citing col. 7:51-54 and col. 9:67-10:1, and that Witness's construction improperly adds the limitations "device" and "passively." Witness contends that NICE disclaimed all but "passive" methods of recording during prosecution, citing '372 Pros. Hist., Office Action at 3, Amend. At 9-10 (wherein NICE distinguished its telecom stage from Knitl prior art by arguing that the telecom stage "monitor[s] information transmitted on communication channels, but are not part of the communications system." Further, Witness argues that the specification supports its construction, citing col. 7:60-8:5 ("[T]elecom stage 102 incorporates a first interface . . . that allows for passive tapping of the phone lines.").

After reviewing the claim language, specification, and relevant prosecution history, the Court concludes that NICE's construction of "telecommunications ('telecom') stage" is the correct one. Under the heading "The Telecom Stage," the specification states:

In accordance with the present invention telecom stage 102 generally functions to capture and pre-process signals from a plurality of communications lines into a format that is recognized by the recorder stage.

(col. 7:51-54.) The specification also states that the telecom and recorder stage interface. (col. 9:67-10:1 (recorder stage has "an interface 120 receiving input from the telecom stage").) Witness's citation to the term "passive" in the specification (col. 7:60-8:5) is unpersuasive because the term is used only in a description of an example of the invention. Likewise, Witness's reference to the prosecution history is also unpersuasive. NICE distinguished a telecom stage from a Private Branch Exchange ("PBX") in a 1993 Knitl patent by explaining:

[T]he PBX cannot be a telecom stage of a data logging system at least because the PBX switch forms part of the communication system, while the telecom stage of [the '372 patent] monitors signals on established communication channels. In fact, the written description at page 3, lines 17-33, specifically mentions problems associated with connecting a logging system to a PBX switch, the clear inference being that a PBX switch is not part of the logging system.

(JCC Ex. 11 at 10.) This is consistent with claim 1 of the patent, and does not support Witness's contention regarding passivity.

GO BACK

1. "for use in a telecommunications system"

The preambles of each of the independent claims at issue state that the invention disclosed in the '184 patent is directed to a method "for use in a telecommunications system." Although the preambles do not provide a specific definition of the term "telecommunications system," they do describe a system wherein interexchange calls initiated by each subscriber are automatically routed over the facilities of a particular one of a plurality of interexchange carriers associated with that subscriber . . . .
each subscriber has a primary interexchange carrier (PIC) over which interexchange calls initiated by that subscriber are carried . . .

Focusing on the phrases "routed over the facilities" and "over which . . . calls . . . are carried," Excel argues that the term "telecommunications system" is limited to the "call-carrying facilities that comprise the United States telecommunications system." (D.I. 300 at 59) In support of their argument, Excel references the language of independent claim 24, which discloses a method for use in a telecommunications system comprised of local exchange carriers and interexchange carriers, said system being arranged to establish telephone connections between subscribers of said local exchange carriers in response to requests for same . . .

According to Excel, use of the phrase "telephone connections" limits the LECs and IXCs that comprise the "telecommunications system" to their "call-carrying aspects." Thus, Excel argues, omitted from the term's purview are any ancillary functions performed by the LECs and IXCs, such as collections and sales, which, although necessary for providing long-distance telephone services, do not involve the use of "call-carrying facilities." (D.I. 300 at 60)

The term "telecommunications system" is neither defined nor used in the specification. Instead, the specification refers to "telephone networks" and "a network of interexchange carrier switches." (’184 patent, col. 1, Ins. 7; col. 3, Ins. 3-4) For example, the operation of a telephone network with respect to long-distance calls is summarized in the specification as follows:

When a long-distance call is initiated by the subscriber, the call is routed through the network of the originating subscriber's LEC, over the network of the PIC and, ultimately, through the network of the LEC which has as one of its subscribers the called party.

Excel argues that, given the language and figures of the specification, the "telecommunications system" referred to in the preambles of the independent claims requires the network of a facilities-based carrier.

AT&T, on the other hand, contends that the term "telecommunications system" is not so limited, arguing instead that it refers to the equal access telecommunications system, which consists of all the long-distance service carriers operating in the United States. (D.I. 300 at 16; D.I. 213 at 13) Specifically, AT&T identifies the following language in the specification that speaks to an IXC's use, not ownership, of facilities for the routing of long-distance calls:

The invention more particularly relates to the generation of message records for long-distance--or so-called interexchange--calls, which involve the use of the facilities of a long-distance, or interexchange, carrier, also referred to as an IXC.
AT&T asserts that there is no support in the patent for a construction of the term "telecommunications system" that would require an IXC to have an ownership interest in the facilities used to carry or route the interexchange calls of its customers.

It is axiomatic that IXCs use facilities such as switches, computers, and transmission lines to provide long-distance service, i.e., to route calls. Nowhere in the '184 patent, however, is there any explicit mention that an IXC must own, as compared to use, the facilities over which the interexchange calls of its customers are carried or routed in order to practice the claimed invention. Rather, the claim language itself and the specification contemplate a "telecommunications system" comprised not only of the facilities such as switches and transmission lines that physically establish the call connections, but also the ancillary facilities such as billing and collections that allow such a system to operate. Accordingly, the court concludes that the term "telecommunications system" is not limited to the network of a facilities-based IXC.

7 Consistent with this construction, the court concludes that the practice of the claimed invention is not limited to those IXCs which own the facilities used to transmit their subscriber's calls. There is no basis for reading an ownership limitation into the claims. Rather, the patent is directed to the generation of message records for long-distance calls "which involve the use[, not the ownership,] of the facilities" of an IXC. ( '184 patent, col. 1, lns. 30-34) (emphasis added). Accordingly, the court concludes that (1) the IXC to which a subscriber may be PIC'd need not be a facilities-based carrier but may be any company that provides long-distance telephone service and (2) the "PIC indicator" and "indication which has a particular value" claimed by the '184 patent is not limited to an indicator of the facilities-based IXC over whose network the subscriber's calls are carried.

4406
"Telemetry transmitter."

To define the term, Plaintiff proposes "any transmitter capable of wireless transmission." Defendants argues that the term means "cellular network based transmitter."

The parties did not dispute in their briefs or at the Markman hearing what a telemetry transmitter does. One skilled in the art would know, and the parties agree, that a telemetry transmitter simply transfers measurable data using telecommunication techniques. However, Defendants want to limit the term in this case to the use of a cellular-based transmitter, and Plaintiff wants to impose the limitation that the transmitter be wireless. There is simply no basis for either limitation.

As anyone who has seen a heart or fetal monitor in a hospital knows, telemetry can be transmitted over wires. Just because that may be impractical for most embodiments of the invention does not entitle Plaintiff to include that limitation.

As to Defendant's "cellular telephone" limitation, the specification is replete with descriptions of the transmission of data by satellite, and radio-telephoned. Col. 1, L. 64-65, Col. 2, L. 26-28, Col. 2, L. 44-45, Col. 2, L. 63-64. If there is any doubt, the specification states: "An alternative embodiment of the system that does NO Juse the cellular network is illustrated in FIG. 10." The specification then describes the use of a satellite. Col. 8, L. 29-30.

The court will define this term as follows:

"Telemetry transmitter" means "a device that transfers measurable data using telecommunication techniques or methods."
2. "telephone answering device"

By the time of the hearing, Klausner proposed that this term be construed as "an electronic device for answering telephone calls," while Vonage proposed "a device for answering an incoming telephone call." Vonage does not appear to seriously dispute the inclusion of "electronic" in the definition of this term. Nor does there appear to be any serious dispute to including the word "incoming" in the definition as the preamble of Claim 3 describes "storing and retrieving information from the incoming telephone calls with a telephone answering device." Throughout the '576 patent, the telephone answering device is described as a device that can receive, store and retrieve messages left by a calling party, i.e., messages coming in to a called party. See, e.g., '576 patent, col. 5:23-31, 34-40. Accordingly, the Court construes this term as "an electronic device for answering an incoming telephone call."

4408

1. "telephone call"

NICE's Construction

plain meaning
Witness's Construction
Entire conversation with an entity from a caller's perspective, including transfers and conferences.

The parties dispute the meaning of "telephone call," as used in the '570 patent (claim 6) and '345 patent (claim 14). NICE contends that the disputed term has a plain and ordinary meaning that requires no construction by the court. Further, NICE contends that Witness improperly relies on an excerpt from the description of the preferred embodiment to read a limitation into the claim. Witness's proposed construction is drawn from the following specification passage:

In other words, within the system of the preferred embodiment, recording is managed in a call-centric (rather than event-centric) fashion. This corresponds with the typical caller's point of view, in which a call is the entire conversation with a business entity, even if the conversation involves transfers to other agents or conferencing of multiple parties.

(Pat. '570, col. 8:5-11.)

After considering the claim language and the specification, the Court construes "telephone call" to mean "the entire conversation between a business entity and a caller to that entity, including transfers and conferences." The specification cited above defines "telephone call" within a broader discussion of a preferred embodiment; the definition of the phrase itself is not the preferred embodiment. Further, the language of the claims suggests the need to differentiate between a "telephone call" and a "telephone call segment." See, e.g., ('570 pat., claim 6(a)("receiving audio data regarding one or more telephone call segments relating to one or more telephone calls").

4409

Telephone Call Center

The parties propose the following construction of "telephone call center."

IEX: "Telephone call center" means "an organization of people, telecommunications equipment and management software."

Blue Pumpkin: "Telephone call center" means "an organization of people, telecommunications equipment, and management software, with a mission of efficiently handling telephone-based customer contact."

The Court recommends "telephone call center" be construed as "an organization of people, telecommunications equipment, and management software, with a mission of efficiently handling telephone-based customer contact."
A.2.d. "telephone-communication facility"

In its asserted interpretation of "dialed-number identification signals" and "identification signals" in the representative claims of the 120 patent, Verizon appears to define the term "telephone-communication facility" as a public switched telephone network. 8 Verizon Brief at 29, 32, 33. Katz, relying on the AT&T Order, asserts that "telephone-communication facility" means "that part of a telephone network that enables a caller to connect to the Katz system." Katz Brief at 52; see also AT&T Order at 598.

The term "telephone-communication facility" means a telephone network that connects remote terminals and other devices having telephonic capabilities, such as the audio response units, for communication. It is not clear to the Court, whether the parties consider the term "telephone-communication facility" to have a plain meaning to one of ordinary skill in the art. However, Webster's defines "facility" as "something . . . that is built, installed, or established to serve a particular purpose," see Webster's Ninth New Collegiate Dictionary at 445, suggesting that the term "telephone-communication facility" means something dedicated to the purpose of telephone communications. See Altiris, 318 F.3d at 1372 ("simply because a phrase as a whole lacks a common meaning does not compel a court to abandon its quest for a common meaning and disregard the established meanings of the individual words."). The specification also sheds light on the meaning of "telephone-communication facility" as "accommodating" the remote terminals and connecting the remote terminals to the central station CS. See 120 patent, Col. 3:36-37; see also Col. 3:31-35 ("The indicated terminals T1-TN represent the multitude of telephone terminals existing in association with a communication facility CO which may comprise a comprehensive public telephone network."); Col. 4:12-15 ("Essentially, as a result of telephonic dialing at one of the terminals T1-TN, the communication facility CO couples the select terminal to an audio response unit."); Col. 7:1-5 ("the caller [actuates] the buttons 14 as for example to input: "1 900 5558945". As a result, signals are provided to the communication facility CO resulting in a connection from the remote terminal T1 to the audio response unit 22."); Col. 7:31-34 ("the caller dials a number . . ., actuating the terminal T1 and the communication facility CO to provide a connection with the audio response unit 18.").

With due deference to the AT&T court, Katz' proposed construction does not appear to be warranted, as the 120 patent specification does not define "telephone-communication facility" as only "that part" of a telephone network that enables callers to connect to the Katz system. That being said, however, communication facility, as construed by this Court, does not exclude the possibility that the communication facility is part of a larger telephone network or the public switched telephone network itself. In addition, the Court's construction is not meant to exclude the possibility that the Katz system is an integral part of (operating within) the communication facility. As to Verizon's asserted interpretation, limiting the term "telephone-communication facility" to a public switched telephone network would import limitations of a preferred embodiment into the claim. The 120 patent specification appears to indicate that the communication facility may be other types of networks. See Col. 3:33-35 ("communication facility CO . . . may comprise a comprehensive public telephone network.") (emphasis added).
6. "First telephone connection means"

"Second telephone connection means"

The parties agree that "first telephone connection means" and "second telephone connection means" are means-plus-function terms under paragraph six of 35 U.S.C. § 112. As the Federal Circuit has explained: "Claim construction of a means-plus-function limitation includes two steps. First, the court must determine the claimed function. Second, the court must identify the corresponding structure in the written description of the patent that performs that function." Applied Med. Res. Corp. v. U.S. Surgical Corp., 448 F.3d 1324, 1332 (Fed. Cir. 2006) (citations omitted).

"Telephone connection means" appears only in claim 1 of the '964 patent. The "telephone connection means" clause reads:

first telephone connection means connected to the control means and operable for connecting through a trunk line to the telephone exchange and for receiving an incoming direct inward dial telephone number on the trunk line from the telephone exchange as part of an incoming call attempt from the subscriber telephone station, the incoming direct inward dial telephone number indicating the number called by the subscriber.

'964 patent, col. 10, 11. 14-21. The "telephone connection means" thus appears to have two functions, being "operable for connecting" and "receiving."

Defendants argue that no structure in the specification corresponds to the "first telephone connection means." 112 Mot. (dkt. # 675) at 10-11. Defendants identify some candidates but discount each in turn:

... the system obtains the direct inward dial number from storage for placing that number on an output connection to the exchange.

... CRU 20 includes a computer, controller, or other suitable data processing unit along with appropriate sensing circuit connections as is conventional for data acquisition and control technology.

... This includes switching functions to handle line (circuit) connections; interactive voice response operations; database controller for subscriber identification; and a system message detail recording (SMDR) unit 24 to provide information necessary to create call records.

'964 patent, col. 4, 11.45-47, col. 6, 11. 48-51, 60-65.

Cygnus points to column 5, lines 10 through 24 of the '964 patent as the corresponding structure for "first telephone connection means." This portion of the specification recites that

[a] signal is sent from the service center to the originator, thus indicating that the originator is identified whereupon the originator is instructed or prompted to terminate the call. Termination by the calling party is sensed at the service center followed by seizing of a first outbound circuit over which the service center outputs the call-back number for the identified originator. This operation reconnects the service center via a voice connection to the originator.

The specification also discusses that the invention relates to a "public telephone network." '964 patent col. 2, 11. 49-50, 59-60. The recitation in the specification of "output connection to the exchange" is sufficient structure to satisfy the
requirements of means-plus-function claiming. Although the drafter could have just called the "telephone connection means" what it appears to be, namely a phone line, one skilled in the art would recognize a telephone line as the structure performing the connecting and receiving functions. 4

4 Defendants also argue that disclosure of the details of James Alleman's "386 System" in the specification would have been necessary to satisfy the written description requirement as to "second telephone connection means." Disputed issues of material fact prevent resolution of this issue.

4413

B.

The parties first seek construction of the terms "telephone device" and "telephony device" as used in Claim 13 of the 298 Patent. Although BMC and Paymentech agree that both terms have the same meaning, they offer different definitions of the terms.

The standard dictionary definition of a "telephone" is "a device, system, or process using electricity to send sound or speech to a distant point." RANDOM HOUSE WEBSTER'S BASIC DICTIONARY OF AMERICAN ENGLISH at 451 (1998). A "device" is "a piece of equipment or mechanism for a special purpose." THE MERRIAM-WEBSTER DICTIONARY at 214 (1997). Thus, in ordinary usage, a "telephone device" means "a piece of equipment that uses electricity to send sound or speech to a distant point."

Paymentech proposes a definition that would require the device to be "designed to perform the function of using electricity to send sound to a distant point. (Def. Op. Br. at 4). Such a construction would add an element to the definition not supported by the specification or the prosecution history. See Texas Digital Systems, 308 F.3d at 1202 (in choosing among multiple dictionary definitions, the court must consult the intrinsic record to determine which of the possible meanings is most consistent with the use of words by the inventor). No intrinsic evidence suggests that the invention requires any specialized equipment. Rather, the PIN-less bill payment processing system described by the 298 Patent requires only an ordinary telephone. (See Plf. App., Exh. 1 at12) ("Still another technical advantage achieved with the invention is the elimination of any specialized equipment on the part of the consumer to process an electronic bill payment [i.e., personal computers, specialized telephones or terminals, etc.].") The court therefore determines that the terms "telephone device" and "telephony device," as used in Claim 13 of the 298 Patent, should be construed to mean "a piece of equipment that uses electricity to send sound or speech to a distant point."

4414

5. "Telephone exchange"

The term "telephone exchange" is not defined in the specification of the '964 patent. NEWTON'S TELECOM DICTIONARY 846 (16th edition) defines "telephone exchange" as "[a] switching center for connecting and switching phone lines. "Wikipedia 3 defines "telephone exchange" as "a system of electronic components that connects telephone calls." Defendants argue that the patent's use of the term is ambiguous because one cannot tell whether "telephone exchange" refers to "the domestic and/or international public telephone network (IXC)" or the "local exchange company (LEC)." See '964 patent, col. 6, 11. 42-43, 45.
"Telephone exchange" is mentioned in claim 1 of the '964 patent:

first telephone connection means connected to the control means and operable for connecting through a trunk line to the telephone exchange and for receiving an incoming direct inward dial telephone number on the trunk line from the telephone exchange as part of an incoming call attempt from the subscriber telephone station, the incoming direct inward dial telephone number indicating the number called by the subscriber;

second telephone connection means connected to the control means and operable for dialing out through the telephone exchange;

id., col. 10, 11. 14-24, as well as in claim 6 of the '964 patent:

A method establishing a telephone communication link between a subscriber telephone station and a destination telephone station, both being connected through a telephone exchange,

The use of the term "telephone exchange" in the patents fits with the dictionary definitions and nothing suggests that one skilled in the art reading the '964 patent would interpret the term otherwise.

Defendants' indefiniteness contention is without merit. "Whether a claim is invalid under 35 U.S.C. § 112, P 2, for indefiniteness is a question of law . . . . The definiteness inquiry focuses on whether those skilled in the art would understand the scope of the claim when the claim is read in light of the rest of the specification." Union Pac. Res. Co. v. Chesapeake Energy Corp., 236 F.3d 684, 692 (Fed. Cir. 2001). The court rejects defendants' contention that the multiple mentions of "telephone exchange" in the '964 patent renders it indefinite. Construing "telephone exchange" (which is not defined in the patent) as "a system of electronic components that connects telephone calls" would allow a single meaning of "telephone exchange" to encompass both the IXC and the LEC. Because 35 U.S.C. § 282 gives a patent "a statutory presumption of validity," a challenger bears the burden of proving "by clear and convincing evidence" that a patent is invalid. Monsanto Co. v. Scruggs, 459 F.3d 1328, 1336-37 (Fed. Cir. 2006). Defendants have not met this burden. "Telephone exchange" means "a system of electronic components that connects telephone calls."
Part of the dispute centers on the fact that there are different kinds of switched networks. Time Warner wants the disputed terms limited to a "circuit switched network," specifically the Public Switched Telephone Network ("PTSN").

As set out in the technology synopses submitted by the parties, one of ordinary skill in the art would know that a "circuit switched network" is one which establishes a connection from one user to the other such that these users have dedicated use of the circuit until the connection is released. In a "packet switched network," data packets are relayed through various stations in a network and are reassembled in proper sequence at their destination. These terms are not uncommon. See Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1344-45 n.2 (Fed. Cir. 2004). The terms were also defined in the "Background of the Invention" section of United States Patent No. 5,341,374 (the "Lewen" patent). See col. 1, ll. 21-27, col. 2, ll. 37-41. This patent was filed on March 1, 1991, and issued August 23, 1994, placing it within the time frame of the patent-in-suit. See also United States Patent No. 5,113,392 (the "Takiyasu" patent), filed June 18, 1990 and issued May 12, 1992, "Background of the Invention" (generally describing packet-based transmission).

There is no reason to limit the construction of "switched telephone network" and "telephone network" to the PSTN, as Time Warner suggests. While USVO's expert stated that, to his knowledge, the only definition or use of the phrase "switched telephone network" during the period 1990-1992 was in the context of the PSTN, he also stated that the PSTN did not have the capability to perform the actions recited in Claim 1 for residential users at that time. Report of Dr. Beckmann, Pl. Op. Claim Const. Br., Ex. D, at 11-12 [Doc. # 149, pp. 12-13 of 35]. Dr. Beckmann went on to state that the characteristics of telephone network 12 disclosed by the '792 patent were consistent with those of an asynchronous transfer mode ("ATM") network, as envisioned in 1990-1992. Id. at 13; Tr. at p. 25, ll. 5-11.

Time Warner disputes this, and points to extrinsic evidence that USVO referred to its patented technology as having the PSTN as one element in its 1992 Quarterly Report. Quarterly Report, Def. Claim Const. Br., Ex. 2-A at 11 (filed under seal) [Doc. # 153, p. 8 of 9]. There is nothing in the claims, the specification, or the prosecution history that indicates "switched telephone network" was intended to be synonymous with PSTN. Neither the claims nor the specification define the "switched telephone network" or "telephone network" as only "circuit switched" or solely "packet switched." The court will not include these limitations in the construction of these terms.

"Telephone" Does Not Encompass all Telecommunications

USVO urges the court to construe the terms to encompass all telecommunications systems. The court concludes that this construction is too broad. The specification repeatedly describes the network as a "commercial telephone network." For example, the Abstract begins with: "A system and method for transferring video programs from a first location to a remote location . . . over selected commercial telephone networks." See Abstract [emphasis added]. This description is repeated in the Summary of the Invention:

Therefore, according to the present invention, a system and method for transferring video programs from a first location to a remote location provides for communication of the programs over selected commercial telephone networks.

'792 Patent, col. 2, ll. 3-7 [emphasis added].

The Description of the Preferred Embodiment states that Figure 1 describes a "system for transferring video programs to a remote location [which] includes a central data facility 10 connected to a commercial telephone network 12." '792 Patent, col. 2, ll. 45-48 [emphasis added]. The specification goes on to state that "[t]elephone network 12 preferably includes optical fiber connections . . . expected to be widely available [in the United States] in the future." '792 Patent, col. 2, ll. 50-54. At the receiving end, (the "remote location") "a telephone 14 and receiving unit 16 are connected to the telephone network 12." '792 Patent, col. 2, ll. 55-56 [emphasis added]. A video display device, such as a television set, is attached to the receiving unit. '792 Patent, col. 2, ll. 56-61.

USVO could point to no description of the patented system which does not include a telephone. There is no basis to expand the terms "switched telephone network" and "telephone network" to include other telecommunication systems such as radio or other broadcast media.

The real dispute in this case is not really over such an expansive construction. The suit arises because fiber-optic cables, originally installed and used for simultaneous broadcast of programs to many customers, can now be used for commercial telephone service.
In order to overcome a prior art rejection, the applicants distinguished the prior art references by characterizing them as providing for "broadcasting over a cable." The applicants went on to state that "the broadcast cable techniques are clearly not relevant to the claimed invention; they provide for transmission to many possible users simultaneously while the claimed system sends a program only to a single intended recipient." Amendment of 5/22/91, Def. Claim Const. Br., Ex. 1-A at 8 [Doc. # 152, p. 9 of 12]. In the "Background of the Invention," the patentee states:

["Programs transferred to a remote location along a specially installed, dedicated cable generally have a reliably good picture quality. However the cable must be installed at each remote location, and controlled through a centralized facility. . . . As is the case with broadcast systems, transmitting equipment must be made available at the time any particular program is to be viewed. The selection of programs and times for viewing are made centrally, as is the case with broadcast systems, and are not under the control of a viewer at a remote location."

'792 Patent, col. 1, ll. 34-46. [emphasis added] The patentee continues: "It would be "desirable to provide a system . . . which overcomes various drawbacks as described above."' 792 Patent, col. 1, ll. 55-58.

While the court is mindful of avoiding importing limitations from the specification to the claims absent a clear disclaimer, the patentees clearly disclaimed distribution of programs by general broadcasts over cable networks. Today, however, cable TV providers offer commercial point to point telephone service over the cables originally installed for broadcast of programs. See Tr. at p. 17, l. 23-p. 19, l. 17. The fact that the cable can be used for general broadcasts, which were disclaimed by the patentee, is not a reason to craft a claim construction which, in and of itself, excludes the same cable when used for point to point telephone service. That is an infringement argument which will depend on evidence about how Defendants supply their "video on demand" services.

The court will define these terms as follows:

"Switched telephone network" and "telephone network" mean "a commercial system that establishes a route for telephone communication from one party to another"
"Telephone number" is a simple and widely used term, and there is no indication that the inventors intended to use the term differently from its commonly understood meaning among persons of skill in the art. Rebtel's proposed definition serves only to introduce additional terms into the claim and would result in confusion for the jury. See Am. Patent Dev. Corp. v. Movieline, LLC, 604 F. Supp. 2d 704, 716 (D. Del. 2009) (refusing to adopt a construction which was "merely a verbose paraphrasing of claim language that otherwise offers little to assist one of skill in the art in understanding the claims"); Parker-Hannifin, 2008 U.S. Dist. LEXIS 108152, at *38 (providing no construction for words which should be readily understood by a jury and where defendant's constructions merely offered synonyms for the claim terms); WIMCO, 2007 U.S. Dist. LEXIS 92502, at *11 (providing no claim construction for a term where "any further definition or paraphrasing would serve no useful purpose."). Consequently, "telephone number" is given its plain and ordinary meaning.

"800" Telephone Number

The term "800 telephone number" appears only in Claim 7. MyMail asserts that an "800 telephone number" is defined as a "toll-free telephone number," while Defendants urge the Court to construe this term as "a toll free telephone number for long-distance calls, with a prefix of 800." The Court adopts MyMail's proposed definition. The specification refers to "an 800 type toll-free number," implying any number in the 8xx-family of toll-free calling prefixes (800, 866, 877, 888, etc). See Col. 14:35-36. The Court finds no support for so narrowly construing "800 telephone number" to require the prefix of "800" or importing the requirement that the call must be long-distance.

A. Telephone Set

The Court agrees with the Defendant that the term "telephone set" in the 848 patent has its ordinary meaning. First, the patent claim does not specifically define the term. Id. at 1388. Second, the Plaintiff's expert concedes that a keypad alone is not a "telephone set." Sykes Dep. at 100. Third, in claims not at issue in this case, the term "telephone set" refers to "audible feedback signals" (Def's. Ex. A, claim 3, col. 21, 11. 23-26; claim 49, col. 30, 11. 6-7) and a "synthesized speech signal" (claim 49, col. 30, 11. 6-10; claim 50, col. 30, 11. 9-10). Consequently, the term cannot mean a keypad alone. See Kingsdown Medical Consultants, Ltd. v. Hoolistr, Inc., 863 F.2d 867, 874 (Fed. Cir. 1988), cert. denied, 490 U.S. 1067, 104 L. Ed. 2d 633, 109 S. Ct. 2068 (1989) (claim construction requires analysis of all claims). Therefore, the Court will accept the Defendant's construction of "telephone set" as a "device that transmits and receives sounds" and keypad alone is not a telephone set.

10. "Telephone signal"

This term appears in claim 25 of the '538 patent. SercoNet construes this term as: "An electrical signal carrying bi-directional speech information in either a digital or analog form." NetGear defines it as: "An analog telephone signal (i.e., the signal that is used for plain old telephone service (POTS))".
Starting with the claim language, claim 25 refers to a "network for transporting digital data and telephone signals" but does not define telephone signals. However, claim 30 of the patent describes a network "wherein the telephone signals are digitized telephone signals." From the plain claim language, therefore, telephone signals are broad enough to encompass digitized telephone signals. In addition, other claims in the patent, such as claims 2 and 12, refer to the term "analog." Yet "analog" was omitted in the term "telephone signal" at issue here. Therefore, the claim language indicates that "telephone signals" are not limited to analog signals, as NetGear's construction proposes.

Turning to the specification for further clarification, the specification defines "analog telephony" as traditional analog low frequency audio voice signals referred to as "plain old telephone service" or "POTS." It then specifically contrasts the term telephony, which in general denotes any kind of telephone service, including digital service such as integrated services digital network. See '538 patent at 1:18-32. Furthermore, the specification explicitly refers to an embodiment that describes both analog and digital telephone networks. See id. at 11:58-67. The term at issue, therefore, is not limited to analog telephone signals, and SercoNet's broader construction is proper.

In sum, and for all the reasons set forth above, the court adopts SercoNet's proposed construction of "telephone signal" and construes the term as: "An electrical signal carrying bi-directional speech information in either a digital or analog form."

---

3. "telephone signals": The court determines that no construction is necessary and the common meaning of this term applies.

4. "telephone signals in a telephone voice band": telephone signals in the range of frequencies between approximately 0-4 kHz.

Defendants proposed construction is adopted by the court. Inline proposes that "telephone signals in a telephone voice band" means "telephone signals that are expressed as analog signals within the voice frequency band of 0-4 kHz on the network of twisted pair wires and on a trunk line in any analog or digital form." The court finds no intrinsic evidence to support Inline's construction. Indeed, Inline acknowledges that "the common specification does not specifically describe telephone signals in a telephone voice band as analog or digitized on a public trunk line . . . ." n25 The court, therefore, declines to construe this phrase as including Inline's additional verbiage. n26

n26 Cf. Superguide Corp. v. DirecTV Enters., 358 F.3d 870, 878 (Fed. Cir. 2004) (reversing district court for limiting "regularly received telephone signals" and "radio frequency information" to analog forms; "[t]he district court should have begun its analysis by first examining the claim language. . . . The claim language does not limit the disputed phrases to any particular type of technology or specify a particular type of signal format, such as analog or digital. Indeed, neither 'analog' or 'digital' appears in any of the asserted claims.").

--- End Footnotes ---

4 Telephone Terminal

The first disputed term of the patent is "telephone terminal." Furnace Brook asserts that the term "telephone terminal" should be interpreted to mean "a customer's terminal, whether hard wired or portable." n1 Overstock asserts that the term
"telephone terminal" should be interpreted to mean "a standard customer telephone unit which may be hardwired or portable and has a standard commercial handset, a touchtone pad, a display unit and an audio unit such that it is not a computer system or personal computer."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n1 As addressed infra, Furnace Brook asserts that the term "customer terminal means" should be interpreted in the same way.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The term "telephone terminal" first appears in Claim One, which recites, in part:

An improved interactive computerized catalog process comprising the steps of:

    storing digitized graphic catalog data in a selectively addressable computer system memory,
    generating a menu of catalog products and services comprising catalog data available for selective viewing at any user's telephone associated terminal screen,
    establishing a selective communication link initiated by a user between said user's telephone terminal and said computer system,
    transmitting said menu of catalog products and services to a user's telephone terminal in response to a user's initial request,

'832 Patent at 10:54-67. The specification explains:

The telephone terminal 13 comprises a standard customer telephone unit which may be hard wired or portable and has a standard commercial handset 20 and touchtone pad 21, a display unit 24 preferably capable of displaying alphanumeric and graphic data and an audio unit 23 such as the speaker phone arranged to free the user from the normal telephone handset.

'832 Patent at 4:7-13. It goes on to describe that:

There are several commercially available screen phones, for example Northern Telephone's Vista 300 phone or Bellcore's Mediacom System which both include digital data terminal features utilizable in accordance with applicants' improved interactive catalog system.

The parties dispute whether the patent covers the use of a cellular phone or a computer by the consumer. Overstock contends that it does not, and that the use of a cell phone or computer instead of a "standard commercial handset and touchtone pad" would not infringe on the patent. Transcript at 27. Furnace Brook responds that the term "telephone" in 1995 would have been commonly understood to include a cellular telephone.

Furnace Brook argues that Overstock's interpretation excluding cellular phones asks the Court to limit a claim to the embodiments disclosed in the specification, as is forbidden under claim construction law. While it is improper to import into a claim limitations that are not part of the claim, see Superguide, supra, it is nevertheless permissible to look to the specification for explanation and understanding, even where the claim language is broader than an embodiment. In this case, there is no dispute that cellular technology was known and developing in the relevant years, and there is no mention of cellular technology in the patent claims or specification.

As just set forth, the specification describes the telephone terminal as being a standard customer telephone unit, which may be hard-wired or portable, along with other features. It describes a "speaker phone arranged to free the user from the normal telephone handset" as an example of an audio unit. Fairly read in the context of the invention and claim language, as informed by the specification language, the term "portable" reveals that the hard-wired user telephone may have a detachable handset, which does not by itself broaden the term "telephone terminal" to include a cellular phone. The Court need not and does not at this stage of the litigation consider whether the use of a cellular phone would invoke the doctrine of
equivalence if the phone comported in all meaningful respects with the telephone terminal claimed in the patent. While Furnace Brook complains that Overstock has not produced evidence to show that cellular telephones were not considered standard telephones in 1995, Furnace Brook has not produced evidence to show that they were. It is well known that the claims of the patent define the invention to which the patentee is entitled the right to exclude. In the absence of any reference whatever to cellular telephones or cellular technology, this 1995 patent is not read to claim such. This patent, as explained by the specification, claims landline telephones, which may or may not have a portable or detachable handset.

Furnace Brook contends and Overstock denies that a telephone terminal could also be a computer. The use of the words "between said user's telephone terminal and said computer system" in Claim One shows that a computer was not contemplated at the user end. When the Patentee intended to talk about a computer, he did so by using the word computer, as was frequently used when describing the retailer end of the invention, but never used when describing the customer end of the invention. A computer is beyond the specified embodiments, which do not limit, but explain this patent's claim of a telephone terminal as a standard telephone with display screen or as a touch tone telephone associated with a cable TV.

Although the prosecution history is generally not as useful a guide to a claim's meaning as the specification, it is worth here noting that in the prosecution history, the Examiner proceeded to describe the unique combination of concepts that ultimately allowed the patent to issue, specifically the "combination of all of the systems into a method of creating an interactive catalogue where the user is given the option of including data from his transactions into a customer marketing profile data file." Id.

The prosecution history includes the following statement by the patent examiner following the amendments filed on December 27, 1996:

The use of a telephone and a computer to communicate a catalogue over the phone lines is known in the art. Similarly, the use of a phone system as a survey tool is also known. Further, it is known that purchases are often analyzed for data relating to the consumer.

Notice of Allowability at 2, OSTKFB001618.

The Examiner then proceeded to describe the unique combination of concepts that ultimately allowed the patent to issue:

However, the prior art does not teach the combination of all of the above systems into a method of creating an interactive catalogue where the user is given the option of including data from his transactions into a customer marketing profile data file.

Id.

The notice of allowance makes plain that on one end is a computer and on the other end is a telephone, which, the patent makes clear, may or may not be associated with a cable TV system. Furnace Brook argues that because the claims do not require two computers does not necessarily mean that two computers could not be used in the invention. But as just noted, the statements of the patent examiner, when allowing the patent to issue make clear that the unique nature of the invention was the combined interaction of a telephone and computer in communicating a catalog over the phone lines, where the user has the option of whether to include "data from his transactions into a customer marketing profile." It would defy the notice purpose of patents to find a user-end computer claimed in this patent.

As earlier noted, Furnace Brook argues that the terms telephone terminal, customer terminal means, and user terminal are used interchangeably because they all mean the same thing. The Court disagrees. As explained infra, the Court concludes that the patentee's use of "customer terminal means" evidences that at the customer end may only be a telephone terminal or a telephone-associated cable-TV. This is supported by the use of the term "plurality of customer terminal means" in Claim 5.

The Court concludes that neither a cellular telephone nor a computer on the user end is claimed by the '832 Patent. Because the terms standard customer telephone unit (hard-wired or portable), standard commercial handset, touchtone pad, a display unit and an audio unit are the named elements that comprise a telephone terminal, the Court concludes that "telephone terminal" means a "standard landline telephone unit, which has a standard commercial handset, a touchtone pad, a display unit and an audio unit, and which may have a cordless handset."
1. With respect to claim 1, Furnace Brook argues that the "telephone terminal" referred to in one of the limitations may be a cellular telephone or a personal computer. We agree with Furnace Brook insofar as it suggests that a "telephone terminal" refers to a device for communicating over a telephone network: a cellular telephone and a personal computer are capable of such communication, and to the extent that they are used to do so, either device can constitute a "telephone terminal." But telephone communication, as discussed in the patent, requires more than just communication over a telephone line. It requires a dial-up connection to the catalog server at the other end of the connection. The specification states that the telephone terminal "dial[s] a predetermined assigned telephone number" used by catalog companies to permit customers to make calls "to their business." '832 patent, col. 3, ll. 1-5. According to the specification, the act of making that telephone call "connects the customer" to the catalog server. Id., col. 3, l. 6. The specification later confirms that requirement, stating that "a telephone call to a predetermined number, e.g. an 800 number" is "recei[ved] by the central data processor of applicants' improved catalog system." Id., col. 8, ll. 3-8.

Thus, the claim 1 limitation reciting the establishment of a "selective communication link initiated by a user between said user's telephone terminal and said computer system" requires that the communication link be established over a telephone network by dialing the computer system directly. Although a personal computer and a cellular telephone are capable of performing that function, those devices must actually be performing that function in order to be "telephone terminals," as that term is used in the '832 patent. The record contains no evidence that the personal computers or cellular telephones of Overstock's customers place such a call when accessing Overstock's website over the Internet. The district court was therefore correct to hold that those devices fall outside the literal scope of the claim 1 limitation.

Furnace Brook notes that the specification discloses an embodiment in which a "terminal" communicates with a catalog server using an "interactive media contact," of which mail, fax, and telephone are given as examples. '832 patent, col. 9, ll. 37-39. Furnace Brook argues that the Internet is a form of interactive media contact and therefore that communications over the Internet do not fall outside the literal scope of claim 1. Even if we assume that the Internet is a form of interactive media contact, Furnace Brook's argument fails because the portion of the specification to which Furnace Brook refers discusses a "terminal" without any further elaboration, whereas claim 1 recites a "telephone terminal." The modifier "telephone" must add some limitation to the noun "terminal" for the modifier to have any meaning. As explained, the specification tells us what telephone communication requires for purposes of the patent. Thus, we reject Furnace Brook's assertion that any embodiment described as a "terminal" in the specification must be a "telephone terminal" within the meaning of claim 1.

Next, Furnace Brook argues that the accused devices, when used to access the Internet, are captured by the doctrine of equivalents, even if they are not within the literal scope of claim 1. The question of infringement under the doctrine of equivalents is a factual question, however, and Furnace Brook has not introduced evidence sufficient to create a genuine issue of material fact as to that question. In its summary judgment briefing, Furnace Brook pointed to the declaration of Dr. Robert Stevenson and the deposition testimony of Dr. Richard Nemes in an effort to show equivalence. Yet none of the facts stated in those sources are material to the equivalents issue before us. Although Dr. Stevenson stated that a personal computer and a cellular telephone can perform the same functions as a standard telephone set, and that those devices can also access the Internet, he did not explain why accessing a computer server over the Internet is equivalent to dialing a computer server over a telephone network. The deposition testimony of Dr. Richard Nemes suffers from the same flaw. Without record evidence to create a genuine factual dispute on the equivalents issue, the district court properly granted summary judgment that Overstock does not infringe claim 1.

1. "telephone wiring network": the network of twisted pair wires extending from the point of convergence where the signal interface may be installed downstream to telephone devices which is shared by information and telephone signals in a telephone voice band.

Inline's proposed construction is adopted by the court. Defendants argue that the "telephone wiring network" "extends or
runs from the telephone devices to the telephone exchange." The patentee did not claim the entire existing communication pathway over which telephone voice signals travel but, rather a system for communicating information from an external source, through the signal interface and downstream to destination devices over the same twisted pair wires that also carry telephone signals. Defendants' proposed preamble limitation, and related construction, would expand the asserted claims to cover the public trunk line all the way back to the telephone exchange in contradiction to the common specification, the claims, and the court's prior claim construction determinations.

The common specification recites:

The present invention relates to a system for simultaneous two-way communication of video signals and other signals between multiple networks of telephone wiring whose twisted pairs converge together into a single bundle, wiring block, or other common point of access, and a high capacity communication line located at that point of access. Each network includes a set of interconnected, active telephone wires (i.e., a group of wires that create a conductive path for telephonic signals) internal to a house, an apartment unit, or a room in a commercial building. Such wiring internal to houses, apartment units, or rooms in commercial buildings shall be referred to herein as "local networks." n17

* * * *

The present invention relates to a system for simultaneous two-way communication of video signals and other signals between multiple networks of telephone wiring . . . providing distribution of . . . signals to a local network of active telephone wiring (i.e., the wiring internal to a house, apartment unit, or a room in a commercial building) from a distribution device that connects to the trunk line of a public or private telephone network. That device is located where the telephone lines for multiple local networks converge to meet the public network trunk (or PBX, in the case office buildings) . . . . n18

"The interface includes a transceiver/switch that is connected to multiple pairs of telephone wiring and is interposed between the telephone wire pairs from the local telephone exchange (the trunk line) and the extended telephone wire pairs leading to separate local networks of telephone wiring." n19

n17 '596 patent, 1:22-33.
n18 Id. 1:62-2:4.
n19 Id. 9:1-6.
- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The court agrees with Inline that "the fact that there is a communications pathway from telephone devices to . . . a telephone exchange does not mean that the telephone wiring network - of the claims - is coextensive with that entire communications path." n20

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

N20 D.I. 480 at 11.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The claims bear out this determination. Each independent claim of the patent-in-suit demonstrates that the "telephone wiring network" cannot include the entire communications pathway extending back to the telephone exchange. Each includes a limitation describing transmission of high frequency signals over the "telephone wiring network" and, therefore, shows defendants' proposed construction is incorrect. For instance, claim 61 of the '596 patent includes an element requiring "circuitry for transmitting to selected sets of one or more of the plurality of transceivers a corresponding plurality of signals in the high frequency band each encoding one of the plurality of information streams over the telephone wiring network." n21
n21 '596 patent, claim 1; see also '446 patent, claim 1 (including the limitations "circuitry for transmitting over the telephone wiring network to the transceiver an internal signal in the high frequency band encoding the information stream" and "circuitry for limiting transmission of the internal signal in the high frequency band from the telephone wiring network to the telephone exchange." (emphases added)); '585 patent, claim 1 (including the limitation "the signal interface includes circuitry for receiving a plurality of external signals encoding information streams from the external source of information, circuitry for transmitting over the telephone wiring network to the transceivers a plurality of internal signals in the high frequency band encoding the information streams, and circuitry for limiting transmission of signals in the high frequency band from the telephone wiring network to the telephone exchange and for passing signals in the telephone frequency band between the telephone wiring network and the telephone exchange." (emphasis added). The figures of the patents also support this conclusion. See, e.g., '596 patent Fig. 1a, Fig. 1b.

In the 2004 Markman Opinion, the court construed the claimed signal interface to be "[a] device interposed on the opposite end (i.e., the local side) of the public trunk line (as defined by the inventor in the patent) from the telephone exchange that performs the recited functions of the incorporated circuitry." n22 The court stated that:

[T]he signal interface is designed to prevent high frequency signals, coming from the external source, from passing onto the public telephone trunk line. . . . The blocking of these high frequency signals from the public trunk line is accomplished by the specific circuitry in the signal interface, low pass filters 474, which block high frequency signals from passing onto the public telephone network, but allow low frequency telephone signals to transmit. n23

Because defendants' proposed construction of "telephone wiring network" would impermissibly permit high frequency signals to be transmitted over the public trunk line, it must be rejected.

n23 Id. at 323.
The parties dispute the meaning of "telephony events," as used in the '570 patent (claim 6) and '345 patent (claim 14). The parties' constructions are identical except for the addition, in Witness's proposal, of "and are not identifying numbers. Agent-entered information is not data regarding telephone events." NICE contends that this addition is not supported by intrinsic evidence and unnecessarily complicates the construction of the term, making it difficult to understand. Witness bases its proposed language on NICE's argument to the examiner during the prosecution of the patent, citing '345 Pat. Pros. Hist., 2nd Prelim. Amend., 4 ("None of the agent entered information is telephony event data, since a telephony event is an action or occurrence, captured by a computer, relating to a telephone call."). In response, NICE contends that this single statement quoted from the prosecution history specifically discusses the Peavey prior art reference, which did not disclose a system that uses a computer to capture an action or occurrence relating to a telephone call.

The Court construes telephony events to mean "Actions or occurrences detected by a computer program and that related to what happens to a phone call (such as the initiation of the call, the addition or removal of callers, the transfer of the phone call, or the termination of the calls)." After considering the claim and the prosecution history cited, the Court concludes the referenced prosecution history goes to a prior art discussion and does not constitute a clear and unmistakable disavowal of claim scope.

1. "Telescope"

The first term that the parties disputed was the word "telescope." "Telescope" appears in every claim in the patent, either expressly or by reference. Id. at 6:29-8:22. As used in the '908 Patent, this Court construes the term "telescope" to include both "reflecting telescopes," which use mirrors as optical elements, and "refracting telescopes," which use lenses as optical elements. n4

Plaintiff contends that the term "telescope" should be restricted to a "Newtonian telescope." n5 (See Plaintiff's Reply Claim Construction Brief, Mar. 10, 2005, "Pl.'s Reply Br." at 3.) Defendant, in contrast, argues that "telescope" is much broader than plaintiff alleges, urging that the term be construed to include both "reflecting telescopes" and "refracting telescopes," thus comporting with the term's dictionary definition. (See Defendant's Brief Addressing Claim Construction, "Def.'s Opp. Br." at 3.) As discussed supra, a court must begin its claim construction analysis by analyzing the language of the claims themselves.

n4 It is also noted that prisms have been used as optical elements in both reflecting and specialized refracting telescopes. (See Markman Hearing, Def. Ex. B, Isaac Newton, Optics 422-23 (1717); Def. Ex. C, John Texreau, How to Make a Telescope 107 (1957); Markman Tr. at 19:14-21.)

n5 For the most part, Newtonian Telescopes are a subgroup of reflecting telescopes. (Markman Tr. at 4:9-11.)
"The doctrine of claim differentiation . . . creates a rebuttable presumption that each claim in a patent has a different scope." Dow Chem. Co. v. United States, 226 F.3d 1334, 1341 (Fed. Cir. 2000). The doctrine is implicit in 35 U.S.C. § 112, P4, which states that "a claim in dependent form shall contain a reference to a claim previously set forth and then specify a further limitation of the subject matter claimed." (emphasis added). Thus, under the doctrine, a dependent claim and a corresponding independent claim should not be construed to have the same scope; the dependent claim should have an additional limitation. The Federal Circuit recently reaffirmed the doctrine of claim differentiation, without using that title, in Phillips, when it stated that "the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." 2005 U.S. App. LEXIS 13954, 2005 WL 1620331, at *7 (citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004)). The doctrine precludes interpretations of claim language that render dependent claims too broad or independent claims too narrow, but it should not be used to interpret an independent claim too broadly either. See Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, (Fed. Cir. 1987) ("Whether or not claims differ from each other, one can not interpret a claim to be broader than what is contained in the specification and claims as filed.") (citation omitted).

b. Analysis

The doctrine of claim differentiation applies to this situation and resolves the dispute as to the definition of "telescope" in favor of defendant, i.e., that "telescope" includes both reflecting and refracting telescopes rather than being limited to Newtonian telescopes. The term "Newtonian telescope" appears in claim 5 of the '908 Patent. '908 Patent at 6:42-43 ("The method of claim 1, further comprising locating the optical element in a Newtonian telescope."). Claim 5 is dependant on claim 1, which describes: "[a] method of aligning an optical element in a telescope." Id. at 6:30 (emphasis added). The "Newtonian" limitation on the word "telescope" in claim 5 would be unnecessary if a person of ordinary skill in the art would have understood "telescope," as used in claim 1, to be restricted to Newtonian telescopes. Based on the doctrine of claim differentiation, the term "telescope" should not be restricted to "Newtonian telescopes."

The next question is what the term "telescope" includes, if it is not limited to Newtonian telescopes. Plaintiff argues that if "telescope" is not limited to Newtonian telescopes, it should be limited to "reflecting telescopes," which would include Newtonian telescopes as a subgroup. (Markman Tr. at 6:12-13.) n6 The doctrine of claim differentiation answers this question as well. The term "reflecting telescope" appears in claim 4. '908 Patent at 6:40-41. Claim 4 is "the method of claim 1, further comprising locating the optical element in a reflecting telescope." Id. (emphasis added). Applying the doctrine of claim differentiation, the term "telescope," as used in claim 1, presumptively cannot be limited to "reflecting telescopes," which is the limitation added in claim 4. Therefore, this Court looks to the specification to determine whether the term "telescope" includes refracting telescopes, as defendant suggests.

n6 Citations to the Markman hearing transcript reference the page and line numbers in the form Page(s):Line(s).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

Plaintiff asserts that the specification "does not describe any method for using this invention to align a [refracting] telescope," and cites Phillips for the proposition that the claims must be consistent with the specification. (Markman Tr. at 6:4-5.) Nonetheless, as plaintiff concedes, the specification expressly states that "the present invention may be used to align refracting telescopes." '908 Patent at 6:11, 19-21 (emphasis added). In fact, the specification even provides a diagram of the invention being used with a refracting telescope. Id. at Fig. 15. Since the patent mentions refracting telescopes in the specification, included a drawing for the invention with a refracting telescope, and uses "reflecting telescope" as the limitation in a dependent claim, it is clear from the intrinsic evidence that the term "telescope," as used in the claims, includes both reflecting and refracting telescopes. n7

n7 Claims 10, 15, 18, and 20 use the term "telescope" without any dependent claims that limit the term; however, this is of no consequence because claim terms are to be construed consistently across all claims. See Southwall Tech., Inc. v. Cardinal IG Co. 54 F.3d 1570, 1579 (Fed. Cir. 1995); accord Phillips, 2005 U.S. App. LEXIS 13954, 2005 WL 1620331 at *6
3. To what extent may the court base its claim construction on the scope of the disclosure in the patent's specification?

Two competing principles of claim construction are at issue in this case. The first, advanced by IPPV, is that claim terms cannot be narrowed by reference to the written description or prosecution history unless the language of the claims invites reference to those sources. Johnson Worldwide, 175 F.3d at 989-90.

In Johnson Worldwide, the patentee claimed a steering device for boats comprising a directional indicator "coupled to" a trolling motor. The question was whether this claim language required that the directional device be "mechanically attached" to the motor, or whether the claim could be interpreted to read upon a directional indicator connected to the motor by wires. The patent specification describes that the preferred embodiment includes a directional indicator mechanically attached to the motor. The Federal Circuit stated that there is a "heavy presumption" against importing additional limitations into claim language. See id. at 989. The court stated that there are two situations in which a claim term should be accorded other than its ordinary and accustomed meaning. The first arises if the patentee has chosen to be his or her own lexicographer by clearly setting forth an explicit definition for a claim term. Id. at 990. The second is where the term or terms chosen by the patentee so deprive the claim of clarity that there is no means by which the scope of the claim may be ascertained from the language used. Id. The court found that the claim language was sufficiently clear that there was no need to import additional limitations from the specification and the prosecution history.

In this case, the claims recite the phrases "generating a television program signal" and "encrypting said television program signal in accordance with said pseudo-random signal." This language is sufficiently unambiguous that the meaning of the claims terms might be ascertained without reference to the specification. In this respect, Johnson Worldwide teaches that the claim language should not be narrowed by importing the limitation "analog" from the specification.

The second principle of claim construction at issue in this case, advanced by Echostar, is that a patentee should not be entitled to claims that are broader than the scope of the patent's disclosure. See Wang, 197 F.3d at 1383. In Wang, Wang sued America Online and Netscape Communications for infringement of a 1984 patent directed to a system for providing users with textual and graphical information from computer-controlled databases via interactive two-way communications over a telephone network. The issue for claim construction and summary judgment was whether the claim term "frames of information" covered both character-based and bit-mapped-based protocols, or whether the term should have been limited to character-based protocols. The preferred embodiment of the invention was directed to character-based protocol systems, although the specification acknowledged that bit-mapped protocols were part of the prior art. The Federal Circuit found that a person of ordinary skill in the art would understand the specification to refer only to character-based systems, and affirmed the trial court's construction that limited the claims to character-based systems.

Section 112, P 1 of the Patent Code requires that a patent specification "shall contain a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains . . . to make and use the same . . . " 35 U.S.C. § 112. The purpose of the written description requirement is to ensure that the scope of the right to exclude, as set forth in the claims, does not overreach the scope of the inventor's contribution to the field of art as described in the patent specification. Reiffin v. Microsoft Corp., 214 F.3d 1342, 2000 U.S. App. LEXIS 12191, 2000 WL 714425 (Fed. Cir. June 5, 2000). Whether the language of a claim is supported by the written description of the patent is a question of fact. See Gentry Gallery, 134 F.3d at 1479. Accordingly, a determination of whether claims comply with the written description requirement is generally made in the context of a summary judgment motion or by a jury.

The Federal Circuit has indicated that in certain situations, a narrow written description may constitute a basis for adopting a narrow construction of otherwise-broad claim language. The Federal Circuit has held that the literal meaning of a claim is fixed upon its issuance. Al-Site Corp. v. VSI International, Inc., 174 F.3d 1308, 1320 (Fed. Cir. 1999). Variants of a claimed
invention that are based on after-developed technology could not have been disclosed in a patent. Chiuminatta Concrete Concepts v. Cardinal Industries, Inc., 145 F.3d 1303, 1310 (Fed. Cir. 1998). When a claim is written sufficiently broadly to cover after-developed technologies, the claims may be construed to limit their scope to those technologies disclosed in the written description of a patent. See Wang, 197 F.3d at 1383 ("The only embodiment described in the '699 patent specification is the character-based protocol, and the claims were correctly interpreted as limited thereto.").

The doctrine of equivalents extends beyond the literal scope of claims, and permits a patentee to exclude others from practicing later-developed technologies that are equivalent to a claimed device. See Overhead Door Corporation v. Chamberlain Group, Inc., 194 F.3d 1261, 1271 (Fed. Cir. 1999) ("Any subsequent change in the state of the art, such as later developed technology would have been eligible for coverage under the doctrine of equivalents, thus defining at least one type of expanded claim coverage under the doctrine.") (citation omitted); Chiuminatta, 145 F.3d at 1310 ("The doctrine of equivalents is necessary because one cannot predict the future."). Later-developed technologies may infringe a patent only under the doctrine of equivalents. Al-Site, 174 F.3d at 1320. ("An 'after arising equivalent' infringes, if at all, under the doctrine of equivalents."). The Federal Circuit has clarified that, although later-developed technologies may infringe a patent under the doctrine of equivalents, such technologies cannot constitute an "equivalent" as would fall within the literal scope of a patent under § 112, P 6. See Al-Site, 174 F.3d at 1320. Accordingly, later developed technologies may not fall within the literal scope of the patent at issue, but may infringe the patent only under the doctrine of equivalents.

The specification of the '942 patent exclusively discusses the encryption of analog signals, without mentioning encryption of digital signals. The apparent reason for the patent's focus on analog signals is that television broadcasting in the early 1980s was conducted solely in an analog format. Both parties acknowledged during oral argument that digital television signals were not developed until after the date of invention. Because the literal scope of the '942 patent was fixed at the date of issuance, the claims must be construed to refer to the kinds of television signals that were being encrypted at that time. See Al-Site, 174 F.3d at 1320. Accordingly, the scope of claim 21 should be limited to refer to the encryption of analog television program signals.

IPPV urges that the claims should not be limited to an analog implementation, because the claims are written in method form. IPPV argues that the scope of method claims should not be limited to the structures discussed in the specification. See Sandisk Corp. v. Lexar Media, Inc., 91 F. Supp. 2d 1327, 1333 (N.D. Cal. 2000).

It is true that method claims are not necessarily limited to the structures recited in the specification. See, e.g., IMS, 206 F.3d at 1432-33. The court finds no support for the proposition, however, that drafting a claim in method format can extend the literal scope of the claim to embodiments that are developed subsequent to the issuance of the patent.

The court will construe the phrase "television program signal" of claim 21 of the '942 patent to mean "analog television program signal."

IPPV argues that the claims should not be limited to an analog implementation, because the claims are written in method form. IPPV argues that the scope of method claims should not be limited to the structures discussed in the specification. See Sandisk Corp. v. Lexar Media, Inc., 91 F. Supp. 2d 1327, 1333 (N.D. Cal. 2000).

It is true that method claims are not necessarily limited to the structures recited in the specification. See, e.g., IMS, 206 F.3d at 1432-33. The court finds no support for the proposition, however, that drafting a claim in method format can extend the literal scope of the claim to embodiments that are developed subsequent to the issuance of the patent.

The parties dispute the meaning of the term "television program signal" of claim 21. IPPV argues that "television program signal" includes video information, while Echostar argues that "television program signal" comprises video information in combination with audio information.

In support of its proposed construction, IPPV points to the term "display" in the preamble of claim 21, and contends that only visual images may be displayed. IPPV argues that because the preamble modifies the rest of the claim, the inventors' use of the term "display" limits the meaning of the term "television program signal" to video information.

IPPV also cites the specification, which states "the present invention relates to the encoding and decoding of video information, and more importantly, to a method and system for secure transmission of television signals for subscription television or similar video services in which only authorized viewers are permitted to view a video program." IPPV argues the references to "video" in this passage limit claim 21 to video information.

- 4674 -
Echostar counters that the term "television program signal" describes a signal comprising a video signal and an audio signal. As support for its construction, Echostar cites the Modern Dictionary of Electronics, which defines "television signal" as "the audio signal and the video signal that are broadcast simultaneously to produce the sound and picture portions of a televised scene." Echostar also points to other claims of the '942 patent that refer to "encoded video signals." Claim 13, for example, claims an "apparatus for decoding an encoded video signal." Echostar contends that the inventors' specific reference to a video signal means that they must have intended a different meaning for "television program signal."

Having considered the parties' positions, the court finds that the inventors did not intend to limit the term "television program signal" to video information or signals. They specifically referred to video signals in multiple parts of the patent, including claims 1, 4, 6, and 11-13, making it apparent that "video signal" and "television program signal" are not synonymous. Moreover, the portion of the specification cited by IPPV distinguishes between television signals and video information in stating that "the present invention relates to the encoding and decoding of video information, and more importantly, to a method and system for secure transmission of television signals. . . ." (emphasis added). If television program signals were composed of only video information, this passage would be redundant. The court therefore finds no reason to limit the conventional definition of "television program signal," and concludes that it comprises audio and video signals that are broadcast simultaneously to produce the sound and picture portions of a televised scene.

A. Disputed Claim Term # 1: "a television transmission system . . ."

The first term in dispute is: 4

"a television transmission system . . . for transmitting television programs thereover for reception by a plurality of receivers" ('320 Patent, Claim 1 Preamble)

"a television transmission system for transmitting programs thereover for reception by a plurality of receivers" ('078 Patent, Claim 10 Preamble)

Plaintiff's Proposed Construction: "a system for transmitting programs to receivers" 5

Defendants' Proposed Construction: "a system that allows multiple viewers to choose the same program at the same time such that once the chosen program is scheduled for transmission on a particular channel, additional viewers can be added by transmitting the appropriate descrambling signals to the requesting viewer's receiver"

Although the disputed term is phrased slightly differently in each patent, the parties agree that the term should be construed the same for both patents.

Plaintiff argues that all four disputed terms need not be construed by the Court, but in the event the claims are construed, it has offered proposed constructions for each.

1. Whether the Preambles Are Limiting

Plaintiff first argues that because this term appears in the preambles of the claims, it is merely informational and does not limit the claims. Accordingly, Plaintiff maintains, the term is of no significance to claim construction and need not be construed by the Court. See Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999) ("If . . . the body of the claim fully and intrinsically sets forth the complete invention, including all of its limitations, and the preamble offers no distinct definition of any of the claimed invention's limitations, but rather merely states, for example, the purpose or intended use of the invention, then the preamble is of no significance to claim construction because it cannot be said to constitute or explain a claim limitation."). According to Plaintiff, the claim preambles merely clarify that the claimed
methods are to be performed within preexisting cable television systems, but nothing in the preambles should be read to otherwise limit the claims.

As the Federal Circuit has held, a preamble is limiting only "if it recites essential structure or steps, or if it is necessary to give life, meaning, and vitality to the claim." Symantec Corp. v. Computer Assocs. Int'l, Inc., 522 F.3d 1279, 1288 (Fed. Cir. 2008) (internal quotation marks omitted) (quoting Catalina Mktg. Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002)). "A preamble is not limiting, however, 'where a patentee defines a structurally complete invention in the claim body and uses the preamble only to state a purpose or intended use for the invention.'" Id. (internal quotation marks omitted) (quoting Catalina, 289 F.3d at 808). In Symantec, the Federal Circuit explained the general rule in determining whether or not a preamble should be read as a limitation:

Absent clear reliance on the preamble in the prosecution history, or in situations where it is necessary to provide antecedent basis for the body of the claim, the preamble "generally is not limiting." Thus, in general, the purpose of a claim preamble is to give context for what is being described in the body of the claim; if it is reasonably susceptible to being construed to be merely duplicative of the limitations in the body of the claim (and was not clearly added to overcome a rejection), we do not construe it to be a separate limitation.

Id. at 1288-89 (internal citation omitted) (quoting Catalina, 289 F.3d at 809).

Despite Plaintiff's argument that the preambles merely provide context, however, the Court finds that the preamble of Claim 10 of the '078 Patent recites essential structure--"a television transmission system"--that is referred to later in the method claims. See '078 Patent, 13:17-20 ("providing a central unit having a collection of stored programs stored on a medium allowing selective reproduction and real-time transmission of said programs over the system" (emphasis added)); id. at 13:25-14:3 ("responding in said central unit to said viewer's request by selecting said viewer-chosen program from said collection and by transmitting in real time over the system said viewer-chosen program at said viewer-requested time for reception by the receiver associated with said requesting viewer" (emphasis added)). The introduction of the "system" in the preamble and the references to the "system" in the claim body demonstrate that the preamble does more than provide context: it gives meaning to the claim itself, as the later references to "the system" would be meaningless without their antecedent basis in the preamble. See NTP, Inc. v. Research in Motion, Ltd., 418 F.3d 1282, 1305-06 (Fed. Cir. 2005) (finding that a preamble limited the claims where the preamble contained "at least one of a plurality of destination processors in the electronic mail system" and the body of the claim referred to "the at least one of the plurality of destination processors"); Seachange Int'l, Inc. v. C-COR Inc., 413 F.3d 1361, 1375-76 (Fed. Cir. 2005) (finding the preamble of a method claim limiting where it described a "processor system" and the body of the claim described several steps of the method that involve "said processor systems"); Pitney Bowes, 182 F.3d at 1306 (finding the preamble limiting where, inter alia, it stated that "the patent claims a method of or apparatus for producing on a photoreceptor an image of generated shapes made up of spots" and the body of the claim contained the term "generated shapes" that could "only be understood in the context of the preamble statement"). The "system" referred to in the claimed methods can only be the same "system" first mentioned in the preamble. If the claimed methods are not performed using the "system," they could not be performed at all.

Likewise, the preamble of Claim 1 of the '320 Patent recites essential structure of the system necessary to give meaning to the methods claimed. For example, the "land lines" of the system are first introduced in the preamble and then referred to several times in the body of the claim. See '320 Patent, 10:46-49 ("providing a collection of stored programs stored on a medium allowing selective reproduction and real-time transmission of said stored programs over the land lines" (emphasis added)); id. at 10:54-55 ("transmitting said chosen program in real-time over said given section of the land lines" (emphasis added)). The same is true for the system's "receivers" described in the preamble. See id. at 10:59-60 ("preventing intelligible viewing of said chosen program at said requested time on all other receivers of said given section" (emphasis added)). Without the structure of the system recited in the preamble, the references to land lines and receivers would be meaningless. Accordingly, because the preambles provide an antecedent basis for the claims, the Court concludes that they should be construed as limiting.

2. Construction of the Disputed Term

With respect to how the term "television transmission system" should be construed, Defendants argue that their construction has support in the specification, which imparts a special meaning to the term. The Court agrees. The specification describes
the system of the "present invention" as one that allows multiple viewers to view the same transmission of a program at the same time:

[T]he present invention minimizes the risk that the viewer will be unable to view the chosen program at the viewer requested time. This risk is minimized for two reasons. First, the preferred embodiment hereof designates sections of the land lines . . . . Secondly, the present invention allows as many viewers as are connected to the system to choose the same program at the same time.

'320 Patent, 10:9-19 (emphasis added). While it would be improper to import limitations from a preferred embodiment to the claim, statements describing "the present invention" (as opposed to "the preferred embodiment") can and do limit the scope of the invention. See, e.g., Verizon Servs. Corp. v. Vonage Holdings Corp., 503 F.3d 1295, 1308 (Fed. Cir. 2007) ("When a patent thus describes the features of the 'present invention' as a whole, this description limits the scope of the invention."); SciMed Life Sys. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1343 (Fed. Cir. 2001) ("[T]he characterization of the coaxial configuration as part of the 'present invention' is strong evidence that the claims should not be read to encompass the opposite structure."). Indeed, in the very same paragraph in which the applicants refer to "the present invention," they state that "[t]he preferred embodiment" performs specific functions that help minimize the risk that a viewer will be unable to view a program at a given time. '320 Patent, 10:12-16. 6 The fact that the applicants used "preferred embodiment" and "present invention" in consecutive sentences demonstrates that the applicants knew when they were defining the invention as a whole and when they were discussing only a preferred embodiment. Therefore, the Court accepts the applicants' statement that "the present invention allows as many viewers as are connected to the system to choose the same program at the same time."

6 As discussed at length in the Court's Memorandum and Order denying Cablevision System Corporation's Motion to Dismiss, the patents originally were obtained by H. Vincent Monslow and Steven Dickey. After a series of transfers, Plaintiff now holds both patents. Accordingly, "the applicants" means Mr. Monslow and Mr. Dickey.

Examination of both the specification and the prosecution history supports the conclusion that the applicants gave special meaning to the "system" in the '320 and '078 Patents. They clearly and consistently described a television transmission system that allowed multiple viewers to watch the same program transmission simultaneously and that used descrambling signals to achieve this objective. To construe the disputed term simply as "a system for transmitting programs to receivers" would fail to capture the precise meaning used by the applicants. Accordingly, the Court will adopt Defendants' construction.
<table>
<thead>
<tr>
<th>Term</th>
<th>VIA &amp; Intel's Proposal</th>
<th>CCCC's Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;the SNOOP signal telling said one of said second plurality of bus masters when to write cached data to the address appearing on the bus&quot;</td>
<td>&quot;The SNOOP signal indicating to one of the bus masters on the second bus when to write cached data to one of the second data storage locations at the address appearing on the bus.&quot;</td>
<td>&quot;The SNOOP signal indicating to a bus master when it may be required to write cached data to the address appearing on the second bus.&quot;</td>
</tr>
</tbody>
</table>

The language here, "the SNOOP signal telling said one of said second plurality of bus masters when to write cached data to the address appearing on the bus," is describing actions taking place on the second bus, as illustrated in the bottom portion of Fig. 1. To properly construe this language, however, it is necessary to look at the context in which the disputed language arises.

This disputed language (underlined below) appears as part of a wherein clause in the preamble. The antecedent basis for this wherein clause is found in the prior paragraph of the claim preamble. Together these paragraphs read:

the second bus providing a second plurality of bus masters connected thereto with data read and write access to second data storage locations mapped to separate addresses within a second address space, wherein one of said second plurality of bus masters writes data to a first particular one of said second data storage locations by placing on the second bus an address to which the first particular one of said second data storage locations is mapped and transmitting the data via said second bus, and wherein one of said second plurality of bus masters reads data from a second particular one of said second storage locations by placing on the second bus an address to which the second particular one of said second storage locations is mapped and receiving data via said second bus,

wherein one of said second plurality of bus masters connected to said second bus caches data read out of a subset of said second data storage locations, said second bus including means for conveying a SNOOP signal with an address appearing on the bus, the SNOOP signal telling said one of said second plurality of bus masters when to write cached data to the address appearing on the bus

It is clear from the claim language that the SNOOP signal indicates to one of the bus masters on the second bus when to write cached data to an address appearing on the second bus. This is nearly a direct transcription of the claim language "wherein one of said second plurality of bus masters connected to said second bus." '369 patent at 13:6-7. But there appears to an issue regarding whether the cached data writing is limited to the second data storage locations on the second bus. Defendants correctly argue that because the "wherein" clause describes the SNOOP signal on the "second bus" to which the "second plurality of bus masters" that cache data read out of "second data storage locations" is connected, it must follow that "the address appearing on the bus" immediately preceding the disputed claim term should also be construed to originate from a device on the second bus. Thus, in light of the preceding paragraph of the preamble, the court concludes that the claim requires that a SNOOP signal indicate to the bus master on the second bus when to write cached data to the corresponding second storage location at the address on the second bus.

Accordingly, the court construes the language "the SNOOP signal telling said one of said second plurality of bus masters when to write cached data to the address appearing on the bus" as saying "the SNOOP signal indicating to one of the bus masters on the second bus when to write cached data to the one of the second data storage locations at the address appearing on the second bus."
The claim term at issue in this case is "the SNOOP signal telling said one of said second plurality of bus masters when to write cached data to the address appearing on the bus." The district court construed this term to mean "the SNOOP signal indicating to one of the bus masters on the second bus when to write cached data to the one of the second data storage locations at the address appearing on the second bus." The district court clarified that this construction "requires the SNOOP signal to indicate to a device on the second bus that it should write data held in that device's cache memory to main memory on the second bus." The parties dispute whether the claimed SNOOP signal must tell a processor to write cached data, or whether it must merely tell the processor to determine whether it should write cached data.

The plain language of the claim states that the SNOOP signal tells the processor "when to write cached data." '369 patent col.13 ll.11-13. The abstract of the '369 patent states that "when accessing a cached memory address, the bus interface circuit places a signal on the second bus telling the second bus master to copy data from the cache memory into the main memory." Id. abstract. The specification also states that the processor on the second bus responds to the SNOOP signal by asserting a retry signal and writing the requested cached data back to main memory. Id. col.2 ll.26-35, col.12 ll.16-24. Thus, the claim language and the patent specification support the district court's construction.

CCCC argues that the specification does not require the processor to respond to the SNOOP signal by writing cached data. Specifically, CCCC points to the following portion of the specification:

To ensure cache coherency, when computer 4 seeks to read access a main memory 3 address, it may assert a SNOOP signal . . . . If any other device on Futurebus 12 such as computer 6 is maintaining a cache for data stored at that memory address, computer 6 may assert a "RETRY" signal which causes computer 4 to relinquish control of Futurebus 12 before completing the address cycle. At that point, computer 6 obtains control of Futurebus 12 and writes the appropriate data from cache memory 7 back into main memory 3.

Id. col.9 ll.47-57. CCCC argues that the construction of "SNOOP signal telling" cannot require writing data from cache to main memory because the computer "may assert a 'RETRY' signal." See id. col.9 ll.52-53 (emphasis added). This portion of the specification, however, does not discuss the claimed invention. It describes the prior art one-bus system in which the computer, not the interface circuit, asserts the SNOOP signal.

Accordingly, "the SNOOP signal telling said one of said second plurality of bus masters when to write cached data to the address appearing on the bus" means "the SNOOP signal indicating to one of the bus masters on the second bus when to write cached data to the one of the second data storage locations at the address appearing on the second bus." This construction requires the SNOOP signal to indicate to a device on the second bus that it should write data held in that device's cache memory to main memory on the second bus.

The district court construed "temperature controller" to mean "the switch, power amplifier or like device that directly adjusts the flow of electric power to one or more heating elements. The temperature controller includes a means for converting temperature data." (J.A. at 31.) Neither party objected to the instructions at trial. Under these circumstances "the issue [is] limited to the question of whether substantial evidence supported the verdict under the agreed instruction." See Hewlett-Packard Co. v. Mustek Sys., Inc., 340 F.3d 1314, 1320-21 (Fed. Cir. 2003) ("When issues of claim construction have not been properly raised in connection with the jury instructions, it is improper for the district court to adopt a new or more detailed claim construction in connection with the JMOL motion. On JMOL, the issue here should have been limited to the question of whether substantial evidence supported the verdict under the agreed instruction."). The question is thus whether the testimony presented by CytoLogix through its expert witnesses constitutes substantial evidence of infringement under the district court's definitions of the claim terms.
Second, Ventana argues that there is no substantial evidence to support a verdict of infringement with respect to claims 10-12. Again, since neither party objected to the instruction, we look to see whether there is substantial evidence under the agreed instruction. The language of claim 10 is somewhat different than the language of claims 1 and 8. Claim 10 requires "temperature controller electronic circuits." '693 patent, col. 13, l. 24. The district court's instruction defined the phrase to mean "electronic components, wiring, and printed circuit board which comprise the power amplifying device and decoder." (J.A. at 31.) CytoLogix's experts, David Gessel and Alexander Slocum, testified that these claim limitations were satisfied in the accused device. (See, e.g., J.A. at 1113-14; 1538-40.) Thus we conclude that the verdict of infringement with respect to claim 10-12 was supported by substantial evidence.

B. Template

Plaintiff's Proposed Construction: a set of parameterized classes, functions, or variables

Defendant's Proposed Construction: a source code substitution feature that defines a set of parameterized types or functions using placeholders that can be filled in by a source code compiler during compilation of a source file

The parties devoted much of their efforts in the briefs and at the claim construction hearing to this term. Interestingly, both sides agree that a "template" is a familiar term in the art, Dft.'s Br., at 14-15, dkt. #34; Plt.'s Br., at 6, dkt. #32, but neither side did a very good job of explaining the concept. Plaintiff says that this term and several others need no explanation because they are "ordinary computer programming terms" and are "understandable to a jury as written," Plt.'s Br., at 1, dkt. #32, but this assumes incorrectly that the jury will consist of computer programmers. Defendant says that it is difficult to describe templates concisely because "[m]ost programming books . . . devote entire chapters to explaining them," Dft.'s Br., at 15, dkt. #34, so it focused on the aspects of the concept that it believes are important to this case.

At the claim construction hearing, the parties agreed that a template involves "parameterized types" in the sense that it uses "placeholders" that can be filled in later. However, defendant argues that a "template" is a very specific kind of "parameterized type" that is not reflected in plaintiff's proposed construction.

As defendant frames it, the issue is whether a template is used only during compilation (that is, during the conversion of the programming language into the binary code of zeros and ones that can be read by the computer) or whether it is used during runtime as well (that is, when the program is being executed). However, that is not an issue that can be resolved in this opinion.

The extrinsic evidence supports a reading that templates are "instantiated" by the compiler during compilation. (The parties agree that "instantiation" is the process by which templates are filled in with information.) The references cited by defendant are uniform in including this reading in their description of templates. E.g., Nishant Sivakumar, C++/CLI in Action 124 (2007) (included as exh. C to dkt. #34) ("templates" are "[i]nstantiated during compilation by the C++ compiler"); Stephen R.G. Fraser, Pro Visual C++/CLI and the .NET 2.0 Platform 164 (2006) (included as exh. D) ("One major difference between generics and templates is when they are instantiated. For templates, it happens at compile time, whereas for generics, it happens at runtime."); Bruce Eckel, Thinking in C++ 582 (1995) (included as exh. H) ("When you use a template, the parameter is substituted by the compiler.").

Nothing in the patent undermines this understanding. Plaintiff is quick to point out that all of defendant's references discuss "templates" in the context of the programming language C++ and that the '368 patent is not limited to that programming language. Both of these observations are true, but they do not provide support for a view that the references cited by defendant are inaccurate reflections of the term in the context of the patent. The specification makes it clear that the concept of templates in C++ is the same concept used by the patent: "The ANSI/ISO working group X3J16/WG21 has standardized a new programming language, C++, based upon C. One of the many features included in the language is 'templates.'" '368
A "pattern" fits the context of the evidence specified by plaintiff, whereas a "functionality" creates an awkward construction by a person based on the layout of a hard copy document or its image (i.e., its nontextual electronic representation). . . ." Id.

The parties have failed to suggest a definition of "template" that I can adopt. Thus, the only issue regarding this term that may be resolved at this stage of the proceedings is that template can be "filled in by a compiler during compilation."

5. "Template": Plaintiff proposes the meaning "Defined functionality which operates to locate information in a target computer file . . ." Amended Joint Claim Construction Chart, Dkt. # 134-2, p. 9. Because the word "functionality" is itself vague and undefined, the Court finds that defendant's proposed construction better fits the intrinsic evidence offered by plaintiff. Specifically, that is the following section of the '697 Patent specification: "In order to generate an input file for a specific application program, the user selects the option to define a document template for use when each month's XYZ Corporation bill arrives." Id., citing '697 Patent, col. 12, lines 31-34. Defendant proposes the construction "a pattern created by a person based on the layout of a hard copy document or its image (i.e., its nontextual electronic representation). . . ." Id. A "pattern" fits the context of the evidence specified by plaintiff, whereas a "functionality" creates an awkward construction.
that is difficult to understand (reading "... the user selects the option to define a document functionality for use ...") The Court therefore adopts defendant's construction, in part. The Court construes the term as: "a pattern created by a person based on the layout of a hard copy document or its image (i.e., its nontextual electronic representation)" without the additional limitations and explanations proposed by defendant.

4436

L. "active template containing terms for use during such a negotiation"

As to this term, this Court ordered the following claim construction:

A set of predefined data fields for terms to be negotiated using the automated negotiations engine that is configured so that certain fields can be used automatically by other programs.

Tr. 49:5-11; 51:23-52:3.

4437

H. "temporarily assigned network address" 

Claim 1 contains the term "temporarily assigned network address": "wherein the dial-up network server communicates a first user ID for one of the users' computers and a temporarily assigned network address for the first user ID to the authentication accounting server." Although the specific term "temporarily assigned network address" is not found in the specification, similar phrases are used instead: "[t]he IP address temporarily assigned to the end user is [] sent back to the end user for use in connecting in the network," (118 patent, 3:10-12), and "[u]pon a successful user authentication, the dial-up network server [] completes the negotiation and assigns an IP address to the user," (118 patent, 5:57-59). Linksmart's proposed construction is "an address that identifies a user for the duration of a networking session." On the other hand, the defendants argue that this term means "an address assigned to a user only for the duration of an authorized session." The parties dispute whether the network address must be temporarily assigned or can it be a pre-existing, permanently assigned address. In support of its proposal covering permanent addresses, Linksmart points to the following language from the specification: "In the preferred embodiment Point to Point Protocol (PPP) is used . . . to dynamically assign the PC [] an IP address from a list of available addresses. However, [in] other embodiments . . ., the IP address may also be permanently assigned to the PC []." (118 patent, 3:63-4:2) (emphasis added). Thus, according to Linksmart, the invention should not be limited to the preferred embodiment, which uses temporarily assigned IP addresses. Although the specification discloses both temporary and permanent addresses, the patentee claimed "temporarily assigned network address" not "network address" generally. The "temporarily assigned" limitation excludes embodiments that are permanent or not assigned by the claimed system. Unlike the term "dial-up networking server" where the patentee explicitly defined the term in a manner that differs from its ordinary meaning, the specification provides no specialized definition for "temporarily assigned network address." Thus, the court will construe the term according to its plain language, which requires temporary assignment. The court is persuaded, however, by the plaintiff's argument that the network address is used to identify users. The '118 patent's Background of the Invention explains that "the end user would be identified by the temporarily assigned IP address." (118 patent, 1:35-37). In all, "temporarily assigned network address" is construed to mean "an address that is assigned to a user and identifies a user only for the duration of a networking session."

4438

6. "temporary storage device" (claims 14 and 41 of the '702 patent)

Acacia contends that "temporary storage device" should be construed to mean "a device into which data may be placed, retained for a limited time, and retrieved" or in accordance with the definitions cited by Defendants, "a storage device
capable of storing data on an intermediate, or impermanent, basis."

 Defendants contend that "in the context of data transmission, one of skill in the art would understand that a temporary storage device is a device in which data may be stored on an impermanent basis." (Defendant's Response to Plaintiff's Claim Construction May 13, 2004 at 25).

 The plain and ordinary meaning of the term "temporary storage device" is defined by the intent of the person storing the information, not whether data is stored on media that can be overwritten. The specification supports the plain meaning by explaining in Figure 6 that "storage 203 allows for temporary storage of the requested item until playback is requested." ("702 patent, 17:37-38). The prosecution history does not rebut the plain and ordinary meaning. The Court construes "temporary storage device" to mean "a device intended to store data for an impermanent basis and allows for stored data to be retrieved from the storage device while the data resides therein."

 Terminal

 The parties agree that a terminal is, "an endpoint for the connection of the package to the outside." Tessera would add a limitation that, "the terminal itself could not be made of solder, because it would melt and lose its shape during solder reflow." n1 Tessera offers two arguments in support of its construction. First, Tessera argues that the first sentence, left on its own, may allow Defendants to "conflate terminals with solder balls," or "turn terminals' into a moving target," and the second sentence would properly characterize terminals as components distinct from the material that serves to physically and electrically connect the terminal to the PCB. n2 Plaintiff's Opening Brief, p.29. Second, Tessera argues that its construction became a part of the prosecution history and deserves deference as intrinsic evidence.

 n1 Tessera's entire proposed additional language is as follows: One of ordinary skill in the art would understand that the terminal itself could not be made of solder, because it would melt and lose its shape during solder reflow.

 n2 After the Markman hearing, the parties attempted to reach a compromise concerning the second sentence, and Plaintiff agreed to drop the reference to solder so long as some negative limitation remained that distinguished terminals from the material connecting the terminal to the circuit board. The Court will focus its discussion on the negative limitation rather than the language about solder balls. See Doc. 167 and 169.

 Although Tessera cites no authority to suggest that the ITC's construction of "terminal" became a part of the prosecution history merely because it was submitted to the Patent and Trademark Office ("PTO"), the Court notes that prior art references submitted to the PTO during prosecution are considered part of the intrinsic record. See Kumar v. Ovonic Battery Co., Inc., 351 F.3d 1364, 1368 (Fed. Cir. 2003). But the ITC's construction is distinguishable from the prior art reference relied upon for claim construction in Kumar. First, the ITC's construction is not prior art. Second, Tessera did not highlight the construction to the PTO during patent prosecution and it is unlikely that the PTO relied upon two sentences in a 54 page claim construction section of a 357 page ITC document. Further, the ITC Court deferred to an expert witness in choosing its construction, and provided no further support for its election. See Phillips, 415 F.3d at 1318 (noting that, "conclusory, unsupported assertions by experts as to the definition of a claim are not useful to a court"). Without any discussion clarifying why the ITC chose its construction, the PTO would have had little reason to rely on the statement.

 The Court may consider the ITC opinion in the interest of promoting, "uniformity in the treatment of a given patent," Markman v. Westview Instruments, 517 U.S. 370 at 390, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). However, at least one Article III Court has adopted the contrary construction Defendants advocate, and for two additional reasons, the Court will
not defer to the ITC construction. See Samsung; see also Tex. Instruments, Inc. v. Linear Techs. Corp., 182 F. Supp. 2d 580, 589 (E.D. Texas 2002)(Court may elect to defer to previous claim constructions on a case by case basis). First, as discussed previously, the ITC Court did not explain why it elected its construction, and the Court is reluctant to defer to a decision whose basis is largely unknown. Second, the two previous constructions are different, so the interest of uniformity does not weigh in favor of one construction over another. See Samsung and ITC. Thus, the Court will elect a construction that is best supported by the entirety of the intrinsic evidence.

Plaintiff argues that its construction will prevent the confusion that could arise if Defendants muddle the distinction between terminals and the surrounding elements. Further, Plaintiff contends that the intrinsic record, "could not have more plainly communicated that terminals’ as used in the patents in suit are not solder balls," and highlights several instances in the 977 specification that describe terminals as distinct components from the material disposed between the terminals and the substrate. Tessera's Opening Brief, p. 28-29. During prosecution of the 419 patent, Tessera distinguished a piece of prior art that utilized solder balls, but not terminals. 419 Prosecution History, 8/20/01 Response at 7. Similarly, the claims treat terminals as distinct from the surrounding components, including the material disposed between the terminals and the substrate. Although the Court agrees that the intrinsic record describes that terminals are not solder balls, that fact does not lead the Court to share Tessera's conclusion that the definition should include a negative limitation distinguishing solder balls from terminals.

The claims and specification clearly communicate that terminals retain their autonomy in the completed assembly without using negative limitations, and Defendants' construction closely tracks the claims and specification. Despite Tessera's suggestion that Defendants' construction leaves the door open for confusion, Defendants' construction invites no more confusion about the relationship between terminals and the surrounding components than a construction of any other component that is closely integrated with other components. Thus, the absence of a negative limitation does not render the construction particularly susceptible to confusion.

The Court is similarly unpersuaded that a negative limitation is the proper way to prevent Defendants from blurring the line between terminals and the material disposed between the package and the PCB. Defendants acknowledge that terminals are distinct components whether they are bonded to solder or another material that serves to connect the package to the PCB, and if they attempted to change their stance at trial Plaintiff can refute those arguments. n3 However, the Court is reluctant to adopt a construction in order to cure confusion that may or may not arise particularly when the additional limitation may cause its own confusion.

The first element of claim 12 requires "electrically connecting each of the electrical terminals of the device to a conductor." The Court defined a "terminal" as "any point on a semiconductor device that can be used to connect the device to the leads." Jury Charge at 14. Defendants argue that because approximately 90% of their devices contain terminals that are connected to test circuitry on the device, and which are not connected to leads, this limitation is not met. TI responds, completely ignoring the Court's claim interpretation, 2 that all of the terminals required for the function of the device are connected to a lead. 3

n3 The Court will look very unfavorably upon any attempt by Defendants to depart from the construction adopted in this order.

Therefore, the Court adopts Defendants construction that a terminal is, "an endpoint for the connection of the package to the outside."
2 This problem is endemic to TI's briefing in response to the JMOL motion. TI obviously believes that the Court's claim interpretation was incorrect. The Court remains convinced that its claim interpretation was proper based on the evidence and argument before it. While TI is to be commended for the courage of its convictions, an argument based on a claim interpretation that the Court did not adopt is hardly persuasive. 3 The Court also notes an inconsistency in TI's argument. In attempting to prove its infringement case with respect to the limitation in claim 12 requiring the device to be attached to a "conductor," TI argues that the die pad's function during manufacture (to conduct electricity and thereby protect the chip from static discharge) should be considered. However, in attempting to prove its infringement case with respect to connection of the terminals, TI argues that the terminal's function during manufacture, when they are "required" for testing the device, should be ignored.

The Court is compelled to find that there is insufficient evidence to support a finding of literal infringement of this element. TI does not dispute that some number of Defendants' devices contain terminals that are not connected to leads. 4 TI has not pointed to any evidence in the record upon which a jury could find that those terminals could not be connected to leads, which is what must be established in order to find literal infringement under the Court's definition. 5

4 TI contends that Defendants' argument should be rejected because they did not prove exactly how many devices had unconnected terminals. This contention ignores the fact that TI is the Plaintiff in this case, and thus had the burden of proving how many devices had all of the terminals connected to leads. If there is a failure of proof, it must be charged to TI as the party with the burden. 5 The Court has some hesitation on this point, because it appears from Dr. Rodgers' testimony that these terminals are never connected to leads, even when they are being used for test purposes. It may be that the testing equipment does not allow them to be connected to leads, in which case the limitation would probably be met. This is pure speculation, however, because there was no testimony on this point. Again, the lack of evidence must be charged to TI, as the party with the burden of proof.

A. Claim Construction

On February 16, 2006, the Court held a claims-construction hearing in this matter. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The Court considered the '136 Patent and prosecution history, the parties' Markman briefs, the applicable law regarding, inter alia, claim construction, indefiniteness, and means-plus-function claims, and the argument of counsel. On May 25, 2006, this Court rendered a claims-construction order (Doc. # 292), which construed the terms as following:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Construed Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Debit Card&quot;</td>
<td>&quot;a prepaid card for exchange of value&quot;</td>
</tr>
<tr>
<td>n2&quot;ID information [stored on the debit card]&quot;</td>
<td>&quot;encrypted data, excluding the card number, stored on the debit card in the form of merchant ID, store ID, or terminal ID&quot;</td>
</tr>
<tr>
<td>&quot;Terminal&quot;</td>
<td>&quot;a point-of-sale apparatus, which includes a central processing unit, a card reader, a keypad, and a communications interface&quot;</td>
</tr>
<tr>
<td>&quot;ID information [stored on the terminal in</td>
<td>&quot;data stored on the terminal in &quot;</td>
</tr>
</tbody>
</table>

- 4685 -
on the terminal"
"the form of merchant ID, store ID, or terminal ID"

"Stored thereon prior to the transaction"
"stored on the terminal prior to the consumer presenting the debit card to the merchant"

"Relates . . . in a predetermined manner"
"prior to a transaction, ID information stored on the debit card and ID information stored on a terminal are capable of being matched"

"Matching" and "Matched"
"determining whether ID information stored on the debit card and corresponding ID information stored on the terminal are equal or identical"

"Retrieving via the terminal"
"locating and returning, by means of the terminal, ID information and a card number stored on the debit card"

"Computer" and "Computer means"
"a data processing device"

"Transmitting to a computer"
"sending by means of a signal path to a computer"

"Validation" and "Valid"
"indication of whether the ID information stored on the debit card matches the corresponding ID information stored on the terminal"

"Computer means disposed remotely"
"a computer that is located apart from a terminal and connected to the terminal by a signal path"

"Card reader means"
"a device, included as part of a terminal, used for retrieving ID information from a debit card"

"Communication means" function
"transmitting the ID information stored on the debit card and the ID information stored on the terminal to the computer means"

"Communication means" structure
"a modem or a signal path"

"Selected from a group of ID information" (Claim 2)
"chosen from one of the following ID information"

--- Footnotes ---
n2 "ID," as used throughout this opinion, in whatever context, is shorthand for "identification."
B. "Terminal"

Tessera proposes that the term "terminal" should be interpreted to mean "an element adapted to make an electrical connection to a mating element." Joint Claim Construction Statement B1:7-8. Tessera relies on the specification which describes the connection from the chip to the contact to the lead to the terminal, and from the terminal to contact pads on the circuit board. '977 patent at 3:35-41; 8:41-47. Samsung, on the other hand, argues that "terminal" means "an externally accessible point of electrical connection." Joint Claim Construction Statement B1:7-8.

Tessera objects to Samsung's proposed construction as adding an impermissible limitation of external accessibility that is not imposed by the claims. However, Samsung asserts that external accessibility is what differentiates "contacts" from "terminals". Samsung also challenges Tessera's construction as unnecessarily complex. Samsung notes that the term "terminal," not construed in the TI Order, was construed in Sharp to mean "an end point for connection of the package to the outside." Cherensky Dec. Ex. P at 54. It is not clear from the Sharp construction whether the ITC meant "outside" to require external accessibility after assembly.

The construction promoted by Samsung is contrary to how "terminal" is used in the specification and claims. Nowhere do the claims or the specification limit "terminal" to an element that is externally accessible. The Court construes "terminal" to mean "an end point for electrical connection of the package to the outside." It is not necessary that a terminal be externally accessible when the chip package is fully assembled.

The Court's determination of no direct infringement by the accused web servers was based on the failure of these devices to meet the limitation common to all of the claims of the '131 patent at issue, the communication of a host processor with a terminal device. The Court defined a "terminal device" as:

a computing device such as a data terminal, workstation, portable computer, or smart phone that enables a user to communicate with a host processor. It manages its associated display itself and manages its internal memory with the assistance of the host processor.

Key to the interpretation of "terminal device" is the limitation of "manages its associated display itself." The '131 specification states in the summary of invention section:

The terminal device, in turn and in accord with an aspect of the invention, displays the object in a form determined solely by the terminal device but in accordance with respective predefined policies.

('131 patent. Col. 2:19-22) (emphasis added). Furthermore, according to the '131 patent, although the host processor may provide some attributes of the objects displayed on the terminal device, such as by providing commands to hide objects, highlight, and display user buttons, none of these attributes control the location of objects in the display. Referring to how a REGION command (from the host processor) partitions a display into regions, the specification states "[i]t is to be understood, however, that the way in which a display is actually partitioned into such regions is under the control of the station set or computer terminal. . . ." ('131 patent col.8:12-15).

At the summary judgment hearings, the Court also considered the prosecution history of the '131 patent. During prosecution, the patentee distinguished his invention from the prior art of the Busboom patent, stating:

a host computer does not specify where an object is to be displayed on the display of a terminal. The reason for this is that it is the terminal and not the host computer that decides where an object is to be displayed on the terminal display.
The Court therefore found that based on the '131 patent specification and prosecution history, that the definition of the terminal device excludes arrangements where the host processor controls the positioning of objects on the display of the terminal device. Defendants' web servers use a position attribute to display objects at certain coordinates programmed relative to the upper left hand corner of the display or upper left hand corner of items on the web page. The Court found therefore that these web servers (host processors) participates in determining the actual location of items in the display of the client's computer. In the accused devices, the client's computer does not manage its associated display itself; thus, it is not a terminal device under the Court's claim construction. The Court therefore held that there was no direct infringement and therefore, in the absence of any direct infringement, there also was no indirect infringement.

II. DISCUSSION

A. STANDARD OF LAW

Under Fed. R. Civ P. 59(e), a motion to alter or amend judgment must be filed no later than 10 days after entry of the judgment. "A Rule 59(e) motion is appropriate if the district court: (1) is presented with newly discovered evidence, (2) committed clear error or the initial decision was manifestly unjust, or (3) if there is an intervening change in controlling law." Circuit City Stores, Inc. v. Mantor, 417 F.3d 1060, 1064 n.1 (9th Cir. 2005) (quoting Sch. Dist. No. 1J, Multnomah County v. ACandS, Inc., 5 F.3d 1255, 1263 (9th Cir.1993).

B. ANALYSIS

Lucent contends that the Court committed clear error when it ruled on summary judgment that the definition of the terminal device excludes arrangements where the host processor controls the positioning of objects on the display of the terminal device. Lucent argues that the Court's interpretation is not supported by the prosecution history, excludes the preferred embodiment of the patent and threatens to render the patent inoperative. n1

n1 Although Lucent also contends that Defendants mislead the Court by "manufacturing" a discussion at the Markman hearing, the Court finds this issue to have no bearing in the instant consideration. Dell raised the prosecution history in its opening brief to its summary judgment motion, thereby providing Lucent ample opportunity to respond and to make any points relative to this issue in its opposition brief and oral arguments. Thus, to the extent the prosecution history was at play, each party had an opportunity to present its interpretation to the Court.

The Court finds on each of these grounds Lucent has failed to meet its burden to demonstrate clear error. In general, Lucent raises the same arguments presented earlier to the Court and thus provides an insufficient basis for motion for reconsideration. See Taylor v. Knapp, 871 F.2d 803, 805 (9th Cir. 1989) (finding that the trial court properly denied the motion for relief from summary judgment where the motion did no more than raise arguments previously rejected by the trial court); Fuller v. M.G. Jewelry, 950 F.2d 1437, 1442 (9th Cir. 1991).

Additionally, these arguments, even with further elaboration in Lucent's instant motion, are again unpersuasive. First, Lucent's reliance on the '131 patent abstract is misplaced; it is the claims, not the abstract or the specification, which control. Second, with respect to the specification, Lucent has not pointed to support for the contention that the host processor can control the location of objects per se. Although the specification explains that the host processor may partition the display into regions, the specification also acknowledges that it is the terminal device which determines how these regions are actually displayed. ( 131 patent col 8:5-18.)

Third, as considered previously by the Court, the applicant made clear disavowals that contradict Lucent's position. To the extent the specification or abstract did support any relative positioning (and it is unclear that it did), the applicant surrendered those features when it distinguished over the prior art referred to in the prosecution history as "Busboom."
While Lucent attempts to persuade the Court that the applicant's statements in the prosecution history were not meant to
distinguish its claims over Busboom and/or to only distinguish the '131 patent claims over a system that specified exact
positions rather than relative positioning, the applicant made statements in the prosecution history that belie Lucent's
position. The applicants stated:

Thus in contradistinction to the claimed invention, the Busboom apparatus specifies the location at which the object is to
be displayed on a display. . . .

In contrast, a host computer in the claimed invention does not specify where an object is to be displayed on the display of
a terminal. The reason for this is that it is the terminal and not the host computer that decides where an object is to be
displayed on the terminal device. . . . The terminal in response [to the host processor] displays the object on the display at a
location selected by the terminal itself.

(Dec. Micallef Supp. Dell's Opposition, Ex. C at 46; emphasis added.) The applicant therefore chose to distinguish its own
apparatus and methods from the prior art because the object was displayed "at a location selected by the terminal itself."
While Lucent may consider in hindsight that the applicant could have chosen other manners to distinguish over the prior art,
such as by attempting to distinguish one that specified an exact location versus a relative location, the applicant chose not to
make this argument. Instead, the applicant disavowed all positioning of the object by the host processor.

Lucent's additional arguments, that the Court's construction excludes the preferred embodiment and/or renders the patent
inoperative, are also unpersuasive. The '131 patent describes a "smart phone" device with many features and hence many
embodiments of the claimed methods. To the extent that the claims are limited by the prosecution history as described, these
limitations do not render many, if not most, of these embodiments inoperative. Furthermore, the '131 specification offers
very little description of any embodiments that relate to the positioning of objects within the display. Although the
specification describes features which allow the processor to partition the station set's display into regions, assign objects to
regions (id. col. 8:5-22), and set the orientation of subordinate regions or non-region objects to the left or right of one
another (id. at col. 8:19-32), it does not offer any description of setting the location of objects e.g., the distances between
objects or their particular placement within the display.

Moreover, while the Federal Circuit has noted that it is rare that a claim construction would exclude a preferred
embodiments, the prosecution history may compel such a result. See North American Container, Inc. v. Plastipak Packaging,
Inc., 415 F.3d 1335, 1346 (Fed. Cir. 2005). Here, as explained, to the extent the '131 patent specification describes a
particular embodiment where the host processor could assign relative positions of regions or non-region objects, the
applicant chose to surrender these aspects in prosecution.

In sum, the Court finds that its interpretation of the term "terminal device" is consistent with the specification and
prosecution history of the '131 patent.

---

4444

3. Terminal device

The court adopts Judge Brewster's construction of "terminal device" in the Gateway action. Accordingly, the court construes
the term "terminal device" to mean "a computing device such as a data terminal, workstation, portable computer, or smart
phone that enables a user to communicate with a host processor. It manages its associated display itself and manages its
internal memory with the assistance of the host processor."

4445

The Court construes "terminal unit" as a "unit wherein voice band services share a loop with modulated data transmission."
The Court agrees with Defendants that no construction is necessary for "modulated data transmitting and receiving unit."
A. Parties' Construction Arguments

Plaintiff argues the phrases "terminal unit" and "modulated data transmitting and receiving unit" should be construed as "digital subscriber line unit." Plaintiff points out that the patent uses the term "ADSL Unit" (or "Assymetric Digital Subscriber Line Unit") repeatedly in the specification to refer to the terminal units located at either end of the communications loop. See, e.g., '323 patent, 3:15-19.

Defendants argue no construction is necessary. Alternatively, Defendants argue "terminal unit" should be construed as "communications device" and "modulated data transmitting and receiving unit" should be construed as "communications transceiver device." Defendants argue no construction is necessary because the terms here are descriptive of the broad range of communications covered by their plain meaning. Alternatively, Defendants argue if the Court wishes to construe the terms, then "communications device" would be broad enough to cover the full range of communications devices covered by the claim (both the wired and wireless devices).

B. Analysis

The Court disagrees with Defendants that "terminal unit" does not require a construction. The term "terminal unit" appears in both the preamble and the body as a limitation in claim 1. Further, the term "terminal unit" is not a term of ordinary use that would be clear to the jury. The Court also disagrees with Defendants' alternative construction of "communications device" because it is overbroad and not grounded in the specification. But the Court disagrees with Plaintiff that "terminal unit" and "modulated data transmitting and receiving unit" should be construed as "digital subscriber line unit." The patent specification never limits either of these phrases to a digital subscriber line (DSL) unit. In fact, the invention states that "while the invention has been described in the context of ADSL units providing an asymmetric data channel, the invention may be applied to other terminal units wherein voice band services share a loop with modulated data transmission, such as Symmetric Digital Subscriber Line (SDSL) and Rate Adaptive Digital SubscriberLine (RADSL) terminal units. '323 patent, 7:34-40 (emphasis added). So according to the specification, the terminal unit could hypothetically be a non-DSL unit where voice band services share a loop with modulated data transmission. The Court concludes, though, that the specification quotation above effectively defines what a "terminal unit" is in the context of this patent. The specification specifically describes a terminal unit as a unit "wherein voice band services share a loop with modulated data transmission." '323 patent, 37-38. Therefore, the Court construes "terminal unit" as a "unit wherein voice band services share a loop with modulated data transmission."

The Court agrees with Defendants that the phrase "modulated data transmitting and receiving unit" requires no construction. The phrase "modulated data transmitting and receiving unit" is only found in the preamble of independent claims 7, 16, and 24, and also in the dependent claims that specifically refer back to the "modulated data transmitting and receiving unit" in the preamble of the independent claims. "Claim construction . . . is not an obligatory exercise in redundancy," U.S. Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997). "[D]istrict courts are not (and should not be) required to construe every limitation present in a patent's asserted claims." O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., Ltd., 521 F.3d 1351, 1362 (Fed. Cir. 2008). The phrase "modulated data transmitting and receiving unit" is not defined in the specification, and in the few times the phrase is mentioned in the specification it cannot be determined a clear meaning of the phrase. See, e.g., '323 patent, 2:63-67 ("The control signal interface may be used for the exchange of both the start-up signal and of data between the modulated data transmitting and receiving unit and customer premises equipment.").

Instead, the claims themselves define the details of a "modulated data transmitting and receiving unit." For example, in claim 7, the preamble introduces the modulated data transmitting and receiving unit and then the body describes the details. See '323 patent, 8:15-18 ("7. A modulated data transmitting and receiving unit, comprising a connector operatively coupling the unit . . . ."). See also IMS Tech., Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1434 (Fed. Cir. 2000) ("The phrase 'control apparatus' in the preamble merely gives a descriptive meaning to the set of limitations in the body of the claim that completely set forth the invention."). So because the claims are instructive of the phrase "modulated data transmitting and receiving unit," no construction is necessary. The Court could alternatively partake an "exercise in redundancy" and merely rearrange the language as to construe "modulated data transmitting and receiving unit" as a "unit that transmits and receives modulated data." But the Court believes that such an exercise is unnecessary and not helpful to the jury. Further, the Court disagrees with Defendants' alternative construction of "communications transceiver device" because it removes the "modulated data" requirement and would be overly broad. Therefore, the Court concludes that the phrase "modulated data transmitting and receiving unit" requires no construction.
D. Terrain

Quoting from The American Heritage College Dictionary 1400 (3d ed. 1997), the Defendants contend that "terrain" has a plain and ordinary meaning -- "the surface features of an area of land; topography" -- and that the use of "terrain" in the patent is consistent with that meaning. The Plaintiff does not offer a dictionary definition of the term, but instead argues that the term "is used in the '189 Patent broadly to include the physical features of an area, object or material, which includes geographic and/or elevation attributes and may include other features, such as color attributes and objects.'"

The purpose of the '189 Patent is to provide three-dimensional images of the Earth's surface to be used by pilots and others, but the specification also provides that "the terrain is not limited to the Earth or parts thereof, and may cover other planets (real or virtual) and/or 3D views of surfaces of real or imaginary objects, such as views showing the atomic structure of a material, and the like." (col. 16, 11. 16-20) Consequently, the term terrain is plainly not limited to the surface of the Earth. The Defendants also accept that the concept of terrain as the surface features of an area can include color. (Transcript, p. 20) The dispute appears to turn, therefore, on whether the term "terrain," as used in the Disputed Claims, includes "objects" overlaid on the surface of the area in addition to underlying topography of the surface of the area. (Transcript, p. 19-20, 21)

The Patent contemplates overlaying additional objects or "virtual structures on the terrain." (col. 8, 1. 51) (emphasis supplied) "For example it is possible to add planned buildings to the terrain and thus see the effect of the buildings on the view. Further alternatively or additionally, the objects may be used to overlay map symbols and other marking on the terrain." (col. 8, 11. 51-55) (emphasis supplied) This allows "an operator of the server and/or the user . . . [to] add to the data which describes the terrain annotations which describe specific points in the scene, such as runways or other destinations. Alternatively or additionally, the operator may add three-dimensional objects, such as planned buildings, vehicles, etc. In a preferred embodiment of the present invention, a group of vehicles are tracked according to their position, and they are constantly superimposed on the landscape images." (col. 2, 11. 55-64) "Preferably, the user is able to switch between viewing the terrain with and without the objects, so that, for example, the user may easily compare the view of a desired area with and without a group of planned structures." (col. 13, 11. 58-61) (emphasis supplied) Accordingly, the additional markings or structures that are overlaid on the terrain or the landscape images are not part of the "terrain".

On the other hand, I find that the specification supports a construction of the term "terrain" that includes existing objects or structures that are captured in the virtual images of the land or other surface. The data blocks are preferably made from "real-life images of terrain areas received from airborne or satellite cameras." (col. 8, 11. 36-37) Such images will include, therefore, structures built on the land, such as existing buildings, that can be viewed sufficiently well. (col. 8, 11. 49-50) In fact, the specification contemplates the processor being able to "automatically derive [] . . . objects from the images. For example, the processor may identify roads and/or runways in the images and represent them as objects so that they appear more clearly in substantially any resolution of display." (col. 10, 11. 9-14) In that example, the roads and runways would be part of the terrain, although the enhancement of them as objects overlaid on the land would not be part the terrain.

Construction: (terrain) the surface features of an area of land, an object, or a material, including color, elevation, and existing objects or structures on the land, object or material.
B. "Terrain Floor Boundary"

Claim 1 of the '080 patent further requires alert envelopes which are calculated in part by a measurement of the "terrain floor boundary." The district court construed the term to mean "a boundary that extends downwardly below the aircraft which is proportional to the distance to the closest runway." Claim Construction Decision, 264 F. Supp. 2d at 150 (emphases added). Honeywell finds no limitation in the claim tying this term to a proportional distance to the closest runway. Again, Honeywell argues that the district court incorrectly read a limitation from the specification into the claim.

As the district court correctly noted, the term "terrain floor boundary" had no ordinary meaning to a skilled artisan at the time of filing of the patent application. Id. at 151 ("Further, there is no evidence to indicate that 'terrain floor boundary' was a term having ordinary meaning known to one skilled in the art at the time of the filing of the patent application."). Without a customary meaning of a term within the art, the specification usually supplies the best context for deciphering claim meaning. Irdeto Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004). Here, the specification states: "The terrain floor boundary is the basis for the terrain threat boundaries and is similar to the terrain floor developed for the GPWS." '080 patent col.10 ll.38-40. The patent then explains: "The terrain floor relates to a distance H below the aircraft and is proportional to the distance to the closest runway to prevent nuisance warnings when the aircraft is taking off and landing . . . ." '080 patent col.10 ll.40-42 (emphasis added). The district court used this general language about the terrain floor as its primary reference for defining "terrain floor boundary." While Honeywell notes that the patent proceeds later to discuss "terrain floor boundary" more specifically as a "function of the distance from the runway," '080 patent col.11 ll.18-19 (emphases added), and again, in the discussion of terrain warning boundaries, the patent defines the H terrain floor as "a function of the distance from a runway," '080 patent col.12 ll.8-10 (emphases added), this function is defined in the specification as distance proportional to the closest runway. As such, this court disagrees with Honeywell that the district court improperly read a limitation from the specification into the claim.

f. "Relay having an operational position and a test position"

Claim 5 requires a "relay having an operational position and a test position." The court begins by construing "operational position" and "test position." As the parties agreed, the claimed relay is the element that separates the high voltage delivery system from the rest of the defibrillator. In one position, which is referred to in the specification as the "normally closed" or "closed" position ('374 Patent at 9:13-14, 10:24-25), the high voltage delivery system is capable only of self-tests in which it sends a current through a test load. 374 Patent at 11:30-42. In this position, the defibrillator cannot shock a patient. 374 Patent at 8:34-38.

In another position, which is referred to as "normally open" or "open," the high voltage delivery system can deliver a shock to a patient, as the parties agree. In addition, however, the defibrillator can conduct other self-tests with the relay in open position. E.g., 374 Patent at 9:4-21 (describing the "Defibrillator Connector/Relay self-test"), 10:14-22 (describing the "HV Isolation Relay self-test").

The "test position" of Claim 5 is the relay position in which the high voltage delivery system can only perform self-tests and cannot shock a patient. The "operational position" is the relay position in which the high voltage delivery system can deliver shock to the patient, although the defibrillator can perform other relay self-tests in this position as well.

The parties' dispute over this term centers on whether the relay may consist of a combination of relays and can have more than two positions, as Philips contends, or whether the relay is a single relay with only two positions, as Defibtech contends.

Philips can point to no intrinsic evidence that discloses more than one relay or more than two positions. Instead, it relies on three arguments: that the specification does not exclude such relays, that dictionary definitions of "relay" do not exclude
such relays, and that the inventors' decision to claim a "relay having an operational position and a test position" is no different than using the open-ended terms "comprising" or "including."

The court finds Philips' first two arguments unavailing. The specification speaks only of a relay with two positions. n10 It does not state that such positions are preferred, and it does not suggest that a relay with more than two positions could have any function in this invention. As for Philips' dictionary definitions, the court declines to rely on them for the reasons stated in its prior order. October 25 order at 5.

n10 The specification also teaches that the relay may become stuck in a position between the open and closed position. 374 Patent at 10:26-28 (discussing possibility that relay could "fail[] to move completely to the normally closed position").

As to Philips' third argument, the term "having" does not carry the presumption of open-ended interpretation that accompanies the term "comprising." Crystal Semiconductor Corp. v. Tritech Microelectronics Int'l, Inc., 246 F.3d 1336, 1348 (Fed. Cir. 2001). Instead, a court must look to the specification to determine what the inventors intended. Lampi Corp. v. Am. Power Prods., Inc., 228 F.3d 1365, 1376 (Fed. Cir. 2000). As already noted, if the inventors intended "having" to be non-limiting, n11 they left no hint in the specification. The specification speaks uniformly of a single two-state relay. The court construes the term accordingly. A "relay having an operational position and a test position" is a single relay with only an operational position and a test position," where "operational position" and "test position" have the meanings the court provided above.

n11 As Defibtech noted at oral argument, the inventors used the term "having" only twice in the 73 claims of the 374 Patent, whereas they used the presumptively open-ended term "comprising" more than 60 times.

As to Philips' third argument, the term "having" does not carry the presumption of open-ended interpretation that accompanies the term "comprising." Crystal Semiconductor Corp. v. Tritech Microelectronics Int'l, Inc., 246 F.3d 1336, 1348 (Fed. Cir. 2001). Instead, a court must look to the specification to determine what the inventors intended. Lampi Corp. v. Am. Power Prods., Inc., 228 F.3d 1365, 1376 (Fed. Cir. 2000). As already noted, if the inventors intended "having" to be non-limiting, n11 they left no hint in the specification. The specification speaks uniformly of a single two-state relay. The court construes the term accordingly. A "relay having an operational position and a test position" is a single relay with only an operational position and a test position," where "operational position" and "test position" have the meanings the court provided above.

n11 As Defibtech noted at oral argument, the inventors used the term "having" only twice in the 73 claims of the 374 Patent, whereas they used the presumptively open-ended term "comprising" more than 60 times.

The Court is asked to construe three similar terms that appear in the '213 and '059 Patents: test pulse, test signal, and signal. The term "test pulse" appears in Claims 1, 10, 17, and 26 of the '213 Patent and Claims 1 and 8 of the '059 Patent. The purpose of the "test pulse" is to test the condition of the defibrillator and its electrodes. Philips asserts that this term should be construed as "any pulse that is associated with testing." Cardiac Science maintains that this term should be defined as "a simulated shock." Test signal" appears in Claims 8, 10, 15, and 24 of the '213 Patent. n9 The parties acknowledge that "test signal" differs in meaning from "test pulse," but each party presents a different proposed construction of "test signal." Cardiac Science asserts that "test signal" should be construed as "a simulated ECG signal." Philips contends that "test signal" should be construed as "any signal associated with testing." Signal" appears in Claims 1 and 9 of the '059 Patent. Philips asserts that "signal" should be construed as "a detectable physical quantity or impulse (as voltage, current, or magnetic field strength) by which messages or information can be transmitted." Cardiac Science contends that "signal" should be defined as "a simulated ECG signal."

n9 "Test signal" also appears in claims 1, 2, 6, 21, 22, 25, 41, 42, 51, 52, 61, 64, 65, 67, and 68 of the '374 Patent and Claim
The specifications describe the test pulses as follows:

If the system passes the ECG tests, it then performs a defibrillator test by generating a pulse through its normal pulse generating circuitry and sending the pulse to the electrodes 204. To initiate the pulse test, the microprocessor sends a charge command to a charge controller 230, which begins charging capacitor 232 in a known manner from power supply 234. When the charge on capacitor 232 has reached the required level (either the charge level required for normal operation or some other test charge level), switch relay 228 moves switches 212 to their other position. This switch position permits the pulse circuit to discharge the capacitor to deliver a damped sinusoidal shock to the electrodes.

('213 Patent at c. 5, ll: 47-59; '059 Patent at c. 5, ll: 43-55.) Yet, the specification also states that "the test pulse may be a voltage pulse of any magnitude, including but not limited to voltage magnitudes used for actual defibrillation." ('213 Patent at c. 3, ll: 39-42.) The test pulses of the '213 and '059 Patents are not limited to a pulse that reaches the magnitude of a shock to a patient, as Cardiac Science suggests. The Court finds that "test pulse" is appropriately construed as "a pulse of any magnitude associated with testing."

The specification repeatedly refers to test signals. ('213 Patent at ll: 24-45.) Cardiac Science asserts that "test signal" is used only in reference to the ECG test. However, the claim language alone points to a broader construction. A comparison of the claims in which "test signal" appears makes clear that the "test signal" is not limited to an ECG signal. (See '213 Patent at cls. 8, 10, 24, 27.) The Court construes "test signal" as "a signal associated with testing."

The specification of the '059 Patent refers to many different types of "signals." The term is not limited to ECG signals, as Cardiac Science proposes. In fact, the specification describes "[a] signal substantially similar to an ECG signal," thus ruling out the "signal = ECG signal" construction that Cardiac Science proposes. ('059 Patent at c. 3, ll: 59-65.) The Court finds that the patent's usage of the term signal is consistent with the dictionary definition set forth by Philips, and the Court construes "signal" accordingly: "a detectable physical quantity or impulse (as a voltage, current, or magnetic field strength) by which messages or information can be transmitted."

3. "test pulse"
4. "test signal"
5. "signal"

The Court is asked to construe three similar terms that appear in the '213 and '059 Patents: test pulse, test signal, and signal. The term "test pulse" appears in Claims 1, 10, 17, and 26 of the '213 Patent and Claims 1 and 8 of the '059 Patent. The purpose of the "test pulse" is to test the condition of the defibrillator and its electrodes. Philips asserts that this term should be construed as "any pulse that is associated with testing." Cardiac Science maintains that this term should be defined as "a simulated shock." "Test signal" appears in Claims 8, 10, 15, and 24 of the '213 Patent. n9 The parties acknowledge that "test signal" differs in meaning from "test pulse," but each party presents a different proposed construction of "test signal." Cardiac Science asserts that "test signal" should be construed as "a simulated ECG signal." Philips contends that "test signal" should be construed as "any signal associated with testing." "Signal" appears in Claims 1 and 9 of the '059 Patent. Philips asserts that "signal" should be construed as "a detectable physical quantity or impulse (as voltage, current, or magnetic field strength) by which messages or information can be transmitted." Cardiac Science contends that "signal" should be defined as "a simulated ECG signal."

n9 "Test signal" also appears in claims 1, 2, 6, 21, 22, 25, 41, 42, 51, 52, 61, 64, 65, 67, and 68 of the '374 Patent and Claim
The specifications describe the test pulses as follows:

If the system passes the ECG tests, it then performs a defibrillator test by generating a pulse through its normal pulse generating circuitry and sending the pulse to the electrodes 204. To initiate the pulse test, the microprocessor sends a charge command to a charge controller 230, which begins charging capacitor 232 in a known manner from power supply 234. When the charge on capacitor 232 has reached the required level (either the charge level required for normal operation or some other test charge level), switch relay 228 moves switches 212 to their other position. This switch position permits the pulse circuit to discharge the capacitor to deliver a damped sinusoidal shock to the electrodes.

('213 Patent at c. 5, ll: 47-59; '059 Patent at c. 5, ll: 43-55.) Yet, the specification also states that "the test pulse may be a voltage pulse of any magnitude, including but not limited to voltage magnitudes used for actual defibrillation." ('213 Patent at c. 3, ll: 39-42.) The test pulses of the '213 and '059 Patents are not limited to a pulse that reaches the magnitude of a shock to a patient, as Cardiac Science suggests. The Court finds that "test pulse" is appropriately construed as "a pulse of any magnitude associated with testing."

The specification repeatedly refers to test signals. ('213 Patent at ll: 24-45.) Cardiac Science asserts that "test signal" is used only in reference to the ECG test. However, the claim language alone points to a broader construction. A comparison of the claims in which "test signal" appears makes clear that the "test signal" is not limited to an ECG signal. (See '213 Patent at cls. 8, 10, 24, 27.) The Court construes "test signal" as "a signal associated with testing."

The specification of the '059 Patent refers to many different types of "signals." The term is not limited to ECG signals, as Cardiac Science proposes. In fact, the specification describes "[a] signal substantially similar to an ECG signal," thus ruling out the "signal = ECG signal" construction that Cardiac Science proposes. ('059 Patent at c. 3, ll: 59-65.) The Court finds that the patent's usage of the term signal is consistent with the dictionary definition set forth by Philips, and the Court construes "signal" accordingly: "a detectable physical quantity or impulse (as a voltage, current, or magnetic field strength) by which messages or information can be transmitted."

Before explaining its construction, the court must specify which instances of "test signal" it is construing. The 374 Patent and the 460 Patent claim a "test signal" in a variety of contexts. The term sometimes appears in the phrase "test signal generator" ('374 Patent Claims 1, 2, 6, 21, 22, 41), and sometimes stands on its own in a set of claims that the court will refer to as "bare" test signal claims. 374 Patent Claims 25, 26, 42, 44, 65, 67-69; 460 Patent Claims 1, 3, 4. n5 In response to
the court's order to choose ten claims for this first round of construction, the parties asserted the bare "test signal" claims but not the "test signal generator" claims. There is no reason to construe these terms separately, however, because the analysis underlying the claims is identical, and because the court must assume, "unless otherwise compelled," that the same claim term used in the same patent "carries the same construed meaning." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1334 (Fed. Cir. 2003).

n5 Several other patent claims use the term "test signal" (e.g. 374 Patent Claims 45-50), but the parties have not asked the court to consider them. The court assumes that Philips has not asserted these claims in this action.

The specification discloses a preferred embodiment that consists of, inter alia, two components. The first is a "system monitor" that sends signals to a test controller to initiate tests, and the second is a controller or CPU that works in conjunction with other components to actually perform the tests. n6 E.g., 374 Patent at 4:60-6:19 (describing "system monitor"), 3:35-38, 6:19-13:48 (describing "controller" or "CPU"). Unfortunately, the specification's terminology regarding the signals that each component generates is inconsistent. The written description of the system monitor sometimes refers to the signals it sends to the CPU as "test signals" (e.g., 374 Patent at 4:60-67), but at other times refers to "test initiation signals" it sends to the CPU. E.g., 374 Patent at 3:51-53, 5:21-33, 6:18-20. In all such references, however, the description leaves no doubt that the signal that the system monitor generates initiates other self-tests and does not perform them.

n6 The specification also notes the possibility that the system monitor and controller could be combined in the same component. 374 Patent at 3:27-29.

The written description of the signals that the CPU uses to perform tests is similarly inconsistent. In one instance, a signal that the CPU indirectly uses in conducting tests is called a "test signal," (e.g., 374 Patent at 8:56-9:3 (describing a "test signal injector" to verify the function of various elements)), but in all other instances, the test signal has a more specific name that corresponds to a particular self-test. E.g., 374 Patent at 8:52 ("artifact test signal"), 9:10 ("test current signal"). Despite these inconsistent uses of "test signal," the claim language and the written description combined reveal that several claims contain limits on the "test signal." In the bare "test signal" claims, all but two of the claims expressly disclose one or more self-tests performed "in response" to the test signal or other stimuli. 374 Patent Claims 42, 44, 65, 67-69; 460 Patent Claims 1, 3, 4. In these claims, therefore, the test signal is a signal that initiates a test, not one that performs it. In the remaining two bare "test signal" claims, the "test signal" is one that the "system monitor" generates, and is thus also a signal for initiating a self-test. 374 Patent Claims 25, 26.

In all but one of the "test signal generator" claims, however, the claim language does not compel the court to limit the test signal to one that initiates testing. Claim 1 of the 374 Patent, for example, discloses a "test signal generator" and a "means for operating [it] prior to any attempted use of the defibrillator." The claim language suggests that the "test signal generator" is the generator that sends signals used in testing, and the "means for operating [it]" is another generator that sends signals to initiate the claimed "test signal generator." The written description supports this interpretation, as it discloses a "signal generator" used to perform "ECG front end tests" and a test signal generator that is different from the "system monitor" that generates initiating test signals. 374 Patent at 8:19-55. It similarly reveals that other "test signal generator" claims depending from Claim 1 use the term to refer to a generator that performs various self-tests. 374 Patent Claim 2 (adding a "functionality tester" to the test signal generator), Claim 6 (adding a "calibration verifier"), Claim 21 (adding a "battery condition tester"). Claim 41 is identical to Claim 1 except that it discloses a "periodic" test signal generator, and thus it also uses "test signal" in the broad sense that Philips advocates. In Claim 22, however, the "test signal generator" is limited to the "system monitor" that the court has already discussed. Thus, the "test signal generator" of Claim 22 generates only signals used to initiate testing.
To summarize, a "test signal" is a "signal associated with testing." In several of the asserted claims, however, additional claim language limits the term to a "signal that initiates testing." Those claims are all of the asserted bare "test signal" claims, as well as Claim 22 of the 374 Patent.

6. Test signal generator

The term "test signal generator" appears in claim 6 of the '681 Patent. Diagnostic asserts that "test signal generator" should be construed as "a device for generating test tones." Benson argues that signals and tones are not the same and therefore it would be improper to import the word tone into the claim. Benson also asks the Court to locate the "test signal generator" in the conventional audiometer based on its prosecution history estoppel argument. Specifically, Benson argues that in order to argue around the Moser Patent, the patentees asserted that their "invention differs in that the audiometer that provides the test signals has certain logical capabilities to conduct the test responsive to the test subject's inputs."

The Court finds that the intrinsic record does not support a departure from this claim term's ordinary meaning. Specifically, the patent specification does not explicitly set forth that test signals are identical to test tones. Further, as discussed previously, the Court rejects Benson's attempt to import structural limitations into the term. The Court, instead, concludes that the term is sufficiently clear and does not require construction. See Lucent Techs., Inc. v. Newbridge Networks Corp., 168 F. Supp. 2d 181, 191 n.3 (D. Del. 2001); Goldtouch Techs. Inc. v. Microsoft Corp., 2000 U.S. Dist. LEXIS 3370, No. A99CA336SS, 2000 WL 855555, at *4 (W.D. Tex. January 14, 2000).

5. "testing"

The term "testing" from Claim 1 of the '884 Patent is also at issue. Philips contends that "testing" should be construed as "checking continuity between the defibrillator electrodes using a test apparatus." Cardiac Science contends that "testing" need not be construed, but if it is, it should be defined as "making a critical examination, observation, or evaluation."

The claim language plainly states that the "testing" of the '884 Patent refers to testing the electrodes, but this can be derived from the context of the word "testing," without needing to incorporate "electrode testing" into the disputed term. The preferred embodiment describes the "test apparatus" as follows:

The test apparatus 13 includes a current source 23, preferably a battery, test circuitry 24, preferably including measurement components and status indication components such as an analog meter, LCD digital display or light emitting diodes, and connectors 21 and 22 for coupling with the package 12 connectors 19 and 20. In use, the test apparatus 13 is connected to the package connectors 19 and 20. The test circuitry 24 is then activated to form a closed current loop to determine whether continuity exists with respect to the enclosed electrode 11, thereby indicating whether the electrode 11 is still functional. Additionally, a load 86 formed of for example a conductive and semi-conductive material layers 85 and 86, may be added to the current loop as for example is shown in FIG. 17, for purposes of measuring the magnitude of current flow for more precise measurement of electrode 11 condition.

('884 Patent at c. 5, ll: 49-66.) Based on this language, Philips maintains that this term requires the testing to be completed by a test apparatus. However, only the preferred embodiment states this requirement. Neither the claim language nor the specification demands that the "testing" of the electrodes utilize a test apparatus. The Court finds that the term "testing" should be construed as "checking or evaluating."

1. It Depends On What the Word "The" Means
The first skirmish involves the word "the." The claim language states "circuitry for recycling the magnetizing energy stored in said transformer to reset it." (Emphasis added). Lambda asserts that the word "the" means all of the magnetizing energy in the transformer. Vicor contends that the claim allows for the possibility that some of the energy may be recycled to reset the core while other energy is delivered to the load. In other words, it argues that the word "the" can mean "some of the," and explains that the word "the" was used to distinguish "the magnetizing" energy from the more general term "energy" that is used earlier in the preamble. Nice linguistic jousting, but the use of the word "magnetizing" alone would have been an adequate adjective to single out the kind of energy intended for recycling. If only some of the transformer's energy needed to be recycled, the word "the" would not have been used.

Lambda's argument that the word "the" connotes all the magnetizing energy is persuasive because it gives ordinary and common sense effect to the word "the" in the claim language. See Merriam-Webster's Collegiate Dictionary 1221 (10th ed. 1993) (giving one definition of "the" as: "used as a function word before a noun . . . to indicate reference to a group as a whole"). This claim thus describes an invention that recycles all of the magnetizing energy to reset the transformer core.

16. Includes the Average elapsed time between visits (First appearing in claim 5 at col. 13, ll. 23-24, and also appearing in claim 26)

Websidestory contends that this phrase does not need construction. Joint Claims Construction Chart at 8. Netratings contends that the phrase needs to be construed based upon Websidestory's preliminary infringement contentions. Netratings' Responsive Claims Construction Brief at 22.

Netratings requests that the Court construe the phrase as, "includes a single value representing the calculated average time between visits." Netratings contends that Websidestory will attempt to read the word average out of the claim language in later proceedings. Websidestory rejects Netratings' proposed construction as improperly importing limitations from the specification and rewriting the clear claim language. Netratings' arguments find support in the specification. The description of the preferred embodiment section of the specification describes the traffic path analysis data in a typical cookie, and notes that, "the average time between website visits is calculated by the server and kept in the cookie . . . ." Patent at col. 9, ll. 27-30. The average elapsed time data is further described in the specification, as "a statistic that is maintained by the traffic analysis server computer," and which is "calculated." Patent at col. 9, ll. 50-53. Netratings' argument that the "average elapsed time" is represented by a single value is supported by that part of the specification which describes "average elapsed time data" as a "statistic." In addition, Figures 8 and 9 in the '479 Patent indicate that, at least in an exemplary cookie, the average elapsed time is stored in the cookie as a single value. The "single value" aspect of Netratings' proposed constructions is consistent with various dictionary definitions of "average," one of which is "an estimate or approximate representation of an arithmetic mean." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 150 (1986).

Websidestory does not explain how or why Netratings' proposed construction would limit the claims, and the Court agrees that Netratings' construction captures the meaning of this disputed phrase. Accordingly, and after reviewing the '479 Patent and the parties' arguments, the Court adopts Netratings' proposed construction, and concludes that the acquired meaning of "includes the average elapsed time between visits" is: "includes a single value representing the calculated average time between visits."

C. "The Computer" (Second and Fifth Clause of Claim 1; Fifth Clause of Claim 2)

Plaintiff's Proposed Construction: A computer previously recited in the claim.

Defendants' Proposed Construction: All occurrences of "the computer" refer to the same computer.
Defendants propose construing all occurrences of the term "the computer" throughout the claims as referring to the same computer. Defendants cite the plain language of the claim and the prosecution history to argue that all events of the '474 Patent must occur on the same computer. When each individual clause is read in context with the entire claim, however, it is clear that "the computer" refers to a computer recited in the preamble of the claim that is capable of processing unique identification codes. The term "the computer" simply refers to "a computer" that is programmed to perform the functions of the '474 Patent. Although one embodiment of the Patent can operate using a single computer, the plain language of the claim illustrates that the Patent does not require operating only one computer.

This construction is further supported by the specification. Two events occur in this Patent. The first is the encoding event, where a person's identifying information is obtained and stored in a magnetic medium. '474 Patent at 10:57-65; 12:6-9. The second is the recognition event, where identifying information is obtained from a live person and compared with the information stored in the magnetic medium. Id. at 10:66-11:11. The specification makes clear that this second event -- the recognition of a live print -- can occur at a number of locations, such as a retail store, and need not occur at the same computer where the print was first encoded. Id. at 10:24-26. Accordingly, the Court finds that the term "the computer" refers to a computer previously recited in the claim, and does not refer to the same computer throughout the claims.

R. "the digital data"

The phrase "the digital data" comes from the very last phrase of Claim One of the '399 Patent, which states: "wherein the second command interpreter is configured to interpret a data request command from the host device to the type of input/output device signaled by the first command interpreter as a data transfer command for initiating a transfer of the digital data to the host device." '399 Patent, col. 13:8-12. The Camera Manufacturers note the antecedent reference to "the digital data" -- "the second connecting device including a sampling circuit for sampling the analog data provided by the data transmit/receive device and an analog-to-digital converter for converting data sampled by the sampling circuit into digital data." Id., col. 12:55-59 (emphasis added). From these two references, they suggest that "the digital data" should be construed to mean "the same digital data output from the analog to digital converter, unmodified by additional processing." CMs' Surreply at 21. Papst offers a more expansive definition, to wit, "the 'digital data,' while referring to the data digitized in the second connecting device, includes data that has undergone further processing, such as digital signal processing." Papst's Slides at 112; see Papst's App. at 4; '399 Patent, col. 13:26-27 (Claim Five, reciting that the processor is a digital signal processor). When the specification describes the preferred embodiment of the invention, it describes the processing by the interface device of the data acquired from the transmit/receive device -- "the digital signal processor implements a fast Fourier transformation (FFT) in real time and also optional data compression of the data to be transferred from the data transmit/receive device to the host device." Id., col. 9:24-26. Papst has the better approach.

The specification for the '399 Patent states that in the preferred embodiment "[t]he digital signal processor 1300 provides on-board digital data processing." '399 Patent, col. 10:56-57 (the number 1300 refers to the location of the processor on Figure 2). Such digital signal processing is only limited by the size of the memory, as the specification explains:

As a result of the option of storing any files in agreed formats in the memory means 14 of the interface device 10, taking into account the maximum capacity of the memory means, any enhancements or even completely new functions of the interface device 10 can be quickly implemented. Even files executable by the host device, such as batch files or executable files (BAT or EXE files), and also help files can be implemented in the interface device . . . .

'399 Patent, col. 7:49-54; see also id., col. 8:37-42 ("Further, an experienced user can intervene at any time on any level of the existing second connecting device by making use of the above mentioned option of creating a configuration file or adding or storing new program sections for the second connecting device."). Thus, "the digital data" means "the data as it is output by the analog to digital converter, and/or the data as it is output by the analog to digital converter after it has undergone additional processing, such as digital signal processing."
A. Claim Construction

Claim construction is a matter for the court. Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995) (en banc), aff’d, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). Claims are construed from the vantage point of a person of ordinary skill in the art at the time of the invention. Id. at 986. In construing a claim, a court looks first to the intrinsic evidence of record, namely, the language of the claim, the specification, and the prosecution history. Insituform Tech. Inc. v. Cat Contracting, Inc., 99 F.3d 1098, 1105 (Fed. Cir. 1996). Extrinsic evidence such as expert testimony may be considered if needed to assist the court in understanding the technology at issue or in determining the meaning or scope of technical terms in a claim. Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1579 (Fed. Cir.), cert. denied, 136 L. Ed. 2d 198, 117 S. Ct. 275 (1996). A court may require expert testimony in order to understand how a person of ordinary skill in the pertinent art would construe a claim. See id. at 1578-79. In this case, the court has relied on such testimony where there is no genuine dispute between the parties as to what one of ordinary skill would have understood or recognized at the time of the '027 invention.

Claim 83 of the '027 patent reads as follows:

83. Apparatus for changing the time-base of a digital information signal having a time-base synchronizing component, comprising:

a randomly addressable digital store having addressed storage locations for receiving and storing successive intervals of the digital information;

means for effecting the storage of successive portions of each interval of the digital information signal at different addressed storage locations of the digital store at times determined by a clock signal;

means for effecting retrieval of the stored portions of the information signal from addressed storage locations at the times determined by said clock signal;

and means responsive to the time-base synchronizing component of the information signal and a time-base reference signal for providing a control signal representative of the time difference between the synchronizing component and the reference signal;

and means responsive to said control signal for adjusting during each interval of the digital information signal the time between effecting storage of each portion of the digital information signal at an address and effecting retrieval of said portion from said address.

Claim 83 is expressed in so-called "means-plus-function" language as authorized by 35 U.S.C. § 112(6), which provides:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

Section 112(6) requires that the court construe means-plus-function claims in view of the structure disclosed in the specification of the patent. Alpex Computer Corp. v. Nintendo Co. Ltd., 102 F.3d 1214, 1220 (Fed. Cir. 1996). Here, it is undisputed that the supporting structures of the means-plus-function limitations of claim 83 are found in certain portions of Figure 4, reproduced below, and columns 13 and 14 of the '027 patent specification.

[SEE FIG 4 IN ORIGINAL]

The court has not endeavored to construe each and every element of claim 83. Rather, the court has looked to the parties to identify the issues that the court must resolve. After hearing testimony and argument on claim construction and reviewing the parties' submissions in connection with claim construction, the court understands the following issues to be in dispute:
1) Whether information must be written into and read out of memory at the same frequency or rate;

2) Whether the entire digitized version of an incoming analog signal, including the time-base synchronizing component, must be stored in memory; and

3) Whether the counter represented by Block 168 in Figure 4 of the specification is the only structure supporting the means referred to in the fourth element of claim 83, that is, the means responsive to the time-base synchronizing component of the information signal and a time-base reference signal for providing a control signal representative of the time difference between the synchronizing component and the reference signal.

* * *

2. Storage of the Digital Information Signal

Mitsubishi next contends that claim 83 requires that the entire digitized version of an incoming analog signal, including the time-based synchronizing component, must be stored in memory. Ampex disputes this contention, arguing that claim 83 requires only that the digital information signal being stored have a time-based synchronizing component associated with it. Ampex also argues that the digital information signal referred to in claim 83 is the signal as it exists at the time it is written into memory, not as it exists immediately after it is converted into digital form.

The preamble of claim 83, "apparatus for changing the time-base of a digital information signal having a time-base synchronizing component," refers to "a digital information signal" without specifying its origin or the information it contains. Likewise, the limitations that follow merely refer to "the digital information" and "the digital information signal." (Emphasis added.) Thus, in order to determine what information must be stored in memory, the court must put claim 83 in context by examining the rest of the '027 patent specification.

As discussed above, the '027 invention converts incoming analog signals into digital signals before supplying them to the apparatus described by claim 83. This analog-to-digital conversion is depicted in Figure 1 of the '027 patent, reproduced above.

The parties do not dispute that, in Figure 1, the time-base synchronizing component of the incoming signal in its original analog form is detected and regenerated by means of a sync separator, represented by Block 134, during the analog-to-digital conversion process. The component, represented as "SIG. H," is then separately made available to other parts of the circuitry. The parties also do not dispute that, in Figure 4, the component, again represented as "SIG. H," is compared to the reference signal, represented as "REF. H," so that the differences between them may be measured and used to control retrieval of information from memory. It is thus apparent that SIG. H is derived before any portion of the digital information signal is stored in memory.

Ampex concedes that, in the embodiment of the patent shown in Figure 4, the time-base synchronization component is digitized and stored in memory with the rest of the digital information signal. However, Ampex points out, and Mitsubishi does not dispute, that after the digital information signal is read out of memory and is converted back to an analog signal, a processor represented by Block 116 in Figure 1 inserts reference synchronization and color burst components into the information signal in place of the digitized time-base synchronization component, which is discarded. Given this fact and the fact that SIG. H is derived during the analog-to-digital conversion process before any information is stored in memory, it is apparent that the synchronizing component need not be stored in memory along with the rest of the digital information signal. It is also apparent that, much like the separation of the time-base synchronizing component, other types of information could be separated from the signal and discarded before the signal is written into memory. Thus, the "digital information signal" referred to in claim 83 must be the signal as it exists at the time it is written into memory.

Accordingly, the court concludes that claim 83 does not require that the entire digitized version of an incoming analog signal, including the time-base synchronizing component, be stored in memory, and that the "digital information signal" referred to in claim 83 refers to the signal as it exists at the time it is written into memory.
By its claim construction order of the same date, the court construed "home page" as "the top-level entry point of a website." Its rationale in narrowing the claims to, essentially, one top level domain was in part due to the claims' use of the phrase "the home page," in contrast to the specification's reference to "home pages" (see, e.g., col. 2, ll. 10-11). That is, the claims' use of the article "the" preceding "home page" (i.e., "the home page") implies that any objective definition must identify just one page. Upon further review, the court does not alter its construction.

In its memorandum opinion, the court rejected defendants' indefiniteness challenge to the '904 patent, based on the fact that the algorithm (trimming steps) described in columns 6 and 7 of the '904 patent achieved "the most representative image" of a web page; defendants suggested that the court construe "home page" as "the web page having the URL produced by the trimming steps described in columns 6 and 7" of the '904 patent. (D.I. 331 at 19-20) Because defendants were able to point to a definition for the term, the court found that "home page" was not so "insolubly ambiguous" as to completely foreclose construction and compel a finding of invalidity based upon indefiniteness.

It has since come to the court's attention that, although the algorithm may result in "a" home page (or top level entry site), the algorithm described in column 7 will not result in "the top-level entry point" of the web site, or the single, highest-most entry level point. Moreover, aside from the algorithm, the specification does not define (or specifically exemplify) "home page," let alone define "the home page" disclosed in the claims. As explained in the court's prior opinion, the parties do not genuinely dispute that the term "home page" was generally understood in the art at the time the application leading to the '904 patent was filed. However, plaintiff concedes that a web site may have more than one "home page" and the evidence indicates that no universal definition existed at the time for "the home page."
because of a misused article. As such, the Court will construe "the master controller" as "a master controller."

4462

A.

The court's claim construction ascribes claim terms the meaning they would be given by persons of ordinary skill in the relevant art at the time of the invention. See 35 U.S.C. § 112; Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1116 (Fed. Cir. 2004). Claim construction begins with the language of the asserted claims. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). The relevant claim language in this case appears identically in independent claims 1 and 10. It provides,

A method of operating a computer system including a processor and a memory system, wherein the memory system includes an array of non-volatile floating gate memory cells partitioned into a plurality of sectors that individually include a distinct group of said array of memory cells that are erasable together as a unit, comprising:

providing said memory array and a memory controller within a card that is removably connectable to the computer system, said controller being connectable to said processor for controlling operation of the array when the card is connected to the computer system, partitioning the memory cells within the individual sectors into at least a user data portion and an overhead portion ...

'987 patent, col. 16, ll. 24-37 (claim 1, emphases added); see also id. at col. 17, ll. 30-44 (claim 10). Although SanDisk also asserted claims 2, 5, 6, 12, and 15 of the '987 patent, each depends from claim 1 or 10 and incorporates the foregoing limitations in relevant part. The parties do not dispute, and the trial court correctly noted, that the preamble recited above is limiting. n2

n2 That is, because "when read in the context of the entire claim" the preamble "recites limitations of the claim ... or ... is 'necessary to give life, meaning, and vitality' to" claims 1 and 10, the trial court properly treated the language as limiting. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999).

Reviewing the partitioning requirement, the trial court concluded that claim 1 and claim 10 require every Flash EEPROM memory cell within an actual device to be grouped into a sector that is partitioned into user and overhead data portions. SanDisk argues that this construction misreads the plain language of the claim. The argument proceeds on two levels. First, by its plain language, claims 1 and 10 require only that the claimed memory system contain some memory cells, grouped into sectors, partitioned into user and overhead data portions. Nothing in the claims precludes additional memory cell configurations, which need not contain such partitioned sectors. Second, claims 1 and 10 are self-evidently drawn to claimed methods. It is fully consistent with practicing the claimed invention to make additional, unclaimed use of Flash EEPROM memory cells, so long as each limitation is satisfied. We agree.

The invention is claimed using non-restrictive terminology. The memory system "includes" an array of "non-volatile floating gate memory cells" which are "partitioned into a plurality of sectors." The claimed method requires "partitioning the memory cells within the individual sectors into at least a user data portion and an overhead portion." As a patent law term of art, "includes" means "comprising." See Amgen Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1344-45 (Fed. Cir. 2003); Hewlett-Packard Co. v. Repeat-O-Type Stencil Mfg. Corp., Inc., 123 F.3d 1445, 1451 (Fed. Cir. 1997). Neither includes, nor comprising, forecloses additional elements that need not satisfy the stated claim limitations. Nor does the choice of articles-"an array" of memory cells, "a plurality of sectors," "said array of memory cells," "the memory cells," or "the individual sectors" - compel a different conclusion. These groupings of Flash EEPROM memory cells provide an antecedent basis for various steps of the claimed method, but nothing in their recitation excludes other configurations of memory cells on a physical device that, in some part, practices the claimed methods. Thus, nothing in the language of claims 1 or 10 prevents the use of Flash EEPROMs containing cells that are not grouped into partitioned sectors.
B.

SanDisk further argues that the '987 patent specification is inconsistent with the trial court's claim construction because, among other reasons, it excludes at least two preferred embodiments: one involving storing a sector defect map in Flash EEPROM memory cells, and another involving using Flash EEPROM cells as a write memory cache. As explained below, the court need only consider the sector defect map to conclude that SanDisk is correct.

The court must always read the claims in view of the full specification. See Vitronics, 90 F.3d at 1582. A claim construction that excludes a preferred embodiment, moreover, "is rarely, if ever, correct." Vitronics, 90 F.3d at 1583; see also C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 865 (Fed. Cir. 2004). The '987 patent specification describes an embodiment involving a sector defect map, which, in brief, contains information mapping defective memory sectors into good ones. See '987 patent, col. 11, ll. 57-60. Although the defect map may be stored in spare, defect-free portions of the affected sector, at some point there will be too many defects to keep the defect map in that location. "Thus, it is preferable in another embodiment to locate the sector map in another memory maintained by the controller. The memory may be located in the controller hardware or be part of the Flash EEPROM memory." '987 patent, col. 11, l. 65 - col. 12, l. 1 (emphasis added). SanDisk argues that because the sector defect map would contain only overhead data, the portions of the Flash EEPROM memory used in the preferred embodiment would not be partitioned into user data and overhead data portions as required by according claims 1 or 10. As the district court's claim construction would foreclose that possibility, the claim construction must be wrong.

The trial court rejected this argument. It ruled, instead,

The fact that the sector defect map contains only overhead data does not prove that the embodiment contemplates sectors with only overhead data. Although the sector defect map is composed entirely of overhead data, the court finds that the sector defect map is located entirely within the overhead portion of a single sector.

We find this reasoning misplaced.

In its brief to this court Ritek concedes that the sector defect map could be located in "a part of memory outside the array of sectors partitioned into a user data and overhead portions, i.e., in an unsectored part of the memory." Ritek Br. at 43-44. If Ritek is correct, then the trial court's claim construction must be wrong. The claims must allow, instead, for Flash EEPROM memory cells that are not sectored, or not partitioned, according to the claimed methods. But since Ritek concedes this point, and both Pretec and Memorex join Ritek's argument, there is no dispute left for the court to resolve. In sum, the trial court's speculative treatment of the preferred embodiment is unsupported by the patent specification, not grounded in the record, and contrary to the reading suggested by all parties. We conclude that SanDisk is correct in faulting the trial court's claim construction.

Ritek contends that the only sectors described in the '987 patent specification are partitioned as illustrated in Fig. 5. Thus, Ritek concludes, the invention is directed only to partitioned sectors. We find this reasoning misplaced for at least two reasons. First, as noted above the language of claims 1 and 10 does not preclude other, unclaimed organizations of Flash EEPROM memory cells. Thus, even if the court concluded that Fig. 5 shows the only partitioning consistent with the claimed methods that would not preclude use of other organizations in the memory system. Second, it is axiomatic that without more the court will not limit claim terms to a preferred embodiment described in the specification. Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations."). The '987 patent specification plainly describes the sector partitioning illustrated at Fig. 5 as a "typical" sector organization. See '987 patent, col. 8, ll. 43-45. It is a preferred embodiment of the sector organization claimed in the claim 1 and 10 methods. In short, Ritek's argument is misplaced. The specification does not contradict the plain meaning of claims 1 and 10.

C.

The prosecution history does not compel a contrary result. The court must always consult the prosecution history, when offered in evidence, to determine if the inventor surrendered disputed claim coverage. See Medrad, Inc. v. MRI Devices Corp., 401 F.3d 1313, 1319 (Fed. Cir. 2005) ("We cannot look at the ordinary meaning of the term ... in a vacuum. Rather,
we must look at the ordinary meaning in the context of the written description and the prosecution history.

After consulting the prosecution history, the trial court ruled that SanDisk disclaimed any method or device in which Flash EEPROM memory cells were not grouped into partitioned sectors. Ritek urges the court to affirm this analysis. SanDisk, however, maintains that the trial court erred in this conclusion. Instead, SanDisk argues, nothing in the prosecution history provides a clear and unmistakable disclaimer as found by the district court. On reviewing the relevant arguments to the examiner, we agree with SanDisk.

1. When the patentee makes clear and unmistakable prosecution arguments limiting the meaning of a claim term in order to overcome a rejection, the courts limit the relevant claim term to exclude the disclaimed matter. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003) ("Where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender."); Standard Oil Co. v. Am. Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985) ("The prosecution history (or file wrapper) limits the interpretation of claims so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance.").

As this court has explained,

The doctrine of prosecution disclaimer [precludes] ... patentees from recapturing through claim interpretation specific meanings disclaimed during prosecution. See Schriber-Schroth Co. v. Cleveland Trust Co., 311 U.S. 211, 220-21, 85 L. Ed. 132, 61 S. Ct. 235, 1941 Dec. Comm'r Pat. 802 (1940) ("It is a rule of patent construction consistently observed that a claim in a patent as allowed must be read and interpreted with reference to claims that have been cancelled or rejected, and the claims allowed cannot by construction be read to cover what was thus eliminated from the patent."); Crawford v. Heysinger, 123 U.S. 589, 602-04, 31 L. Ed. 269, 8 S. Ct. 235, 1888 Dec. Comm'r Pat. 185 (1887); Goodyear Dental Vulcanite Co. v. Davis, 102 U.S. 222, 227, 26 L. Ed. 149, 1881 Dec. Comm'r Pat. 131 (1880); cf. Graham v. John Deere Co., 383 U.S. 1, 33, 15 L. Ed. 2d 545, 86 S. Ct. 684 (1966) (ruling, in addressing the invalidity of the patents in suit, that "claims that have been narrowed in order to obtain the issuance of a patent by distinguishing the prior art cannot be sustained to cover that which was previously by limitation eliminated from the patent").

An ambiguous disclaimer, however, does not advance the patent's notice function or justify public reliance, and the court will not use it to limit a claim term's ordinary meaning. See id. at 1324 (collecting cases). There is no "clear and unmistakable" disclaimer if a prosecution argument is subject to more than one reasonable interpretation, one of which is consistent with a proffered meaning of the disputed term. See Golight, Inc. v. Wal-Mart Stores, Inc., 355 F.3d 1327, 1332 (Fed. Cir. 2004) (finding no disclaimer because "the statements in the prosecution history are subject to multiple reasonable interpretations, they do not constitute a clear and unmistakable departure from the ordinary meaning of the term at issue"); Cordis Corp. v. Medtronic AVE, Inc., 339 F.3d 1352, 1359 (Fed. Cir. 2003) (concluding that a statement made during prosecution "is amenable to multiple reasonable interpretations and it therefore does not constitute a clear and unmistakable surrender"). The question, therefore, is whether any of SanDisk's prosecution arguments to the examiner have no reasonable interpretation other than to disavow any memory system in which Flash EEPROM memory cells are not grouped into partitioned sectors.

2. In this case the relevant prosecution argument responded to an obviousness rejection. The '987 patent is sued from application Ser. No. 174,768 ("the '768 application"). On December 7, 1995, the examiner rejected original claims 79
(which issued as claim 1) and 85 (which issued as claim 10) in the '768 application as obvious under Burke in view of Yorimoto. The examiner explained that Burke - an Australian patent, No. AU-B-83 22536/-taught a memory system including "an array of cells which are inherently partitioned into a plurality of sectors because Burke's array is to 'emulate' a magnetic disk which has sectors." As the examiner explained, Yorimoto - European patent application No. 86114972.2, Pub. No. 0 220 718 - "teaches partitioning the cells with a sector into portions, each portion is for storing a specific type of information." Rejecting claim 85 (issued claim 10), the examiner concluded,

It would have been obvious to one having ordinary skill in the art at the time the invention was made to use Yorimoto's memory (of EEPROM type) and Yorimoto's memory cells partitioning in place of Burke's memory.

The artisan would have been motivated to use Yorimoto's EEPROM in the place of Burke's memory because Yorimoto's EEPROM can be partitioned into sectors and Burke's emulation inherently suggests that the emulating memory should be able to emulate the sectors of Burke's magnetic disk.

SanDisk argued that the examiner was mistaken. In particular, SanDisk explained:

The memory cell array is divided into sectors, with the cells within each sector being erasable together as a unit. Stored in each sector is a sectors [sic] worth of user data and some overhead information (a header) about the sector and/or about the user data stored in the sector.

(quoted at Pretec SJ Order, slip. op. at 25). Relying heavily on SanDisk's description of "each sector", the trial court concluded that SanDisk was referring to every sector on the '987 patent EEproms. Id. at 26. Ritek contends that the trial court's analysis was correct, and with this language SanDisk disclaimed its current claim construction. We disagree, and find no clear and unmistakable disclaimer in this passage.

The trial court's and Ritek's reasoning assumes its conclusion. The quoted passage begins with the proviso that "The claims a re directed to a flash EEPROM system[.]" If, when viewed in context, SanDisk used this passage to describe the memory cell array - and, in particular, the claimed sector organization subject to the methods in original claims 79 and 85 - then there is no prior reason why that memory cell array or the discussion of it should be presumed to exhaust every cell on every EEprom in the "memory system" recited in the claim preambles. Given the open language in the claims, there is no reason for the court to read the prosecution argument with such a presumption in mind. Put differently, the reference to "each sector" means "each sector" subject to the claimed method, and no more. In short, SanDisk's reading of this prosecution argument is at least reasonable. Thus, focusing on this passage alone, there is no "clear and unmistakable surrender" within the meaning of Golight.

The trial court further reasoned that because SanDisk sought to emulate a disk drive with the claimed memory system, it followed that SanDisk intended to group every Flash EEprom memory cell into a partitioned sector. The trial court focused on the following prosecution argument, responding to the obviousness rejection of original claim 79:

The claims in this application each define more than the desire to make a semiconductor memory system look on the host system side of the memory controller to be a disk drive. They define a way of configuring and using a semiconductor memory on the memory side of the controller in a way similar to a disk drive. Claim 79 defines a flash EEPROM system with an array that is divided into sectors of cells that are erasable together as a unit. This is not new by itself but is a particular type of memory ... to be used to emulate a disk drive. None of the ... cited references suggest use of such a type of memory. The only mention of an EEPROM system is by Yorimoto et al. but their embodiments appear to be generically described for use with either an EEPROM or a battery backed volatile RAM. Nothing is said by Yorimoto et al. of a flash EEPROM system that is operated with sectors of cells that are erasable together as a unit. It is the use of this type of memory that allows the memory itself to be operated very similarly to that of a disk drive, with individual sectors that store both user data and overhead data (a header for the sector). It is the operation of the flash EEPROM memory by the memory controller with the sectored and partitioned characteristics of a disk drive memory that is novel and non-obvious.

Ritek contends that the trial court correctly read this passage to disclaim the claim construction set forth above. Again, we disagree.

First, as with the last passage, this argument is directed to explicating the claimed invention. It does not purport to exclude
from the "memory system" other configurations of Flash EEPROM memory cells. Even though SanDisk identifies the novel invention as "operation of the flash EEPROM memory by the memory controller with the sectored and partitioned characteristics of a disk drive memory," that statement goes to the claimed memory organization.

Second, the fact that with the claimed invention SanDisk sought to emulate a disk drive memory storage configuration does not compel the conclusion that SanDisk required every Flash EEPROM memory cell in the "memory system" recited in the claims to be grouped into partitioned sectors. The trial court's reasoning, in short, relies on a false analogy. Though every memory cell on a disk drive might have a physical location in a partitioned sector, it does not follow that to "emulate" that function every memory cell in a Flash EEPROM array must also be so grouped. To the contrary, the organization of memory cells in the Flash EEPROM is physically limited only by the requirement of a simultaneous erase by sector; in other respects, the cells are grouped into sectors by a logical allocation. Thus, while physical organization of memory on a disk drive might require every memory cell to be placed in a partitioned sector, the physical organization of memory cells on an EEPROM does not.

The prosecution history as a whole confirms this point. In an earlier passage, SanDisk argued:

The claimed memory system looks to the host computer as if it was a disk drive system, similar to the goal stated in the cited Burke patent. But a significant difference is the claimed operation of the flash EEPROM array with many incidents of a disk system. It is divided into sectors that are operated as a unit, including overhead data (a header) as well as user data, and, in some of the claims, the overhead data is read from an addressed sector before user data is written into that sector. (emphases added). The passage focuses on the claimed operation of the flash EEPROM memory cell array, the subject of claims 1 and 10; it does not address itself to unclaimed uses of the memory cells. Moreover, according to SanDisk, that particular EEPROM configuration was not obvious from combining Burke, which emulated a disk drive, and Yorimoto, which claimed an EEPROM array:

This is quite different from the way that semiconductor memory arrays are usually operated. ... The present claims ... define a disk like approach to semiconductor memory operation. The fact that the system of the Burke patent may look to the host system as a disk memory system does not mean that its array is operated in sectors, with headers, etc., as claimed. ... 

... The flash EEPROM system employed in the present invention, unlike typical RAMs, do have memory operations that can benefit from auxiliary information. The provision for making such information available in a header of each sector in the context of a solid state memory is part of the present invention.

An underlying assumption made throughout the Examiner's Action is that it is inherent in the system of the cited Burke reference to operate its volatile RAM array with sectors, and thus obvious to include overhead data (headers) in individual sectors. This premise, and thus all the rejections based upon it, is respectfully submitted to be incorrect. Contrary to the position taken in the Examiner's Action, it is submitted that the fact that Burke's system looks to the host system as a disk drive memory does not compel this conclusion. The alleged inherent Burke disclosure upon which nearly all the grounds of rejection are based does not exist.

In other words, it was novel to organize the cells into partitioned sectors for purposes of the claim, but the claimed purpose of emulating a disk drive did not compel sorting every memory cell - even those not subject to the claimed method - in that fashion.

In sum, we conclude that SanDisk did not unmistakably surrender the grouping of Flash EEPROM memory cells into non-partitioned sectors. The prosecution history is consistent with the plain meaning of claims 1 and 10, and does not compel the trial court's contrary reading.
The parties propose very different interpretations of the retrieving steps of the ‘597 patent. Detroit Diesel contends that the retrieving steps require the retrieval of one set of data representing a fuel delivery limit curve if the cruise control is engaged, and the retrieval of a different set of data representing a different fuel delivery limit curve if the cruise control is not engaged. Detroit Diesel bases its interpretation on the plain language of the claim and on the dictionary definition of "other." Detroit Diesel also refers the court to what it deems an admission by Caterpillar to the European Patent Office during prosecution of the same claim with that office that the claim is invalid unless the retrieving steps are limited to mutually exclusively retrieving one or the other set of data depending on whether the cruise control is engaged. In response to an objection from the EPO, Caterpillar inserted a reference to prior art WO-A-8403911 (the Thompson Patent European counterpart), explaining in its letter to the EPO presenting the amended application that the reference "does not suggest using a high horse power curve during cruise control engagement and a lesser horsepower curve simply because the cruise control is engaged." Caterpillar amended the claim to explain that WO-A-8403911 "does disclose limiting fuel supply to a to a lower range of values … when cruise control is off than when it is on, even though the limitation to using a lower range of values is not primarily determined by whether or not the cruise control is engaged or disengaged." See Exh. F to Detroit Diesel's Motion.

Caterpillar, on the other hand, contends that when properly interpreted in their open format, the retrieving steps are not limited in the manner Detroit Diesel proposes. Caterpillar claims that the first retrieving step can only be interpreted to require retrieval of at least one set of data, representing one or more fuel delivery limit curves, when the cruise control is engaged. Caterpillar explains that the lower limit curves (which would, under Detroit Diesel's interpretation, be available only when cruise control is not engaged) may also limit the command signal if cruise control is engaged, as shown in the preferred embodiment, in which the additional power is not retrieved unless power above the lower limit curve is needed to maintain the cruise set speed:

Higher rated rack limits, and thus higher engine output torque and horsepower levels, are made available when: (1) the cruise control is engaged; (2) the cruise control set speed is greater than a minimum predetermined speed; and (3) the vehicle speed is less than the cruise control set speed plus a predetermined value.

* * *

If any of the questions posed by the blocks 130, 132, or 134 [of Figure 3] is answered in the negative, then it has been determined that the increased rack limits represented by the torque curves 120A, 122A and respective horsepower curves 120B and 122B are not to be used.

‘597 Patent, Col. 6, lines 23-29 and 62-66. Caterpillar thus concludes that the specification itself contradicts Detroit Diesel's interpretation because it describes a situation where cruise control is engaged but the upper limit curve is not retrieved. The preferred embodiment thus evaluates conditions other than whether the cruise control is engaged before selecting a particular set of data. Because the claim is written in an open format, Caterpillar argues, it will read on devices that include additional elements not referenced in the claim.

According to Caterpillar, the second retrieving step must be read to allow the retrieval of more than one set of data from memory when cruise control is not engaged, and cannot be read as restricting retrieval of the second (lower) fuel delivery limit curve to when the cruise control is not engaged. Claiming to construe the patent practically and in accordance with its purposes, Caterpillar asserts that the second retrieving step may properly be construed to require retrieval of the lower fuel delivery limit curve where power is demanded through the throttle (where by definition the cruise control is not engaged), and to "preclude throttle retrieval of the higher curve in other circumstances."

Caterpillar objects to Detroit Diesel's reliance on the EPO documents, claiming they are presented out of context and in edited form, and are not legal admissions by Caterpillar, and do not support Detroit Diesel's arguments. The correspondence, Caterpillar claims, merely shows its disagreement with the EPO about whether the Thompson Patent European counterpart taught use of the cruise control as a determining step for accessing additional power.
Lastly, Caterpillar argues that the court cannot accept Detroit Diesel's interpretation of Claim 1 because it would mean that "the fuel delivery limit curves in Figures 2A and 2B are mutually exclusive," which in turn would make Claim 3 11 of the patent directly contradicted by Claim 1 and rendered meaningless. Detroit Diesel's reply seems to accept Caterpillar's assertion that its interpretation of Claim 1 would make Claim 3 contradicted by Claim 1 and rendered meaningless, but points out that claim differentiation 12 is a "guide, not a rigid rule." See Autogiro, 384 F.2d at 404.

--- Footnotes ---

11 Claim 3 of the '597 patent provides: "3. The method of claim 1, including the further steps of determining whether the speed of the vehicle is less than the set speed plus a predetermined value and retrieving at least a portion of the other set of data from the memory (86) when the vehicle speed is not less than the set speed plus the predetermined value."

12 The doctrine of claim differentiation is a canon of claim construction which holds that when a patent contains both broad and narrow claims, the additional limitation of the narrow claim should not be read into the broad claim. The doctrine embodies the common sense notion that ordinarily language of one claim should not be so interpreted as to make another claim, such as a claim dependent on the first claim, identical in scope. Motorola, Inc. v. Interdigital Technology Corp., 930 F. Supp. 952, 965 (D.Del. 1996) (quotations and citations omitted).

--- End Footnotes ---

Detroit Diesel's reply brief makes two points relevant to construction of the retrieving steps. Detroit Diesel criticizes Caterpillar's interpretation of the retrieving steps as doing "violence to language as a tool for communication" by effectively eliminating the determining step altogether since, according to Caterpillar, the same sets of data may be retrieved without regard to whether the cruise control is engaged. Detroit Diesel also presents the deposition testimony of the first named inventor of the '597 patent, Michael Moncell, who explains:

Q. So the first and second retrieving steps are mutually exclusive of one another depending on the answer to the determining step; is that accurate?

A. (Mr. Moncell): Yes, they are mutually exclusive. You choose one or the other.

Moncell Dep. at 31. In his affidavit, Mr. Moncell explains that the steps are mutually exclusive in that one or the other sets of data is retrieved (engine fuel delivery necessarily is restricted at any point in time by one of the limit curves), but that this does not mean that the higher fuel delivery curve is the only accessible curve during cruise control engagement. Moncell Aff., PP 10-11.

After examining the claim and the entire specification and considering the parties' arguments, the court agrees with Detroit Diesel's construction of the retrieving steps of the '597 patent. The claim states that one of the sets of data representing one of the fuel delivery limit curves is retrieved when cruise control is engaged, and the other set of data representing the other fuel delivery limit curve is retrieved when the cruise control is not engaged. As Detroit Diesel argues, the claim allows for the cruise control to be in one of two states (engaged or not engaged), and one of two different sets of data is retrieved depending on whether the cruise control is engaged or not engaged. By its own words, the claim sets up two mutually exclusive possible situations.

The court cannot reconcile Caterpillar's urged interpretation with the language of the claim. Caterpillar argues that because the claim is written using "comprising," i.e. in open format, limitations that are not present in the claim's language cannot be read into the claim. While it is true that a claim written in open format does not exclude additional unrecited elements, see Moleculon Research Corp. v. CBS, Inc., 793 F.2d 1261, 1271-1272 (Fed. Cir. 1986), Caterpillar's interpretation is not based on additional unrecited elements. Caterpillar argues for an interpretation of the retrieving steps in which neither step is limited even to the language set forth in the step. The claim's words must be given their ordinary and accustomed meaning unless it appears that the inventor used them differently. ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1579 (Fed. Cir. 1988); Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759 (Fed. Cir. 1984). The first retrieving step provides for retrieval of one set of data when the cruise control is engaged, and the second step provides for retrieval of the other set.
when the cruise control is not engaged. Caterpillar now argues that either set may be retrieved when the cruise control is engaged, and that when the cruise control is not engaged, the first set may nonetheless be retrieved, such as during power take-off. Caterpillar's asserted construction of Claim 1 may make sense in a vacuum, and even jibe with the purposes of the patent (making additional power available when necessary to maintain the set speed), but it finds no support in the claim's language. 13

13 The court does not rely on the EPO documents in reaching this conclusion, and determination of their meaning and status as "admissions" is not necessary.

Caterpillar's reference to portions of the preferred embodiment to support its interpretation is likewise unconvincing. The portion of the preferred embodiment Caterpillar references supports its assertion that in the preferred embodiment additional power is not retrieved unless power above the lower limit curve is needed to maintain the cruise set speed, but the portions Caterpillar cites recite additional steps (corresponding to blocks 132, 134, and 136 of Figure 3) that are not contained in Claim 1, but rather can be seen in the language of Claims 2 and 3 of the patent.

Lastly, Caterpillar's claim differentiation argument does not alter the court's conclusion. Caterpillar contends that Claim 1 cannot be interpreted in the manner urged by Detroit Diesel--"that the fuel delivery limit curves in Figures 2A and 2B are mutually exclusive"--because it would make Claim 3 of the patent directly contradict Claim 1. Caterpillar has not, however, explained how or why Detroit Diesel's interpretation would render Claim 3 contradicted by Claim 1 and "meaningless", and the answer is not obvious to the court.

GO BACK

4464

1. Claim interpretation

Claim 1 of the '447 patent recites:

A method for producing a tone by reading a waveform memory storing a predetermined waveform by an address signal of a selected repetition frequency comprising:

- a step of multiplying the output of said waveform memory with a parameter;
- a step of adding the multiplication product to said address signal; and
- a step of reading said same waveform memory by means of the output resulting from said addition,

a tone being produced by using the output of said same waveform memory.

(emphasis added).

The district court decided that the "output of said same waveform memory" in the last clause must be identical to that in the first step. Based on its interpretation of that phrase, the district court concluded that claim 1 requires that the same output from the waveform memory be simultaneously fed-back and fed-forward, with a tone being produced after downstream processing. Because ESS's device at no time feeds back the same output as it feeds forward, the district court decided that Yamaha was not likely to prove literal infringement.

On appeal, Yamaha challenges the district court's claim interpretation of these two key phrases. Yamaha admits that the term "output" in the last clause of the claim generally refers to the same "output" in the first step of the claim. Yamaha insists, however, that because of the timing delay involved in the arithmetic unit, the "output" in the first step need not be the same data value as used in the last clause to produce a tone. Moreover, even if the two outputs are identical, Yamaha contends that
"by using" is an expansive phrase which merely requires that the output be somehow used to create the ultimate tone. Based on these interpretations, Yamaha argues that the same output need not be simultaneously fed-back and fed-forward to produce a tone.

We interpret the claim in view of its language, the specification, and the prosecution history. Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1578, 37 U.S.P.Q.2d (BNA) 1365, 1370 (Fed. Cir. 1996). As explained below, we agree with the district court and likewise reject Yamaha's proffered interpretation.

We begin first with Yamaha's contention that the output in the last clause need not be the same data value as that in the first step. By using a definite article "the" to describe "output" in the last phrase, Yamaha raises the inference that the term refers to the same value as in the first step. Cf. Zenith Elecs. Corp. v. Exzec, Inc., No. 93-C-5041, 1995 U.S. Dist. LEXIS 6177, 1995 WL 275591, at *5 (N.D. Ill. May 8, 1995) (stating that a definite article such as "the" refers back to an earlier recitation of the element); accord Slimfold Mfg. Co. v. Kinkead Properties, Inc., 626 F. Supp. 493, 495, 229 U.S.P.Q. (BNA) 298, 299 (N.D. Ga. 1985), affirmed, 810 F.2d 1113, 1 U.S.P.Q.2d (BNA) 1563 (Fed. Cir. 1987). The diction chosen by Yamaha therefore suggests that the two uses of "output" refer to identical data values.

To respond to this strong inference, Yamaha notes that the third step of the claim creates another output from the waveform memory, albeit an implicit one. Therefore, Yamaha argues, it makes no sense to require that the output value in the last clause be the same value created by the first step; the last clause could as well refer to the output value created by the third step.

We disagree with Yamaha's argument. If Yamaha meant for "the output" in the final clause to refer to a different value in time from that in the first step, it could have explicitly so stated. * For example, the claim could have been written so that in the last clause, the tone is produced by using "an output" or "the output of the waveform memory in the third step" as opposed to that in the first step. Instead, there is no mention whatsoever of any output that may be created by the third step.

--- Footnotes ---

* Indeed, claims 2 and 3 each use words such as: "first parameter" and "second parameter," "the multiplication product" and "second multiplication product," and "the waveform memory" and "second waveform memory." Apparently, Yamaha's attorney knew how to refer to different signal values when desired.

--- End Footnotes ---

Yamaha's interpretation would change "the" in the last clause to "an." The claim, however, cannot bear such a weight. Unless there exists a strong indication to the contrary, Yamaha must live with its choice of claim language and the inferences to be drawn therefrom. The language of the claim therefore supports the interpretation requiring the same output value to be both fed-forward and fed-back.

This interpretation also finds support in the specification. Although claims are not limited to particular embodiments described in the specification, such embodiments may inform the meaning of terms within the claims. See Autogiro Co. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 397-98, 155 U.S.P.Q. (BNA) 697, 702-03 (Ct. Cl. 1967). In the '447 patent, the basic organization of the invention is described by Fig. 1. This figure admittedly does not depict timing elements; yet the junction following the sinusoid memory (23' at the point labeled sin y) indicates that the same data value is simultaneously both fed-forward (as shown by the arrow pointing to the right) and fed-back to the multiplier 13. Fig. 1, therefore, supports the district court's interpretation.

Fig. 16, which describes the subject matter in claim 3, is also instructive because only claims 1 and 3 twice use the output of said waveform memory. Claim 3 recites "a step of multiplying the output of said waveform [memory] with a first parameter; . . . a step of multiplying the output of said waveform memory with a second parameter." Fig. 16 reveals that the same output signal of the waveform memory undergoes both multiplication steps. Because the multiplication operations on the memory output in claim 3 lack the timing delays involved with the arithmetic unit in claim 1, there is no reason to believe that the output value applied to the first multiplier 13-1 in claim 3 differs from the value applied to the second multiplier 28. Instead, Fig. 16 indicates that both uses of "output" refer to the same data value. This use in claim 3 again lends support to the district court's interpretation of claim 1.
In fact, each of the drawings in the specification indicate that the same output value is both fed-forward and fed-back. In addition to Figs. 1 and 16 described above, Figs. 17, 19, and 24 also depict the output being directly both fed-forward and fed-back. Only in Fig. 9 is the output not directly fed-forward, but even in that case it is clear that the same value fed-back via multiplier 13-1 is also fed-forward to multiplier 27, albeit via multiplier 13-1. In contrast to the inferences created by these drawings of the specification, Yamaha points to no drawings, timing diagrams, or language in support of its interpretation that the last clause in claim 1 refers to an output value of the waveform memory in general, without reference to time. The description in the specification, therefore, weighs in favor of the interpretation adopted by the district court.

In light of the claim language and the specification, we agree with the district court that claim 1 requires that the output value in the first step be the same as the output value in the last clause. The identity of these two outputs, in turn, supports the district court's overall interpretation of the claim as requiring that the same signal be simultaneously both fed-back in the first step of the claim and fed-forward in the last clause.

Despite this interpretation of "output," Yamaha insists that the same output value need not be simultaneously fed-back and fed-forward. Yamaha argues that the claim employs the broad phrase "by using," which requires only that the output eventually be used to produce a tone. In support, Yamaha notes that the specification and all of the drawings recognize that some additional downstream processing will always be required before the waveform memory output is converted into a tone.

This broad reading of "by using" would encompass ESS's device; in each iteration, the output is used to create the next output, with the twenty ninth output being the only one fed-forward to produce a tone. Indirectly, then, each output of ESS's device is used to create the ultimate tone. We, however, disagree with Yamaha's overbroad characterization of this phrase.

As Yamaha itself explains, the first three steps of the claim refer to feedback. The last clause, in contrast, refers to the feed-forward aspect of the claim -- the downstream processing necessary to convert the waveform memory output into a tone. Although the phrase "by using" encompasses such downstream processing, it does not necessarily encompass any processing that occurs during additional feedback. Indeed, the prosecution history of claim 1 confirms our view that the phrase "by using" points to downstream processing, rather than indirect use during the feedback cycle.

Claim 1 as originally filed was substantially similar to the claim as issued except that the last clause as originally filed read: "a tone being produced by using the output of said waveform memory or said multiplication product." (emphasis added). Fig. 1 shows that this multiplication product, labeled \( \beta \sin y \), occurs within the feedback loop. As originally filed, then, the claim contemplated a tone being produced "by using" either downstream processing or processing within the feedback loop.

The examiner rejected this original claim, inter alia, as drawn to an invention not disclosed because "the phrase 'or said multiplication product' cannot be understood as it appears that the tone would be produced only from the output of the waveform memory." In response, Yamaha deleted the objectionable phrase and stated "the claim as amended is clearly drawn to an invention which is disclosed, for example in Fig. 1."'

By eliminating the output of the multiplication product as a source used to produce a tone, Yamaha's amendment indicated that the tone was to be produced via the feed-forward mechanism rather than the feedback mechanism. Therefore, although "by using" may be broad, it is not without bounds, and does not support Yamaha's view.

In sum, we agree with the district court's interpretation of "the output of said waveform memory." Based on this interpretation, we also agree that the claim requires that the same output value be simultaneously fed-back and fed-forward.

4465

G. "the plurality of media player devices including a media asset portability application"

Claim 7 of the '704 patent requires "a plurality of media player devices associated with the user account, the plurality of media player devices including a media asset portability application that enables the user to access the plurality of media assets referenced in the virtual media asset library." "Media asset portability application" is not found in the specification.
The plaintiff recommends that this term should be construed as "two or more 'media player devices' with software permitting a 'media asset' to be copied or moved." On the other hand, the defendant's suggested construction is "each of the media player devices has a software program that allows the media player user to access files stored at the portal in the user's virtual media asset library."

The parties' two primary disagreements are (1) can media player devices transfer media assets directly to other media assets or are they limited to transferring directly to and from the portal; and (2) is each media player device required to run the media asset portability application. First, Apple argues that the media asset portability application is limited to transfers between the media player device and the portal. According to the defendant, the specification contains no references to direct transfers of assets between media player devices. As to the claims themselves, Apple contends that the language of claim 7 mentions nothing about direct transfer of assets from device to device.

In response, Zapmedia notes that the specification discusses watermarking a media asset to associate the asset with a user's family of media devices. (°704 patent, 11:37-42). The specification goes on to explain, "[T]he user will have access to those assets from one client media player device to another in seamless fashion. This example illustrates a capability . . . to move or copy an asset from any home, car, portable, computer, or other computing device." (°704 patent, 11:44-48) (emphasis added). Watermarking an asset for use on multiple media player devices would be superfluous if each media player device were required to download the asset from the portal. Furthermore, the plaintiff argues that dependent claims 8 and 9 provide support for its proposed construction. Claim 8 further limits claim 7 by requiring a media player device to upload a media asset to the virtual media access library portal before it may be downloaded from the portal to the other media player devices. Under Apple's proposed construction, claims 7 and 8 operate in the same manner. Next, claim 9 states that the media asset portability application moves the media assets from one media player device to another; no intermediate step of uploading to the virtual media asset library is mentioned. Thus, the specification and the claims disclose direct transfers of assets among media player devices.

Second, Apple asserts that each of the plurality of media player devices must have the media asset portability application, whereas Zapmedia contends that only or more, not all, of the devices must have the application. According to the plaintiff, claim 7 requires that the plurality include a media asset portability application; it does not refer to multiple applications or state that each asset must have an application. Instead, Zapmedia argues that a single media player device with the media asset portability application may move or copy assets to other media player devices lacking the application. In claim 8, the media asset portability application also posts assets to the virtual media asset library, but the claim language does not state that the application is required "for access by the other of the plurality of media player devices." Thus, it is possible for the media asset portability application to run on only a single device and yet permit access by other devices not running the application. Therefore, the court construes the term "the plurality of media player devices including a media asset portability application" to mean "two or more 'media player devices,' with at least one of the devices having software permitting a 'media asset' to be copied or moved."

4466

Gathering parts-related information for one or more parts within the plurality of parts which meets the customer's requirements

Defendants urge the Court to construe this term as "gathering information about parts that meet the customer's requirements from the electronically specified part information." Defendants argue this construction is necessary to define what is meant by "the plurality of parts," which refers to the parts that were defined in element (b) of claim 1 with the language "electronically specifying information identifying a plurality of parts." Defendants' construction requires multiple parts to meet the customer's requirements; the claim language requires one or more parts. Defendants construction is also susceptible to being misunderstood. Orion seems to understand the construction to mean that the information is gathered from the electronically specified part information. Defendants contend that the plurality of parts are those that were electronically specified.

The Court agrees with Orion that this phrase does not require construction. In some contexts, "the plurality of parts" or similar terms may be confusing to a lay jury. Here, the antecedent "plurality of parts" is identified in the previous step. Given the close proximity of the phrases, it is highly unlikely to be confusing.
2. The language of the radio transmitter limitation is not insolubly ambiguous

The third part of the "remote unit" disclosed in Claim 61 is "the transmission power level selection circuit." There are a number of disputes with respect to the claim language describing this component. First, there is a dispute over whether the language is too ambiguous for construction.

Claim 61 is the first disclosure of a selection circuit. Under the conventions of claim drafting, which follow the normal rules of grammar, the first time a part is mentioned, it should be preceded by the indefinite article "a," i.e., "a selection circuit." Subsequent references to that circuit should be preceded by the definite article "the" or with "said." See MPEP Section 2173.05(e). The first disclosure of a selection circuit Claim 61 uses the definite article, "the." The lack of an antecedent disclosure of "a selection circuit" potentially makes the reference to "the" selection circuit ambiguous. An ambiguity in a claim is problematic for claim construction because it could render the claim "insolubly ambiguous." When a claim is "insolubly ambiguous," a court need not construe the claim because it is indefinite. However, when, despite an ambiguity, the "meaning of the claim is discernible," the court should proceed to construe the claim in accordance with that meaning. See Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001).

The Court finds that the use of "the" instead of "a" to be an error in drafting that does not obscure the ability of the Court to discern a meaning of "the selection circuit," when the claim language is construed in light of the specification. The Court proceeds to consider the other disputes with respect to the selection circuit.

Claim 26, with the disputed terms in bold, states:

The system of claim 25, wherein the data from each of the various sensor appliances is transmitted to the server as it is created, wherein there is further included a monitor associated with the server for displaying data, the server adapted for showing image data in a step video format.

Claim 28, with the disputed terms in bold, states:

The system of claim 25, wherein the data generated by each of the sensor appliances is stored in the memory at each appliance and is transmitted to the server upon occurrence of an event within the zone of operation of each sensor.

Claim 29, with the disputed terms in bold, states:

The system of claim 25, wherein the event is created by the server.

Defendant March Networks argues that the term "the server" is indefinite, or in the alternative that it should be construed as "the initial server." E-Watch contends that the term is not indefinite and that it should be interpreted to mean "the initial network-based server."

If a claim is subject to interpretation, i.e., it is not insolubly ambiguous, then the claim term is not indefinite. See Bancorp Servs., 359 F.3d at 1371. "[T]he definiteness of claim terms depends on whether those terms can be given any reasonable meaning." Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1347 (Fed. Cir. 2005). In determining whether a claim is insolubly ambiguous, the court should construe the terms according to the general principles of claim construction. Id.

Construing a term in accordance with the principles of claim construction, however, is different than correcting terms.
because of a typographical or clerical error. The court can correct such an error only if: (1) the correction is not subject to reasonable debate based on consideration of the claim language and the specification; and (2) the prosecution history does not suggest a different interpretation of the claims. Novo Industries, L.P., 350 F.3d at 1357.

The parties agreed that Claim 25 identifies two servers. The one they have agreed to call the "initial server," is mentioned several times in Claim 25: "a plurality of sensor appliances [which are connected] to a network based server for monitoring, logging, and transmitting data to the server . . ." Part (a) of the claim then describes "a plurality surveillance sensor appliances controlled by the server . . ." And "a data signal indicating a condition in the monitored area controlled by the server, whereby the server receives and logs signal data." Part (c) of Claim 25 then states: "a network for communicating the plurality of sensor appliances with a central server."

The term "server" in Claims 26, 28, and 29 was not the result of a typographical error in leaving off the letter "s." E-Watch would not agree that "the server" in Claims 26, 28, and 29 referred to both servers described in Claim 25, pointing out that too much bandwidth would be needed for all data going to all of the initial servers to also go to the central server. Tr. p.83, ll. 3-17. The specification described the initial servers at a school campus being in use during classroom hours but being shut off after hours, when the central server could monitor all areas. '183 patent, col. 9, ll. 1-7; see also ‘183 patent; col 18, ll. 21-30.

Likewise, E-Watch would not agree that "server" in Claims 26, 28, and 29 referred to the "central server," even though it could be argued that the "central server" is the one specifically claimed in Claim 25. Tr. p. 79, ll. 24-25, p. 80, ll. 1-20.

To the extent that E-Watch argues that the failure to include "initial" before "server" was a typographical error in the patent and should be corrected, the court concludes that the proposed correction of "initial server" is subject to reasonable debate. See Novo Industries, L.P., 350 F.3d at 1357. In the end, deciding which "server" is described in Claims 26, 27, and 29 is a toss-up. Given the claim language, it is just as likely to be the "initial server" as the "central server." True, with a 50-50 chance one can pick the initial server and argue that it is not insolubly ambiguous, merely debatable. But the only "debate" is how the coin toss comes out. Therefore, the court finds that this term is insolubly ambiguous. The court is constrained to find that Claims 26, 28, and 29 are indefinite.

4469

B. What are the Disputed Issues of Claim Construction?

Intel presents one general claim construction question with respect to all of the claims of the '943 patent: Must the gate electrode be doped prior to differentially thermally growing the dielectric over the gate electrode, or can the gate electrode be doped during a later step of the process? Intel argues that the plain language of independent claims 1, 6, and 15 requires the manufacturer to dope the gate electrode prior to the differential thermal growth step. Furthermore, Intel argues that the specification and the prosecution history demonstrate the importance of doping for differential growth. TENA argues that differential growth can occur without doping, and that the claims allow for doping to occur at any time during the fabrication of an MOS transistor. Moreover, TENA argues that the specification and the prosecution history teach that doping may occur at any time and that the differential growth required by the patent does not require prior doping.

Examining independent claim 1 in light of Intel's general claim construction question, the court must construe the meaning of the phrases "forming a doped gate electrode . . .; then" in step (a), and "differentially thermally growing an oxide . . . whereby a relatively thicker layer of oxide is developed on the top and sides of the gate electrode and a relatively thinner layer of oxide is developed on the intended source and drain regions of the substrate" in step (b) (emphasis added). The court must construe the meaning of the phrases "forming a doped polysilicon gate electrode" in step (a), and "growing a dielectric layer over the gate electrode by a process controlled to develop a high differential of dielectric thickness such that the dielectric is relatively thick over the top and sides of the gate electrode and relatively thinner over the intended source/drain regions" in step (b) (emphasis added).

Examining independent claim 15 in light of Intel's general question, the court must construe the meaning of the phrases "forming a doped gate electrode . . .; then" in step (a), and "establishing an isolating oxide on the top and sides of the gate
Techniques" section of the specification describes a version of the patented process that dopes the gate electrode after electrode, which suggests that doping can occur at any time during the process. Second, TENA argues that the "Alternative patent. First, TENA asserts that the patent does not teach that doping promotes differential growth. Rather, TENA argues that those skilled in the art would understand doping only to refer to improving the electrical conductivity of the gate electrode, which suggests that doping can occur at any time during the process. Second, TENA argues that the "Alternative Techniques" section of the specification describes a version of the patented process that dopes the gate electrode after
dielectric growth. Third, TENA argues that the final paragraph of the specification, which states that “the sequence in which some steps are practiced may be altered to suit a particular application or processing environment,” indicates that doping need not occur prior to the differential thermal growth step.

Contrary to TENA’s first assertion, claim 10, at column 10, lines 7-9, and the specification, at column 3, lines 30-33, specifically state that doping increases differential dielectric growth. Therefore, even if those skilled in the art were not aware prior to the issuance of the patent that doping promotes differential growth, the patent clearly teaches that effect. In addition, as set out above in the description of the preferred embodiment, the ”Alternative Techniques” do not involve differential dielectric growth and thus do not appear relevant to the patent claims as issued. According to Dr. Chung’s declaration, the initial claims in the ’943 patent did not require differential growth and thus supported this section of the specification. However, when Mr. Manzo, the prosecuting attorney for the ’943 patent, added the differential growth limitation during the prosecution, these ”Alternative Techniques” became irrelevant. Based on the prosecution history as set out below in the discussion of TENA’s claim differentiation argument, Dr. Chung’s characterization appears to be correct.

Even if these ”Alternative Techniques” were relevant, however, the mere fact that doping can occur at any stage of the process in order to give the gate electrode its electrical conductivity does not answer the question of whether the patent claims nevertheless require doping prior to the growth of the dielectric to promote differential growth. TENA cannot use the ”Alternative Techniques” section or the generic catch-all paragraph at the end of the specification to overcome specific limitations of the claims. See Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1562 (Fed. Cir. 1991) (stating that a patentee cannot use the specification to avoid specific limitations of his claims and to interpret a claim contrary to its plain meaning).

2. Does the doctrine of claim differentiation prevent the court from construing claims 1, 6, and 15 to require doping prior to dielectric growth?

TENA admits that claim 10 requires doping prior to dielectric growth. However, TENA argues that the language of claim 10 that requires this limitation, read in connection with the prosecution history, establishes that prior doping is required only for the differential growth of claim 10. Thus, under the doctrine of claim differentiation, the court cannot construe claims 1, 6, and 15 to require doping for differential growth. TENA’s argument requires a detailed examination of the relevant prosecution history.

a. A chronology of the relevant prosecution history

1) The language of the claims as filed

When Manzo first filed the application that resulted in the ’943 patent, the patent had only two independent claims. These two claims ultimately issued as claims 1 and 6 of the ’943 patent. As initially filed, claim 1 stated in relevant part:

. . . .

(a) forming a gate electrode insulated from the substrate;

(b) forming an implant mask of a controlled width on the sides of the gate electrode;

. . . .

As initially filed, claim 6 stated in relevant part:

. . . .

(b) defining a polysilicon gate electrode over the gate insulator between the intended source/drain regions;

(c) establishing a dielectric layer over the gate electrode and the gate insulator such that the dielectric is relatively thick at least over the sides of the gate electrode and relatively thinner over the intended source/drain regions

. . . .
Neither claim 1 nor claim 6 contained the words "doped" or "then" or the phrases "differentially thermally growing" or "differential growth." However, claim 6 contained language suggesting that a differential must exist between the dielectric over the sides of the gate electrode, where it must be "relatively thick," and over the intended source/drain regions, where it must be "relatively thinner."

2) The first rejection and amendment

The Patent and Trademark Office ("PTO") examiner rejected TENA's claims as obvious in light of the combination of U.S. Patent No. 4,182,023 issued to Cohen et al. (the "Cohen patent") and U.S. Patent No. 4,234,362 issued to Riseman (the "Riseman patent"). The examiner observed that Cohen discloses a layer of oxide overhanging the gate electrode that acts as a shield to prevent the source/drain regions from being implanted next to the gate electrode. Therefore, a subsequent heat driving step would laterally diffuse the edges of the source/drain regions until they were in substantial alignment with the edges of the gate electrode.

In response to this rejection, Manzo added the word "then" after step (a) of claim 1. To explain this change, Manzo stated that the Cohen patent requires the implant mask to be formed before or simultaneously with the gate electrode. Conversely, the invention of the '943 patent forms the gate electrode and "then" forms the implant mask. Although Manzo did not add the word "then" to claim 6, it appears from his argument that the sequence of forming the gate electrode prior to forming the implant mask was important in distinguishing the Cohen patent.

3) Subsequent rejections and amendments

Manzo filed additional amendments to the two independent claims in response to two subsequent rejections that are not relevant here. However, Manzo did file two relevant new independent claims, which ultimately issued as claims 10 and 15 of the '943 patent. As initially filed, claim 10 stated in relevant part:

(a) forming a defined gate insulated from and over a substrate; then

(b) establishing an isolating oxide layer of controlled dimensions by a differential thermal growth process such that the oxide layer covers the top and sides of the gate and regions in the substrate where the source and drain will be formed, the oxide being thicker on the top and sides of the gate than above the prospective source and drain; then

As initially filed, claim 15 stated in relevant part:

[a)] forming a gate electrode insulated from the substrate; then

[b)] establishing a dielectric on the top and sides of the gate electrode and over the substrate adjacent to the gate electrode such that the dielectric on the top and sides of the gate electrode is relatively thick compared to the dielectric over the substrate;

Thus, claim 10 was the first independent claim specifically to recite "differential thermal growth." Claims 6 and 15 contained language suggesting some differential between the dielectric layer over the gate electrode and the layer over the substrate, albeit not necessarily from thermal growth.

Manzo also amended some of the dependent claims in ways that are relevant to the present discussion. In particular, he added differential thermal growth to some of the dependent claims to establish a more narrow basis for patentability. In
addition, he further added anisotropic etching to some of these dependent claims. Manzo argued that, at a minimum, the prior art never suggested using differential thermal growth in combination with anisotropic etching to make a zero overlap MOS transistor.

4) Final rejection

The examiner issued a final rejection of all of the claims in spite of these amendments. Specifically, the examiner stated that the claims were obvious in light of the combination of the Cohen patent and U.S. Patent No. 4,139,402 issued to Steinmaier et al. (the "Steinmaier patent"):

Steinmaier et al. discloses forming an insulated polysilicon gate on a substrate, growing a thermal oxide over the gate and substrate, implanting source and drain regions on either side of the gate through the thin oxide over the substrate, heat driving the source and drain, and forming contacts. The thermally grown oxide is inherently thicker on the top and sides of the polysilicon gate than on the silicon substrate…. It would be obvious to routinely optimize the process of Steinmaier et al. to obtain the advantages of the aligned, nonoverlapping gate structure of Cohen et al.

Thus, the examiner determined that even the dependent claims, some of which contained both differential thermal growth and anisotropic etching, were obvious in light of the prior art.

5) Manzo's "First Proposed Amendment"

In his "First Proposed Amendment After Final Rejection," Manzo made substantial changes to the patent claims. He amended claim 1 to state in relevant part:

…. (emphasis added)

Manzo amended claim 6 to state in relevant part:

…. (emphasis added)

Manzo amended claim 10 to state in relevant part:

…. (emphasis added)
(b) establishing an isolating oxide layer on the top and sides of said gate by thermal oxidation under ambient conditions controlled such that the oxide layer covers the top and sides of the gate and regions in the substrate where the source and drain will be formed, the oxide growing substantially thicker on the top and sides of the gate than above the prospective source and drain; then

…. (emphasis added)

Finally, Manzo amended claim 15 to state in relevant part:

…. 

[(a)] forming a gate electrode insulated from the substrate, said gate being polysilicon doped to a sheet resistance of about 20 ohms per square, said substrate being monocrystalline silicon; then 

[(b)] establishing a dielectric on the top and sides of the gate electrode and over the substrate adjacent to the gate electrode such that the dielectric on the top and sides of the gate electrode is relatively thick compared to the dielectric over the substrate, said establishing step including oxidizing in a steam atmosphere at a temperature which promotes high differential rates of growth as between the doped poly gate and the substrate;

…. (emphasis added)

When Manzo submitted these amendments, he explained in detail the reasons for the changes. In particular, he focused on the examiner's conclusion as a part of his final rejection that the Steinmaier patent inherently disclosed differential growth. Manzo argued that although some differential growth does occur between a gate electrode constructed of one material and a substrate constructed of another, as in the Steinmaier patent, this differential is very small. He argued that differential dielectric growth is more dependent upon the doping of the elements and the ambient conditions, which include the temperature and water content of the atmosphere during the dielectric growth step.

In support of his arguments, Manzo submitted an article by T.I. Kamins entitled "Oxidation of Phosphorous-Doped Low Pressure and Atmospheric Pressure CVB Polycrystalline-Silicon Films," in Volume 126 of the Journal of the Electrochemical Society: Solid State Science and Technology (May 1979) (the "Kamins article"). Manzo stated that the Kamins article demonstrates that when an undoped polysilicon gate electrode on a monocrystalline substrate is placed in a dry oxygen gas atmosphere over a temperature range of 950 [°C] to 1150 [°C], there will be 7% to 9% greater thickness of oxide on the gate electrode. However, based on the Kamins article, Manzo stated that when the ambient conditions are changed to include a steam atmosphere, a differential of 30-35% results. Moreover, Manzo stated that if the gate electrode is doped first, the Kamins article demonstrates that a differential of 300% results.

Manzo contrasted the Steinmaier patent by observing that it recited dielectric layers of "substantially equal thickness" because it involved dry oxidation without doping. He emphasized that in the Steinmaier patent, "polysilicon gate 14 is not doped at the time of oxidation" (emphasis in original). He then described the preferred embodiment of the '943 patent, stating that doping of the gate electrode to a sheet resistance of 20 ohms per square is "very substantial doping" (emphasis in original). Manzo further stated:

It will be appreciated that the polysilicon gate electrode oxide grows about 300% faster than the monocrystalline silicon [substrate] oxide. This accords with the teachings of Kamins in Table I which shows that at a temperature of 850 [°C] [C], the differential between highly doped polysilicon and slightly doped crystal silicon in a steam atmosphere is 327%.

This is an enormous difference in kind between the dry oxidation of an undoped polysilicon gate on an exposed single crystal silicon substrate, where the differential is [7%]. (emphasis in original)

Thus, Manzo distinguished the inherent differential growth between an undoped polysilicon gate electrode and a monocrystalline silicon substrate, as shown by the Kamins article and the Steinmaier patent, from the differential growth of the '943 patent.

The changes to the claims reflect Manzo's arguments that doping and ambient conditions create greater differential growth than recognized by the Steinmaier patent. To claim 1 he added "doped" and "controlling ambient conditions to promote a
high rate of oxidation on the top and sides of the doped polysilicon gate compared to the silicon substrate, whereby a relatively thicker layer of oxide is developed on the top and sides of the gate and a relatively thinner layer of oxide is developed on the intended source and drain regions of the substrate. To claim 6 he added "heavily doped" and "a process controlled to develop a high differential of dielectric thickness as between the gate and other areas." To claim 10 he added "doped to promote a high rate of differential thermal oxidation" and "thermal oxidation under ambient conditions controlled such that . . . the oxide grow[s] substantially thicker on the top and sides of the gate than above the prospective source and drain." Finally, to claim 15 he added "doped to a sheet resistance of about 20 ohms per square" and "establishing a dielectric . . . , said establishing step including oxidizing in a steam atmosphere at a temperature which promotes high differential rates of growth as between the doped poly gate and the substrate."

The examiner stated in response to these amendments that he would not consider new limitations to the claims after final rejection. Instead, he stated that Manzo would have to file a continuation application. Manzo subsequently filed a request for a File Wrapper Continuing Application (the "FWC request").

6) The FWC request

Manzo focused almost exclusively on the Steinmaier patent in his FWC request. He strenuously attempted to distinguish the Steinmaier patent from the processes claimed in the ‘943 patent based on the differential growth resulting from the doping of the gate electrode:

There is absolutely no mention that oxidation growth in the Steinmaier patent is differential in nature . . . . There is not even a clue in the Steinmaier patent that if the poly [gate electrode] layer were doped prior to the formation of the oxide layer 21, there would be an even thicker formation of oxide on the top and sides of the gate . . . . Applicants submit that there is nothing whatsoever in Steinmaier et al. alone which suggests that there is an advantage in doping the poly layer. (emphasis in original)

Manzo further argued that combining the Steinmaier and Cohen patents still failed to teach the advantage of doping the gate electrode "to promote a high rate of oxidation."

Subsequent to the submission of the FWC request, the examiner interviewed Manzo to discuss claims 1, 6, and 15 in light of the Cohen and Steinmaier patents. The examiner stated the following in his "Examiner Interview Summary Record" ("EISR"): "Mr. Manzo to submit preliminary amendment to place case in condition for allowance. Anisotropic etching limitation to be added to claims 1, [6, and 15]." At this point, independent claim 10 already had an anisotropic etching step. In response to the EISR, Manzo submitted a voluntary amendment.

7) The voluntary amendment

As part of Manzo's voluntary amendment, he added an anisotropic etching step after the differential dielectric growth step of claims 1, 6, and 15. He also removed some relevant language from each of the claims. In claim 1 Manzo removed "controlling ambient conditions to promote a high rate of oxidation on the top and sides of the doped polysilicon gate compared to the silicon substrate." In claim 6 he replaced "heavily doped" with "doped" and "establishing a dielectric layer" with "growing a dielectric layer." Finally, in claim 15 he replaced "said gate being polysilicon doped to a sheet resistance of about 20 ohms per square" with "doped gate electrode."

Manzo explained that he amended the claims to include anisotropic etching to overcome a rejection based on a U.S. Patent No. 4,400,866 issued to Yeh et al. (the "Yeh patent"). Apparently, the examiner cited the Yeh patent "to show differential oxidation for providing a gap for a source/drain implant." Manzo did not explain why he removed the additional language from the claims. He merely stated that the independent claims include features of a doped gate and differential dielectric growth.

b. Is TENA's claim differentiation argument valid?

TENA now asserts that when the examiner issued his EISR requiring the additional limitation of an anisotropic etching step, he was indicating to Manzo that the patent claims did not require "substantial" differential growth as recited by claim 10. Therefore, TENA asserts that Manzo amended claims 1, 6, and 15 to provide for lesser levels of differential growth. For
example, claim 1 only requires a "relatively thicker layer of oxide" over the gate electrode, and claims 6 and 15 require that the oxide layer is "relatively thick" over the gate electrode. However, Manzo left the language in claim 10 that requires doping of the gate electrode "to promote a high rate of differential thermal oxidation" resulting in a "substantially thicker" layer of oxide over the gate electrode. Based on these assertions, TENA argues that the doctrine of claim differentiation prevents the court from construing claims 1, 6 and 15 to require prior doping to promote "substantial" differential dielectric growth.

As a threshold matter, TENA's argument contains a number of factual weaknesses. The EISR is ambiguous and does not support clearly TENA's assertion that the examiner did not think "substantial" differential growth was important to allowing the claims. To the contrary, the court could as easily interpret the EISR as supporting the notion that "substantial" differential growth was a necessary but insufficient condition for allowance. In addition, Manzo's removal of some language from the claims does not indicate clearly that doping was not important for differential growth. Manzo did not remove the word "doped" from the first step of claims 1, 6, and 15, nor did he remove the differential language from each of these claims. In particular, claims 6 and 15 still recite that "a high differential" of growth is required.

Even assuming that TENA's assertions regarding the EISR and Manzo's amendments are factually correct, however, TENA's claim differentiation argument suffers from two fundamental errors. The doctrine of claim differentiation prohibits construing one claim to include a limitation expressed in another claim if that construction renders one of the claims "superfluous." Tandon Corporation v. United States International Trade Commission, 831 F.2d 1017, 1023-24 (Fed. Cir. 1987). The first error is that there are a number of differences between the independent claims beyond the level of differential growth that is required, such as the requirement of contact points, the use of dielectrics other than oxide, and so on. Thus, the court need not find a difference between the required levels of differential growth merely to prevent the claims from being "superfluous." See id.

Second, the court can construe the claims as providing for different levels of differential growth consistently with the notion that doping of the gate electrode must occur first. Differential growth depends both on the amount of doping and on the ambient conditions during the growth stage. Lighter doping of the gate electrode might suffice for claim 1 because that claim does not require a "high differential" of dielectric growth as do claims 6 and 15. Furthermore, claim 15 requires steam oxidation, which will further increase the differential rate of growth over that which results from merely doping the gate electrode. In other words, Manzo's amendments affected how much doping or differential growth was required by each of the claims, not whether doping must precede dielectric growth. In fact, Manzo's removal of the "ambient conditions" language from claim 1, rather than implying that "substantial" differential growth is not important, more logically underscores the importance of doping alone to create sufficient differential growth to overcome the examiner's rejections over the Steinmaier patent and the Kamins article.

3. What is the effect of adding the word "then" prior to the word "doped" in claims 1 and 15?

TENA is correct that the word "then" was added to claims 1 and 15 before the word "doped." However, it is not at all clear that this fact alone would suggest that "then" does not apply to doping. As set out above, the plain language and sequential ordering of the claims in conjunction with the word "then" suggests that doping is required prior to differential dielectric growth. Moreover, when Manzo added the doping requirement in step (a) of each claim, he continually argued to the examiner that the doping was necessary to create sufficient differential growth to overcome the Steinmaier patent. At that point, the word "then" took on greater significance than requiring that the gate electrode be formed prior to the formation of the implant mask. The word "then" took on its natural meaning that each part of the preceding step had to be completed prior to the following step. This includes the requirement that the gate electrode be "doped" prior to differential dielectric growth.

4. Do claims 16 and 17 prevent the court from construing claim 15 to require doping prior to differential growth?

TENA argues that dependent claims 16 and 17 specifically allow for doping during the implantation of the source/drain regions. Thus, TENA argues that claims 16 and 17 recognize that doping need not occur prior to the differential growth step. TENA then argues that the court cannot construe claim 15, from which claims 16 and 17 depend, more narrowly than the required scope of claims 16 and 17. In other words, the court cannot construe claim 15 to require doping of the gate electrode prior to the differential thermal growth stage when claims 16 and 17 do not require this sequence.
Assuming for the sake of argument that TENA is correct in its assertion that claims 16 and 17 allow for doping during the implantation step, it does not follow necessarily that claims 16 and 17 recognize that doping need not occur prior to the differential growth step. An alternate reading of claims 16 and 17 suggests that the gate electrode can be doped prior to and after the differential growth stage. This reading is consistent with independent claim 15's requirement that doping must occur prior to differential growth. TENA argues, again under the banner of claim differentiation, that this reading would render claims 16 and 17 superfluous. However, Dr. Chung's declaration states that a second doping can produce improved electrical conductivity. Thus, reciting the possibility of a second doping after the differential dielectric growth step does not appear to render claims 16 and 17 "superfluous."

TENA's reading of claims 16 and 17 would require the court to remove the specific limitation in independent claim 15 that doping of the gate electrode must occur prior to differential thermal growth. The court cannot use a potentially broad reading of a dependent claim to ignore a specific limitation of the independent claim from which it depends, particularly when a logical alternative reading of the dependent claim exists.

5. Does it matter if the prior art does not require doping of the gate electrode prior to differential dielectric growth?

TENA argues that no prior art requires doping of the gate electrode prior to differential dielectric growth. Even if that were true, TENA cannot now eliminate a specific claim limitation that Manzo added to overcome a rejection by the PTO. See Parks v. Fine, 773 F.2d 1577, 1579 (Fed. Cir. 1985) (stating that the insertion of a limitation to overcome an examiner's rejection is strong evidence of materiality); Kinzenbaw v. Deere & Co., 741 F.2d 383, 389 (Fed. Cir. 1984). Manzo ardently argued to the examiner that the Steinmaier patent did not teach doping the gate electrode to achieve differential growth. Moreover, Manzo never withdrew the word "doped" from step (a) of each of the claims even after he added the anisotropic etching step, and he never commented to the examiner that the sequential order of prior doping was no longer material to allowance of the claims. Given the plain meaning of the claim language, the teachings of the specification, and Manzo's arguments before the PTO, the court can only conclude that all of the claims of the '943 patent require doping of the gate electrode prior to the differential dielectric growth step.

B. "automated thermal cycler"

Applera asks the court to construe this term as "an instrument for use in a nucleic acid amplification reaction comprising multiple thermal cycles for alternately heating and cooling samples." Stratagene advocates defining the term as "an instrument that can be programmed to heat and cool a surface or vessel." I adopt Applera's definition.

To define "automated thermal cycler," I must determine how a person trained in the art would have understood the term in 1991. In doing so, I "must define the term in a manner consistent with the scientific and technical context in which it is used in the patent." See AFG Indus., Inc. v. Cardinal IG Co., 239 F.3d 1239, 1248 (Fed. Cir. 2001).

Although the specification does not define "automated thermal cycler," it uses the term in a way consistent with Applera's proposed construction. Every reference to "thermal cycler" or "thermocycler" appears to identify an instrument used for conducting nucleic acid amplification reactions comprising multiple thermal cycles.

At the Markman hearing, Applera presented the testimony of Dr. Carl Batt, who testified that persons trained in the art in 1991 would have understood "automated thermal cycler" as a specialized instrument for use in a nucleic acid amplification reaction comprising multiple thermal cycles for alternately heating or cooling samples. I credit his testimony. Based on the fact that he authored a paper describing PCR technology submitted for publication in 1991 (see Tr. 74-76), I find that he was trained in the art in 1991 and is qualified to testify on this issue. Stratagene has presented no evidence suggesting that persons trained in the art of nucleic acid amplification in 1991 would have understood this term in any other way.

I acknowledge the Federal Circuit's admonition that extrinsic evidence is less reliable than intrinsic evidence. Phillips, 415 F.3d at 1318. In Phillips, the Federal Circuit advised courts to discount expert evidence at odds with the intrinsic evidence. Id. Nonetheless, consulting extrinsic evidence is appropriate when the internal evidence is ambiguous. See Storage Tech. Corp. v. Cisco Sys., Inc., 329 F.3d 823, 832 (Fed. Cir. 2003). Dr. Batt's testimony does not contradict the internal evidence;
Stratagene's proposed construction is too broad and does not reflect the scientific and technical context of the patent. Stratagene's only support for its proposed construction is the specification's reference to "a spectrafluorometer capable of heating and cooling a surface, or vessel." (Col. 12, ins. 14-15.) The specification contrasts this to a spectrafluorometer housed independently of a thermocycler. As Stratagene itself notes in its post-hearing brief, the specification was first drafted for the method patent application. For this reason, the specification reads more broadly than the claim itself. For example, as discussed below, the specification refers to various methods of DNA amplification, including isothermal reactions. But the claimed instrument is limited to reactions comprising multiple thermal cycles. Likewise, the specification refers to various methods of detecting nucleic acid amplification, even if the claimed instrument performs only one such method. My conclusion that the amplification reaction must comprise multiple thermal cycles reinforces the proper construction of "thermal cycler." The evidence shows that a person trained in the art in 1991 would have understood "thermal cycler" or "thermocycler" in the context of amplification reactions comprising multiple thermal cycles in the way suggested by Dr. Batt.

After reviewing the claim language, the specification, and the extrinsic evidence (i.e., Dr. Batt's testimony), the only conclusion consistent with the context of this patent is that "thermal cycler" refers to "an instrument for use in a nucleic acid amplification reaction comprising multiple thermal cycles for alternately heating or cooling samples."

"thesaurus"

Claims 1, 25, 27, 28, and 31 of the '819 Patent contain the term "thesaurus." IPI contends that "thesaurus" means: "A data structure that defines semantic relatedness between words. It is typically used in information retrieval to explain search terms with other closely related words. Even if the thesaurus is not explicitly computed, the mapping performed by query expansion explicitly defines a thesaurus." Google contends that the term means "a data structure that defines semantic relatedness between words." The language in both parties' proposed constructions is taken directly from the specification. '819 Patent, col. 1:51-56. However, the parties dispute whether the construction requires the inclusion of two additional sentences from the specification that discuss how a thesaurus is generated and used.

IPI contends that the inclusion of the last two sentences in its proposed construction are important to clarify that the '819 Patent teaches a "thesaurus" both implicitly and explicitly. IPI asserts that the mapping performed by query expansion defines a "thesaurus" even when one is not explicitly computed and thus, the construction of the term should include this important aspect of a "thesaurus." Google contends that the term is explicitly defined in the specification to mean "a data structure that defines semantic relatedness between words." Google argues that neither the asserted claims nor the summary of the invention or detailed description in the specification mention "query expansion." Google further argues that IPI's proposed construction attempts to expand the reach of the claims by including a description of "how" a thesaurus are generated in the prior art, instead of defining what a thesaurus is. The Court agrees with Google that the inclusion of the additional discussion of "how" a thesaurus is generated and used is beyond the scope of the definition of the term set forth in the specification. Accordingly, the Court adopts Google's proposed construction and construes the term "thesaurus" to mean "a data structure that defines semantic relatedness between words."

c. "third data link"

Plaintiffs contend that “third data link” means “a third communications link that is either a separate link or a combination of the first and second links.” Opening Brief at 27. They point to the specification, which describes the “third data link” in two forms. First, the “third data link” can
directly connect between the peripheral management station and the jukebox. Id., Ex. 7 at 5:1-4. Second, the “third data link” can indirectly connect to the jukebox by utilizing a link between the main data server and the jukebox (the first link) and a link between peripheral management station and the main data server (the second link). Id. at 6:8-14. In this embodiment, the main data server acts as a switch for data flowing between the peripheral management station and the jukebox. Id., Ex. 7 at 3:43-46 (“the main server receives a corresponding connection call from the management station and switches this through to the corresponding ISDN line.”).

Defendants contend that plaintiffs' construction is incorrect because the specification states that the third data link must allow uninterrupted communication between the peripheral management station and the jukebox and because plaintiffs, while prosecuting the patent, distinguished prior art by arguing to the examiner that the third data link must carry different information from the first and second data link. They contend, therefore, that the third data link must allow uninterrupted communication between the peripheral management station and the jukebox. Defendants base their proposed construction on the requirement in one embodiment that the first and second data links be connected in a series, and their expert's opinion that devices connected in series provide uninterrupted communication. Resp. Brief, Ex. F at ¶ 56. Plaintiffs' expert disagrees, opining that a person with ordinary skill in the field would not understand that a serial connection requires uninterrupted communication. Reply Brief, Ex. 21 at ¶ 41. Defendants also point to the description of a preferred embodiment in the specification, which states that “the information on the multimedia box connected in each case is available directly without any additional data transmission being required.” Opening Brief, Ex. 7 at 2:62-65.

The Court need not rely on the conflicting testimony of the experts to construe this term. The claims do not limit the third data link to one allowing uninterrupted communication, and the portion of the specification cited by defendants does not require such a construction. The specification simply does not say that the communication must be “uninterrupted,” as defendants contend. Rather, the preferred embodiment cited by defendants relates to the storage of data on the management station, not whether the third data link allows uninterrupted communication. The Court also rejects defendants' contention that
the third data link must carry different information from the first and second data links. They argue that plaintiffs disclosed such a limitation to the examiner to overcome prior art. But defendants have taken this portion of the prosecution history out of context. The prosecution history reveals that plaintiffs were explaining to the examiner the function of the three different data links. They did not say that the third link—when physically comprised of the first and second links in series must carry information different than the first and second link. Resp. Brief, Ex. N. at 12-13. Indeed, such a construction makes no sense. It would prevent one of the preferred embodiments (using the first two connections in series to form the third) from falling within the scope of the claims. Such a construction would be incorrect. See MBO Lab., 474 F.3d at 1333 (“[A] claim interpretation that excludes a preferred embodiment from the scope of the claim is rarely, if ever, correct.”) (citation omitted). When the third data link is comprised of the first two links, obviously there must be overlap among them. The Court therefore construes “third data link” as “a third communications link that is either a separate link or a combination of the first and second links.”

Third party

Plaintiff sets forth a construction for the term "third party" of "a payment receiver, i.e., a party that is neither the merchant or merchant processor." Defendants, on the other hand, argue for the construction, "party other than the merchant." The main distinction between Defendants' and Plaintiff's proposed construction is that Plaintiff seeks to exclude merchant processors from the definition of "third party," whereas Defendants' position is that the "third party" can be the merchant processor itself.

The term "third party" is expressly recited in the second element of claim 10 as follows: "means for forwarding a portion of the payment to the third party to reduce the obligation." Col. 8, lines 19-20. In claim 10, the portion of the payment that would otherwise go to the merchant from the merchant processor is instead sent to a separate party that is the payment receiver, i.e., the "third party." The "third party," as this claim language indicates, is that party which receives the portion of the payment that is forwarded by the merchant processor. The payment receiver is referred to as a "third party" in claim 10 because the payment receiver is a party other than the merchant or merchant processor.

The '281 patent specification describes the environment of the invention as the purchase transaction diagramed in Figs. 1A and 1B. Both the merchant and the merchant processor are shown. The automated repayment system of the invention is shown in Fig. 1C, which illustrates an additional party (lender 60) that receives a payment from the merchant processor. Because the merchant processor is identified as a principal, it cannot also be a third party to the same transaction. The claim language finds support only in construing "third party" to be an entity that is not the merchant or the merchant processor.

Accordingly, the Court adopts Plaintiff's construction and construes the term "third party" to mean a "payment receiver, i.e., a party that is neither the merchant or the merchant processor."
A. "a third party for determining"

Term | Plaintiff's Definition | Defendants' Definition
--- | --- | ---
"a third party for determining whether the at least a portion of the received funds transfer information is authentic by using the VAN" | A party or system that performs the determining step of the claim. | A party different from the party performing the other steps of the claim, for determining.

This term appears in claim 41 of the '302 patent. The parties dispute whether the "third party" is permitted to perform any of the other steps enumerated in Claim 41. Claim 41 is a method with four steps:

41. A method for authenticating the transfer of funds from a first account associated with a first party to a second account associated with a second party . . . the method comprising:

- receiving funds transfer information from the first party, including at least information for identifying the first account of the first party, and information for identifying the second account of the second party, and a transfer amount;
- generating a variable authentication number (VAN) using at least a portion of the received funds transfer information;
- a third party for determining whether the at least a portion of the received funds transfer information is authentic by using the VAN; and
- transferring the funds from the first account of the first party to the second account of the second party if the at least a portion of the received funds transfer information and the VAN are determined to be authentic.

Both parties agree that the third party must perform the "determining" step. Plaintiff argues that the plain language of the claim does not prohibit the third party from performing any of the other three steps. As none of the other three steps recite an actor, Plaintiff argues that the language of the claim indicates that the inventor did not intend to restrict those steps to (or from) particular parties. According to Plaintiff, a third party could receive the funds transfer information and use that to generate a VAN.

Plaintiff further argues that Defendant's construction would read out a disclosed embodiment. In the "paperless/cashless transaction system," the transaction system is a terminal belonging to the payment recipient, or "second party" as recited in this claim. '302 patent, 24:5-10. The terminal receives funds transfer information from the payment originator, or "first party" in this claim, generates a VAN, and authenticates the payment originator using the VAN. '302 patent, 14:10-20. Plaintiff argues that the transaction system is the third party of Claim 41, and performs the "receiving," "generating," and "determining" steps.

Finally, Plaintiff argues that the prosecution history supports its construction. When the inventor amended Claim 41, the inventor told the examiner, "In this scheme, the payment originator is a first party, the recipient is a second party, and the system which approves or disapproves the payment is a third party. The use of a third party to authenticate a VAN and transfer of funds is recited in claim [41]." Plaintiff's Brief, Ex. D at 55. This, according to Plaintiff, shows that the third party performs the "determining" step and the "transferring" step. 1

--- Footnotes ---

1 Plaintiff inserted [sic] following "transfer of funds" to suggest the erroneous insertion of the word "of" by the inventor during prosecution of the patent. Pl. Brief at 9.

--- End Footnotes ---
Defendants argue that in the context of Claim 41, the inventor chose to specify the "third party" to differentiate the party that performs the determining step from the party performing the other steps. According to Defendant, a party, which is neither the first nor third parties, receives "funds transfer information" from the payment originator, generates a VAN, and "informs the first party's bank to transfer the funds." Def. Brief at 21. Defendants also argue that it would make no sense to have the same party that receives the funds transfer information and then generates the VAN be the party to authenticate the VAN it just created.

Defendants also rely on the prosecution history, wherein the inventor added the term "third party" by amendment. According to Defendants, "If a 'third party' is the same party performing the other steps of the claim, the recitation of a 'third party' in the claim would not have been necessary." Def. Brief at 22. Defendants also disagree with Plaintiff's reading of the office action response in which the amendment appears. Defendants argue that the sentence, "The use of a third party to authenticate a VAN and transfer and transfer of funds is recited in claim [41]," should be read to mean the third party authenticates a VAN and, thereby, authenticates a transfer of funds.

With respect to the embodiments, Defendants argue that Plaintiff's arguments are misleading. Defendants say that the "system" recited in the prosecution history is not the same "paperless/cashless transaction system" described at the end of the preferred embodiment. See '302 patent, 24:14-24. See also Pl. Br., Ex. D at 55 ("the system which approves or disapproves the payment is a third party"). Defendants attempt to refute Plaintiff's argument that Defendant's construction does not read on the paperless/cashless embodiment by arguing that Claim 41 is not intended to read upon that particular embodiment.

Plaintiff argues that it is "black letter law" that the construed claims must read on all of the preferred embodiments. Pl. Reply at 4. Here, however, is a case where the embodiments are so varied that a single claim is not expected to read upon all of them. See '302 patent, 6:12-45 (describing two authenticating parties, one of which does not and cannot generate a VAN: authenticating transfer information at the originator's bank with a VAN; authenticating the recipient at the recipient's bank without using a VAN). See also id at 24:5-24 (describing a system where the recipient is never authenticated).

Defendant's argument is not without force. A construction that allows the party that generates a VAN to turn around and authenticate that very VAN would be nonsensical. As urged at oral argument, however, the same party might authenticate the VAN it had previously created when the payee presents the check at the issuing financial institution for payment. Inartfully drafted though the claim may be, using Defendant's proposed construction would require four parties, which is not mandated by the claim language, specification, or prosecution history. If the third party is not permitted to perform any of the other steps, then it becomes clear that some additional party or parties must perform the receiving and generating steps.

The Court rejects this view of the claim and construes this limitation to mean, "a party, other than the first or second parties, that performs the determining step of the claim."

Microsoft argues that plaintiff's proposed construction of thread as an "executable entity within a process," Pl Br (Doc # 331) at 19, fails to be sufficiently specific. Microsoft cites plaintiff's discussion of the definition of thread in a reply to the patent office concerning newly cited references. In this discussion, plaintiff stated:

The phrase "sequence of instructions executed by a processor" could not possibly have constituted an all-inclusive "definition" of the term "thread" because the phrase is so broad as to refer to many distinct and different things, such as (1) a program, (2) a routine, (3) a subroutine, (4) a function, (5) a job, (6) a task, (7) a thread, (8) an algorithm, (9) a process, or (10) a procedure, each of which consists of or comprises or refers to a "sequence of instructions executed by a processor."

11/18/93 Affidavit at P11, cited in Def Exh I (Doc # 311, Exh # 16).

Microsoft, however, fails to note plaintiff's definition of thread stated within the same discussion.
"To simplify in order to provide some sorely needed clarity, a "process" is the instance of running a program, whereas in current terminology a "thread" is the execution of a sequence of instructions constituting one of the possibly many procedures, functions or subroutines within the program. That is, in current terminology, a "thread" is merely one of the many resources of a "process."

Id at P14.

The parties dispute whether a thread, or an execution of a sequence of instructions within a program, is required to have its own private memory stack. Because a thread is interrupted during multithreading, the thread's context must be saved and retrievable when the thread is ready to resume execution. The question is whether a thread, by definition, saves its context in a private memory stack or whether multiple threads may share a stack in which their contexts is saved. Microsoft, citing a variety of technical treatises and plaintiff's own reference to these treatises in communications with the patent office, argues that a thread is required to have its own private memory stack. Plaintiff disputes this requirement.

Plaintiff's patents explicitly refer to the compiler and editor in the preferred embodiment as threads: "In this illustrative example, one of the program threads is an editor and another thread is a code processing routing in the form of a compiler. '603:2:3-5. The editor and compiler are not, however, assigned their own private memory stack in which to save their context.

The court is, therefore, faced with a conflict between two sources of evidence of the meaning of claim terms. Dictionaries and technical treatises are generally considered sources of extrinsic evidence. See e.g., Vitronics Corp v Conceptor, Inc, 90 F3d 1576, 1583 (Fed Cir 1996). Plaintiff, however, repeatedly quoted dictionary and treatise definitions of thread to the patent office in an attempt to distinguish his invention from prior art, bringing these definitions within the realm of intrinsic evidence.

Plaintiff engaged in a lengthy discussion of the use of "thread" in his patent applications in a 1993 response to the patent office regarding newly cited references. 11/18/93 Affidavit, cited in Def Exh I (Doc # 311, Exh # 16). In particular, plaintiff attempted to distinguish the use of the term "process" in the Dufond reference from plaintiff's use of the term "thread." As noted above, plaintiff argued that while a process was, essentially, a program, a thread was a sequence of instructions within that program. See id at PP12-15. In support of this distinction, plaintiff cited several industry definitions, some of which included the requirement that a thread have a private memory stack. Plaintiff, for example, cited:

To work successfully with multitasking, you need to understand clearly the difference between a process and a thread. A process is simply the code, data, and other resources of a program memory, such as the open files, allocated memory, and so on. MS OS/2 considers every program that it loads to be a process. A thread, which is everything else required to execute the program, consists of a stack, the state of CPU registers, and an entry in the execution list of the system scheduler.

It is important to note, however, that plaintiff cited such definitions in an attempt to distinguish between a process and a thread. Microsoft cites other technical treatises in support of its position that a thread must have its own private memory stack. Microsoft cites, for example, one of its programmer reference guides, which provides:

Threads are the basic entity to which the operating system allocates CPU time. Each thread maintains a set of structures for saving its context while waiting to be scheduled for processing time. The context includes the thread's set of machine registers, the kernel stack, a thread environment block, and a user stack in the address space of the thread's process.

Although the patents provide that when the compiler of the preferred embodiment is interrupted the stack pointer and other CPU registers are saved by the interrupt service routine, the compiler is not allotted a private memory stack. See '603:4:25-30. Microsoft's proposed construction, therefore, runs up against another principle of claim construction, which, in Microsoft's preferred position, was argued with vigor, namely: "[A] claim interpretation that would exclude the inventor's device is rarely the correct interpretation." Modine Mfg Co v United States Int'l Trade Comm'n, 75 F3d 1545, 1550 (Fed Cir 1996). Further:
A patent claim should be construed to encompass at least one disclosed embodiment in the written description portion of the patent specification. * * * A claim construction that does not encompass a disclosed embodiment is thus rarely, if ever, correct and would require highly persuasive evidentiary support.

Johns Hopkins Univ v Cellpro, Inc, 152 F3d 1342, 1355 (Fed Cir 1998), citations and internal quotations omitted.

It is also worthy of note that at the time of plaintiff's patent applications, the idea of a "thread" was a new one:

Until the latter half of the 1980s, most operating systems allowed a process to have only one thread of execution. (In fact, most operating systems used the term process to refer to an executable entity. Thread is a relatively new term.).

Helen Custer, Inside Windows NT, Microsoft Press, 1993 at 93.

Clearly, plaintiff intended to distinguish a thread from a process. Further, when a thread is interrupted, its context must be saved in some manner and be retrievable when it begins to operate. Yet in light of plaintiff's general definition given to the patent office and in light of the patents' preferred embodiment, the court cannot conclude that a thread must have its own private memory stack. As a result, the court determines that the proper construction of thread is that which plaintiff provided to the patent office in November of 1993. Accordingly, a thread is the execution of a sequence of instructions constituting one of the possibly many procedures, functions or subroutines within the program. Further, when interrupted, a thread's context must be saved and retrievable when a thread is reassigned control of the CPU and resumes execution. If a determination of whether a thread is required to have a private memory stack becomes central to determining infringement, the court may be open to revisiting its construction of this claim term.

D. Three Dimensional Position

The parties present nearly identical definitions for "three dimensional position." Scanner asserts that the term refers to "the X, Y and Z values for the top of at least one ball of a ball grid array." (Scanner Post-Hr. Br. at 13). ICOS asserts the following definition: "the determination of the actual X, Y and Z coordinate positions of the balls." (ICOS Post-Hr. Br. at 23). Because these definitions are similar, it is apparent that the parties do not genuinely dispute the definition of the term as it applies to the patents at issue. The Court adopts the definition set forth by Scanner. Accordingly, for the purposes of this case, "three dimensional position" is defined as "the X, Y and Z values for the top of at least one ball of a ball grid array."

3. Threshold.

The court construes the term "threshold" to mean "the value of current, voltage or other quantity at which something happens." The court has considered both of the parties' arguments on this point and has concluded that this definition is appropriate in the context of the claims. In particular, this construction gives meaning to the term threshold as it is used in claim limitations requiring certain events to occur if a value is at or above a threshold, and it also provides an appropriate meaning for use in limitations which may require something else to occur if the value is below the threshold. See '722 Patent, claim 14 (claiming "an inverter circuit as claimed in claim 12, wherein if said feedback signal is below said predetermined threshold . . . ").

20. "threshold error-detection-and-correction time"
"Threshold error-detection-and-correction time" appears in claim 5 of the 229 patent and claims 14 and 26 of the 148 patent. The specification never explicitly defines this term and only uses the term when paraphrasing the claims. 229 patent 23:4-9, 24:13-15, 24:50-53, 24:61-25:15. Both MoSys and TSMC contend that this term is indefinite; MoSys also asserts that to the extent the term can be construed, it means "the point at which the error correction scheme of the prior art can no longer overcome errors." Jt Cl Const, Ex B at 26; TSMC Br at 39-42. UniRAM proposes a highly-similar construction that defines the term as "the time past which the error correction scheme can no longer consistently and accurately correct errors." Jt Cl Const, Ex B at 26.

UniRAM's proposed construction is problematic because the "consistently and accurately" limitation is never mentioned in the specification. More importantly, UniRAM's construction seems indefinite because it adds a meaningless limitation to the claims. For example, after replacing "threshold error-detection-and-correction time" with UniRAM's proposed construction, each of the claims would read: "an error code checking [ECC] and correction means *** for checking and correcting substantially all memory read errors within the time past which the error correction scheme can no longer consistently and accurately correct errors." The phrases "checking and correcting substantially all memory read errors" and "consistently and accurately correct errors" both refer to an ECC's effectiveness. Accordingly, when used together, either the former or the latter phrase is superfluous. Because a limitation cannot be construed out of the claims, UniRAM's proposed construction cannot be correct. Texas Instruments v United States ITC, 988 F2d 1165, 1171 (Fed Cir 1993).

MoSys's proposed construction suffers from the same indefiniteness problem. The specification notes that "[t]he ECC circuit [used in this invention] is well known to the art, so we do not discuss it in further details." 229 patent at 11:61-63. Accordingly, the terms "an error code checking [ECC] and correction means *** for checking and correcting substantially all memory read errors" and "the point at which the error correction scheme of the prior art can no longer overcome errors" both rely directly on the effectiveness of prior art ECCs.

But simply because UniRAM's and MoSys's proposed constructions are indefinite does not necessarily mean that the claim is "insolubly ambiguous" or that "no narrowing construction can properly be adopted." Honeywell Int'l, Inc. v. ITC, 341 F.3d 1332, 1338-39 (Fed Cir 2003) (quoting Exxon Research, 265 F3d at 1375). Rather, UniRAM's expert, Carl Sechen, notes that "threshold error-detection-and-correction time" likely relates to a memory cell's refresh time, which is the time period since data was last fully written to the memory cell. UniRAM Br, Ex 3 PP 190-93. By improving the capability of a memory cell to correct errors, an ECC circuit allows a memory cell to have a longer refresh time, Tecc, as compared to the refresh time if there were no ECC, Tmin:

When a memory device is equipped with an ECC circuit, it will correct most single-bit errors. As a result, the refresh time of the memory device is no longer dependent on the worst bit in the memory. Instead the device will *** function until the errors are more than what the ECC mechanism can correct. The refresh time (Tecc) is therefore higher than Tmin as shown in FIG. 20(a).

'229 patent at 25:9-14.

Accordingly, the specification supports modifying MoSys's construction so that "threshold error-detection-and-correction time" means the "maximum refresh time beyond which the ECC and correction means can no longer overcome errors." Because this definition imports the concept of a refresh time, constructing the term this way does not render it superfluous as used in the claims.

The term "threshold voltage" appears in claim 1 of the 229 patent and claims 1 and 22 of the 148 patent. MoSys and TSMC contend that threshold voltage should be defined in terms of a specified current that operates under normal conditions. Jt Cl Const, Ex B at 27. UniRAM instead defines threshold voltage as the critical gate electrode to source electrode voltage that turns on the transistor. Id.

Contrary to MoSys's and TSMC's proposed construction, the specification never discusses how threshold voltage depends...
on current flow or operating conditions. But the specification does discuss "[t]he threshold voltage of those depletion mode transistors" in the context of activating those transistors with gate select and drain select signals. 229 patent at 16:57-17:34. Because this intrinsic evidence is more consistent with UniRAM's construction, the court defines threshold voltage is "the critical gate electrode to source electrode voltage that determines whether a field effect transistor is on or off."

This Court therefore turns to the meaning of the '849 Patent's claim 1, and particularly to the portion emphasized in the earlier quotation of that claim, to determine whether the elements of that claim do or do not call for disclosure of Calabrese's admittedly preferred embodiment of the circuits referred to there. It is at that point that Calabrese is forced to resort to the least tenable position of all--one in which he urges an extraordinarily strained and insupportable meaning for the word "through" that appears at '849 Patent col. 2, lines 31 and 44.

As the Special Master's Report at 4-5 reflects, Calabrese's position is that the '849 Patent's reference to data being transmitted "through" the data relays should be read in the same sense in which, though a car is accurately said to pass "through" an intersection, a different meaning is intended by the colloquialism that refers to the car's passing "through" the controlling traffic light--in the latter case, what is meant is simply going past the light. That purported analogy is of course wholly nonanalogous. Here, after all, we are dealing with electric current, which by definition passes "through" the circuitry in the common-sense usage of that term, as contrasted with the wholly figurative concept of passing "through" a traffic light.

As the Special Master's Report accurately finds, the data relays of the '849 Patent are connected by circuitry, and at the time that Calabrese filed the application the best mode that Calabrese knew of for accomplishing that connection comprised the input and relaying circuits that were shown (and acknowledged to be the preferred embodiment) in the application that later matured into the '451 Patent. In advertising to the transmittal of data in '849 Patent col. 2, lines 31-32 and 43-44, Calabrese expressly said that was done sequentially "through" each of the data relays. And it is no accident that in the contemporaneous application that ultimately produced the '451 Patent, the word "through" was used in the identical sense (its col. 2, lines 15-21 referred to the address being received by the data relay and then sent "to" the next data relay "through" the relaying circuit, and at col. 2, lines 22-27 data is said to be transmitted "through" the input circuit where it is reinforced and directed "through" the relaying and input circuits of data relays between the addressed relay and the host (normally a computer).

Calabrese cannot successfully escape his own original usage and its truly unambiguous plain meaning through his attempted post-hoc disclaimer, when he now regards such a new rationalization as redounding to his advantage. This is not at all an instance of the weighing or discrediting of evidence in violation of the basic Rule 56 standards. On the contrary, Calabrese's own contemporaneous conduct in applying for what became the '451 Patent, with its express disclosure of a preferred embodiment, establishes conclusively that--at the very time that he filed the application that ultimately ripened into the '849 Patent--he considered the reinforcing circuitry to be the best mode of connecting the data relays to the bus in order to improve remote data acquisition. That reinforcing circuitry is utilized in connection with the identical data relay system that Calabrese disclosed in the '849 Patent, and it is therefore also the best mode for transmitting data and addresses through each data relay for the system at issue.

In sum, it is Calabrese's own conduct that has driven the nails into the best-mode coffin in which the '849 Patent must be buried. Calabrese's attempts to climb out of that coffin (in the best Bela Lugosi tradition) via his current unpersuasive attempt to give the patent's language a different meaning cannot succeed in the bright sunlight of analysis (or even, to pursue the Lugosi metaphor, at midnight).

The case was remanded to the district court. Judge Shadur requested that the case be reassigned. The case was reassigned by lot to this court.
DISCUSSION

Summary Judgment Motions as to Best Mode

Summary Judgment Motions as to Infringement

A patent infringement analysis involves two steps. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1581 (Fed. Cir. 1996). The first step is the proper construction of the claim, i.e., determining the meaning of the claim language. Id. at 1581-1582. This step is decided as a matter of law. Id. at 1582. The second step is the comparison of the accused device to the properly construed claim. Id. The second step is a factual determination. Spectrum Intern., Inc. v. Sterilite Corp., 164 F.3d 1372, 1378 (Fed. Cir. 1998).

The court will begin its analysis with the first step, the construction of the claim. In order to ascertain the meaning of a claim, the court should consider three sources: the claims, the specification, and the prosecution history. Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995). The court may also consider extrinsic evidence in aiding the court's understanding of the patent, although extrinsic evidence may not be used to vary or contradict the terms of the claims. Markman at 981. Extrinsic evidence consists of all evidence external to the patent and the patent's prosecution history. Markman at 980. Extrinsic evidence includes dictionaries, expert testimony, and inventor testimony. Markman at 980.

The parties dispute the meaning of the word "through" as used in Claim One. The word "through" appears twice in Claim One. In each usage the word "through" is used to indicate the movement of "data" in relation to "data relays":

"data line means . . . for transmitting data sequentially through each of said plurality of data relays to said host device,

. . .

"means for serializing the parallel data group selected by said sequencing means and for transmitting said selected serialized data group to said data line means whereby the serialized data will be sequentially transmitted through the data relays intermediate the addressed data relay and said host device to said host device."

(emphasis supplied)

Calabrese argues that "through" as used in the claim means to "go past," as in "going through a stop light." Square D argues that "through" means "to enter into and to exit."

The court has carefully examined the claims, the specification, and the prosecution history for other indications of what the word "through" should be interpreted to mean. The court finds that neither the claims, the specification, or the prosecution history provide any clear indication as to the exact meaning of the word as used in the claims. The court further finds that "through" is a common, everyday word and not a technical term. In light of these circumstances the court will turn to extrinsic evidence, specifically a dictionary, in order to determine the word's definition. See Markman, 52 F.3d at 980 (court may use dictionary as extrinsic evidence).

Both the plaintiff's and the defendant's suggested meanings are supported by dictionary definitions. Merriam-Webster's Collegiate Dictionary, Tenth Edition (1996) defines "through" as follows: "used as a function word to indicate movement into at one side or point and out at another and esp. the opposite side of (drove a nail through the board)." This definition is essentially the same as the defendant's suggested meaning, "to enter into and to exit."

The same edition of the same dictionary also defines "through" as "without stopping for; past (drove through a red light)." This definition is essentially the same as the plaintiff's suggested meaning, "to go past."

The question then is whether the word "through" as used in "data transmitted through data relays" is more closely analogous
The court finds that to pick one or the other would be to split linguistic hairs, as the two meanings are so similar as to be virtually identical. The classification of the Merriam-Webster definitions reflects how close the two meanings are. In the Merriam-Webster dictionary the two definitions are listed as subsenses 1 and 4 of subsense 1a. Subsense 1a is itself one of two subsenses of definition 1. The court will therefore define the word "through" as used in the claim as follows: "to go past, or to enter into and to exit."

The court has now resolved the one disputed issue of claim construction, therefore completing the first step of the Markman analysis.

III. RELEVANT LANGUAGE OF THE PATENT-IN-SUIT

The parties agree that what remains at issue before the Court in this Markman process is the correct interpretation of the portion "throughhole passing through the dielectric layer" as used in the claims 1 and 15 of the '555 Patent. Specifically, the '555 Patent claims the following:

1. A deactivatable resonance label, comprising: a dielectric layer having first and second opposed faces;

   a first conducting layer on the first face of the dielectric layer, the first conducting layer being shaped to form an inductor and a first capacitor plate;

   a second conducting layer on the second face of the dielectric layer, the second conducting layer being shaped to form a second capacitor plate, the first and second conducting layers being at least partially superposed, said first and second conducting layers and said dielectric layer forming together and oscillating circuit; and

   shorting means for enabling creation of a short-circuit between the first and second conducting layers when it is desired to deactivate the oscillating circuit, the shorting means being comprised of at least one throughhole passing through the dielectric layer to provide a short circuit path between the first and second conducting layers.

15. A method for fabricating a deactivatable resonance label, said method comprising steps of:

   providing a planar dielectric layer having first and second faces . . . . and

   forming shorting means in the dielectric layer for enabling creation of a short-circuit between the first and second conducting layers when it is desired to activate the oscillating circuit, the shorting means being comprised of at least one throughhole passing through the dielectric layer to provide a short circuit path between the first and second conducting layers.

'555 Patent, col. 7, ln. 33-52; col. 8, ln. 33-34, 47-55 (emphasis added).

IV. CLAIM CONSTRUCTION

The scope of protection provided by a patent is determined by the language of the claims and the brief sentences or paragraphs which "particularly point[] out and distinctly claim[] the subject matter which the applicant regards as his invention." 35 U.S.C. § 112. The first step in determining the infringement of a patent is an interpretation of the scope and meaning of the patent claims alleged to be infringed, and construction of those patent claims is a matter of law to be decided by the Court. See Markman, 52 F.3d at 979. In order to aid the Court in this determination, the parties submitted written briefs and made presentations at a Markman hearing. The parties have presented competing descriptions of the proper construction of the patent claims.
A. Summary of Positions on Claim Interpretation

1. Checkpoint

- 4734 -
Plaintiff Checkpoint argues that the proper interpretation of the claimed dispute of the '555 Patent is that the "throughhole" is only properly interpreted as its name suggests. That is, the throughhole is a hole (air-filled space, free of dielectric layer material) through one of the energy conducting layers of the resonance labels, which makes the resonance label operate more efficiently and effectively.

Furthermore, Checkpoint argues that the throughhole is a structural implementation that uniquely improves and advances the design of the resonance label, and sets it apart from prior versions of the label.

It is Checkpoint's position that "the 'throughhole' provides a short circuit path between the conducting layers." Checkpoint disagrees with Defendants' definition, infra, of the throughhole as being limited by and distinguishable from Defendants' use even if there is a difference in or there is uniformity of the thickness of the conducting layers. Simply put, Checkpoint argues that the meaning of "throughhole" puts no limitation on where the hole can be put on a conventional label, and that the "throughhole" works regardless of what the thickness of the label is like where the hole is placed. To that end, Checkpoint argues that the patentee did not and would not have disavowed having the hole in an area of reduced thickness, as Defendants suggest.

As a matter of law, Checkpoint states that the Federal Circuit's recent ruling in Phillips v. AWH Corp. controls the proper construction of a patent's claims in support of Checkpoint's proposed meaning of "throughhole". 415 F.3d, 1303, 1312 (Fed. Cir. 2005). Specifically, Checkpoint argues that the court in Phillips has stated that an inventor's claims should be used to determine what he regards as his invention when there is an ambiguous claim term, but should not necessarily limit the scope of the patent's protection. Id. at 1312, 1323.

2. All-Tag

Defendant All-Tag relies on a different reading of the Phillips court's pronouncement that the specification "is always highly relevant to the claim construction analysis . . . [and] [u]sually, it is dispositive; it is the single best guide to the meaning of a disputed term." Id.

All-Tag argues that claim construction turns on the meaning of the word "throughhole" and the word "layer" as used intrinsically, in the context of the entire claim. All-Tag's position, based on its reading of Phillips is that because "throughhole" and "layer" are not ordinary terms of art, the specification and prosecution history, rather than the inventor's claims, should be used to construe the terms for purposes of determining the validity of the '555 Patent in the Defendant's favor. According to All-Tag, Checkpoint's construction of the "throughhole" as a "space" cannot survive the specification and prosecution history analysis set forth and required by Phillips.

Furthermore, All-Tag argues that its use -- selective reducing of the thickness of a layer in the resonance label -- is specifically critical of and inapposite to the asserted design of the '555 Patent. Thus, All-Tag's position is that its product and design do not infringe upon the '555 Patent.

3. Sensormatic

Defendant Sensormatic's argument parallels Defendant All-Tag's in that Sensormatic states that the term "throughhole" must be construed according to specification and prosecution history in accordance with legal principles of claim construction. Specifically, Sensormatic argues that the term "throughhole" did not appear in the original application for the '555 Patent. Rather, "throughhole" was added to the application for the express purpose of distinguishing the "hole through the layers design" (Checkpoint's alleged use) from the "reduced thickness in layers design" (All-Tag & Sensormatic's alleged use).

B. Interpretation of the Terms of the '555 Patent

There is no dispute that both Plaintiff's and Defendants' proposed labels are workable, functional structures. Therefore, the language of the claims and the brief sentences or paragraphs must "particularly point[] out and distinctly claim[] the subject matter which the applicant regards as his invention." 35 U.S.C. § 112. Furthermore, in order for the Court to accept Defendants' construction of "throughhole" such that the functional "hole through the layers design" is distinguishable from the functional "reduced thickness in layers design", the record must reflect the patentee's clear intent to disavow placement of the hole in some area of reduced, or otherwise non-uniform, thickness. See Katz, 63 F. Supp. 2d at 591 (citing York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1572 (Fed. Cir. 1996)) ("[u]less altering claim language to
escape an examiner rejection, a patent applicant only limits claims during prosecution by clearly disavowing claim coverage, that is, by making a statement that concedes or disclaims coverage of the claims at issue based on a piece of prior art.

Checkpoint's proposed construction of "throughhole" is consistent with the context of the patent claims. Claims 1 and 15 describe a "throughhole passing through the dielectric layer to provide a short circuit path between the first and second conducting layers". (col. 7, ln. 49-52; col. 8, ln. 51-55.) Defendants' proffered construction describes "an opening extending through the entire, predetermined, uniform thickness of the dielectric layer". (Def. Sensormatic Electronics Corp.'s Initial Claim Construction Brief 24; All-Tag Defs.' Brief on Claim Construction at 24.) However, this construction imposes a limitation that is inconsistent with the language evidenced by the patent claims.

The prosecution history supports the inventor's use of the term "throughhole" inasmuch as the term "throughhole" was used in place of "hole or cut" without any additional qualification or disavowal of a specific thickness of the layer through which the hole or cut is made. Furthermore, the language in the '555 Patent specification that describes the absence of "[e]ffects such as fluctuations in thickness" (col. 2, ln. 45-47) is properly understood in the full context of the claim as the manner in which deactivation occurs, not a departure from the prior art regarding fluctuations in thickness of the dielectric layer. ('555 Patent, fig. 3; see col. 3, ln. 48-49 and col. 6, ln. 45 (illustrating an embodiment of the invention where the dielectric layer is reduced in thickness)). Rather, it is the continuous hole that is the deviation from prior art and therefore the inventor's invention. (col. 4, ln. 11-13.)

V. CONCLUSION

Having found no clear intent on the part of the patentee to require uniform thickness in the material penetrated, this Court concludes that the term "throughhole" and layer as used in the claim "throughhole passing through the dielectric layer" means "a space between the first and second conducting layers free of dielectric layer material". Furthermore, "throughhole" is not an ambiguous term. This term is construed in accordance with the claim and specification, and dictated by its ordinary and customary meaning. The Court agrees with Checkpoint's proposed construction because it is supported by the consistent use of the word "through" in the claim language ("one through hole passing through the dielectric layer"), in the context of the entirety of the invention, and construed in accordance with the specification. See Markman, 52 F.3d at 979 (stating that claims must be read in view of the specification of which they are a part.). Claim 1 only qualifies the term "throughhole" as "passing through the dielectric layer," and does not include language limiting a throughhole to an area of uniform thickness in the dielectric layer. Therefore, the construction of "throughhole passing through the dielectric layer" as "a space between the first and second conducting layers free of dielectric layer material" is proper as evidenced by the patent's claim, the specification, and the prosecution history. An appropriate Order follows.

AMENDED ORDER

AND NOW, this day of February, 2007, IT IS HEREBY ORDERED AND DECREED that the Court's January 24, 2007 Order (Doc. 213) is AMENDED as set forth herein and as set forth in the accompanying memorandum.

Upon consideration of the briefs and materials submitted by the parties, and after a Markman hearing on patent claim construction, it is hereby ORDERED that the disputed term "throughhole" in the claims of United States Patent No. 4,876,555 (the '555 patent) shall be construed to have the definition herein assigned to it. The Court concludes that "throughhole" means "a space between the first and second conducting layers free of dielectric layer material".

4483

2. Throughput maximizing unit

The plaintiff proposes that the term "throughput maximizing unit" is "an element of the controller that processes memory requests in response to scheduling constraints of the synchronous DRAM." The defendants contend that the term "throughput maximizing unit" is a means-plus-function limitation. After considering the arguments of counsel, the court concludes that the term "throughput maximizing unit" is not a means-plus-function limitation. Accordingly, the court construes "throughput maximizing unit" to mean "an element of the controller that processes memory requests in response to scheduling constraints of the synchronous DRAM, which maximizes throughput."
1. Throughput maximizing unit for processing said memory requests to the synchronous DRAM in response to scheduling which maximizes the use of data slots by the synchronous DRAM

The court first considers whether § 112 P 6 applies. The plaintiff asserts that it does not and that the phrase "throughput maximizing unit for processing said memory requests . . ." means "an element of the controller that processes memory requests in response to scheduling constraints of the synchronous DRAM which maximizes the use of data slots." In their response brief, the defendants contend that "maximizing throughput of said memory requests . . ." is a means-plus-function limitation. The defendants argue that "claims 1 and 3 fail to recite any structure for processing memory requests to maximize the use of data slots, and claims 11, 13, and 20 fail to recite any acts prescribing how to maximize the use of data slots." Defendants' Response Brief at 71. The absence of the word "means" raises a presumption that § 112, P 6 does not apply.

The court concludes that "throughput maximizing unit for processing said memory requests . . ." is not a means-plus-function limitation. The court therefore adopts the plaintiff's construction and construes "throughput maximizing unit for processing said memory requests" as an "element of the controller that processes memory requests in response to scheduling constraints of the synchronous DRAM which maximizes the use of data slots."

8. "Thumbnail visual image": "A miniature image of a web page." The parties agree that a thumbnail image is a "miniature" image, and this construction is consistent with Figures 1 and 2 of the specification. The court finds no occasion to limit the term, as defendants suggest, to further require that the miniature image contain the "complete visual contents" of the web page. In addition, the provisional application (to which the '904 patent claims priority) included images comprising only a portion of the web page. (D.I. 386, ex. 3 at JA277, ex. 4 at JA285 1)

1 Plaintiff did not cite to the original provisional application, which does not appear to be of record. In their responsive papers, defendants assert that the provisional application does not support the '904 patent, and note that the images in the provisional application were omitted from the '904 specification in any event. (D.I. 379 at 21) Defendants do not specifically dispute that the images in the provisional were less than complete web pages. (Id.)

We begin with the construction of the claim term "tile," which the district court interpreted to exclude a single row of pixels on the basis of the language in the specification referring to "four corners" and the word's plain and ordinary meaning. Slip. op. at 5-6. On appeal, LizardTech asserts that the district court erred in its claim construction by 1) misinterpreting the crucial portion of the specification relating to the definition of a tile and 2) improperly applying the ordinary meaning of the word tile from the inapposite realms of roofs and bathroom floors to the arena of complex computer algorithms. For its part, ERM submits that the district court properly rejected LizardTech's construction of the term that embraced a single row of pixels as unsupported by the specification and contrary to the ordinary meaning of the word "tile." We agree with LizardTech, for our analysis of the specification and the claim language, viewed in the context of the invention as a whole and through the lens of one skilled in the relevant art, reveals that the claim term "tile" does not exclude a single row of pixels.

The portion of the specification relating to the definition of a tile includes the disclosure that "the four corners of a tile are given by" the following equations:

\[
t_{00,ij} = iW[t] \\
t_{01,ij} = \min((i + 1)W[t - 1], W[i - 1])
\]
\[ t[10,ij] = jH[t] \]
\[ t[11,ij] = \min((j + 1)H[t - 1], H[i - 1]). \]

‘835 patent at col. 6, ll. 35-39. In the foregoing set of equations, the first equation defines the left boundary of the tile; the second defines the right boundary; the third defines the upper boundary; and the fourth defines the bottom boundary. LizardTech asserts, and ERM admits, that the equations permit a solution in which the top and bottom boundary have identical values, such that the equations would define a single row of pixels. Accordingly, LizardTech submits that far from precluding a construction of the claim term tile as encompassing a single row of pixels, the specification, as viewed by one skilled in the art, is fully consistent with tiles of varying heights, including a single row.

--- Footnotes ---

3 LizardTech supports this argument using testimony from its expert, Dr. Stanley Osher, who analyzed the meaning of the four equations and concluded that "one of ordinary skill in the art reading the '835 Patent would recognize that the '835 Patent does not exclude a row of input image data as [a] possible tile shape, but rather clearly supports such a tile shape. DWT processing of such tiles in accordance with the '835 Patent is well within the knowledge and capability of persons of ordinary skill in the art."

ERM responds to this argument by contending that an interpretation of a tile as including a single row, with only two unique coordinates, would conflict with the specification's description of "the four corners of a tile." 835 patent at col. 6, ll. 35. Simply put, a "corner" is defined as "the meeting place of two converging lines," while the solutions to the equations for a single row tile are the two end-points of the row, and thus not "corners" at all. Webster's Ninth New Collegiate Dictionary (1988). In other words, ERM argues that the specification's allusion to the "four corners" of a tile requires that the tiles defined therein contain four distinct coordinates with four distinct boundaries. We disagree.

The reading of the specification urged by ERM and adopted by the district court is at odds with a contextual reading of the specification by one skilled in the art that would account for both the significance of the equations and the purpose of the disclosed invention. We think the district court's reliance on the specification's use of a single word--"corner"--impermissibly infused the particular form or shape of a tile with an importance that the equations belie. See Seal-Flex, Inc. v. Athletic Track & Court Constr., 172 F.3d 836, 844-45, 50 U.S.P.Q.2D (BNA) 1225, 1230 (Fed. Cir. 1999) (rejecting an argument that attempted to construe a claim on the basis of a single passage without regard to the context of the rest of the specification or claimed invention). There is no dispute that the equations that immediately follow the specification's reference to the "four corners" of a tile permit a solution in which a tile comprises a single row of pixels. Further, in the context of the claimed invention, the definition of the term "tile" is pertinent to a "tiling" technique for dividing a large image into subparts that form the entire image when superposed. In addition, the superposition of tiles may form the entire image irrespective of whether they contain one, two, or more rows of pixels. ‘835 patent at col. 11, ll. 41-43. The exclusion of one row of pixels from the definition of the term "tile," absent a demonstration that image subparts with such a shape modify the nature of the claimed invention, improperly elevates the technical meaning of a single word ("corner") used in the specification over the substance of the equations defining the tile and the purpose of the invention.

--- Footnotes ---

4 Because we conclude that the specification supports LizardTech's construction of the term "tile" to include rows of a single pixel, we reject ERM's argument that such a construction would violate the written description requirement of 35 U.S.C. § 112. Cf. Gentry Gallery, inc. v. Berkline Corp., 134 F.3d 1473, 1476, 45 U.S.P.Q.2D (BNA) 1498, 1500-01 (Fed. Cir. 1998).

--- End Footnotes ---

Finally, we part company with the conclusion of the district court, echoed by ERM, that permitting the term "tile" to encompass a single row of pixels traduces its plain and ordinary meaning. In support of this proposition, ERM points out
that we have often relied on dictionary definitions in construing words in patent claims, and in this instance, the dictionary definition of the word tile refers to something used to cover a floor, a roof, or a wall. See York Prods., Inc. v. Cent. Tractor Farm & Family Ctr., 99 F.3d 1568, 1572-73, 40 U.S.P.Q.2D (BNA) 1619, 1622 (referring to dictionary definitions of "substantially" and "plurality"). As an initial matter, it is not clear that the dictionary's reference to bathroom tiles and roof tiles suggests that a single row of pixels cannot constitute a tile, since the superposition of rows would form the entire image just as the superposition of bathroom tiles forms the entire floor. 5 It is true that we have indeed relied on non-technical dictionary definitions to construe non-technical terms, such as "substantially" and "plurality." See York Prods., 99 F.3d at 1572-73, 40 U.S.P.Q.2D (BNA) at 1622. However, the word "tile," as utilized in disclosing and claiming a patented method for transforming and compressing digital images, is manifestly a technical term. The effort to restrict the meaning of the word "tile" in the context of digital image compression on the basis of the definition of the word in the inapposite context of a bathroom floor or a roof violates the essence of the claim construction inquiry: to adduce the scope of the claimed invention. For that reason, we construe the claim term "tile" from the perspective of one skilled in the art, instead of a layperson reading a dictionary. See K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1365, 52 U.S.P.Q.2D (BNA) 1001, 1006 (Fed. Cir. 1999) ("Claim construction is firmly anchored in reality by the understanding of those of ordinary skill in the art."). Based on the expert testimony presented by LizardTech and the role of "tiling" in the context of the claimed invention, we hold that the "plain and ordinary meaning" of the term "tile" to one skilled in the art includes within its scope a single row of pixels. The district court's contrary interpretation and its resulting conclusion that the ER Mapper does not infringe the '835 patent as a matter of law are erroneous.

5 ERM's argument to the contrary depends on the fallacy that bathroom and roof tiles have two dimensions, while a row of pixels is only one-dimensional. As a matter of both logic and geometry, this contention is incorrect, since a row of pixels, unlike a one-dimensional line, has both a width (however many pixels are in the row) and a height (1 pixel), so that superposing each row would yield the entire image.

A. "time compressed representation"

The term "time compressed representation" appears in every independent claim of the Burst patents. The parties have relied on the reference in claim 1 of the '839 Patent for the purposes of discussion:

1. A method for handling audio/video source information, the method comprising:
   receiving audio/video source information;
   compressing the received audio/video source information into a time compressed representation thereof having an associated burst time period that is shorter than a time period associated with a real time representation of the received audio/video source information;
   storing said time compressed representation of the received audio/video source information;
   transmitting, in said burst time period, the stored time compressed representation of the received audio/video source information to a selected destination

The parties dispute whether the term "time compressed representation" had an accepted scientific or engineering meaning when it was used. Compare Hemami Report at 42-43 with Halpern Report at 8-12. The term was not explicitly defined in the specification. The main dispute is whether the term teaches data compression. Burst argues that it does. Apple's
preferred construction, however, excludes data compression in favor of a reading of "time compressed representation" to refer to time compressed multiplexing. In the alternative, Apple presents an invalidity argument in the guise of contesting Burst's construction as indefinite. First, the court will examine whether "time compressed representation" excludes data compression. Having resolved that dispute, it will construe the term and address Apple's indefiniteness argument.

The literal language of "time compressed representation" tends to favor Apple's preferred construction. While "time compression" was not a widely used term at the time the patents were drafted, the ordinary meaning would suggest time compression and exclude data compression. See Halpern Report at 8. Indeed, Burst's expert concedes that, at the time the patents were filed, there were several meanings of the phrase "time compression," none of which would include data compression. Additionally, TCM would fall within the likely accepted meanings of "time compression" at the time. Hemami Report at 42-43. Further, the expression "burst" was linked to TCM in describing the high-rate bursts at which information is transmitted. See Data Communication Principles at 607-669; Modern Dictionary of Electronics at 122. The use of the term "burst" was unknown in the field of data compression.

The presumption that the term "time compression" is meant to convey its ordinary meaning can be overcome. An inventor may "choose[] to be his or her own lexicographer" by expressly defining terms in the specification. Johnson Worldwide, 175 F.3d at 990. While the term "time compressed representation" is not defined in the specification, the intrinsic evidence establishes that "time compressed representation" refers to data compression. Indeed, the Federal Circuit has concluded that such lexicography by implication may be appropriate, particularly where the prosecution history indicates that the patentee intended to deviate from a term's ordinary and accustomed meaning. Teleflex, 299 F.3d at 1326.

The intrinsic evidence demonstrates that "time compressed representation" refers to data compression. Significantly, the parties do not dispute the fact that the specification does not disclose TCM. The specification refers in several places to data compression and data compression techniques. See, e.g., '995 Patent at 2:42-51 (including as one of the objects of the patent to "provide an audio/video recorder utilizing a data compression technique for efficient storage, transmission, and reception"). The preferred embodiment describes the algorithms used for compression, "which enable the representation of a series of numbers by a reduced number of digits." Id. at 4:63-68; see also id. at 5:20-24 (using "data compression technique" to refer to "the above compression techniques"). The algorithms discussed in the preferred embodiment for performing the compression are types of data compression algorithms--intraframe video compression, interframe video compression, and inter-sample audio compression--which would have no relevance for TCM. See id. at 4:68-5:8 (intraframe video compression); id. at 5:9-18 (interframe video compression); id. at 5:28-33 (inter-sample audio compression). The parties do not dispute that these algorithms are exclusively used for data compression and that they have no use for TCM. n2 Instead, Apple notes that the patents link data compression to more efficient storage and not to faster-than-real-time transmission. See, e.g., id. at 2:42-45 ("A still further object of the invention is to provide an improved audio/video recorder which maximizes storage capacity, through the use of a data compression technique."); but see id. at 2:46-51 ("A still further objection of the invention is to provide an audio/video recorder utilizing a data compression technique for efficient storage, transmission, and reception of digitized audio/video program. . ."). The court will address this argument in more detail below; however, it is not convinced that the patents limit data compression to storage.

n2 In response to the argument that Apple's reading excludes the preferred embodiment, Apple contends that Burst's construction is also not disclosed in the specification. Apple contends that the specification does not support Burst's proposal to link data compression to faster-than-real-time transmission. The court will address the merits of this argument independently. The court is convinced, however, that this contention does not rebut the fact that Apple's construction would exclude the preferred embodiment.

The sequence of three processes within the disputed claims--compression, storage and transmission--supports Burst's construction. See, e.g., '839 Patent at 13:1-16. Burst contends that Apple's proposed construction would not conform to the sequence mandated by the claims because storing information after it had been TCM-compressed would lose the effects of compression. At the Markman hearing, Apple presented several examples of storing TCM-compressed information after
In sum, the court finds that the Burst patents do not exclude data compression. Appropriate); Plastipak, 415 F.3d at 1345-46 (describing the high level clarity of the disclaimer in the prosecution history).

and “the unambiguous language of the amended claim” that construction which excluded the preferred embodiment is

O.U.R. Scientific Intern., Inc., 214 F.3d 1302, 1308 (Fed. Cir. 2000) (concluding on the basis of clear prosecution history

Apple's proffered reading is not the most reasonable one. Therefore, the court is persuaded that TCM does not conform to the sequence of processes in the disputed claims.

The prosecution history appears, at worst, ambivalent and more likely to support Burst's construction. Apple offers two types of evidence from the prosecution history to support its view that Burst abandoned its claim to data compression. First,

Apple argues that Burst's statements during prosecution to distinguish the Izeki patent excludes data compression from the meaning of disputed terms. In its statement, the applicant distinguished the Izeki patent, which "mentions data compression," as "not the equivalent by any means of [the applicant's] specifically claimed time compression." ’705 File History, Brown Dec., Exh. L at APBU 551. The applicant continued to explain that the Izeki patent "contains absolutely no recognition of the need for time compression of audio/video source information or of the need for transmission of time compressed audio/video source information in a burst time period." Id. As Burst points out, this statement, read in context, suggests that the Izeki patent did nothing more than data compression, while the claimed invention combined data compression with faster than real time transmission. Id. Subsequent correspondence with the PTO confirms that the applicant did not disavow data compression because the PTO and the applicant both discuss data compression in the prior art. In particular, they referred to data compression's utility in increasing storage capacity. Fourth Office Action Brown, Dec., Exh. L at APBU 554-58 (noting that using compression for increasing storage capacity was known in the prior art).

Burst further emphasizes that the applicant never distinguished the Izeki patent based on the type of compression utilized. If the applicant had intended to claim TCM, then it could have easily distinguished Izeki on the basis that Izeki employed data compression. See, e.g., North American Container, Inc. v. Plastipak Packaging, Inc., 415 F.3d 1335, 1346 (Fed. Cir. 2005) (concluding from certain description of prior art, which would have been unnecessary under proposed construction, that applicant did not intend proposed construction). Indeed, the applicant distinguished Haskell, a patent that teaches TCM, on the basis that it teaches TCM. In the amendments to the application which resulted in the”705 Patent, the applicant noted that "Izeki teaches a compression technique without transmission. . . . Haskell [] teach[]es a system for time compression multiplexing so that multiple clients can receive audio/video information in real time." ’27 Application, August 7, 1997 Preliminary Amendment, Def.'s Exh. L at APBU 620-21.

Apple also points to statements in Burst's patent application before the European Patent Office to establish that Burst disclaimed data compression. The patent examiner rejected certain claims on the basis that the phrase "time compression" was not supported in the specification. The examiner noted that "compression of information refers to a reduction of a number of digits." File History for European Patent ’561, Brown Dec., Exh. T at APBU 415342-43. In response, the applicant deleted the word "time" from the claims. File History for European Patent ’561, Brown Dec. Exh. W at APBU 415441. However, this deletion does not indicate that Burst disclaimed data compression but rather that it discarded the "time compression" formulation in order to clarify that it meant data compression. The evidence from the prosecution history does not convince the court that the applicant disclaimed data compression.

Second, Apple draws the court's attention to the inventor's amendment of the original claims to demonstrate that Burst abandoned data compression. However, this history is consistent with Burst's construction. Apple argues that, in its original claims, the patentee claimed data compression. ’932 File History, Brown Dec., Exh. 0, at APBU 167. n3 However, the PTO rejected each of the claims in the application, citing patents which showed the transmission of data compressed video. Id. at APBU 199-207. In response, the inventor, along with a new patent lawyer, amended the claims. These amendments cancelled all existing claims and introduced new ones with the term "time compressed representation" in them for the first time. Id. at APBU 212. However, the introduction of a new term does not conclusively demonstrate that Burst disavowed data compression in the original language. In short, the prosecution history is inconclusive on this issue. It certainly does not rise to the level of highly persuasive evidence necessary for a construction that excludes the preferred embodiment, as does Apple's construction which reads data compression out of "time compressed representation." See Elekta Instrument S.A. v. O.U.R. Scientific Intern., Inc., 214 F.3d 1302, 1308 (Fed. Cir. 2000) (concluding on the basis of clear prosecution history and "the unambiguous language of the amended claim" that construction which excluded the preferred embodiment is appropriate); Plastipak, 415 F.3d at 1345-46 (describing the high level clarity of the disclaimer in the prosecution history).

In sum, the court finds that the Burst patents do not exclude data compression.

- Footnotes -

- 4741 -
n3 For the purposes of this argument, Apple argues that the use of the word "compressing" without the word "time" must indicate that Burst claimed data compression. The court is unconvinced by this argument but will assume that it is accurate for the purposes of evaluating the contention that Burst disclaimed data compression.

The term "time compressed representation" appears in eight phrases throughout the patents, frequently in a format with "burst time period." Burst's proposed construction of "time compressed representation" includes that term along with other language connecting it to terms such as "the burst time period." Apple argues that these are distinct terms, and the court agrees. Therefore, the court will consider the two terms separately. The parties agree that there was no accepted meaning in the relevant community for "time compressed representation" at the time of the patent application. The relevant part of Burst's proposed construction is as follows:

a [digital] version of audio/video source information having a reduced number of bits [that allows data transfer / that is received / being received] over an external communications link.

Burst argues that "time compressed representation" contains three elements: 1) a temporal element; 2) a compression element; and 3) a transmission and/or reception element.

The temporal element proposed by Burst is the crux of the dispute. Burst argues that the word "time" in the disputed term refers to the "associated burst time period" that appears in most of the phrases containing the disputed term. Burst construes "burst time period" to mean a transmission time period which is shorter than the time required for normal playback. By contrast, Apple argues that the temporal element of this term refers to TCM and that the "burst time period" is a transmission time period known at the time of compression to be shorter than the time required to play the source information in real time.

The court must address whether the temporal element refers to TCM or the concept of faster-than-real-time transmission. The court adopts the latter construction for the following reasons. The more reasonable interpretation of the temporal element refers to faster-than-real-time transmission. Burst argues that the sequence presented in the claims excludes TCM. Several of the claims require compression and then storage of the "time compressed representation" before transmission. See, e.g., '995 Patent, claim 1; '839 Patent, claim 1. TCM requires immediate transmission after multiplexing; storage of the data after multiplexing but before transmission is, therefore, inconsistent with TCM. Apple's proposed construction would also give the word "compression" two meanings: data compression and TCM. Apple acknowledges that the compressor/decompressor 26 in Figure 2 runs data compression algorithms. Therefore, for the specification to accommodate both data compression and TCM, the word "compression" must accommodate both meanings. Such a reading would render claims such as claim 1 of the '839 Patent nonsensical.

The prior art disclosed in the patent does not support Apple's proposed construction. The court has reviewed the treatment of the Izeki patent, which explicitly disclosed data compression, in the Burst patent application. As Apple notes, the applicant distinguished Izeki in amendments to its '727 Patent application (which resulted in the '705 Patent) in response to the PTO's rejections of its application. The first relevant PTO rejection occurred in February 1997 and noted that Izeki disclosed an apparatus for receiving, compressing and storing audio/video information and later transmitting the information to another apparatus. '705 File History, Brown Dec., Exh. L at APBU 582. In its first response, Burst distinguished Izeki by noting that "Izeki teaches a compression technique without transmission." Id. at APBU 620. The PTO's second rejection was identical to the first. Id. at APBU 625. In response, Burst's amendments noted that Izeki "does not provide for burst transmission of video programs over a communications channel" but rather is "intended to facilitate production of a master tape." Id. at APBU 649-50. Based on this history, Apple argues that the Burst patents contemplate "burst" transmission through TCM, while Izeki discloses data compression. As noted earlier, the court is not persuaded that such statements amount to a disclaimer of data compression. Apple also argues that the treatment of the Haskell patent in the file history indicates that the Burst patents necessarily include TCM. Haskell is a patent for TCM of video signals for transmission to multiple users in real time. In distinguishing Haskell in the patent application, the Burst patents note that Haskell employs TCM for real-time delivery and that the subject invention relates to "a delivery technique that uses compression to transmit a time
compressed representation in a burst time period" shorter than real time. '705 File History at APBU 620. Notably, the application used the phrase "a delivery technique that uses compression" not the phrase "time compression multiplexing." Therefore, the treatment of Haskell does not mean that the Burst patents employ TCM for faster-than-real-time transmission. The court concludes that the temporal aspect of the term does not refer to TCM.

The compression aspect of the term, Burst argues, is that the representation is the result of the compression process. This reading finds support in the specification. For example, claim 1 of the '839 Patent teaches "[a] method for . . . compressing the received audio/video source information into a time compressed representation thereof." '839 Patent at 13:1-6. The compressing, as noted above, is data compression. As the parties agree, the result of data compression is a reduction in the number of bits. Accordingly, the representation is the product of the data compression process. At the Markman hearing, Apple explained that TCM could result in a representation. The use of the word "representation" seems better suited to data compression. A "representation" is the result of reducing bits from the original audio/video information.

According to Burst, "time compressed representation" contains a third element related to transmission/reception. The claims refer to the "time compressed representation" as "transmitting" in a burst time period and that the time compressed representation is "received" in a burst time period. See '839 Patent, claim 1. Burst argues that this context imbues "time compressed representation" with a transmission/reception element that requires transmission over an external link. The court is not convinced that the phrase "time compressed representation" necessarily contains a transmission element. The plain language of the term does not suggest transmission. The inventor demonstrated his ability to adequately describe transmission where he intended. Where the inventor chose to describe transmission, he used separate nomenclature for doing so. Indeed, it would be redundant to include a transmission element in the term "time compressed representation" when Burst offers a similar construction for the term "transmission." Therefore, the court declines to adopt Burst's transmission limitation on the term "time compressed representation."

Finally, Apple challenges Burst's construction on the grounds that the claims link compression and faster-than-real-time transmission but Burst's preferred construction does not. As a result, Apple contends that the court should not adopt Burst's construction of "time compressed representation" because it is indefinite. Apple states that the disclosed technology, data compression, would not by itself enable the stated option of faster-than-real time transmission. Thus, Apple reasons that the patents-in-suit must teach TCM in addition to data compression because data compression alone is insufficient to perform the claimed function. However, this much is acknowledged in the patents themselves. Compare '995 Patent at 7:55-64 (noting that transmission of a video over a fiber optic line would take "less time than it would take to view the program") with '995 Patent at 8:49-57 ("[T]he time required to communicate a video program over a conventional phone line may exceed the time it takes to view the program."). While the patent discloses various transmission technologies, only one of them, a fiber optic line, would have been able to transmit compressed data faster-than-real-time. But, Apple notes, the fiber optic line would have achieved faster-than-real-time transmission of uncompressed data; therefore, the data compression does not enable the claimed function. At the Markman hearing, Apple argued that Burst's specification citations would reflect only the law of nature that compressed signals would be transmitted faster than uncompressed.

Apple's indefiniteness argument boils down to one based on invalidity. This type of invalidity argument, the Federal Circuit warns, is not a proper consideration at claim construction:

While we have acknowledged the maxim that claims should be construed to preserve their validity, we have not applied that principle broadly, and we have certainly not endorsed a regime in which validity analysis is a regular component of claim construction. Instead, we have limited the maxim to cases in which the court concludes, after applying all the available tools of claim construction, that the claim is still ambiguous. In such cases, we have looked to whether it is reasonable to infer that the PTO would not have issued an invalid patent, and that the ambiguity in the claim language should therefore be resolved in a manner that would preserve the patent's validity.

Pfizer, Inc. v. Teva Pharmaceuticals, USA, Inc., 429 F.3d 1364, 1376 (Fed Cir. 2005). Because the court has concluded that there is no ambiguity in the relevant claims, Apple's argument is best reserved for a later stage of litigation. Apple also uses this argument to attack the limitation in Burst's construction that the representation "allows" transfer in shorter than the time required for normal playback. This, too, is an invalidity argument best reserved for later.
The court construes "time compressed representation" to mean "a version of audio/video source information having a reduced number of bits."

4488

(1) time division multiplexed bus 4

For this first term, N-Data and National assert that the patents offer a straightforward explanation of the term, and, as such, it needs no construction. '395 Patent, col. 3, ll. 2-6. N-Data also provides an alternative definition, should the court determine the term needs construction. Dell seeks to impose a function-of-time and purpose limitation. During the claim construction hearing, N-Data agreed with the court that the patent requires the intervals to be arranged as a function of time. In support of their own incorporation of such a limitation, N-Data pointed to their alternative proposed definition, requiring the data to be "arranged as a repeating series of frames." As explained in the hearing, N-Data's primary concern is that Dell's limitation is "of a fixed nature" that limits the term to the IsoEthernet, which has very specific discreet time frames of a fixed nature.

As a threshold matter, contrary to N-Data and National's argument, these terms should be construed. Even with contextual clues provided by the specification and explanations provided by the parties, the court believes that the average juror is going to need assistance in giving a meaning to the above terms. Further, while the court agrees with N-Data to the extent that Dell seeks to limit the term to a discrete time interval, N-Data's supposed function-of-time support is not adequate. Its alternative construction would not assist the jury in assigning a function of time to such terms. Finally, the court does not find any support for the inclusion of a purpose limitation as Dell suggests; such limitation would be extraneous and improper.

Accordingly, the court defines "time division multiplexed bus" as "a bus wherein data from a data source is put into time intervals and arranged as a repeating series of frames or templates."

4489

2. time integration quantity of a brightness change/ideal quantity of light in a stationary state

AUO contends that the term "time integration quantity of a brightness change" means "a quantity of light equal to the actual brightness level output through a liquid crystal, summed over the rise and fall response time of the liquid crystal." D.I. 376 at M-13. According to AUO, the plain meaning of "integration, in this context, is summing a change value (here, brightness level) over a period of time (here, the response time of the crystal)." Id. AUO also contends that the term "ideal quantity of light in a stationary state" refers to the "quantity of light emitted by a pixel during one time increment in which the pixel is in a non-changing state." Id.

LGD contends that these terms are indefinite. In the alternative, LGD appears to conflate the terms and offer a combined definition as follows: "quantity of light based on the actual response characteristic of the liquid crystal cell when the liquid crystal cell is provided with the next brightness level during the next time increment and the previous brightness level before and after the next time increment." D.I. 376 at Exh. M--13.

After reviewing the claim language in light of the specification, the Court concludes that the terms are not indefinite and will adopt AUO's proposed construction of these terms. The specification explains that the "[q]uantity of light can be..."
considered as a time integration quantity of a brightness change." '160 patent, col. 4, ll. 53-57. The specification further explains that "brightness of a pixel to the human eye . . . should be considered in terms of the quantity of light, that is brightness change integrated with respect to time." Id. col. 8, ll. 30-34. In the Court's view, this supports AUO's position that the "time integration quantity of a brightness change" is the quantity of light that is emitted due to the change in brightness. LGD's proposed construction adds limitations that are not supported by the specification.

Likewise, the Court will adopt AUO's proposed construction of the term "ideal quantity of light in a stationary state." The specification teaches, by way of example, that an ideal quantity of light is that quantity of light output by an ideal LC over one time increment. Id., col. 4, ll. 42-47, Fig. 4. However, an ideal LC does not exist, id. at col. 8, ll. 63-65, and the specification's example teaches that the ideal quantity of light from a conventional LC is that quantity of light emitted from the LC during one time increment when the brightness is constant, meaning the image is stationary. Id. col. 8, ll. 37-39 (when the particular pixel or LC is driven at a target brightness for an entire time increment, the pixel or LC may be described as being in a non-changing or "stationary state"). As with LGD's previous construction, its proposed construction of "ideal quantity of light in a stationary state" adds limitations that are not supported by the specification.

B. "Time slot"

There is significant disagreement between the parties over the proper construction of this term. WiAV asserts that the correct construction is: a time interval that a telecommunication protocol has defined as the basic unit recognized by devices operating according to that protocol. The Defendants assert that the term should be construed as: one of 8 physical channels in each time-division multiple access (TDMA) frame of a 200 kHz GSM radio channel.

1. Words of the Claims

Claims I and 2 of the '920 Patent claim a method of operating a mobile station, comprising

   scanning broadcast information in a wireless communication network for a short page channel;

   receiving a single time slot of said short page channel containing one group of call alert data … said single time slot being less than one millisecond in duration and representing less than 128 data bits. . .

   receiving a short page channel transmitted by a wireless communication system operating in accordance with the GSM standard;

   extracting paging data from a time slot of said short page channel;

   determining from said paging data in said time slot that a telephone call or paging message may have been directed to said mobile stations, said time slot being less than one millisecond in duration and representing less than 128 bits; and

   receiving four time slots of a paging channel and responsively determining whether the mobile station is an intended recipient of a telephone call or paging message.

Id. at 26:2-16 (emphasis added).

WiAV argues that "time slot" as used in the claims is consistent with its dictionary meaning. (Pl. Br. at 10.) WiAV begins with the proposition that the Federal Standard 1037C, Telecommunications: Glossary of Telecommunication Terms defines a time slot as: (1) "[p]eriod of time during which certain activities are governed by specific regulations," and (2) [a] time interval that can be recognized and uniquely defined." WiAV further argues that, here, the "regulations" are communications protocols that "uniquely define" the time slots so the devices can "recognize" them. While the words of the claim do not
contradict this construction, there is no intrinsic evidence to support such a construction.

The Defendants correctly assert that the language of the claims place two important limitations on the construction of the term "time slot." First, the time slot must be transmitted by a "wireless communication system operating in accordance with the GSM standard." '920 Patent at 25:38-40; 26:1-4. Second, the time slot must be "less than one millisecond in duration and represent[] less than 128 data bits." Id. at 25:40-42; 26:9-11. Both of those limitations are found directly in the claims. And, the first limitation, which shapes the Defendants' construction, is described further in the specification.

2. Specification

The term "time slot" appears throughout the specification. When described in accordance with the GSM standard, 2 the specification provides:

FIG. 2 illustrates wireless communication signal data transmitted by a base station 104 and structured in data frames, sometimes called time-division multiple access (TDMA) frames, according to the GSM standard. The GSM specification provides eight time slots (or physical channels) in each 200 kHz radio channel. An entire data frame has a duration of 4.615 milliseconds. Each time slot has a time length of 577 microseconds (4, 615/8=577). Because a mobile station 106 may use only one time slot in any data frame, it must transmit information within 577 microseconds.

'920 Patent at 7:40-50 (emphasis added). Additionally, the specification incorporates a textbook, "An Introduction to GSM" into the specification by reference. Id. at 17:1-4 ("See … Siegmund M. Redl, et al., An Introduction to GSM, 40 (1995) which is hereby incorporated by reference herein in its entirety."). The Redl textbook provides:

Considering that the GSM channel spacing is 200 kHz, it would be rather wasteful for a system not to subdivide this resource any further, since regulatory bodies and operators continue to strive for increased efficiency in the use of spectrum. To achieve this, the GSM system makes use of TDMA techniques, with which each frequency channel is further subdivided into eight different time slots numbered 0 to 7.

Ex. F at WIAV000612 (emphasis added). ) The Defendants' construction is well-supported in the embodiments described in the specification as well as Redl's general description of a time slot operating within a GSM system.

- - - - - - - - - - - - - Footnotes - - - - - - - - - - - - -

2 The GSM standard is the only standard described in the specification.

- - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - -

WiAV takes issue with the Defendants' construction for two reasons. First, the Defendants' construction, WiAV argues, seeks to limit the term to a preferred embodiment, a practice which the Federal Circuit repeatedly has cautioned against. It is correct that the limitations suggested by the Defendants appear in the embodiments, but it is clear that those limitations are general ones that apply to all systems operated in accordance with the GSM standard. As noted above, Redl's textbook, discussing the GSM system in general terms, supports the Defendants' construction.

Second, WiAV notes that the claimed range for the time slot (less than 1 millisecond) is broader than the exact GSM time slot in the specification, 577 microseconds. '920 Patent at 7:46-48. Because the claim language allows for a longer time range than the exact GSM time range in the specification, WiAV argues that there is a lack of intent to limit "time slot" to the GSM standard. This argument is refuted by both the words of the claims, which show a clear limitation to the GSM standard, and the specification, which describes the invention in terms of the GSM standard alone.

Instead, WiAV asserts that the specification uses the term "time slot" consistently with its dictionary meaning, as reflected in WiAV's proposed construction. For example, WiAV points to Figures 2 and 5, which show that data is transmitted in data frames 202, which are divided into time slots. '920 Patent at Figs. 2 and 5. Significantly, the figures cited by WiAV show that each TDMA data frame is divided into 8 time slots each, which, of course supports the construction that the term is as used in the incorporated Redl textbook and in the specification.
Additionally, WiA V argues that the specification as a whole demonstrates that its construction is correct because the specification provides that "alternative embodiments of the present invention operate using different time slot formats." Id. at 9:66-10:1. WiA V's point here is misleading. When read in context, the cited passage merely explains that the data transmitted within each GSM time slot may be packaged in different formats, such as a normal burst, synchronization burst, or other variation. The time slots themselves, however, are as set forth in the GSM standard alone.

3. Prosecution History

There is a significant dispute between the parties regarding the appropriate interpretation of the prosecution history. WiA V argues that the prosecution history shows that "the USPTO [] refused to limit 'time slot' to a specific format or protocol." Under WiA V's assessment of the prosecution history, Claim 34 of the '920 Patent was rejected over Raith. (Pl. Ex. 7 at 7-8.) Nevertheless, WiA V contends, the USPTO concluded that Raith disclosed a "time slot" and rejected the claims. (Pl. Ex. 7 at 7 - 8.) Thus, says WiA V, the ordinary meaning (as set out in the dictionary definition discussed above) of the term "time slot" must have been applied by the Examiner in rejecting the claim and should be applied now.

The Defendants' analysis of the patent rejection is quite different. They assert that the Examiner concluded that it was the GSM system, rather than Raith, that disclosed a time slot according to the claims. Thus, under the Defendant's view, the prosecution history actually provides very little support for the broad construction of the term "time slot" urged by WiA V. And, the Defendants argue, the applicant disclaimed all non-GSM systems during prosecution when it distinguished prior art that did not use the GSM standard. For example, in a June 17, 1999 response to the Examiner, the applicant wrote that the "radio communication system disclosed in Raith I is not … a communication system in accordance with the GSM standard … Rather than being based on GSM, the system disclosed in Raith I relies on radio channels in accordance with the IS-54B standard." (Def. Ex. D at WIA V0020096.) This indicates that the '920 Patent is, in fact, a system that operates under the GSM standard. That, in turn, would mean that the time slots within that system must also operate within the GSM standard.

4. Proper Construction of "Time Slot"

Overall, the Defendants' construction is consistent with the intrinsic evidence and will be adopted. To begin, WiA V's very approach to construction is inconsistent with the Federal Circuit's teaching in Phillips. There, the Federal Circuit assessed an earlier-decided case, Texas Digital Systems, Inc. v. Telegenix, Inc., 308 F.3d 1193 (Fed. Cir. 2002). In Texas Digital, the Federal Circuit explained that a court must consult the patent's specification and prosecution history to determine if the patentee used "the words [of the claim] in a manner clearly inconsistent with the ordinary meaning reflected, for example, in a dictionary definition." Phillips, 415 F.3d at 1319 (citing Texas Digital, 308 F. 3d at 1204.) The Phillips court called the Texas Digital approach into question, noting that it placed too much emphasis on extrinsic sources, such as dictionaries, and too little emphasis on the specification and prosecution history. Phillips, 415 F.3d at 1320. The Federal Circuit wrote:

In effect, the Texas Digital approach limits the role of the specification in claim construction to serving as a check on the dictionary meaning of a claim term. . .That approach, in our view, improperly restricts the role of the specification in claim construction.

Id. The Texas Digital approach, the court added, creates the risk that the claim term will be defined out of context, resulting in an "unduly expansive" construction. Id. at 1321. Rather, the Phillips court stated, a court should "focus[] at the outset on how the patentee used the claim term in the claims, specification and prosecution history, rather than starting with a broad definition and whittling it down." Id.

WiA V uses the approach rejected by Phillips by beginning with a dictionary definition and selectively examining the specification and prosecution history as a "check" on that definition. Doing so assigns too limited a role to the specification and ignores how the words of the claims and specification would be read by a person of ordinary skill in the art in the context of the patent.

Not only is WiA V's approach questionable, but its proposed construction is not supported by even the extrinsic evidence offered. For example, WiA V offers no support that a time slot is a "basic unit." This terminology does not appear in the
intrinsic or extrinsic evidence. Rather, WiAV's construction appears to be an amalgamation of definitions spliced together and supplemented by WiAV to suit its own needs.

The Defendants' construction, on the other hand, is well-supported by the intrinsic evidence. First, the words of the claims indicate that the wireless communication system, of which the time slot is a part, must operate in accordance with the GSM standard. And, the intrinsic evidence leaves no real question as to what "time slot" means within a GSM system. The GSM standard, according to the specification, requires each data frame to contain eight time slots for each 200 kHz radio channel. And, each of those time slots are 577 microseconds. Those requirements are consistent with the time slot described in the Redl textbook and made a part of the specification. Thus, "time slot" will be construed to mean: one of 8 physical channels in each time-division multiple access (TDMA) frame of a 200 kHz GSM radio channel.

2. "time slot assigned to each of said application programs"

Claim 1 also requires that the remote units receive messages from the master unit and respond in a "time slot assigned to each of said application programs." The parties' dispute concerns whether the "assignment" function must occur at initialization of the application program (the defendants' construction) or whether it may occur at any time. The plaintiff argues that the defendants' construction is inconsistent with the disclosure because the remote units can request additional time slots during data transmission, which is after initialization. See '819 patent, 2:18-26, 3:7-11. The defendants argue that the specification repeatedly discloses time slots assigned to applications at initialization. See '819 patent, 2:46-49, 5:42-43, Fig. 6, Fig. 7.

Although the specification refers to the assignment of time slots during initialization, there is nothing in the patent that requires the claims to be limited in this manner. The court construes "time slot" to mean "an interval of time during which data from an application program is transmitted." All other terms have their plain and ordinary meaning.

I

A single claim limitation, common to both patents, is dispositive of this appeal. Each patent sets forth an independent first claim followed by two dependent claims. Claim 1 of the '589 patent reads as follows in pertinent part:

A dynamically reconfigurable time-space-time (DRTST) switching system for use in conjunction with a high speed transmission media which conveys a plurality of time division multiplex (TDM) channels within a repeated frame of data, comprising:

... a time-space-time (TST) switch having a space switch including a plurality of inlet ports and a plurality of outlet ports each having a memory;...

Claim 1 of the '907 patent contains essentially the same preamble and also requires "a TST switch connected to receive said channels of data from the first line terminating unit at the inlet ports thereof." Both patents share the same written description, and the '589 patent is a continuation of the '907 patent. Consequently, the district court determined that a common construction of the TST switch limitation for both patents was appropriate.

The district court construed the TST switch limitation to require a three-stage switch. The first and third stages are time switches, which allow a change in the time slot occupied by a channel of data within a frame of channels. The first and third stages include the ports of the TST switch, with each port having a memory. The second stage is a single-stage space switch, which performs a change in the physical transmission path of a channel. To reach that construction of the TST switch
limitation, the court relied primarily on the sole embodiment of the invention set forth in the written description and illustrated in figure 3 of each patent. Although the written description refers to TST switches and systems disclosed and claimed in several other patents, the court declined to consider the teachings of those patents to ascertain the meaning of the term as used in the '589 and '907 patents or as understood by a person skilled in the telecommunications art.

In construing the TST switch limitation, the district court properly consulted the written description and figure 3 of the patent. See, e.g., CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1153, 42 U.S.P.Q.2d (BNA) 1577, 1583 (Fed. Cir. 1997). The written description and the drawing, however, do not suggest that Collins was using the term "TST switch" in a special manner in the two patents. In particular, nothing in the claims, descriptions, or drawings of the '589 and '907 patents requires limiting the TST switch to a single-stage space switch. Nor does any point of novelty or asserted advantage of the Collins inventions depend on the TST switch having a single-stage space switch. Accordingly, the normal rule of construing patent terms as persons skilled in the art would understand them applies in this case.

Even when prior art is not cited in the written description or the prosecution history, it may assist in ascertaining the meaning of a term to persons skilled in the art. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584, 39 U.S.P.Q.2d (BNA) 1573, 1578 (Fed. Cir. 1996). When prior art that sheds light on the meaning of a term is cited by the patentee, it can have particular value as a guide to the proper construction of the term, because it may indicate not only the meaning of the term to persons skilled in the art, but also that the patentee intended to adopt that meaning.

The '589 and '907 patents note that "system improvements attainable with time division transmission and switching techniques are very significant, and have resulted in the development of TST switches and systems described and claimed in, for example, U.S. Pat. Nos. 3,925,621; 3,956,593; 4,005,272; and 4,038,497." '589 patent, col. 2, ll. 1-6. The cited patents indicate that switches with time-switch inputs and outputs and with multiple intermediate space switches are referred to as TST switches, even though such structures can also be called, for example, TSSST switches. Based on the way the term "TST switch" is used in those patents, and the absence of any indication in Collins's patents or in their prosecution histories that the term was meant to have a different meaning in the '589 and '907 patents, we agree with Collins that the TST switch limitation allows a multiple-stage space switch, rather than just a single-stage space switch.

Collins presses its argument farther and urges us to adopt a broader construction that would allow any combination of intermediate stages that includes at least one space-switch stage and that would allow a space switch to contain additional structure for time translation. The evidence, however, does not support that construction. The prior-art patents indicate that a space-switch stage is just that -- a structure that provides space translation without time translation -- and therefore contains no structure used for time translation, such as memory for channel storage.

Regarding the intermediate stages, we adopt the meaning of TST switch that is used in the patents referred to in the written description, which appears to be the meaning given the term by a person skilled in the art. Thus, we construe the TST switch limitation to mean a structure with time-switch input and output stages, and with one or more intermediate space-switch stages containing only structure for space translation.

Claim 1 of the '589 patent further requires each of the inlet and outlet ports of the TST switch to have a memory. The written description states that "with N bi-directional links, there will be 2N memories," '589 patent, col. 5, ll. 26-27, indicating that the memory associated with each port of the TST switch is a distinct structure, which is "sized to store one frame . . . that will be accessed at one switch port," id., col. 3, ll. 31-33. The district court construed the '907 patent to require the same individual-memory structure, even though the '907 patent does not contain the additional claim language found in the '589 patent regarding individual port memories. The Collins patents -- one a continuation of the other -- use an identical written description, and the prior-art patents cited by the written description disclose TST switch embodiments that all use individual port memories. For those reasons, it may be appropriate to apply the additional limitation to the '907 patent as well. Nortel, however, has not argued that the individual-memory requirement applies to the '907 patent, and we need not reach that issue for purposes of this appeal.
the time when cellular telephone signals were received at the cell site." (144 patent, col. 5, ll. 15-18)

1. "time-division multiplexed bus"

The first term for construction is "time-division multiplexed bus." The plaintiff argues that the term means "a bus having a
bandwidth partitioned into regular time slots, that is shared by two or more sources of data by limiting each source's transmission opportunities to discrete intervals of time. The defendants argue that the term means "a group of one or more conductors that is shared among several users by allowing each user to use the bus for a given period of time in a defined, repeated sequence." The parties appear to agree that a bus allows different sources of data to share bandwidth. The principal dispute is whether the transmission sequence must be a "defined, repeated sequence."

The defendants cite to portions of the specifications that refer to repeated frames for a fixed portion of the TDM bandwidth. See '858 patent, 4:56-57, 5:21-6:5. In addition, the defendants point to extrinsic evidence. See The New IEEE Standard Dictionary of Electrical and Electronic Terms, at 1377 (5th ed. 1993). The plaintiff argues, however, that by limiting the transmission sequence to be a "defined, repeated sequence," the defendants' construction would exclude a preferred embodiment where data sources are skipped when they have no data to send. See '858 patent, Fig. 6, 7:25-9:15.

The court agrees that the patent discloses an embodiment where certain data sources are skipped when they have no data to send. For this reason, the "defined, repeated sequence" more appropriately describes the frames for the fixed portion of the TDM bandwidth. So viewed, the court agrees that the frames are arranged in a "defined, repeated sequence." Accordingly, the court construes the term to mean "a bus having a bandwidth partitioned into a defined, repeated sequence of time slots, that is shared by two or more sources of data by limiting each source's transmission opportunities to discrete intervals of time."

Hidden time-shared set of log-in information

In this phrase, the words "hidden" and "time-shared" are two separate modifiers to the claim term "set of log-in information," which the Court defines in a later section.

MyMail asserts that "hidden" means "not easily accessible to the user." Defendants assert that it means "unknown and inaccessible to the user." Because "hidden" is a normal, non-technical word, the Court notes that the definitions proposed by MyMail and Defendants are correct. Since the patent defines "hidden" as "not easily accessible to the user," the Court will adopt MyMail's definition. Col 18:25.

MyMail proposes defining "time-shared" as "usable by multiple NSPs or multiple users during a period of time," while Defendants propose defining it as "allocated to multiple users each for a separate period of time." The Court adopts Defendants' construction. "Time-shared" is a word familiar to those in the computing field. The Microsoft Press Computer Dictionary defines time-sharing as running separate programs concurrently by interleaving portions of processing time allocated to each program user. See MICROSOFT PRESS COMPUTER DICTIONARY (3d ed. 1997). Put simply, computer time-sharing is analogous to condominium time-sharing, where many lessees each take turns occupying a vacation property for a fixed period of time. Defendants' definition better reflects the meaning of time-shared, as understood by one skilled in the art.

"Timer" and "timing signal corresponding to the application of electrical energy"

At oral argument, the court proposed definitions for "timer," which appears in Claims 1 and 9, and "timing signal," which appears only in Claim 1. The court proposed that a "timer" is a "device or component capable of measuring time and capable of producing output corresponding to its time measurements," and that a "timing signal corresponding to the application of electrical energy" is a "signal that the timer produces corresponding to the elapsed time of a defibrillator shock pulse or phase of a pulse." These definitions are derived from the three paragraphs in the specification that discuss the timer. 212 Patent at 7:3-31. The parties seemed to accept these definitions when the court proposed them. In any event, they offer no compelling evidence in support of different definitions.
The court notes that the specification describes the timer as capable of cutting off a defibrillator pulse when it receives information from another device indicating that the pulse voltage or current has dropped below a threshold value. 212 Patent at 7:12-15, 7:29-31. Defibtech suggested at oral argument that the "timer" of Claims 1 and 9 requires such a capability, but the court finds no indication that the inventors intended such a limitation on the claimed timer.

Microsoft argues that timeslice has a different meaning in the context of periodic multithreading, which is the subject of plaintiff's patents, and priority-based multithreading, which is the method utilized by other forms of multithreading, including some prior art that plaintiff distinguished during prosecution. Microsoft argues that in priority-based multithreading, a timeslice is the maximum amount of time a thread may run without being interrupted and preempted. If a higher priority thread is ready to run during the timeslice, the lower priority thread will be interrupted. See Def Br (Doc # 310) at 17. In periodic multithreading, however, Microsoft argues that a timeslice is a fixed length of time during which a thread operates before it is interrupted.

Microsoft's construction is supported by the language of the patents and their prosecution history. Towards the end of his patent prosecution, in order to overcome prior art (the "Cheriton" reference), plaintiff vigorously argued to the patent office that his form of multithreading was novel and distinct, because in plaintiff's invention the timeslice during which a thread may operate was a fixed length of time.

In Cheriton the timing of preemption of the active process occurs at variable non-predetermined times whenever another process, having a higher priority than the active process, happens to become "ready" (for execution), and this event is neither predetermined nor predictable

In applicant's invention preemption of a currently executing thread occurs at fixed predetermined time intervals at the expiration of its current execution timeslice of fixed predetermined duration.

This interpretation of timeslicing is buttressed by plaintiff's specification. Plaintiff argues that the editor in his preferred embodiment may be interrupted before its timeslice has run and, therefore, that "timeslice," as used in the claims, refers to a maximum period, not a necessary period, during which a thread may run. Besides conflicting with the prosecution history, however, this interpretation conflicts with plaintiff's description of his embodiment. The (single) paragraph discussing timesliced preemption in the patents' written description refers only to "the interrupt which causes control of the CPU to pass from the compiler to the editor." '603:13:8-9; '604:10:3-4. The patents' description does not even mention the possibility that the editor may be interrupted before it has processed the keystroke.

At the claim construction hearing, when asked for support in the patents for the claim that the editor could be interrupted before completing its task, plaintiff's counsel cited the last sentence of the patents' timesliced preemption paragraph, which states: "For most applications clock interrupts at intervals of about ever 10 to 30 milliseconds should be frequent enough to keep up with the keys struck at the keyboard." '603:13:17-20; '604:10:11-14. Plaintiff argues that this sentence indicates that the editor too may be interrupted at intervals of 10 to 30 milliseconds. This interpretation, however, is contradicted by the preceding language of this paragraph. After noting that the compiler may be interrupted and the input port polled to determine if a key has been struck, the patents state that if a key has not been struck,

   the interrupt is terminated and control returns to the compiler. If polling the port reveals that a key has been struck then the interrupt service routine editor takes control and is executed in the manner described in the above embodiment.

The description of the editor's execution in the above embodiment does not provide a mechanism by which the editor may be interrupted. As a result, the court concludes that the proper construction of timeslice is the fixed, predetermined length of
time during which each thread is given uninterrupted control of the CPU, at the expiration of which the executing thread is preempted in favor of another thread.

2. "timing characteristic"

Both parties appear to agree that the prosecution history provides guidance on the proper construction of this term. In the prosecution history, the examiner requested clarification of the phrase "timing characteristic." Response to Office Action, Oct. 14, 1994, at 2. In response, the applicant stated that "timing characteristic" was "used in its normal sense with respect to the memory signals . . . " and that it "may pertain to the memory signal itself or may pertain to a timing relationship between two signals." Id. 2-3. The applicant also gave examples of timing characteristics which include "the time duration (active time) of a memory signal and the elapsed time between a predefined event in a first memory signal and a predefined event in a second memory signal . . . " Id. The applicant, however, explicitly states that "the present invention is not limited to these examples . . . ." Id.

The plaintiff contends that no construction is needed and argues that the phrase is not limited to memory signals nor does it mean anything other than a characteristic related to timing. The defendant proposes "either the time between events in a single signal or the time between corresponding events in two signals," and contends that the term cannot have a plain and ordinary meaning if the examiner requested clarification.

The Court agrees with the defendant's argument. The examiner's request for clarification implies that the term was not understood according to its plain and ordinary meaning. When the examiner allowed the claim based on the applicant's clarification, the applicant implicitly limited the term to what was stated in that clarification. The defendant's proposed construction, however, is too limiting because it limits the term to specific examples listed by the applicant. The sentence prior to the specific examples provides the appropriate guidance for this construction. It states that the timing characteristic "may pertain to the memory signal itself or may pertain to a timing relationship between two signals." Response to Office Action, Oct. 14, 1994, at 2. Accordingly, the Court construes "timing characteristic" to mean "characteristic related to the timing of a signal itself or to the timing relationship between two or more signals."

3. Claim Construction

When construing an asserted claim, the court should first look to intrinsic evidence, namely the patent itself - including the claims and the written description - and, if in evidence, the prosecution history. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996). In this case, the main issue is whether the accused devices contain a "timing circuit" as claimed in the '009 patent. The district court interpreted the meaning of "timing circuit" in the following way: "a timing circuit is a circuit [assemblage of electronic components] which controls the duration of the connection between the power source and the lights after the switch closes. A predetermined time means a reasonably predictable, as opposed to random, time after the switch closes. A predetermined time means a reasonably predictable, as opposed to random, time after the switch closes. The timing circuit is not limited to integrated circuits."

The written description of the '009 patent describes the timing circuit as being responsive to the transition of the switch from "off" to "on" state to turn off said light source after a predetermined illumination duration and to prevent re-illumination of said light source until a further "off" to "on" transition of said switch. Thus . . . the light cannot be on continuously but only for a predetermined interval after the switch goes to "on" state. The battery life is thus prolonged and an exciting flashing effect is produced.

'009 patent, col. 1, ll. 24-34 (emphasis added). The prosecution history of the '009 patent indicates that the purpose of the timing circuit is to provide an automatic turn-off of the light source, regardless of whether the switch is in the "on" or "off" state, to prolong battery life. In the original application, the claims did not include a timing circuit. The PTO rejected all the
claims under 35 U.S.C. § 102(a) "as being anticipated by Dana III (European 121,026). It is inherent that the mercury switch is selectively connecting and disconnecting the light source by the motion of the wearer." Rodgers amended the claims 4 to include a circuit that was "designed to connect the light source to the power source responsive to switch transition to 'on' state but further adapted to disconnect the power from the battery a predetermined time after transition." The inventor went on to distinguish his invention by stating that "the claimed invention thus provides motion responsive shoe illumination where the automatic turn-off allows the shoe to be stored in any attitude without risk of running down the battery and provides prolonged battery life."

--- Footnotes ---

4 Claim 8 in the application was issued as claim 1 of the '009 patent; the claims were nearly identical in Rodgers' office response. The only difference is that the final claim element in claim 8 - corresponding to the timing circuit limitation in claim 1 of the '009 patent as issued - requires "said circuit being adapted to disconnect said power source from said light source a predetermined time after said transition."

--- End Footnotes ---

This claim was rejected as being obvious; the examiner stated that "Dana III (U.S. 4,158,922) shows that it is old to use a switch which alternated 'off' and 'on' to turn the light on and off." Rodgers then added the timing circuit element, explaining that "the independent claims have been amended to expressly refer to a timing circuit. . . . the cited art does not show such a timing circuit and applicant's claimed invention prolongs battery life, is energy efficient and allows encapsulation." Thus, in order to overcome Dana III, Rodgers explicitly distinguished the process of extinguishing the illumination through the use of a timing circuit from extinguishing illumination through the use of a switch which alternated between "off" and "on."

Based on the written description and the prosecution history of the '009 patent, we interpret "timing circuit" within the context of the '009 patent to be an assemblage of electronic components that cuts off the power to the light source a predetermined time after a switch, responsive to the motion of the footwear, transitions between the "off" to the "on" state. The timing circuit cuts off the power to the light source regardless of the position of the switch, i.e., if the switch remains in the "on" position, the light source will be disconnected from the power source, preventing battery exhaustion.

--- 4501 ---

Subparagraph (b)(iii) of 16 states:

a timing module having an input coupled to said trigger output of said resistive switch, a control output coupled to said generator control input and an arm/ disarm output coupled to said arm/ disarm input of said resistive switch.

This claim will be construed as: a specific distinct timing module having an input and two outputs. The input is connected to the trigger output of the resistive switch. A control output is connected to the high voltage generator control input. An arm/ disarm output is connected to the arm/ disarm input of the resistive switch.

--- 4502 ---

Lastly, the last clause of subparagraph (b)(iv) states:

said timing module disarms said trigger circuit of said resistive switch upon said activation of said timer module until said timer module is reset.

This clause will be construed as: the timing module has an output that is coupled to the trigger circuit of the resistive switch to disarm the trigger circuit until a power on reset signal re-enables or re-sets the timing module.
4503

4. "timing parameter"

The plaintiff proposes that no construction is required because the term can be understood according to its plain and ordinary meaning. The defendant proposes "the selectable values which are used to control the timing characteristic of the memory signals."

The plaintiff contends that the defendant's proposal simply repeats limitations already in the claim, i.e., selecting values and controlling the timing characteristic of memory signals. The defendant, on the other hand, points to the prosecution history where, in response to a rejection, the applicant stated that "timing parameters . . . are the selectable values which are used to control the timing characteristics of the memory signals." Response to Office Action, Oct. 14, 1994, at 3. In reply, the plaintiff argues that this statement does not dispositively indicate that the applicant intended to use the phrase in a manner inconsistent with its ordinary meaning.

The Court agrees with the plaintiff that the defendant's proposed construction simply restates limitations already in the claim. The last portion of the claim specifically states that the timing control signal controls "the timing characteristic" of the memory signals. The claim language and the specification provide the proper guidance for construing this term. Claim 7 states that a timing control signal is generated "in response to the selected timing parameter." '924 patent, 10:38-40. The specification also states that the timing parameters are converted into timing control signals by the timing control units. '924 patent, 3:47-52. In light of the claim language and the specification, "timing parameter" means "value used to generate timing control signals."

4505

a. "Timer" and "timing signal corresponding to the application of electrical energy"

At oral argument, the court proposed definitions for "timer," which appears in Claims 1 and 9, and "timing signal," which appears only in Claim 1. The court proposed that a "timer" is a "device or component capable of measuring time and capable of producing output corresponding to its time measurements," and that a "timing signal corresponding to the application of electrical energy" is a "signal that the timer produces corresponding to the elapsed time of a defibrillator shock pulse or phase of a pulse." These definitions are derived from the three paragraphs in the specification that discuss the timer. 212 Patent at 7:3-31. The parties seemed to accept these definitions when the court proposed them. In any event, they offer no compelling evidence in support of different definitions.

The court notes that the specification describes the timer as capable of cutting off a defibrillator pulse when it receives information from another device indicating that the pulse voltage or current has dropped below a threshold value. 212 Patent at 7:12-15, 7:29-31. Defibtech suggested at oral argument that the "timer" of Claims 1 and 9 requires such a capability, but the court finds no indication that the inventors intended such a limitation on the claimed timer.

4506

3. Titanium Film Containing Nitrogen Atoms

A "titanium film containing nitrogen atoms" is a thin titanium layer with nitrogen atoms. It may be a composite film
including a thickness with a substantial nitrogen concentration and a thickness with little or essentially zero nitrogen concentration. It may include titanium nitride at some point in its thickness.

1. Titanium Nitride

Titanium nitride is a compound with a one-to-one ratio of titanium atoms to nitrogen atoms.

L. "To," "From" and "Through"

Rejecting the parties' arguments that "to," "from" and "through" should be specifically construed, the magistrate judge recommended that the terms "should be given their generally understood and customary meanings." First Report at 6. Visa objects to the magistrate judge's recommendation, seeking claim construction. Def. Obj. to First Report at 10. Visa contends that "to" should be construed to mean "directly arriving at and not by way of another named party unless otherwise recited in the claim; i.e., having a destination address of." Id. Visa proposes that "from" be defined as "originating from the sender [of the transmission], who is; i.e., having a source IP address of." Id. "Through" should be construed to mean "by way of a second transmission originating with a party with the source address of." Id. After proposing these definitions in place of the magistrate judge's reference to the ordinary and customary meaning of the terms, Visa states its belief that in the context of the '878 patent, Visa's proposed construction are the same as the generally understood and customary meanings of the words "to," "from," and "through." Visa concludes by stating that it proposed its constructions "in order to eliminate any possible ambiguity." Id.

The Federal Circuit reiterated in Phillips that words of a claim "are generally given their ordinary and customary meaning." Phillips, 415 F.3d at 1312 (quoting Vitronics Corp., 90 F.3d at 1582. Ordinary and customary meaning is "the meaning that the term would have to a person of ordinary skill in the art at the time of the invention[.]") Id. at 1313. "In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words." Id. at 1314. This is just such a case. Moreover, the court agrees with Plaintiffs that Visa's proposed definitions are "remarkably detailed" and that Visa is attempting to "import[ ] very specific and lengthy technical definitions[ ] onto these "simple phrases." Pl. Reply to Def. Obj. to Second Report at 6. Finally, Visa admits that its proposed construction are the same as the generally understood and customary meanings of the words "to," "from," and "through" and that it is merely seeking to avoid any ambiguity. Def. Obj. to First Report at 10. Accordingly, the court determines that the magistrate judge correctly concluded that "to," "from" and "through" "should be given their generally understood and customary meanings." First Report at 6. Accordingly, the court overrules Visa's objection.

6. The term "to a monitor mode" should be interpreted as follows: "to the point the microprocessor is executing a line of code as part of the program."

2. "to a television set"

The plaintiff contends that the term "to a television set" as used in claim 8 of the '094 Patent means to a television set or a receiver for a television set. Joint Claim Construction Brief, Exh. A. The defendants, by contrast, argue that the term means
that the broadcast must be directly to a television set and not to any component residing outside of a television set. Id.

Although the plaintiff argues that its construction comports with the ordinary meaning of the phrase "to a television set," Broadcast's Opening Claim Construction Brief at pp. 18-19, where does the additional language of "or a receiver for a television set" have its origin? According to the plaintiff, the specification describes an embodiment in which receiving and decoding are accomplished by a set top box or receiver connected to the television, and not by the television set alone, pointing to the following:

In conceptual terms, the database receiver at a receiver station generally comprises decoder means, receiver processing means, memory means, input means and means for communicating selected database data.

'094 Patent, col. 4, lines 43-46.

The defendants argue that the doctrine of claim differentiation precludes the plaintiff's proposed construction. The doctrine of claim differentiation provides that when a limitation is included in several claims but stated in terms apparently different in scope, "there is presumed to be a difference in meaning and scope. . . ." Tandon Corp. v. U.S. Int'l Trade Comm., 831 F.2d 1017, 1023 (Fed. Cir. 1987).

In support of their claim differentiation argument, the defendants point out that while claim 8 limits a broadcast "to a television set," claim 22 concerns the receipt of broadcast data by "a communications device such as a personal computer or television or set top box adapted to receive a data stream. . . ." Similarly, claim 29 concerns the broadcast of a carrier signal to "a user."

When the inventors meant to be expansive in describing various receptors of a broadcast, they used expansive language, including receipt by "a personal computer or television or set top box," '094 Patent, col. 23, lines 17-19, and receipt by a "user." Id. at col. 24, lines 14-15.

The plaintiff argued for the first time at the Markman hearing that the use of different language can be explained by the fact that claim 8 concerns broadcasting information, not receiving it, and therefore less thorough language was used. Claim 22, the plaintiff argues by distinction, concerns receiving broadcast information, and there the more expansive language of receipt "by a personal computer or television or set top box" is used. Record, pp. 35-37. The difference in language can be explained by the different purposes of the claims. But as the defendants countered at the Markman hearing, the inventors used the most expansive language of all--broadcast "to a user"--in claim 29, a claim dealing with broadcasting, like claim 8, and not with receiving a broadcast. Record, pp. 77-78.

The plaintiff has presented no evidence to rebut the presumption that the use of different and far more restrictive language in claim 8, concerning broadcasting "to a television set," was not intentional. Modine, 75 F.3d 1545, 1551. Applying the doctrine of claim differentiation, I agree with the defendants, and I construe the term "to a television set" as used in claim 8 to mean directly to a television set and not to any component residing outside of a television set. I reject the plaintiff's position that "to a television set" includes also to a receiver for a television set. GO BACK

4511

3. "To Allow the Device to Withstand Relatively High Breakdown Voltages"

13. IXYS asserts that the language "to allow the devices to withstand relatively high breakdown voltages" requires that the claimed base profile increase breakdown voltage over the same device structure without a deep base portion.

14. It is the case that the claim is directed to base structures that improve the ability of the base to withstand breakdown. The specification states that the "lower portion" of the lightly doped material has a thickness and resistivity selected to withstand the desired breakdown voltage -- "The lower portion has the high resistivity desired to produce high reverse voltage ability, and will have a depth dependent on the desired reverse voltage for the device." ('699 patent, 2:17-19.) Thus, in testing whether or not the deepened base portions have the effect of improving breakdown voltage, it is important to keep the "lower portion" -- the portion of the device between the lowest extent of the base-drain junction and the high conductivity
"drain conductive region" -- constant in terms of its thickness and resistivity. If that is done, and for a given voltage applied across the device, the claimed base structure should have reduced peak electric fields, and hence reduced susceptibility to breakdown, than the same device (i.e., a device having the same thickness and resistivity of the material beneath the base) without the deepened base portion.

15. A MOSFET or IGBT will breakdown at the point of the structure with the greatest susceptibility to breakdown. This could be in the center of the chip, or it could be at the edge, or it could be at the substrate, or it could be somewhere else on the chip. The invention is directed to a structure that improves the breakdown voltage performance of one portion of the device -- the base-drain junctions near the top surface of the active area. Design decisions concerning other aspects of the device (such as the edges or the substrate) will not detract from improvements in breakdown performance at the base-drain junction, even if those other design decisions result in the device breaking down at points away from the base-drain junction.

16. The use of guard rings and field plates to improve breakdown performance at the edge of a chip was well known in the art in 1978. The '699 patent refers explicitly to a field plate: "Source electrodes 22 and 23 can be laterally extended as shown to serve as field plates to help spread the depletion region created during reverse voltage conditions." ('699 patent, 3:55-59.) The use of guard rings and field plates to improve breakdown voltage at the edge of the chip is not inconsistent with the use of deepened base regions to improve breakdown voltage in the active area.

17. For these reasons, this claim limitation is properly construed to permit improvements in breakdown performance of the base-drain junction, even in designs where breakdown first occurs in other locations of the device.
4513

Element (d) of Claim 1 is also subject to claim construction: "a remote control system … for permitting a viewer of said television to direct said microcontroller to perform a search on at least said updated television programming information contained in said RAM of said microcontroller. ..." Gemstar and the Defendants agree that the phrase "to perform a search" means that the viewer would direct the microcontroller to retrieve all of the desired programming information of a particular type, e.g., all sports programs or all movies. SuperGuide maintains the phrase means to retrieve at least a subset of the programming, i.e., an examination of less than all the records in RAM. The specification provides:

If the viewer wished to view a subset of the information, e.g., the television program schedule for the day, the viewer, through a different set of code signals which might include the direct keying of the date on the handheld remote control unit 32, could then direct the microcontroller to output only a part of the information stored in the microcontroller RAM. Likewise, if the viewer wished to see a listing of the sports events being shown on television on a particular day, the viewer could direct the microcontroller to search through the information in the RAM and retrieve only the requested information.

... The next command of the viewer at 105 might indicate whether the viewer wished to see all of the information contained in the RAM, e.g., a complete dump of the RAM, or whether a subset of that information was desired. ... In this manner, the microcontroller would perform the function of a microprocessor in performing a search on the information contained in the RAM and determining, for example, a listing of all the television movies that are to start between 6 and 11 P.M. on a particular date.

Reiter '578, at Col. 5 ll. 16-27, 67-68; Col. 6 ll. 1-3, 17-21 (emphasis added). It is clear from the language of the claim and the specification that the search is of all the information contained in the RAM in order to produce the subset of data specified by the viewer. In addition, the invention envisioned the storage of information unrelated to television programming, such as local movie times, in the RAM. Id., at Col. 5 ll. 37-49 ("The invention envisions that additional information other than television scheduling information may be contained within the RAM of microcontroller 60."); Col. 6 ll. 60-68. Thus, the claim provides that the search will be conducted on "at least said updated television programming information." The Defendants' construction is therefore the appropriate one. The phrase "to perform a search" means a user-directed examination by the microcontroller of all the television programming information stored in the random access memory of the system and the retrieval of a subset of that information which meets the criteria specified by the user for display on the television set.

4514

b. Processing ... an electronic payment ... from the user "to the one of the multiple institutions" to which the form is directed.

Plaintiff asserts Defendant's XAP System meets this limitation because the XAP System processes a payment to an institution. Defendant, however, contends the phrase "to the one of the multiple institutions" in this limitation necessarily requires the direction of any form to multiple institutions. Because Defendant's XAP System does not direct forms to multiple institutions, Defendant argues the XAP System does not meet this limitation.

The Court agrees with Plaintiff that Defendant misinterprets this phrase and that the words "to the one of" unambiguously describe a system by which a form associated with an electronic payment is sent to one of multiple institutions. Contrary to Defendant's position, this limitation does not require a system that allows a form to go to multiple institutions.

4515

Token
Digital Reg contends "token" should be construed as "a file indicating whether access should be granted." Defendants contend "token" should be construed as "A file indicating whether the transaction has been approved; i.e. whether the object should be installed and access granted. The token is not stored on the client." Thus, the parties dispute whether a token indicates whether a transaction has been approved and whether a token must not be stored on the client.

To support their constructions, both sides point to the same part of the specification. The specification states:

"Upon receiving a message from the authorization center indicating either acceptance or rejection of the transaction, the payment server transmits a "token" back to the client computer. The token is a file indicating whether the transaction has been approved, i.e. whether the objection should be installed and access granted. If the token indicates approval, the token causes the client computer to execute the install process discussed previously, wherein, for example, a unique coded key corresponding to the object is installed at the client, along with the client machine identification code.

Col. 4:65-5:7 (emphasis indicating what the parties base their arguments on). The statement in the specification that the token indicates approval of a transaction is made in the specific, illustrative context of the execution of a payment transaction. "Token," when read in the full scope of the disclosure, is not limited to a transaction. See col. 3:16-18 (describing that access is regulated through payment transactions or other authorization information); claim 13 ("the token received is based on a result of the authorization procedure"); claim 18 (limiting claim 13 to an authorization procedure that involves a payment transaction). The full disclosure requires only that "token" means "whether access should be granted."

Defendants also contend that the token may not be stored on the client. Defendants rely on the prosecution of claim 3. During prosecution, the applicant stated:

"The token is not stored, but rather is used as a permission at the client to store the unique key. The token, incapable of interception during transmission, exists on the client only long enough to generate the unique key. No longer existing, the token is incapable of being transferred to another client."

Defendants' Markman Brief (Docket No. 238), Ex. B at 134. 2 This was said in response to the examiner's rejection under 35 U.S.C. § 112, P 1 of claim 3, that "the token on which selectively granting access [is based] is not transferable to another client." The examiner then stated, "The specification discloses writing the unique key, i.e. token, to a Windows registry file on page 16. However, the specification does not disclose a method to prevent transfer of the unique key to another client." Ex. B at 133-34.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 Exhibit B to Defendants' Markman Brief (Docket No. 238) is the prosecution history. For ease of reference, all cites to the prosecution history will be cited to as "Ex. B at ."

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

Neither claim 1 nor the specification expressly require that the token not be stored. Claim 3 adds a further limitation about how the token is used rather than what the token is. During prosecution, the applicant was clarifying that the token is used at the client and exists at the client long enough for the generation of the unique key. The applicant was clarifying to the examiner that the token and unique key were not the same thing. The token is necessarily stored on the client long enough to generate the unique key. Thus, this statement is not tantamount to a disclaimer that the token should be limited to not being stored. Claim 1 is non-specific and is not written to disclaim storage of the token in the client's registry.

Accordingly, the Court construes "token" as "a file indicating whether access should be granted."
The parties dispute whether a token consists of a four-part data structure. NetApp contends that it does, and Sun proposes a much more general definition of the term. To begin its analysis, the Court first turns to the claims themselves. The term "token" appears in claims 3, 4, 6, 7, 8, 10, 13, 16, 21, 22, 23, and 24 of the '683 patent, and in claims 1, 8, 11, 14, 16, and 18 of the '249 patent. Claims 1, 11, and 16 of the '249 patent state that the host state is a tree structure including elements in a hierarchical relationship, with "the elements being given value by associated tokens, the elements and associated tokens representing hardware and software components of the computer system." '249 patent at 39:5-10, 40:29-33, 40:65-41:3; see also '249 patent abstract. This claim language demonstrates that tokens give value to elements and represent hardware and software components of the computer system. Other claims also reflect that tokens communicate information about elements, but these claims vary in their specificity. See, e.g., '683 patent at claim 6 ("searching the token data base for at least one token that refers to the respective element type"); claim 16 ("at least one token respectively associated with each of the elements"); claims 3 and 21 ("each of the token types having a value of one aspect of the component information and an indication of an association with one of the elements in the static tree"); claim 23 ("at least one token that refers to the respective element type"). While this claim language indicates that tokens communicate information about elements, the claims do not specifically define what a token is. Nor do the claims rule out the possibility that a token may have other attributes, as evidenced by the varying specificity in which different claims discuss the relationship between tokens and the objects to which they refer. For example, claims 3 and 21 discuss tokens having a value of the component information and an association with an element, while other claims merely discuss the reference to an element. The claim language, therefore, neither defines tokens, nor precludes tokens having certain structural components.

Certain claims refer to the constituent parts of a "token." Claim 16 of the '683 patent, for example, refers to the test output value and the identifier of the element. However, as NetApp notes, reference to the constituent parts of a "token" in certain claims does not provide a basis for disregarding a definition provided by the specification. In Honeywell Int'l, Inc. v. Universal Avionics Sys. Corp., 488 F.3d 982, 990 (Fed. Cir. 2007), for example, the Federal Circuit upheld the district court's construction based on the specification, where the specification made clear that the disputed term "look ahead distance" was a function of both speed and time, even though the claim language described a signaling device for "defining a look ahead distance as a function of the speed of the aircraft" only. Id. (emphasis added). In the present case, therefore, even if certain claims only refer to certain parts of the token or describe tokens very generally, the token may still have a four-part data structure if the specification defines "token" to have such a structure. Accordingly, the Court turns to the specification.

NetApp relies heavily on the following definition of "token" in the specification in support of its proposed construction, while Sun disputes that the patentee was acting as a lexicographer in this passage:

In order to extract information from the diagnostic data stream, "token types" are utilized. A token type defines each token to have a token name and a test name. A test name comes from the tests shown e.g., in Table 1 or in Table 2, and indicates which test output contains the information for each token. In addition to a token name and a test name, each token has a label and a value. The label for the token gives the token knowledge about what element the token is associated with, i.e., the parent of the token which is an element. The value of the token provides a value extracted from the diagnostic data that gives value to the element.

'249 patent at 7:10-20; '683 patent at 6:33-43 (emphasis added). NetApp argues that Sun's construction ignores this four-part structure of a token that includes: a name, an identifier of an element (token label), an identifier of a test to be performed on the element (test name), and a test output value (value of the token). In addition, NetApp argues that the following paragraph, which also appears in both patents, provides further confirmation that "token" refers to a four-part data structure:
For instance, assume a disk element exists with a name of "c0t10d0." Assume also that a token exists for such a disk element indicating the number of sectors per cylinder. The name of such a token would be, e.g., "number of sectors per cylinder." The test name in the token would be "vtsprobe" since the output of that test provides the information needed for the number of sectors per cylinder. The label for the token would be "c0t10d0" indicating that token is associated with a particular disk having that name. Finally, the token would have a value which indicates the number of sectors per cylinder.

'249 patent at 7:21-35; '683 patent at 6:44-58 (emphasis added).

The issue here is whether or not this four-part data structure limitation applies to all of the references to "tokens" in the patent claims. Statements that "describe the invention as a whole, rather than statements that describe only preferred embodiments, are more likely to support a limiting definition of a claim term." C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004) ("Statements that describe the invention as a whole are more likely to be found in certain sections of the specification, such as the Summary of the Invention."). Here, the passage describing the four-part structure is not in the summary of the invention. However, while statements that describe the invention as a whole are more likely to be found in certain sections of the specification of the invention, such as the summary of the invention (see id.), they need not be contained in only certain parts of the specification. For example, as NetApp notes, in Sinorgchem Co. v. International Trade Commission, 511 F.3d 1132, 1136 (Fed. Cir. 2007), the Federal Circuit applied the definition of the term "controlled amount" that appeared in the "detailed description of the invention" in the middle of a long paragraph describing embodiments. See Weber Decl, Ex. 1 (U.S. Patent No. 5, 117,063 at 4:48-52). In Sinorgchem, the Court noted that the presence of quotation marks around the claim term strongly indicated that what followed was a definition. See 511 F.3d at 1136.

In the present case, the above passage defines the parts of a token. While the phrase "token" does not appear in quotation marks in this section of the specification, the phrase "token types" immediately proceeding the token term is in quotes, and the passage defines "tokens" in the context of "token types." In addition, the passage explicitly uses the word "defines" when outlining the token's components. Sun argues that the use of "define" has a specific meaning in computer science that refers to the creation of an object or variable in a programming language. Declaration of Dr. Hugh Smith P 38. The same term "define" is used in a computer language sense in another part of the specification. See '249 patent at 9:42-48 ("an element can have a token defined that is the mathematical result of other tokens"). The sentence following the description of the token name and test name, however, states that "[i]n addition to a token name and a test name, each token has a label and a value," which indicates that the term "define" is used according to its normal usage in the passage at issue. '249 patent at 7:15-16. See also Reply Declaration of Professor Darrell Long P 5 (noting that "define" is not used as a programming term in the patent). Even if the term "define" is being used in the computer language sense, however, a token would still require a four-part data structure under Sun's expert Dr. Smith's own reasoning. See Smith Decl. P 38 (claiming that if the specification defined a token to mean integer, it would simply mean that tokens would have integer values); Long Reply Decl P 5 (noting that under Dr. Smith's analysis, "because the specification states that token type defines a token to be a four-part data structure, tokens will have that four-part structure").

Footnotes:

1 The Court recognizes the limited role of expert testimony in construing claims, but relies on it for background on the technology at issue and to analyze how a person of ordinary skill in the art understands various aspects of the patent. See Phillips, 415 F.3d at 1318.

Furthermore, while other parts of the specification point out that certain descriptions are "exemplary," the passage defining "token" cited by NetApp does not contain such language. For example, the specification points out the exemplary nature of static trees discussed in the preceding passage, but not of the four-part structure of tokens. See, e.g., '249 patent at 6:5-6, 6:54-57. Rather, the passage defining the token components is itself followed by a more specific example, starting with "for instance," of what these specific components of a token may be. Id. at 7:10-36. This language further supports NetApp's assertion that its proposed definition of token is not limited to the preferred embodiment. Rather, the part of the specification on which it is based provides a high-level description of "token."

The specification then notes that there are two types of tokens: element realizing tokens, which provide a way to determine
whether an element should be included when building a particular host state, and data tokens, which provide additional information about an element. This subsequent high-level description of tokens discusses the two types of tokens and reinforces the generalized nature of the "token" discussion. The specification then notes another "exemplary" output of a diagnostic test, before stating that the preferred implementation of the invention described is in an object-oriented computer language. Id. at 7:66-67, 8:8-10. Finally, the patent states that in "preferred embodiment the tokens in token data base 207 are stored as a hashtable to provide faster access to subsequent processing steps of building the representation of the system." '249 patent at 8:32-36. The above passages demonstrate that the patentee knew how to describe certain aspects of the invention as "exemplary" or "preferred implementations," yet did not so limit the four-part structure of tokens.

Sun relies on TiVo, Inc. v. Echostar Communis. Corp., 516 F.3d 1290 (Fed. Cir. 2008), arguing that NetApp seeks to improperly limit the claim term. In that case, Echostar argued that a construction requiring the use of object-oriented software was proper, because the patent described an embodiment that used terms characteristic of object-oriented programming. Id. at 1307. TiVo is distinguishable, however, because the applicant had not expressly defined a claim term. The Federal Circuit held that the use of an example that employs object-oriented programming is insufficient to require that the claims be limited to embodiments using such programming. Id. In contrast, the specification here defines the term "token type," and in that context, tokens themselves, in a higher level discussion of the term.

In addition, even if the specification describing the four-part structure did not provide an explicit definition, if the patentee uses the term throughout the entire patent specification in a manner consistent with this meaning, the term is defined by implication. See Bell Atl. Network Servs. v. Covad Commc'ns Group, Inc., 262 F.3d 1258, 1271 (Fed. Cir. 2001). Therefore, while the Court finds the lexicography relatively clear here, it turns to the other examples of tokens in the patent specification to examine whether they utilize a four-part data structure. The Court concludes that they do.

Turning to the various examples in the patent, as discussed above, Column 7 of the '249 patent discusses element realizing tokens. Sun argues that such tokens do not have a four-part data structure. Element realizing tokens "provide a way to determine whether an element should be included when building a particular host state." '249 patent at 7:42-50. A disk name token is a type of element realizing token that provides the parent field or the name. Element realizing tokens obtain information about the specific system to build a host state representation of the system. Hearing Tr. at 36. Such tokens, while not explicitly described as having a four-part data structure, follow the discussion of the four-part structure and fit into such a structure. As NetApp notes, the "test" for the disk name token would be the method by which the name is retrieved, and the name of the disk constitutes the value. 2

2 Sun maintains that NetApp's expert, Professor Darrell Long, provided examples of tokens that include only a two-part structure, giving the example of an element realizing token that identifies a disk drive and provides its name. Sun argues that a token that only provides information as to whether or not a disk exists in a certain location has only a one-part structure. However, as NetApp notes, the value component is really a value field for holding value information. This type of information will differ for different tokens. Therefore, even where the token is merely ascertaining whether or not a disk exists, the value field would still exist, but would not be populated in the ordinary sense of the word, as it would have a zero or blank value, as NetApp notes. In other words, regardless of whether or not the value is a name or a number or yes/no information, the value field exists to hold that type of information.

In addition, as noted above, the paragraph following the description of the four-part data structure gives an example of a data token that retrieves the number of sectors per cylinder, which explicitly has a four-part structure. Another subsequent example refers to at least three parts of that structure: "For example, another token associated with that disk element might be a disk manufacturer token that identifies the manufacturer as 'Seagate.' The value of the token in such an instance would be 'Seagate.'" '249 patent at 7:32-35. In this example, the token name would be disk manufacturer, and the label or element identifier would be the name of the disk, for example c01t10d0. While the patent does not explicitly discuss a test name for this example, the test name would be the name for the process used to retrieve the name, such as "get name," as Professor Long persuasively noted at the hearing. In other words, there is some type of operation or query by which the name "Seagate" must be retrieved. Because this example immediately follows the discussion of the four-part data structure, it utilizes a four-part structure, even though the patentee was emphasizing the value component, i.e., the manufacturer name,
in this example.

The '249 patent discusses yet another example of a token, stating:

An element can have a token defined that is the mathematical result of other tokens. For example, a disk space free token is derived from a simple subtraction from a disk used token and a total disk space token.

Id. at 9:42-49; '683 patent at 8:54-61. According to Sun, because the above mathematical operation is so basic, there is no "test to be performed" and no "test output value" generated. Smith Decl. P 37. Thus, Sun contends that NetApp's construction improperly excludes this particular embodiment. While Dr. Smith argues that the basic mathematical operation to be performed for those tokens defined as a subtraction of the values of two other tokens does not generate a "test output value," the specification does not support his conclusion. Even a straightforward computer operation involving subtraction generates an output and involves a subtraction "test" or method, albeit a simple one. In fact, NetApp's expert, Professor Long notes that a person of ordinary skill in the art would understand that for a disk space free token, the test output value is the amount of free disk space determined through the subtraction, and the test to be performed is the subtraction operation. Long Reply Decl. P 8. This is both logical and persuasive.

Another example of a token implementation involves tokens that are stored in a hashtable, which is a particular type of lookup table:

In a preferred embodiment the tokens in token data base 207 are stored as a hashtable to provide faster access to subsequent processing steps of building the representation of the system. A hashtable is a common key/element pair storage mechanism. Thus, for the token hashtable, the key to access a location in a hashtable is the token name and the element of the key/element pair would be the token value. . . . Token types are run against the test output indicated in the test name in the token. For example token types having a test name parameter of "df" are run against "df" test output.

'249 patent at 8:28-47; '683 patent at 7:47-65. According to Sun, this portion of the specification does not indicate that an "identifier of a test to be performed" is stored in the hashtable. Sun argues that based upon the invention's design, there would be no reason to store an identifier of a test to be performed in the token database or hashtable, because at this point in the process, the relevant data has already been collected and properly associated with the correct element in the tree structure. Smith Decl. P 39.

Sun's arguments are not persuasive, however. The hashtable discussion expressly repeats that the test name is part of the token. In addition, Sun is not really arguing that the hashtable example is at odds with a four-part data structure. Rather, Sun seems to maintain that the hashtable example has no need for all of the parts of the token that are in NetApp's definition. For example, while Sun's expert agrees that varying information can be associated with the hashtable, Sun notes that because a hashtable could contain only yes/no information, this type of hashtable would not conform to the four-part structure. However, as NetApp notes, yes/no information is itself a type of value. See footnote 2, above. In sum, Sun's argument regarding hashtables is at odds with the discussion of hashtable in the specification, which discusses all four parts of the data structure and provides an illustrative test name and test output. In addition, Sun's own expert agreed that the hashtable could have more than two elements. Hearing Tr. at 23.

Sun argues that other parts of the specification support its own proposed construction. However, these portions of the specification actually reveal that Sun's own proposed definition is too general. For example, Sun notes that the abstract of the '683 patent states that data segments that "are defined by respective token types are identified and stored as tokens in a token data base. Each of the tokens has a value field holding a value associated with the element and a parent field referring to an element with which the token is associated." See also '249 patent abstract (noting that tokens are associated with elements and give the elements value). At the hearing, Sun conceded that each token is associated with an element, which is to say that it has a parent field, and Sun's expert stated that the invention requires a correlation between the element (i.e., parent field), and the value (i.e., value field). The abstract, therefore, shows that, contrary to Sun's proposed construction, a token must have at least two components: a value field and a parent field that refer to an element.

Sun also claims that the preferred embodiment description supports its definition, in particular the statement that the system received incoming diagnostic data from a monitored computer system and subsequently the test data "is processed by token processing 211 to extract the information associated with hardware and software components in the monitored system." '249
patent at 5:36-41; ’683 patent at 5:4-11. The patent then notes that: "An element has tokens associated with it. Thus, a partition element may have a disk percentage token, disk name token, and space available token associated with it." ’249 patent at 5:61-64; ’683 patent at 5:26-32. However, this latter excerpt shows that "elements" may be associated with tokens, each token capturing different aspects of the element, and the passage merely lists token types - it does not define the term token itself.

Finally, Sun argues that the ’249 patent emphasizes the flexible and varying nature of tokens. See Sun Opposition at 7 (quoting ’249 patent at 7:55-59; ’683 patent at 7:9-13) ("The exact nature of the tokens and the total number of tokens will depend upon the system that is being monitored . . . ."). Just because tokens may be flexible and variable, however, does not mean that tokens do not share a common structure. The passages quoted by Sun discuss examples of token types and the purpose of tokens, but these passages do not provide a definition of token. In addition, the ’683 abstract refers to two different parts of a token data structure, which is inconsistent with Sun's proposed construction of unstructured data. And, as NetApp notes, even though the abstract refers to certain parts of a "token," this reference does not provide a basis for disregarding the definition provided by the specification. Cf. Honeywell, 488 F.3d at 990.

Turning to the prosecution history, NetApp contends that the applicant made a statement during prosecution of the ’249 patent reinforcing the four-part definition of token. Specifically, in response to the non-final office action filed on March 8, 1999, the applicant stated: "For a description of elements and tokens, please see, for example, pages 9-13 of the specification." See Nathan Decl., Ex. 5 at NAC0015585. NetApp argues that this patent prosecution history is similar to that in Irdeto Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295 (Fed. Cir. 2004), in which the Federal Circuit upheld the construction of the term "group keys" based in part on the applicant's statement during prosecution that the term had no accepted meaning in the art, but that the meaning was described in the specification. Id. at 1300, 1302-1303. The prosecution history here, however, does not inform the analysis of this term, because the parties are not arguing about whether the construction of "token" has an accepted meaning in the art apart from the specification, as the parties argued in Irdeto. 3 Irdeto merely indicates that the definition of "token" may be found in the specification, but the parties here both agree that the specification defines the term (although they disagree as to the claim term's ultimate meaning).

3 In Irdeto, the Court was addressing rejections based on indefiniteness. In response to the examiner's finding certain terms indefinite, the applicant stated that those terms were clearly defined in the specification. During claim construction, however, the patentee tried to argue that the term had an ordinary meaning in the art. The Court rejected this argument, relying on the prosecution history. Id. at 1298, 1300, 1303. In contrast, here, the patentee cited to pages 9-13 of the specification describing tokens and elements in order to overcome the examiner's rejection of certain claims as being unpatentable in view of prior art. The patentee was arguing that the description of elements and tokens are different from prior art. See Nathan Decl, Ex. 5 at NAC0015585.

Finally, according to Professor Long, all tokens must have the same number of fields to be consistent with the defined computer science format so that the system will work. Hearing Tr. at 57-58. While Sun's expert noted that this argument presupposes a four-part data structure, Dr. Smith did not dispute the fact that a computer system with a defined format must use that format in order to work properly and avoid crashing. Accordingly, the intrinsic evidence, most significantly, as well as the extrinsic evidence, on balance supports NetApp's proposed construction.

In sum, the Court finds that the token examples in the specification utilize a four-part data structure. However, NetApp's proposed construction is not entirely accurate for a number of reasons. First, as noted above, the "test" associated with each token is not necessarily a "test" in the normal sense. In other words, in computer language, this process may be called a test, but this does not necessarily comport with common usage, as it would likely be understood by a jury, so defining a token in this way could lead to juror confusion. Rather, the test is really a method by which the value is generated or by which the value field is populated. NetApp itself articulated the test as "deriving information about the particular system for which you want to build a representation." Hearing Tr. at 33. In addition, as Sun notes, the specification makes no reference to a test "to be performed" on the "element," as NetApp proposes in its construction. ’249 patent at 7:10-15. In fact, the above example involving the subtraction of one token value from another to determine free disk space does not involve a test performed on an element.
Second, the portion of the specification relied upon by NetApp does not discuss a "test output value." Rather, it refers to a token having a value, which "provides a value extracted from the diagnostic data that gives value to the element." '249 patent at 7:17-20. Finally, the examples above make clear that the value field need not be populated, as NetApp itself conceded that a value could be zero or blank, i.e., empty.

In sum, the Court proposes construing "tokens" as "a data structure consisting of a name; an identifier of an element with which the token is associated; an identifier of the method by which the value field may be populated; and the value field, which holds the value associated with the element, which can include an empty value." While this is a proposed construction, the parties may only comment if they find a mistake or ambiguity in the wording, as opposed to disagreeing with the Court's reasoning, and they must do so within ten days of the date of this Order.

12. Tone generator

The term "tone generator" appears in claim 4 of the '482 Patent. Diagnostic asserts that "tone generator" should be construed as "a device for generating sounds of distinct pitch, quality, and duration; i.e., tones." Benson does not propose a definition, but asserts that the "tone generator" must be located in the conventional audiometer.

The dictionary definition of "tone" is "[a] sound of distinct pitch, quality, and duration; a note." American Heritage Dictionary 1886. Therefore, the plain and ordinary meaning of "tone generator" is "a device for generating sounds of distinct pitch, quality, and duration." Next, the Court must examine the intrinsic evidence to determine whether that ordinary meaning has been rebutted or altered. Diagnostic argues that nothing in the specification or prosecution history assigns a different meaning to "tone generator." Based on its prosecution history estoppel argument, Benson argues that the Court must construe the term "tone generator" so as to require that it be located in the conventional audiometer. Finding nothing in the prosecution history that clearly limits the claim so as to require it to reside in the conventional audiometer, the Court assigns the term its plain and ordinary meaning. The Court therefore construes the term as "a device for generating a tone, or a sound of distinct pitch, quality, and duration."

4518

c. "total area of said single substrate" or "total area of said substrate"

The plaintiffs propose "the total surface of the supporting material upon or within which is formed an interconnected array of circuit elements." The defendants propose "area enclosed by the outermost edges of the substrate." This term is used in the context of memory which is claimed to occupy "a majority" of the "total area" of the substrate. The issue is what constitutes the "area."

The plaintiffs argue that the defendants' proposal would include areas of the substrate that are not being actively used (e.g., the sides and back of the substrate). According to the plaintiffs, the proper approach is to refer to the portion of the substrate that has active circuitry as depicted in Figure 9 of the '148 patent.

The area of the substrate refers to the top portion of the substrate, and not the sides or back. See '148 patent, Fig. 9. The Court construes the term to mean "the total top surface area of the substrate."

4519

"Total Traffic Load"

Alcatel's proposed construction is "information indicative of the aggregate traffic of a multiplexed output data stream"
obtained from the traffic load parameters." Cisco's proposed construction is "comparator for the total traffic of all input data streams on an output port."

Essentially, Alcatel relies on its proposed constructions for the terms "multiplexed output data stream" and "traffic load parameters," discussed above, in its definition of the term "total traffic load." Cisco, on the other hand, seeks to construe this term by using the word "comparator" and, once again, incorporating the word "port." In addition to disputing the use of these words in Cisco's construction, Alcatel also disputes the use of the word "all."

A plain reading of the claim supports Alcatel's view. The language of claim 6 clearly indicates that the total traffic load is obtained from traffic load parameters of each of the input data streams that comprise the multiplexed output data stream. See DePrycker, at 15:8-19. Cisco is correct that the use of the word total does imply that the total traffic load is comprised of the traffic load parameters from all of the input data streams. However, as stated in the claim, it is the total of the traffic load parameters of all of the input data streams that form the multiplexed output data stream that determine the total traffic load, and not all of the input data streams on an output port, as Cisco suggests. Therefore, the proper construction of "total traffic load" is "information indicative of the aggregate traffic of a multiplexed output data stream obtained from the traffic load parameters of all input data streams forming said multiplexed output data stream."

Both parties characterize the "total wager amount" as "a sum of all wagers made for each prize award." Where they differ is that Defendants claim the amount should be an actual number "not implicit from or capable of being derived from the hardware and/or software of the gaming device," whereas Plaintiff claims the number can be created by a person or the system in order to meet the needs of various criteria. (Pl. Resp. at 8.) In addition, Defendants emphasize that the total wager amount serves as a link between devices and prizes, while Plaintiff argues that linkage may occur, but it should not be a limitation of the claim. (Pl. Resp. at 7-8.)

The specification supplies a definition for total wager amount:

For a progressive prize, this is the theoretical sum of all wagers made for each prize award event. The total wager amount must be of a value that will support all the criteria for the prize starting value, increment values, and any other values generated as a result of contribution percents applied against wagers.

(‘460 Patent, col. 8:10-15.) When a specification reveals a special definition for a term, the inventor's lexicography governs. Phillips at 1316. Thus, the above definition forms the basis for our construction. We now look at the specification and prosecution history to determine whether the limitations suggested by Defendants should be adopted as well.

The Background of the Invention portion of the specification emphasizes that prior art had the wager amount and odds fixed.
in the individual devices, thus making any change of those amounts, for example due to varying market or regulatory conditions, costly and difficult. ('460 Patent, col. 3:34-42.) In contrast, this invention can use a common total wager amount to link devices with different fixed or programmable currencies and wagers together in order to share a progressive prize. (Id. at col. 3:64-67, col. 5:5-14.) This process is most clearly explained in the prosecution history:

Unlike prior art methods, the preferred embodiment can link gaming devices regardless of the wager/odds combination because the preferred embodiment utilizes a theoretical total wager amount to obtain a maximum random number range. Thus if a player wants to play a progressive game, a theoretical total wager amount is used, e.g. $10,000,000. The total wager amount may then be divided by the player's wager amount of $2 to obtain a maximum random number range of 50,000. The free play apparatus then generates a random number within 50,000 or the corresponding maximum random number range. If the generated random number matches a predetermined prize winning number, then the player is awarded a progressive prize. ('460 prosecution history at 136, Def. Hearing Ex. I.) Thus, an advantage of the instant invention is its ability to link devices with differing odds and wagers by dividing the theoretical total wager amount for each prize award by the individual wagers of the machines to achieve a number range from which a random number can be generated.

The total wager amount's ability to link devices is clearly an important aspect of the invention, as is its status as a theoretical amount, rather than the actual total of wagers bet. However, that does not mean that devices that do have total wager amounts inherent in them cannot be linked to the progressive prizes in this invention, or that those total wager amounts may not be considered somehow in the formulation of the theoretical total wager amount. The purpose of the invention is to link devices together, some of which may have fixed total wager amounts, through a theoretical total wager amount which may override the fixed ones through a free play apparatus. This purpose does not preclude using fixed total wager amounts, or the regulatory, industrial, or mechanical limitations that created them, from influencing the setting of theoretical total wager amounts. Therefore, Plaintiff's proposed construction, which recognizes the diverse considerations going into formulating a total wager amount, is more in line with the specification than Defendants' proposed construction, the adoption of which could unnecessarily preclude the consideration of the hardware or software of a particular device. Because we are not authorized to read into a claim an element that is not present in the claim itself, McCarty v. Lehigh Val. R. Co., 160 U.S. 110, 116, 16 S. Ct. 240, 40 L. Ed. 358, 1895 Dec. Comm'r Pat. 721 (1895), particularly where another construction "most naturally aligns with the patent's description of the invention," Phillips, 415 F.3d at 1316, we reject Defendants' proposed limitation that the total wager amount must not be implicit from or capable of being derived from the hardware and/or software of the gaming device.

However, Defendants' proposed limitation that the total wager amount must serve as a link between the devices is naturally aligned with the specification, and thus presents more of a dilemma. While the total wager amount's linking role is not mentioned in Claim 11, it is touted as a salient point of the invention throughout the specification. (E.g., '460 Patent, col. 3:46-56, "This invention incorporates [the advantage of linking a gaming device to a progressive prize without changing the device's hardware or software] by using the total wager amount as the basis of linkage between a prize and a gaming device;" id., col 5:5-10, "Unlike prior art progressive gaming systems and methods that control linkage between progressive prizes and game pay lines based on some representation of a coin of a specific denomination issued in a specific currency, this invention uses the total wager amount as a common element shared between progressive prizes and the linked game pay lines.") The specification does not discuss any characteristic or component other than the total wager amount as a means of linking the devices with the prizes. Therefore, it is hard to envision an embodiment of this invention that does not utilize the total wager amount as the basis of linkage between the devices and prizes.

Finally, while Claim 11 does not specify that the total wager amount is the link, when the role of the total wager amount is isolated within the claim, it appears to be a linking role. Step (B) provides for determining a total wager amount for a progressive prize. Steps C and D occur at the individual device level, setting up factors to be considered with the total wager amount in generating a random number for an individual hand pull (Step E), to be compared to the prize's winning number (Step F). Because the total wager amount provides part of the equation used in generating the random number, and because the wager is discussed by the specification as being potentially device-specific, and is put forth in the claims at the device level, the role of the total wager amount as the link between the device and a particular prize is implicitly provided in Claim 11. Thus, the meaning of the total wager amount should include its role as a link between devices and prizes. However, we do not see the need to limit that meaning to be the only link between devices and prizes.
Therefore, we adopt the following construction of total wager amount as used in Step (B) of Claim 11:

The theoretical sum of all wagers made for each prize award event. The total wager amount must be of a value that will support all the criteria for the prize starting value, increment values, and any other values generated as a result of contribution percents applied against wagers. The total wager amount serves as a link between devices and a progressive prize.

"touch sensitive screen"

Claims 1, 12, and 14 of the '057 patent contain the term "touch-sensitive screen." Typhoon defines the term as "a screen which is responsive to the touch of a finger." Defendants suggest that the term means "a device, on which a display's output is shown, that recognizes inputs in response to touch." The parties' dispute surrounds whether 1) the term "screen" needs further definition in order to contrast it with the invention's "display" and 2) whether "touch-sensitive" is limited to touch "by a finger."

With regard to the first issue, the patent makes a distinction between a "display," which is an output device that produces images viewable by the user, and a "touch-sensitive screen," which is a separate device that receives input from the user. See '057 Patent at 2:53-55 ("The input/output device has a touch sensitive screen superimposed over a display, for example, a liquid crystal display ("LCD")."). This distinction is expressed sufficiently in the claims themselves. Id. at 31:14-17 ([A] combined input/output device including a display for displaying outputs on a touch-sensitive screen, said screen superimposed over said display . . ."). Thus, contrary to Defendants' arguments, there is no need to define "screen" with regard to its relationship with the display as that relationship is sufficiently communicated in the claim language. See id.

With regard to the second issue, the specification does not limit touch-sensitivity to "touch by a finger." Typhoon cites to a number of references in the specification that clearly refer to a particular embodiment of the invention. See, e.g., id. at 10:38-41 ("A scale or bar graduated, for example, from 1 to 10 can be provided, which has a marker which moves in response to movement of a user's finger across the bar.") (emphasis added); 19:44-46 (explaining that a particular embodiment of the invention would have the ability to respond "with the touch of a finger"). Additionally, neither the claims nor summary of the invention contain any reference to "touch by a finger." It is clear from the context of Typhoon's intrinsic citations that the inventor regarded "touch of a finger" to be a convenient example for explaining the operation of the touch-sensitivity, rather than intending to limit the term to only finger sensitivity.

This conclusion is bolstered by the intrinsic evidence showing that the inventor provided a host of prior art to the Patent and Trademark Office ("PTO") describing "touch-sensitivity" that was sensitive to a variety of different stimuli. See, i.e., U.S. Patent No. 4,653,086 (filed March 15, 1985) (disclosing touch sensitivity to a stylus or pen, but not sensitivity to a finger); U.S. Patent No. 4,555,699 (filed Jan. 10, 1983) (disclosing a data entry system using a stylus or finger and "touch-sensitive" tablet). Thus, the inventor indicated to the Patent and Trademark Office ("PTO") that "touch sensitivity" based on various stimuli (not restricted to a "finger") was well-known in the art and considered when conceiving of the invention described in the '057 patent. Considering both the intrinsic and extrinsic record, references in the specification to touch-sensitivity "with a finger," were not meant to be definitional. Therefore, imputation of such a limitation into the meaning of "touch-sensitive" would be improper. Accordingly, "touch-sensitive screen" is defined as "a screen which is responsive to touch."

"Touch switch"

The invention of the '701 patent activates its shredding function using a "touch switch." Fellowes maintains that the term "touch switch" should be construed to mean a switch that requires physical contact in order to be activated. (See Fellowes's Opening Brief at 20.) Michelin, however, contends that the term "touch switch" means "touch switch, or any other kind of switch." (Michelin's Opening Brief at 10.)
Michilin conceded that "the conventional definition of a 'touch switch' means a switch that must be physically touched to be activated" (Fellowes's Opening Brief, Ex. H, Michilin's Response to Fellowes's Requests for Admissions at 4), and now cites no alternative definition of touch switch offered in the '701 patent. This matter, then, is conclusively established pursuant to Federal Rule of Civil Procedure 36(b). Fed. R. Civ. P. 36(b) ("Any matter admitted under this rule is conclusively established unless the court on motion permits withdrawal or amendment of the issue."). Moreover, Michilin did not contest at the supplemental scheduling conference held on March 29, 2006 that a touch switch requires physical contact, and Michilin II granted Fellowes's request for summary judgment of literal noninfringement. Id., 433 F. Supp. 2d at 12-13. Michilin cannot now revive an argument it opted to waive. In any case, the ordinary meaning of touch switch requires the switch to be physically touched. The claim language is clear and unambiguous. "Touch switch" means a switch that requires physical contact in order to be activated.

"tournament game"

The game machine described in the '887 patent allows each video game "to be played in either a regular (non-tournament) mode, or in a tournament mode." '887 patent at 3:8-9. According to JVL, the patentee acted as lexicographer by defining a "tournament game" as "an extended version of a standard game" that "must have more rounds than a standard game." JVL's Markman Hrg. Presentation, '887 patent at 8 ("Def.'s '887 Presentation"). Merit does not offer a specific construction for "tournament game," but it disclaims acting as a lexicographer and argues neither of JVL's limitations should be read into the construction.

A patentee acting as its own lexicographer can create a new word, assign a meaning to a word without regard to the ordinary and customary meaning of the word, or modify a word's ordinary meaning. Vitronics, 90 F.3d at 1582. Although lexicography does not require a rigid statement of definition, its assigned meaning must appear with reasonable clarity and precision in the patent. Astrazeneca AB, v. Mutual Pharm. Co., Inc., 384 F.3d 1333, 1339-40 (Fed. Cir. 2004). The specification sheds light on whether the inventor has chosen to act as his own lexicographer and used terms in a manner "inconsistent with their ordinary meaning," that is, ascribing the inventor's own meaning to the term. Vitronics, 90 F.3d at 1582.

The specification states that "a tournament game consists of an extended version of the standard game." '887 patent at 9:15-16. In construing "tournament game," the critical issue is whether this statement applies to the patent without qualification or whether it describes only a specific embodiment of the invention. JVL argues this statement is not exemplary, but unambiguously applies to the invention as a whole. Merit disagrees, insisting this language merely describes the preferred embodiment of Figure 10.

To resolve this dispute, it is necessary to consider the context of the statement. The language at issue appears in the section of the patent entitled "Detailed Description of Automated Tournament System." This section includes descriptions of the drawings included in the patent. It states "if the Tournament Setup button" of Figure 9, "is pressed on the initial setup display screen, the Tournament Setup display screen of Figure 10 appears." '887 patent at 7:54-56. Figure 10 is a "Tournament Setup display screen" for a preferred embodiment of the invention. See '887 patent at 2:27-29, 2:48-49. This "Tournament Setup display screen allows access" to a number of functions depicted in Figure 10. See '887 patent at 7:57-58; '887 patent, Fig. 10. Following the functions listing, is "an example of recommended prices for the Credit Fields of the tournament games shown in Figure 10," which depicts, among other things, three rounds of a Solitaire tournament game being offered for eight credits. Id. at 8:65 - 9:11. Following is the terminology at issue:

As noted above, a tournament game is played in the same manner as a standard (non-tournament) game. However, a tournament game consists of an extended version of the standard game. For example, the standard Solitaire game may have only one round and may cost one credits [sic], while the tournament game offers three rounds for eight credits.

'887 patent at 9:13-18. (emphasis added)

To refute JVL's argument that the italicized language provides an unqualified definition of "tournament game," Merit insists...
Figure 10 is simply an "example" relating to "recommended default prices for the Credit Fields," not a definition of tournament games. The issue is not what Figure 10 depicts. It is whether the sentence refers only to Figure 10 or to the patent generally.

Although the context does not clearly indicate an intention to limit application of the "extended version of a standard game" language to Figure 10, the record does not show that Merit acted as its own lexicographer. Merit was free to assign "tournament game" a meaning other than its ordinary one. In order to do so, it had to "deliberately and clearly point out how [this term differs] from the conventional understanding." Apple Computer, Inc. v. Articulate Systems, Inc., 234 F.3d 14, 21 n.5 (Fed. Cir. 2000) (citation omitted). The patentee's lexicography must, therefore, appear 'with reasonable clarity, deliberateness, and precision' before it can affect the claim." Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998) (quoting In re Paulsen, 30 F.3d 1475, 1480 (Fed. Cir. 1994)).

Merit did not assign any unconventional meaning to "tournament game." JVL cites a single sentence in the entire patent application/specification to support its argument. There is nothing in that sentence and the context in which it appears to support a "clear" or "deliberate" intention to redefine the term. Therefore, the first part of JVL's proposed construction, "an extended version of a standard game," is not adopted.

JVL also construes a "tournament game" as having "more rounds than a standard game." Def.'s '887 Presentation at 8. As noted above, the specification states "the standard Solitaire game may have only one round and may cost one credit [sic], while the tournament game offers three rounds for eight credits." '887 patent at 9:16-18. This language describes recommended tournament game prices for the Tournament Setup display screen example of Figure 10 which relates to the preferred embodiment of a tournament system found in Figure 1. See id. at 2:48-49; 7:19-20. It describes what may, not what must, occur. Id. In other words, it is a possibility that does not limit a "tournament game" to always having more rounds than a standard game. Phillips, 415 F.3d at 1323. Nor, contrary to JVL's suggestion, can a blanket limitation be found in the example of default prices for the Credit Field of the tournament games shown in Figure 10. The patent states that the default prices are merely an example applicable to Figure 10. '887 patent at 8:65-9:12. Accordingly, the second aspect of JVL's construction of "tournament game" is not adopted.

"Tournament game" as used in the '887 patent is simply "a game playable in the tournament mode." As the specification describes, "[i]n the tournament mode, a plurality of tournament games are playable by a plurality of players …" '887 patent at 2:1-2. The "detailed description of the invention" distinguishes when a player plays what JVL might call a "standard" game from a tournament game: "[t]he video game machine may allow for each of the video games to be played in either a regular (non-tournament) mode, or in a tournament mode." Id. at 3:7-9. The specification's "overview of automated tournament system" prescribes certain necessary functions:

1. A selected number of pre-loaded video games are designated as games which can be played in the tournament mode;

2. A portion of each tournament game price is programmed to be allocated to the prize pool. An initial seed amount may also be set;

Id. at 3:21-27. This juxtaposition suggests that a "tournament game" is one of the pre-loaded games described in the first clause. Accordingly, "tournament game" is construed as "a game playable in the tournament mode."

The next disputed term, "tournament period for each tournament game" is part of the means-plus-function limitation of Claim 1(c) ("means for programming a tournament period for each tournament game, . . ."). JVL defines a "tournament period for each tournament game" as "a block of time during which each tournament game in a sequence can be played, which is defined before the sequence begins." Def.'s '887 Presentation at 18. Merit defines the function in this means-plus-function limitation as "programming a tournament duration for each tournament game in the sequence of tournament games." Pl.'s '887 Presentation, Ex. 2 at 2.
The specification clearly states that each tournament game has a programmed tournament duration. '887 patent at 2:7-8 ("… a tournament period is programmed for each tournament game.") Thus, this aspect of both constructions is correct.

JVL and Merit disagree as to when the length of the tournament period is programmed. JVL contends the tournament period is defined during setup, before the sequence begins. It relies primarily on the following specification language:

During the setup mode, the tournament duration for each tournament game is set and stored in the tournament duration selector/memory 22. Specifically, start and stop dates and times are selected. The tournament duration may be as short as a few hours, or may be very long, such as a month. The processor 14 is programmed to allocate a percentage of the coin drop 20 to a prize pool 24 during the duration of the tournament. Once all of the setup parameters are entered, the video game machine 12 is placed in a game play mode or normal operating mode.

'887 patent at 4:57-66 (emphasis added). The cited language describes that the tournament period is fixed during the setup mode, not when the machine is in the tournament mode. In other words, the time limitations are set before the tournament games are played.

Merit equates JVL's "before the sequence begins" language with "preprogramming" and notes that the patent specifies "programming" as opposed to "preprogramming" with respect to the tournament period. The brief summary of the invention states:

One or more sequences of tournament games are preprogrammed from the plurality of tournament games, and a tournament period is programmed for each tournament game. The preprogrammed tournament game for each sequence is playable during the programmed tournament period for the respective sequence. A plurality of sequences of tournament games may be preprogrammed to run simultaneously.

'887 patent at 2:6-13 (emphasis added). The language of claim 1 makes the same distinction. Claim 1(b) discloses a "means for preprogramming at least one sequence of tournament games from the plurality of tournament games." Claim 1(c) states "means for programming a tournament period for each tournament game, the preprogrammed tournament game for each sequence being playable during the programmed tournament period for the respective sequence." The specification and claim language clearly distinguish between "preprogramming" sequences of tournament games and "programming" tournament periods, indicating that tournament game sequences are programmed earlier than tournament periods.

JVL suggests that the duration for each tournament game is set before the sequence is played. It does not contend that the tournament period is set or programmed before the sequence of tournament games is programmed. Sequences of tournament games can be preprogrammed and the tournament period for each tournament game can be programmed subsequently without undermining the fact that the programming of the tournament period occurs in the setup mode before the video game machine is placed in game play mode and made available for users to play tournaments. Consequently, Merit's arguments do not undermine JVL's "before the sequence begins" construction. Nonetheless, this language is redundant as the patent teaches that the setup functions occur before a player can play any games. '887 patent at 3:38-39 ("Next, the setup mode is exited and the video game machine becomes ready for game play.") JVL’s construction is not adopted in its entirety.

"Tournament period for each tournament game" is construed as "a period of time, set during the setup mode, during which each tournament game in a sequence can be played."

1. "Track"

Both patents at issue in the instant case use the word "track" in similar contexts. For example, Claim One of the '531 Patent states in relevant part:

upon completion of the data entry, copying the working directory from the updatable memory to the track on the CDROM containing the last entered data, writing a track information map, and closing the track where the data is entered.
Each party's proposed claim construction of "Mack" is as follows:

<table>
<thead>
<tr>
<th>Optima's Proposed Claim</th>
<th>Roxio's Proposed Claim</th>
</tr>
</thead>
<tbody>
<tr>
<td>Construction</td>
<td>Construction</td>
</tr>
<tr>
<td>&quot;Track&quot;</td>
<td>A data structure</td>
</tr>
<tr>
<td>A sequence of sectors,</td>
<td>comprising one or more</td>
</tr>
<tr>
<td>the sector numbers of</td>
<td>groups of contiguous</td>
</tr>
<tr>
<td>which form a contiguous</td>
<td>data blocks.</td>
</tr>
<tr>
<td>ascending sequence. No</td>
<td></td>
</tr>
<tr>
<td>sector belongs to more</td>
<td></td>
</tr>
<tr>
<td>than one track.</td>
<td></td>
</tr>
</tbody>
</table>

The parties agree that the term "Track" is a well-known term in the art of Compact Discs; however, Roxio argues that Optima modified the term's meaning by defining it in the '531 Patent and thus acting as a lexicographer. (Roxio's Opening Claim Construction Brief, p. 15.)

The Court agrees with Roxio and finds that Optima acted as its own lexicographer by defining the term "Track" in the '531 Patent. This finding is compelled by the following language in the "Definitions" section of that patent: "A packet is a grouping of contiguous user data blocks and is the smallest unit of data that can be written to a recordable CD. . . . A track is a grouping of one or more packets." ('531 Patent, col. 3, ll. 2-15.).

The Court construes the term "Track," as used in the '531 Patent, to mean a grouping of one or more packets, each of which is comprised of a grouping of contiguous user data blocks. 12

The term "Track" is used in the '686 Patent as well; however, Roxio did not include a definition of the term and thus did not act as its own lexicographer. Therefore, the Court finds that the customary meaning of the term will be applied to the '686 Patent. Optima's proposed construction is consistent with the customary definition 13 and thus is accepted by the Court as the proper definition of the term "Track," as used in the '686 Patent.

Optima's proposed construction, "A sequence of sectors, the sector numbers of which form a contiguous ascending sequence. No sector belongs to more than one track," mirrors the language of TC 15 Working paper (1992), a document cited by both parties as an industry standard.

In the Markman hearing this Court found that the '531 patent "relates to a new October 6, 2005, recording technique that allows a standard recordable CD-ROM drive to appear to, and be accessed by, a user in the same manner as a non-volatile memory." (Markman Order, p. 2.) The Court held that the '531 patent specification demonstrated that the patentee, acting as his own lexicographer, defined "track information map" as: "A data structure that is stored on the last use data blocks on the last packet of the track. It contains the start logical block address of the directory, and the start and end logical block address of every track." (Id., p. 17.) Put another way, the track information map includes the logical block addresses for the start of...
the directory, the start of every track on the CD, and the end of every track on the CD.

4527

D. "Track pitch"

Plaintiff's construction: the distance between adjacent track centerlines, as measured in the radial direction

Defendants' construction: the distance between pits in the adjacent tracks (represented in FIG. 3 as Pt)

The parties dispute whether "track pitch" should be defined in terms of "pits" or "tracks." This dispute seems to be less about the actual construction of the term and more about trying to predict what the other side will argue in the context of an infringement or invalidity analysis. Although the parties argue vigorously in favor of their own proposed definitions, the parties' proposed constructions are not very different. The parties agree that the distance "Pt" in Figures 3 and 5 of the '651 patent illustrates the track pitch:

[SEE FIG. 3 IN ORIGINAL]
[SEE FIG. 5 IN ORIGINAL]

Defendants' construction is ambiguous as proposed because it is unclear whether the track pitch should be measured from the outside edge of the pits, the center of the pits or somewhere else. At the claims construction hearing, defendants clarified that they are satisfied with measuring track pitch from the center of the pits; indeed, they even are willing to embrace the term "centerline" so long as it is clear where to place it. Transcript, dkt. 92, at 105. Plaintiff, however, hews to its position that we're talking about the pitch between tracks, not pits, so that pits should not be the frame of reference. Id. at 44-47.

Plaintiff has the better argument; my only concern is its use of the word "centerline," which is not used in the '651 patent. Although the meaning of "centerline" may be inferred from Figure 3 of the patent, it will avoid confusion by changing the definition to "the distance between the center of adjacent tracks, as measured in the radial direction."

Court's construction: the distance between the center of adjacent tracks, as measured in the radial direction

4528

1. "tracking movement of the device relative to a region of an environment in which said device resides"

Avago proposes that the above phrase be construed as "tracking movement relative to features in the environment where the device operates." Elan proposes the following construction: "Tracking changes in the position and angular orientation of the device in a three-dimensional environment."

Claim 14 is not limited to a device that tracks angular rotation. The written description describes translating pitch as vertical movement, and yaw as horizontal movement, but then states that "[i]n this embodiment, translational movement of the device may also be detected and utilized, so that vertical and horizontal movement of the device translates to a corresponding vertical or horizontal movement of the screen cursor." Col. 4, ll. 15-21. Furthermore, the doctrine of claim differentiation suggests that the Court should not construe Claim 14 as limited to angular movement, as Claim 15 specifically adds the limitation of angular movement.

The remainder of the contested claim language, "environment in which said device resides," refers to a three-dimensional environment. The plain and ordinary meaning of "environment" is as three-dimensional space --unlike a point, a line, or a plane. Furthermore, "environment" as used in the claim language is specified as that "in which said device resides." Claim 14 (emphasis added). The residence of the device is distinguishable in the plain and ordinary lexicon from a planar surface on which the device operates. Such a distinction is also supported by the patent's description of the problem the invention
was intended to solve: "The concern is that there may not be a suitable planar operating surface that is convenient to the operator." Col. 1, ll. 63-65.

Avago argues that the device may not be limited to necessarily being capable of operating in three dimensions. Whether the device claimed by Claim 14 operating in only two dimensions would infringe on a device that is capable of operating in three dimensions is a question for a later stage in this litigation. For the purposes of construing the claims in this patent in light of the specification, "environment in which said device resides" means "the three-dimensional space in which said device may operate," and thus, "tracking movement of the device relative to a region of an environment in which said device resides" is construed to mean "tracking movement of the device relative to a region of the three-dimensional space in which said device may operate."

C. The Proper Construction of Claim 10

"The focus in construing disputed terms in a claim language is not the subjective intent of the parties to the patent contract when they used a particular term." Markman, 52 F.3d at 968. Rather, the focus is on the objective test of what one of the ordinary skill in the art at the time of the invention would have understood the term to mean. Id. (emphasis added). The Court will follow the precedent established by the Eleventh Circuit in Markman and construe the terms "traditionally connectible" and "standard" I/O port to mean devices that were "traditionally connectible" and I/O ports that were "standard" at the time of the invention. Therefore, the Court defines traditionally connectible as a device that would be connectible to a computer as it was in October of 1988. See Webster's New World Dictionary 1417 (Victoria Neufeldt ed., Simon & Schuster 1988) (defining traditional as conforming to tradition; conventional). The Court construes the word "standard" as "regularly and widely used, available or supplied" as of October 1988. See Novo Nordisk A/S v. Becton Dickinson & Co., 2000 U.S. Dist. LEXIS 3384 (S.D.N.Y .) aff'd, Novo Nordisk v. Becton Dickinson & Co., 304 F.3d 1216 (Fed. Cir. 2002); See Webster's New World Dictionary 1306 (Victoria Neufeldt ed., Simon & Schuster 1988) (defining standard as conforming to what is usual; regular or typical). As a result, the claim construction analysis of claim 10 is similar to the analysis found in claim 1.

A. "Traffic channel encoding selector"

The parties now agree that the proper construction of this term is: a module that selects the encoding scheme to apply to a traffic channel. I This construction is consistent with the words of the claim, specification, and prosecution history.

1 During briefing, the parties offered slightly different constructions. WiAV proposed the construction: module that selected the encoding scheme for a traffic channel. (emphasis added). The Defendants proposed the construction: module that selects the encoding scheme applied to a traffic channel. (emphasis added). The difference in proposed construction stems largely from the parties' disagreement over whether an encoding scheme must be applied to a traffic channel at all as well as the timing of that application and the structure that performs it.
a control channel signal quality estimator; and

a traffic channel encoding selector coupled to said control channel signal quality estimator, said encoding selector selecting an appropriate error correction [overhead] scheme to apply to data transmissions on said at least one traffic channel in response to said control channel signal quality estimator …

205 Patent at 14:1-14; 14:40-51 (emphasis added). The claims themselves use the phrase "to apply to" and support a construction that uses that phrase as well.

2. Specification

The specification describes the function of the traffic channel encoding selector, referring to it as the "overhead selector 148." According to the specification, the overhead selector 148 "may be embodied in many ways, such as program executing on the processor for the mobile or base station, or both, or as firmware or as a separate circuit." Id. at 7:26-29. The specification describes several steps that must take place to select and apply an encoding scheme. First, the overhead selector 148 receives information about the bit error rate (BER) from the channel quality estimator 150. Id. at 6:35-36. Information about the BER may also be shared from station to station "so that each station may adjust the amount of error correction overhead in direct relation to the quality of the channel over which that station must transmit data." Id. at 10:22-27.

Next, using the BER provided by the channel quality estimator, "[t]he overhead is selected with an overhead selector 148." Id. at 7:25-26. The exemplary embodiment described in the specification allows the overhead selector to compare the BER with three different thresholds and, based on that comparison, select from three error correction schemes. Id. at 7:62-8:11.

Finally, the selected scheme is applied to adjust the overhead. To accomplish this goal, the specification describes an embodiment in which the "channel quality estimator 150 reports the BER to the processing and control circuitry which in conjunction alters the error correction scheme (encoding) for the outgoing data on the traffic channel." Id. 9:58-61. The specification also describes an embodiment in which "the overhead scheme selector 148 (FIG. 2) selectively adjusts the amount of error correction overhead applied for the data on the traffic channel." Id. at 8:12-15. That embodiment suggests that the overhead selector can, in fact, apply the encoding scheme to the traffic channel, though it is not the only method of application.

This three-step process supports the agreed-upon construction given to the term because it shows the process by which an encoding scheme is selected to apply to a traffic channel. And, it makes clear that the encoding selector, or overhead selector, is the module that makes the selection.

3. Prosecution History

Finally, the prosecution history consistently uses the phrase "to apply to" when referring to the encoding selector's function of choosing an encoding scheme to apply to a traffic channel. The Examiner, for example, referring to prior art, wrote that "Schrader, et al disclose a method…comprising the steps of:…selecting an encoding scheme or data rate to apply to the traffic channel." (Pl. Ex. 9 at 2 (emphasis added).) Additionally I an amendment to the Patent stated that "the method selects an encoding scheme or data rate to apply to the traffic channel." (Pl. Ex. 10 at 2 (emphasis added).)

4. Proper Construction of "Traffic Channel Encoding Selector"

Because the intrinsic evidence illustrates that the phrase "to apply to" appears consistently throughout the claims, specification, and prosecution history, and because, in their briefs, the parties essentially agree on the construction, the term "traffic channel encoding selector" means: a module that selects the encoding scheme to apply to a traffic channel.
Alcatel's proposed construction is "two or more parameters each of which characterize at least the data rate of an input data stream." Cisco's proposed construction is "values identifying the traffic load."

Alcatel argues that, in construing the term "traffic load parameters," the Court should first construe the term "traffic load." Alcatel contends that the ordinary meaning of "traffic load" is some measure of data transmitted over some time period. In other words, according to Alcatel, it is an amount of traffic, expressed as a rate. 21 Alcatel claims that patent specification supports this construction. In particular, Alcatel cites a portion of the specification that reads, "To this end, the average value ABR and the maximum value MBR of the traffic load or bit rates of the forthcoming communication . . ." DePrycker Supp., col. 4, ll. 44-47 (hereinafter DePrycker, at 4:45-47). Alcatel contends that the language "traffic load or bit rates" is a clear definition of "traffic load" as synonymous with "bit rates." Furthermore, Alcatel argues that in every embodiment of the '052 patent, "two different parameters each characterizing a rate of a proposed stream are compared to a predetermined limit that is defined in terms of a rate." Alcatel's Responsive Markman Brief on Claim Construction Regarding United States Patent No. 5,020,052 , (DePrycker et al.) ("Alcatel's '052 Responsive Brief") at 9 (citing DePrycker, at 4:45-5:11, 6:5-30, 6:41-59, 7:19-24, 10:26-46).

21 Alcatel also argues that the plural term "parameters" indicates a requirement of more than one parameter.

Additionally, the claim language itself cites rates (ABR (average bit rate) and MBR (maximum bit rate)) when referring to "traffic load parameters." See DePrycker, at 15:16-19, 15:43-46. Finally, according to Alcatel's expert, "one of ordinary skill in the art at that time would have understood the term 'load,' used with reference to data communications system, to mean an amount of bandwidth (i.e. capacity) which is measured in terms of rate as opposed to a quantity that could be described by generic traffic parameters." Lucantoni '052 Decl., at P 28.

Cisco's primary contention with Alcatel's proposed construction is its argument that "traffic load parameters" do not always need to be expressed as rates. Cisco's entire support for this argument is the testimony of its expert, Prof. Acampora, who claims, as does Cisco, that "traffic load parameters" are not always traffic rates. Acampora cites three examples of parameters from a prior art reference that are not rates. See Lumish Decl., Ex. S ("Acampora '052 Report"), at 10. Nevertheless, Lucantoni disputes these references, and Acampora's conclusion in general, claiming that those references are examples of traffic descriptors, not traffic load parameters. See Lucantoni '052 Decl., at P 29. Therefore, neither experts' opinion is particularly helpful to the Court in determining the ordinary or accustomed meaning of the term.

In construing claim terms, when the inventor was not his own lexicographer (which the inventor was not with regard to this term), there is first a presumption that the term has its full ordinary or accustomed meaning. See K-2 Corp., 191 F.3d at 1362-63; Johnson Worldwide Assoc., 175 F.3d at 989 ("[A] court must presume that the terms in the claim mean what they say, and, unless otherwise compelled, give full effect to the ordinary and accustomed meaning of claim terms."). In this instance, it is unclear whether or not the accustomed meaning requires the traffic load parameters to be expressed in terms of a rate. Nevertheless, the ordinary or accustomed meaning of the term, whether it requires the use of rates or not, must also be tested against the particular use of the word in the patent, in order to determine its proper construction. See, e.g., Cortland Line v. Orvis Co., 203 F.3d 1351, 1356-57 (Fed. Cir. 2000) (after determining the ordinary meaning of a disputed word, the court proceeded to compare that word to its use in the patent specification and the prosecution history).

Here, as evidenced by the references to "traffic load" and "traffic load parameters" in the claims and the specification as referring to rates, plus the complete lack of intrinsic evidence identified by Cisco in support of its construction and in opposition to Alcatel's construction, the Court finds that the term "traffic load parameters (ABR, MBR)" as used in claims 6 and 9 22 is to be construed as "two or more parameters each of which characterize at least the data rate of an input data stream."

22 Claim 9 is dependent on claim 6.
23 The term "input data stream" has been agreed upon by the parties to mean "data stream entering the data processing system." See Revised Joint Statement, Ex. A, at 5. It is clear from the plain language of claim 6 that the parameters are based on the input data stream. See DePrycker, at 15:8-19.

C. "transaction administrator" or "TA"

The magistrate judge recommended that "transaction administrator" or "TA" be construed as "an entity which authenticates entities and validates the content of the transaction by the originator." First Report at 4. No objections have been filed with respect to the magistrate judge's proposed construction. After careful review of the magistrate judge's findings and conclusions, record, legal briefing, and applicable law, the court determines that the magistrate judge's proposed construction of "transaction administrator" or "TA" in patent '878 is correct, and it is hereby accepted as the court's construction of "transaction administrator" or "TA."

6.

Claims 1 and 13 of the 298 Patent and Claim 1 of the 456 Patent refer to "storing the account payment number and payment amount in a transaction log file of the system." (Plf. App., Exh. 1 at 16-17 & Exh. 3 at 42) (emphasis added). A similar reference to "transaction file" appears in Claim 6 of the 456 Patent. (Id., Exh. 3 at 43). Paymentech argues that "transaction log file" and "transaction file" both should be construed to mean "a file of transaction data that is individually kept by the system for each payee for periodic transmission to the payee and stored in time order as it is received, having a plurality of records where each record contains data including debit card number, payor account number, payment amount, time/date, and approval code." (Def. Op. Br. at 18). BMC urges that the terms be given their ordinary meanings. (Plf. Op. Br. at 18).

In computer terminology, a "file" is "a collection of related data records." MERRIAM WEBSTER COLLEGIATE DICTIONARY at 434 (1993). A "transaction" is an "exchange or transfer of goods, services, or funds." Id. at 1252. Taken together, the ordinary definition of a "transaction file" is "a collection of related data records pertaining to an exchange or transfer of funds." A "log" is "a record of performance, events, or day-to-day activities." Id. at 685. Thus, a "transaction log file" is "a collection of related data records pertaining to exchanges or transfers of funds occurring during a given day."

Paymentech admits that its suggested construction is a hybrid definition comprised of the ordinary meaning of the disputed terms plus examples drawn from the specifications. However, it is generally impermissible to import limitations from the specification to restrict the meaning of claim terms. See Arlington Industries, 345 F.3d at 1327; see also CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed Cir. 2002) (the presumption of ordinary meaning cannot be rebutted "simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history"). Other than the examples set forth in the specifications, there is no support for Paymentech's definition. The court should construe "transaction file" to mean "a collection of related data records pertaining to an exchange or transfer of funds" and "transaction log file" to mean "a collection of related data records pertaining to exchanges or transfers of funds occurring during a given day."

Claim Construction: "Transaction Type" and "Transaction Parameters"

As discussed above, claim 1 requires that all financial transactions include both a transaction type and a plurality of transaction parameters. Amazon argues that "transaction type" should be defined as "an account balance inquiry or kind or type of asset transfer that is selected as part of a financial transaction," and that "transaction parameter" should be defined as "information necessary to define a given financial transaction." IPXL advocates for a broader definition of these terms.
Specifically, IPXL contends that "transaction type" means any type of financial transaction and that "transaction parameter" means any parameter related to a financial transaction.

The specification in the '055 does not provide express definitions of these terms; however, it does provide relevant examples of each:

... selecting a type of transaction or function (withdrawal, deposit, transfer, payment, balance inquiry, etc.)

Col. 1, ll. 31-33

...transaction parameter (e.g., the amount to be withdrawn). ... selecting one or more transaction parameter (e.g., accounts, dollar amounts, etc.).

Col. 1, ll. 59; Col 5, ll. 53-54). 3

--- Footnotes ---

3 These sets of examples are consistent with the sparse discussion of "transaction type" in the prosecution history. "For example, one screen may seek selection of the transaction type, the next screen may ask for the user to select an account, another may ask for the amount of the transaction, etc." (IPXL 89) This sole reference to "transaction type" in the prosecution history merely supports the proposition that "accounts" and "amounts" are not transaction types.

--- End Footnotes ---

Although a proper construction of "transaction type" and "transaction parameter" must encompass the examples set forth in the specification, the Court recognizes that the Federal Circuit has cautioned against limiting the claimed invention to the specific examples cited in the specification. See e.g., Texas Instruments, Inc. v. United States Int'l Trade Comm'n, 805 F.2d 1558, 1563 (Fed. Cir. 1986)

Accordingly, the Court has looked beyond the specific examples and has carefully considered both the language used in the claims and the context of the entire patent. In defining these claim terms, the Court will apply the definition of "transaction" that it has already found in its construction of the terms "transaction types" and "transaction parameters." Second, the Court will incorporate the enumerated examples listed in the specification into its construction. Given this carefully prescribed context of these claim terms, the Court will again use dictionary definitions to confirm and support the ordinary meaning of "transaction type" and "transaction parameter." The following dictionary definitions are instructive:

| Type: d: a particular kind, class, or group. |
| Parameter . . . 2: any of a set of physical properties whose values determine the characteristics or behavior of something. |

Merriam-Webster's Collegiate Dictionary (Tenth Edition, 1996) 843, 1278. Using these ordinary meanings to define the claim terms at issue, in light of the context of the patent, and encompassing the examples set forth in the specification, the Court construes the term "transaction type" as follows:

A particular kind, class, or group of electronic transfer[s] of funds or a particular kind, class, or group of electronic inquiry[ies] as to funds. Examples of transaction types include withdrawals, deposits, transfers, payments, and balance inquiries.

The Court construes the term "transaction parameter" as follows:

A property whose value determines the characteristics of (1) an electronic transfer of funds, or (2) an electronic inquiry as to funds. Examples of transaction parameters include the identification of the specific account, and the specific dollar amount.
Claim 11 covers a "transactional database." The specification explains that this database "records and stores information related to each transaction performed at each point-of-sale site," and is capable of "transmitting sales data to a requesting publisher." 823 Patent at 2:7-12. Because the court finds no material difference between the parties' proposed definitions, it construes the term to mean "a structured computer memory for storing and accessing data related to transactions," as this definition reflects the ordinary meaning of the term and the disclosure of the database in the specification.

1. "transceiver"

The Court finds that claim 1 of the '222 patent requires a "transceiver," whereas claim 7 of the '222 patent requires a "wireless transceiver." Claim 1 requires that the transceiver has both a transmitter for transmitting and a receiver for receiving. In the Background and Summary of the Invention section, the specification expressly states that a transceiver is "capable of transmitting and receiving information (voice, data or video) in the form of electromagnetic signals," "may be fixed or portable," and in personal communications networks may be a "portable radio unit." '222 patent, 1:33-36, 1:43-45. The Court finds that the ordinary definition of the term "transceiver" is a device that both transmits and receives data. While the Court finds that a two-way radio unit may be a transceiver, the Court rejects Wi-LAN's argument that the transceiver must necessarily be limited to a radio unit.

The Court finds that the primary dispute between the parties is whether certain advantages or benefits of the disclosed system are merely optional or are mandatory omissions from the definition of a "transceiver." Defendants argue that the specification makes repeated disclaimers of prior art transceiver components throughout the specification and distinguishes the "present invention" from the prior art on the basis that it omits a number of components found in prior art transceivers. Defendants argue that the Federal Circuit is clear that when the specification makes clear that the alleged invention does not include particular items those items are outside the scope of the claims. The Court disagrees with Defendants' arguments. While there is language in the specification indicating that the present invention distinguishes prior art as requiring certain attributes of the transceiver that are not required in the applicants' invention, the Court finds that the language is not a clear limitation that the term transceiver is to be so limited. Rather, the Court finds that certain omissions of the present invention, compared to the prior art, are merely advantageous and not necessary. The Court finds that the "not required" language in the specification does not necessarily mean "omitted" or "excluded." For example, in the Detailed Description of the Preferred Embodiments section, the language only states that some of the prior art components of a transceiver are "not required" or "not used" and briefly describes how the "omissions" of these components can be done without impairing the quality and capacity of the system. '222 patent, 4:55-63; 12:45-50. The Court finds that there is no express requirement that the present invention necessarily excludes the optional components nor is there any express disavowal that the term "transceiver" excludes the optional components. The Court finds that not a single claim in the '222 patent includes the
requirement that these optional components must be omitted from the transceiver. Further, because claim 7 provides certain limitations of the width of the frequency band so that "neither carrier nor clock recovery is required at the second transceiver," such a limitation would be meaningless if the transceiver had already expressly omitted clock recovery and carrier recovery. The Court finds that, in the entirety of the specification and the claims and considering the ordinary meaning of the term, the omission of the disputed elements is merely optional, i.e. "not required," and is not a necessary exclusion. Thus, the Court construes the term "transceiver" as "a device that transmits and receives data."

The Court lets stand its previous definition of "transceiver" to mean a singular device capable of both sending and receiving information.

The dispute regarding this term involves competing dictionary definitions. Broadcom cites the Oxford English Dictionary and Newton's Telecom Dictionary for the proposition that a transceiver is "a combined transmitter and receiver." (Broadcom Opening at 45.) Agere cites the IEEE Dictionary for the more specific definition of a transceiver as "transmitting and receiving equipment in a common housing, usually for portable or mobile use, and employing common circuit components for both transmitting and receiving." (Agere Resp. at 16.)

Seeking support for its broader definition, Broadcom relies heavily on the Federal Circuit's statement that "if more than one dictionary definition is consistent with the words in the intrinsic record, the claim terms may be construed to encompass all such consistent meanings." Texas Digital, 308 F.3d at 1203 (citing Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1343 (Fed. Cir. 2001)); see also Inverness Med. Switzerland GmbH v. Warner Lambert Co., 309 F.3d 1373, 1379 (Fed. Cir. 2002) (same). The Texas Digital court noted, however, that "the intrinsic record may show that the specification uses the words in a manner clearly inconsistent with the ordinary meaning reflected . . . in a dictionary definition. In such a case, the inconsistent dictionary definition must be rejected." Texas Digital, 308 F.3d at 1206. Indeed, as the Federal Circuit stated in Toro Co. v. White Consolidated Industries, Inc., when each side propounds its own dictionary-supported construction, "this question cannot be decided by a dictionary. . . . Dictionaries provide general definitions, rarely in sufficient detail to resolve close questions in particular contexts. " 199 F.3d 1295, 1300 (Fed. Cir. 1999); see also Inverness, 309 F.3d at 1379 (noting that, in determining which dictionary definition to use, court "must determine whether the specification or prosecution history clearly demonstrates that only one of the multiple meanings was intended"). 21 Thus, the instant term cannot properly be construed without analyzing the intrinsic record.

--- Footnotes ---

--- End Footnotes ---

The claim text teaches a communication module "comprising . . . at least one of a plurality of wireless transceivers." (705 patent, col. 38, ll. 14-16, col. 39, ll. 8-10.) In light of the parties' competing dictionary definitions, the Court must look to the specifications in order to determine whether the context of the claims supports either of the proposed constructions. Agere has provided convincing textual support for its limitation that the transmitter and receiver must be "equipment within..."
common housing . . . employing common circuitry." The written description in the specification refers to a "modular transceiver" (id., col. 3, ll. 33-34), and teaches that multiple transceivers can be contained on one single radio card (id., col. 4, ll. 3-4 ("The radio card may contain more than one type of radio transceiver.")). Furthermore, the embodiments in the specifications also describe "transceiver modules" (id., col. 15, ll. 33-34) and transceivers that are contained within a communication module (id., col. 37, ll. 47-49 ("The communication module . . . contains multiple transceivers.")). As discussed previously, a "module" is a self-contained assembly of electronic components and circuitry. See supra Part II.D.2. Thus, the Court finds that the written description's reference to a "modular transceiver" and "transceiver modules," clearly suggests that the transmitting and receiving components reside in common housing and employ common circuitry.

Accordingly, the Court adopts Agere's proposed construction.

7. "Transceiver" ('366, Claims 5, 19; '311, Claim 16; '771, Claim 1) As discussed previously, see supra Part II.D.4, the Court looks to the specifications to determine which dictionary definition of this term is most appropriate for each patent: Broadcom's proposal of "a combined transmitter and receiver" or Agere's proposal of "transmitting and receiving equipment in a common housing . . ., employing common circuit components for both transmitting and receiving."

a. '771 Patent

The claim text teaches a base station "having" a transceiver ('771 patent, col 54, ll. 14-15) and a roaming terminal "comprising" a data collection system "having" a transceiver (id., col. 54, ll. 18-20). It is undisputed that both base stations and roaming terminals are "combined transmitters and receivers" (see Goodman Rep. P 159); the relevant question, therefore, is whether base stations and roaming terminals also have "transmitting and receiving equipment in a common housing . . ., employing common circuit components for both transmitting and receiving."

Although it is a close case, the Court finds insufficient support in the specifications for Agere's proposed construction. In arguing that the specifications support its definition, Agere cites language referring to "transceiver units" ('771 patent, col. 7, ll. 29-32), "transceiver circuitry" (id., col. 52, ll. 52-54), and the "terminal radio" (id., col. 53, ll. 54-62). These specifications, however, do not indicate any necessary limitation of the invention to commonly-housed or commonly-circuited transceivers. First, all three of these citations refer to specific embodiments of the device, and as such do not provide a basis for limiting the broader claim text. Second, contrary to Agere's argument: (a) "transceiver unit" could refer to a linked, but separately-housed, transmitter and receiver; 36 (b) "transceiver circuitry" could refer to the aggregate circuitry of the transmitter and receiver without requiring that this circuitry be shared; and (c) "terminal radio" suffers both of these ambiguities. Thus, in the absence of stronger textual indications that the term should be limited, the Court finds that the term at issue should be construed using the broader dictionary definition.

b. '366 and '311 Patents

36 The Court conceives of a device, such as a handheld scanner, wherein the transmitting portion of the transceiver is physically located inside the scanner while the receiving portion is, for example, clipped to the user's belt and attached by a wire to the rest of the device. Such a design would appear to satisfy Broadcom's definition of transceiver but not Agere's, but there is no indication, other than the fact that it is not a preferred embodiment, that this design would be excluded from the patent.

The Court agrees with Agere, however, that Broadcom's proposed construction is even broader than the OED and Newton's definitions on which it relies. Unlike Broadcom's construction, which refers merely to "a combined transmitter and receiver," both dictionaries, like the IEEE, specifically refer to physical devices. (Broadcom Opening at 45 (citing OED definition, "instrument," and Newton's Telecom Dictionary definition, "device").) Thus, the Court adopts Broadcom's proposed construction but modifies it to match the broadest dictionary definition, found in the OED, which is "an instrument combining a radio transmitter and a radio receiver."
Each of these patents teaches "bridging nodes" "having" transceivers. (‘366 patent, col. 20, ll. 44-46, col. 21, ll. 57-59; ‘311 patent, col. 21, ll. 5-7.) As with the ‘771 patent, Agere cites portions of the specifications referring to "transceiver units" for the proposition that transceivers must be "unitary," and therefore share common housing and circuitry. As discussed above, the Court finds this argument unpersuasive both because it relies on preferred embodiments and because the word "unit" does not necessarily imply that the receiving and transmitting elements themselves are contained within the same physical structure, as opposed to being connected to the same structure. Thus, the Court adopts the broader construction of transceiver for these patents as well.

7. digital camera picture image data transfer and repository device n3

--- Footnotes ---

n3 The corresponding phrase is "digital data transfer and repository device."

--- End Footnotes ---

This phrase appears in the preamble of several of the claims in both patents-in-suit. The plaintiff contends that this phrase from the preamble should not be read into the claim limitations. To the extent that it is added as a limitation and needs construction, the plaintiff proposes "a device capable of transferring and storing picture image data from a digital camera." The defendants propose "an intermediary repository device whose principal functionality is to transfer picture image files from a digital camera flash memory module by temporarily storing them in the repository device preparatory to copying them to a computer, without independent capability to edit, manage or display the stored file."

The plaintiff agrees that the device is an intermediary device. Furthermore, the defendants correctly state that the body of the claims derive an antecedent basis from the preamble because the claims refer to the "repository device" described in the preamble. However, the defendants' proposed construction includes additional limitations not supported by the intrinsic evidence. Accordingly, "digital camera picture image data transfer and repository device" means "an intermediary repository device for storing picture image data from a removable flash memory module of a digital camera and transferring the picture image data to a user's computer."

1. The phrase "TRANSFER FUNCTION" (claims 9, 10, 20, and 21) requires no construction.

4. "transfer of data"

The parties agree that the term "transfer" means to transmit something from one node to another. See Modern Dictionary of Electronics, 6th Ed. (1997) at p. 1053. However, the parties dispute the meaning of the term "data" as used in the phrase "transfer of data." The term is not explicitly defined in the patent.

Intel proposes that data should be construed to mean anything passed between nodes that conveys meaning, and includes information defining the format set that is sent from one node to another in addition to other data that may later be sent between the nodes. In support of its proposed construction, Intel argues that the term "data" is used throughout the specification in a variety of ways that indicate the term is to have its broad, ordinary meaning.

Broadcom asserts that Intel's proposed construction of the term "data" is overbroad in two ways. Broadcom first argues that
the term "data," as used in the patent, should be limited to basic elements of information that are organized into a frame that identifies the source and destination of the information. A frame is a packet of information that includes the data to be transmitted, an identification of the node that is transmitting the data, and an identification of the node that is the intended recipient of the data. In addition to arguing that data must be information that is sent in frames, Broadcom also draws a distinction between substantive information, which it calls "data," and certain setup information that is transmitted between nodes, which despite the fact that it conveys meaning, is not "data," according to Broadcom.

(i) does "data" need to be transmitted in frames

Broadcom supports their argument as to why the meaning "data" includes frames by relying on the declaration of their expert, Dr. Tobagi. In his declaration, Tobagi asserts that "[a] person of ordinary skill in the field of the invention would understand that a "transfer of data" over a communication medium means that the data is transmitted in 'frames' because that is the way that data is transmitted over a computer communication system." Tobagi Decl. at P 7. Broadcom finds support for this definition in the specification, noting that every embodiment of the invention that is shown and described in the specification transfers data in frames, which include the addresses of the node that initiated the transfer of data and the address of the node to which the data is intended to be sent.

Broadcom also argues that this definition of data is compelled by the patent's definition of the term "format," which is defined in the specification as "the convention used for data transmission which defines frame organization and content." Col. 3:20-21. Broadcom argues that if the data is not required to be transmitted in frames, this definition of format would be rendered meaningless.

Intel argues that the limitation that Broadcom seeks is unsupported by the claim language and asserts that nothing in the 830 patent requires that data must be transferred in frames. Intel also points out that Dr. Tobagi's statement that the claim language must be limited in this way because networks have to transfer data in frames having source and destination identifiers may itself be too broad. Intel notes that Dr. Tobagi's own book, "Advances in Local Area Networks," which is relevant to how one of ordinary skill would construe the patent claims because it was published one year before the 830 patent was filed, see Schering Corp. v. Amgen Inc., 222 F.3d 1347, 1353 (Fed. Cir. 2000), recognized that only "some of the information [in local area networks] is sent in packets containing a destination address." Advances in Local Area Networks (Karl Kummerle, Fouad A. Tobagi, and John O. Limb eds. 1987).

The court finds that the definition of "data" does not require that data is specifically transferred in frames. The ordinary meaning of the term "data," as understood by those with ordinary skill in the art at the time the patent was filed, did not include this limitation. As Broadcom itself noted in its Opening Brief, "the ordinary meaning of the term 'data' is basic elements of information which can be processed or produced by a computer." Broadcom's Opening Br. 10. No ambiguity in the claims requires the court to resort to the specification to understand the claim language.

Moreover, even when examining the specification, nothing in the specification indicates that the ordinary meaning of the term "data" should be limited in the manner urged by Broadcom. Broadcom's argument that the use of frames is compelled by the patent specification's definition of the term "format" is unavailing. First, Broadcom misquotes the specification. The specification defines "protocol," and not "format," as "the convention used for data transmission which defines frame organization and content. . . ." Col. 3:20-23. The term "format" is used in the claim language. The term "protocol" is not. According to the specification, "format" is defined in terms of data rate and/or data architecture, which includes "one or more of" a set of data transmission characteristics that includes encoding, encryption, compression, and protocol. Moreover, the patent specification makes it clear throughout that the diagrams of data frames are only examples of embodiments that could be formed based on the claims. Therefore, Broadcom's argument that the specification's definition of protocol does not require that the term "data" is transmitted using frames.

(ii) Is certain setup information excluded from the definition of "data"

Aside from the definition that includes a requirement that "data" is transmitted using frames, which has been rejected by the court above, Broadcom has not presented to the court a more limited construction that reflects its view that Intel's proposed construction is overbroad. However, Broadcom argues that Intel is wrong in claiming that data is "any thing passed between nodes that conveys meaning." because certain information that is passed between nodes conveys meaning, but is not, in Broadcom's estimation, encompassed by the term "data." In support of this argument, Broadcom refers to the description of
the "inquiry dialog" in the patent specification, which describes frames that are passed between the nodes which convey meaning, but are not referred to in the patent as "data."

The inquiry dialog is initiated by the source node when the source node cannot find the format set for the selected destination node in its cache of format sets. Col. 5:15-22, 5:62-64. "The source node transmits an SFInq frame (Supplemental Format Inquiry frame) to the destination node." Col. 5:64-65. Broadcom notes that the SFInq frame, which is illustrated in Figure 12, does not include any "data." Rather, it includes "two or more flags, destination node address, source node address, type field, FCS, flag and abort. The type field indicates that the frame is an SFInq frame." Col. 7:30-32. In contrast, Broadcom notes, the response to the SFInq frame, sent by the destination node, is a "SFResp frame" that does include data. The SFResp frame includes "two or more flags, source node address, destination node address, type field, data, FCS, flag and abort." Col. 7:35-36 (emphasis added). The "data" is the destination node's format set: it is the "data specifying dest. node format Set (FsetEff)" shown in the illustration of the response frame in Figure 13. Therefore, Broadcom concludes that Intel's construction of "data" is overbroad because it includes information such as the SFInq frame sent by the source node to request the destination node's format set, which conveys meaning, but Broadcom claims is nonetheless not data.

In response, Intel claims that the frames shown in Figures 9 - 13 derive their organization from the fact that they had to be compatible with the Apple Computer's Appletalk networking system, which was the "default format" of the preferred embodiment. Intel claims that these examples should not be construed to limit the claim language, especially when the patent explicitly indicates that the invention can be implemented in many different environments. See Col 1: 16-23.; Col. 9:19-20.

While "the descriptive part of the specification aids in ascertaining the scope and meaning of the claims inasmuch as the words of the claims must be based upon the description," what is claimed should not be restricted to the examples given in the specification. Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988). As noted by the Federal Circuit: "Where a specification does not require a limitation, that limitation should not be read from the specification into the claims." Id.; see also Ekchian v. Home Depot, Inc., 104 F.3d 1299, 1303 (Fed. Cir. 1997).

As acknowledged by the parties, the ordinary meaning of the term "data" is quite broad. Moreover, it seems that the term "data" is used throughout the patent in a number of different ways. For example, in one section of the specification, the term "data" refers to a field within a frame, as indicated in Figure 11 and Figure 13. Col. 7:37-39. However, in another section of the specification, the term "data" refers to the entire frame that is sent from the source node to the destination node. Col. 5:55-61. At yet another point in the specification, the term "data" seems to refer to information generally. Col. 2:46:52.

It is improper to pick one of those uses and limit the claim to that one definition. Rather, the court's task is to construe the meaning of the term "transfer of data" as it is used in elements (b) and (c) of claim 1, which recite:

(b) a plurality of nodes coupled to said communication medium for the transfer of data between said nodes; wherein said transfer of data is a transfer of data from a source node selected from said nodes to a destination node selected from said node, and

(c) transfer format selection means for selecting a format for the transfer of data from said source node to said destination node;

Broadcom asserts that it is not unusual, in the field of communications systems, to distinguish between "data" and other information such as setup information. However, the court disagrees. Nothing indicates that this distinction was adopted in the 830 patent.

While other elements of claim 1 are limited by a number of wherein clauses that follow, the term "data" is not so circumscribed. The unmodified use of the term "data" in the claims themselves indicates that the claim drafter did not intend to vary from the term's broad ordinary meaning. The term "data" in claim elements (b) and (c) encompasses any information that is sent between nodes. Accordingly, the court finds that, in light of the claim language and specification, the term "data" means any thing passed between nodes that conveys meaning.
3. Transfer of payment

Claim 4 of the '364 Patent discloses: "The process of claim 3, wherein said process (g) of providing authorization data comprise the transfer of payment." '364 Patent, col. 16, ll. 13-15.

DE contends that "transfer of payment" means "data enabling the electronic record to facilitate payment." Dell contends that the phrase means "data enabling the electronic record to effect payment."

The language of the specification indicates that the transaction system "can arrange for the funds to be provided to the international carrier ... when the commercial title, bill of lading, etc. are presented so that the goods can clear national customs." '364 Patent, col. 14, ll. 16-18. The specification also provides that, "the present system is capable of arranging payments with local carriers." Id. at col. 14, l. 25.

Accordingly, the court finds that the plain meaning of the phrase, "transfer of payment," is "data enabling the electronic record to authorize payment."

GO BACK

4. "transfer peripheral device command"

EMC asks the Court to construe this term as: "A command that transfers new microcode to the peripheral device." 7 HP proposes (in its opposition brief):

A command sent by the operating system to a peripheral device in response to a transfer peripheral device request sent by an application program to the operating system. The command is received by the peripheral device while the device is in a waiting state, and it causes the peripheral device to download new microcode. The command is separate and functionally different from a previously received initiator peripheral device command.

The transfer peripheral device command is one that an operating system sends to the peripheral device in response to a routine legitimately called by an application program (e.g., a write or read request), as opposed to a special command for the peripheral device to which an application program would not normally have access.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

7 EMC stated at the Claim Construction Hearing on April 5, 2004, that it is willing to add language similar to the language added for the prior term. Transcript of April 5, 2004 Hearing, 88:21-24. Obviously, EMC did not intend to adopt the exact language, and thus the Court must alter it so that it is consistent with the meaning of this term. The Court assumes, only for the purposes of assisting in the discussion, that EMC intended to add the following to its proposal: "This command is sent by the operating system to a peripheral device in response to a transfer peripheral device request sent by an application program to the operating system, and causes the peripheral device to receive new microcode."

- - - - - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Although the claim language does not clearly define the term, it indicates, consistent with the specification, that the peripheral device receives the transfer peripheral device command while it is in the waiting state. The new microcode is transferred to the peripheral device when it detects the transfer peripheral device command. Additionally, the transfer peripheral device command corresponds to a transfer peripheral device request sent from the application program -- executed by the computer system processor -- to the operating system routine. The written description further explains:

The operating system provides operating system routines, legitimately accessible to an application program, for providing
such access. In response to a call by an application program to such an operating system routine, the operating system will send a specific peripheral device control command . . . to the peripheral device to perform the requested access.

801:2/4-10.

HP’s proposal includes reference to the initiator peripheral device command. As discussed above, the prosecution history indicates that the patentee intended to claim an invention that uses a "two command sequence . . . to download replacement microcode." Deringer Decl., Separate Appendix, vol. 1, pp. 0170, 0174-75. This interpretation is consistent with the claim language and the specification, both of which describe a sequence of actions through which the peripheral device may receive microcode. That is, the peripheral device cannot receive microcode as part of the transfer peripheral device command prior to entering the waiting state in response to an initiator peripheral device command. HP also proposes language excluding a "special command." As stated above, a construction that includes access by an application program necessarily precludes the possibility of special commands.

Accordingly, the Court construes this term as "a command received by a peripheral device -- after it has entered the waiting state in response to the initiator peripheral device command -- from an operating system in response to a transfer peripheral device request sent by an application program to the operating system, and which causes the peripheral device to receive new microcode."

8. “Transferring”

“Transferring” is utilized in asserted claims 15-16 and 29 of the ‘335 Patent. The Plaintiff asserts that the “transferring” does not need construction. Alternatively, if construed, the Plaintiff asserts that the proper construction is “sending.” The Defendants assert that the term should be construed as “sending toward a destination and relinquishing control of.”

The parties agree to the use of the term of “sending” but disagree as to whether any additional language is necessary. With regard to the Defendants’ use of “toward a destination,” it is noted that the surrounding claim language of each claim already includes this concept. For example, claim 15 states that the transferring is of “a request from an HTTP-complaint device to a page server.” Similarly, claim 29 states that the transferring is of “a request from an HTTP-complaint device to a dispatcher.” The inclusion of “toward a destination” within the term “transferring” itself is therefore unnecessary based upon the context of the claims themselves.

With regard to the “relinquishing control of” language sought by the Defendants, the Defendants point to a Microsoft Press Computer Dictionary definition that includes in transferring the concept of passing program control. Further, the Defendants assert that the purpose of the patent is to reduce processing burden. The Plaintiff argues that two other dictionary definitions noted by the Defendants do not include the relinquishing concept.

Once again, it is more instructive to look to the claims themselves. More particularly, in claim 15 of the ‘335 Patent immediately after the “transferring…to a page server” the claim continues with “said page server receiving said request and releasing said HTTP-compliant device to process other requests…” Likewise, claim 29 of the ‘335 Patent includes later in the claim “said page server receiving said request and releasing said HTTP-compliant device to process other requests…” To include relinquishing within the definition of transferring would possibly conflict with the latter claim language or alternatively be redundant. Further, to the extent that the Defendants assert that the purpose of the patent is to reduce processing burden, the recited releasing language is more related to that concept than the transferring.

As both parties have proposed definitions using the term “sending,” the Court includes that term in its construction. The Court construes “transferring” to mean “sending.”

4546
The Court is of the opinion that the findings and conclusions of the Magistrate Judge are correct. Therefore, the Court hereby adopts the Report of the United States Magistrate Judge as the findings and conclusions of this Court.

1. "device"

In the "Field of Invention" portion of the '740 patent, "the present invention" is described as "related to a projection exposure apparatus for use to form a pattern of a semiconductor integrated circuit, or liquid crystal device, or the like." See Patent '740 at 1:16-18. Claim 10 repeats this use of "device," discussing a "method of producing a device, comprising . . . using an exposing method recited in claim 8." Id. at 46:3-5. As with any other term, the court must read "device" in accord with its claim- and specification-language context, both of which suggest that "device" means something more particular than the superficially generic "object or item" phrase ASML forwards. The claim language denotes a particular lithography-related "device," viz., the device produced through the lithographic process of transferring a pattern to a workpiece. Specification language, in turn, refers repeatedly to the imaging of a "circuit" "pattern" onto a substrate, typically in reference to various patent figures. See, e.g., 39:41-46 & 42:52-58; figures 29 & 32. Congruent with this intrinsic evidence, the court thus construes "device" to mean "an integrated circuit or similar item."

2. "workpiece"

Similar logic applies to evaluation of the term "workpiece." As it is used in claim 10, "workpiece" unequivocally refers to a substrate. In the lithographic process, the substrate (or wafer) is the item onto which the pattern is transferred; the text of claim 10—which discusses the transferring of a pattern—makes clear that "workpiece" is the item that receives the pattern. Taken together, these two conclusions make clear that "workpiece," as used in this context, is synonymous with "substrate." The court construes "workpiece" accordingly.

3. "transferring a device pattern to a workpiece"

Because the court has already construed "device" and "workpiece," it remains only to construe the meaning of "transferring." When read in context, the claim text discusses more than the act of transferring a generic device to a generic workpiece; it discusses, instead, "a lithography step of transferring a device pattern on a workpiece using an exposing method." See '336 Patent at 46:3-5 (emphasis added). The specification language likewise teaches that this lithographic "step" involves the formation of a "circuit pattern of a semiconductor device" through "a method[] in which a reticle [] pattern is formed on a substrate such as a semiconductor wafer." Id. at 1:21-25. Only because this substrate is "applied with photosensitive photoresist," the specification language adds, can a "circuit pattern [be] transferred"; that is, the transfer depends on the presence—and reactive quality—of photoresist. The meaning of "transferring a device pattern" reflects, and is defined by, this specification language.

Still, important as it is for the court to understand—and to construe—claim terms in the context in which they appear, it is equally important for the court to avoid folding independent claim (or specification) language into the construction of every discrete claim term. The court cannot ignore that the definition of "pattern" is itself finite; it does not embrace a summary, however pithy, of the operation of the entire photolithographic apparatus. Intrinsic evidence teaches that "transferring a device pattern on a workpiece" means "conveying, through a photolithographic process, the pattern for an integrated circuit or similar item onto a substrate with a photoresist layer." Standard canons of claim construction preclude the court from adding more.

5. Transferring Electrical Energy at a Predetermined Radio Frequency Range as Arcs in Ionized Conductive Pathways at a Predetermined Power Level Within the Gas Jet in an Electrical Circuit Which Includes the Tissue
The final disputed claim term "transferring electrical energy at a predetermined radio frequency range as arcs in ionized conductive pathways at a predetermined power level within the gas jet in an electrical circuit which includes the tissue" is found in Claim 10 as set forth above.

ConMed's Proposed Definition: Transferring electrical energy through an electrode within the nozzle or gas flow at a predetermined radio frequency by imparting an electrical charge to particles of the gas stream that allows the formation of the improved eschar.

Canady's Proposed Definition: A fulguration mode of operation.

(Docket No. 58, Ex. B, pp. 9-10; Docket No. 58, p. 20). Unlike the terms of Claim 1, this term at issue in Claim 10 is not a means plus function claim. Rather, I must give the terms their ordinary meaning as set forth under the standards above. I note from the Joint Disputed Claim Terms Chart that the terms ionized conductive pathways and gas jet are not in dispute. 14 See, Docket No. 58, Ex. B. p. 3. Thus, I must seek to construe the other disputed claim terms.

--- Footnotes ---
14 According to the parties, "ionized conductive pathways" is construed as pathways which carry electrical current, as opposed to radiate current and "gas jet" is construed as a directed or substantially laminar flow stream. Docket No. 58, Ex. B. p. 3.
--- End Footnotes ---

The specification provides as follows:

The ESG 46 supplies electrical energy over a supply conductor 56 of the cord 48 to the pencil 42. The conductor 56 is electrically connected in the pencil to a needle-like electrode 58 which extends into the nozzle 52. The electrical energy supplied by the ESG 46 is of predetermined characteristic sufficient to ionize the gas flowing through the nozzle 52 and to create ionized pathways in the jet 54. The electrical energy travels in the ionized pathways in the jet 54 to a body tissue 62 where it creates a predetermined electrosurgical effect on the tissue 62.

In the fulguration mode of operation of the ESU, also referred to herein as a "macro" mode of operation, electrical energy is transferred in the ionized pathways in the form of arcs 60. The arcs 60 travel within the jet 54 until they reach the tissue 62 at the electrosurgical site. The jet 54 expands slightly above the surface of the tissue 62 and the arcs 60 disperse over a slightly enlarged area of the tissue surface compared to the cross-sectional area of the jet 54. The electrical energy of the arcs is transferred into the tissue 62 and creates the upper arc hole reticulum or layer 30 and a desiccated layer 32 therebelow.

Docket No. 58, Ex. A. col. 8, ll. 14-37. The specification also teaches that "[e]lectrical power at a predetermined level is delivered from the power supply 308 to an RF drive circuit 312. The logic control 304 delivers RF switching signals to the RF drive 312, thereby causing the RF drive 312 to selectively couple energy from the power supply 308 to a resonant output circuit 314 at a frequency established by the RF drive pluses. Energy is transferred from the resonant output circuit 314 to the pencil 42, and current is returned to the resonant output circuit 314 from the patient plate 70 (FIG. 4)." Id. at col. 15, ll. 26-40. Consequently, I construe the term to mean transferring electrical energy, at a predetermined radio frequency from the RF drive to a resonant output circuit to the pencil to the needle-like electrode, which extends into the nozzle, to the tissue as arcs in ionized conductive pathways in a gas jet.

ConMed argues that the term "means transferring electrical energy at a predetermined radio frequency range" found in the second means-plus-function clause of Claim 1 must have the same meaning as the disputed term "transferring electrical energy at a predetermined radio frequency range as arcs in ionized conductive pathways at a predetermined power level with the gas jet in an electrical circuit which includes the tissue" found in Claim 10. Docket No. 58, p. 19. I disagree. To begin with, Claim 1 is in a means-plus-function format and Claim 10 is not a means-plus-function format. Second, the claim term at issue in Claim 10 contains additional language, namely "as arcs in ionized conductive pathways at a predetermined power level with the gas jet in an electrical circuit which includes the tissue," which must be given its ordinary and customary meaning or defined by the intrinsic evidence. Consequently, I reject ConMed's argument in this regard.
In addition, I reject Canady's proposed definition. (Docket No. 66, p. 54). Canady's proposed definition fails to take into consideration the entirety of the claim term at issue as well. Id.

5. "transform object"

TiVo argues no construction for this term beyond a definition for "object" is necessary, or, if construed, should mean "the portion of computer program that stores and retrieves data streams onto a storage device." See TiVo's Op. Br. at 22-23; '389 patent at cols. 7:48-50, 8:39-40, 14:62-64, 18:11-12; TiVo's Markman Slides at 140-49, 154-57.

EchoStar argues "transform object" means "a software object that changes the form of the data upon which it operates." See '389 patent at cols. 7:47-57, 7:66-8:18, 8:49-65, & Fig. 8; EchoStar's Opening Br. at 23-25; EchoStar's Slide Presentation at 121-22.

The Court finds it need look no further than the claims themselves to arrive at the plain and ordinary meaning for this term. For clarification purposes, however, this Court construes the term "transform object" as "a collection of data and operations that transforms the form of data upon which it operates."

4. "transformation component"

The term "transformation component" appears in several claims of the '990 patent (claims 1-7, 9-15). Informatica contends that the term "transformation component" is synonymous with the previously defined "transformation object," from the '670 and '775 patents, and thus proposes the two terms be construed to have the same meaning. Informatica proposes: "A reusable component for processing data according to predefined instructions." BODI proposes: "A transformation component is the same as a transformation object, which is a software binary file acting as an individual unit that possesses built-in autonomy and encapsulates the functionalities of a transformation. The autonomy of each transformation software component is manifested in two dimensions. The first dimension of component autonomy relates to how each transformation component implements staging (storing) the incoming data fields as it processes these data fields. The second dimension of component autonomy relates to how each transformation component automatically selects its own mode of manipulating data input/output. Each transformation component either pushes data to another transformation component, or performs a push/pull operation on the data."

The Detailed Description of the '990 patent specifically states that "[i]n the following detailed description of the present invention, some of the interchangeable key terms relating to the present invention are collected and defined in the section below to resolve possible ambiguity and to facilitate future reference." The precise term at issue here is listed immediately below this statement. "A transformation component is the same as a transformation object, which is a software binary file acting as an individual unit that possesses built-in autonomy and encapsulates the functionalities of transformation." These statements evince the patentee's intention to depart from the ordinary meaning of transformation component. The introductory language makes clear that it is discussing the components of "present invention." The statements in the specification about the meaning of a transformation component are not merely exemplary, rather they define the patentee's understanding and use of the terra transformation component in light of the claimed invention. "Because the inquiry into the meaning of claim terms is an objective one, a patentee who notifies the public that claim terms are to be limited beyond their ordinary meaning to one of skill in the art will be bound by that notification, even where it may have been unintended." Innova/Pure Water, Inc., 381 F.3d at 1117; see also Watts v. XL Sys., Inc., 232 F.3d 877, 883 (Fed. Cir. 2000) (concluding that the written description limits the invention by "stating that 'the present invention utilizes [the] feature'").
The term "transformation object" appears in numerous claims of the '670 patent (claims 1-5, 7-18, 20-35, 38-39) and three claims of the '775 patent (claims 1, 9, 11). Informatica points to the plain meaning of the term, as understood by one skilled in the art, and proposes the term be construed to mean "A reusable component for processing data according to predefined instructions." BODI proffers the construction "A transformation object is an object which transforms (i.e., modifies) data according to some predefined behavior or rule. An object has two parts. The first part has a declaration for the ports and attributes of the object, and the second part has a definition of the behavior of the object. A transformation object has input and output ports. Different transformation objects perform different, unique functions, and are selected according to the functions which need to be performed in order to generate the desired transformations."

As with the previous term, BODI advocates for a narrow construction of this term and relies on language in the intrinsic record. None of the indicia of a patentee's intent to limit the claims is present here. The intrinsic record provides no indication that the patentee acted as its own lexicographer during the prosecution and explicitly defined the term "transformation objects" to differ from its otherwise ordinary meaning. CCS Fitness, 288 F.3d at 1366. Nor is there any evidence before the Court establishing that the patentee distinguished this term from prior art on the basis of a particular embodiment or expressly disclaimed subject matter. Id. Finally, as discussed above, the specification does not state that TDL is the actual invention, nor is there any clear and unmistakeable disclaimer of the claim scope. "Absent a clear disclaimer of particular subject matter, the fact that the inventor may have anticipated that the invention would be used in a particular way does not mean that the scope of the invention is limited to that context." Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 909 (Fed. Cir. 2004) (internal quotation omitted). The Court declines to limit the claim to the preferred embodiment disclosed in the specification.

The Court adopts Informatica's proposed construction and construes the phrase "transformation object" to mean: A reusable component for processing data according to predefined instructions.

The phrase "TRANSFORMED SIGNAL HAVING A PREDETERMINED MATHEMATICAL RELATIONSHIP" (claims 1 and 13) means a signal representative of light of a second wavelength scattered by the tissue sample and that has a predetermined mathematical relationship to the first probe signal. There is no requirement that the transformation itself must be performed based on a predetermined mathematical relationship.

"a device that performs an N-point transform on each set of N data symbols to generate modulated data symbols as output, the modulated data symbols corresponding to a spreading of each data symbol over a separate code selected from a set of more than one and up to M codes, where M is the number of chips per code"
output, the modulated data symbols corresponding to a spreading of each data symbol over a separate code selected from a set of more than one and up to M codes, where M is the number of chips per code and where M equals N.

Claim 4 requires a transformer for operating, where M is the number of chips per code. The specification provides that "[t]he alternative transmitter shown in FIG. 4 includes a transformer 20 for operating on each set of N data symbols to generate N modulated data symbols as output. A series of transforms are shown." '802 patent, 4:40-43. The specification also describes "[e]xamples of the N-point transforms." '802 patent, 4:66. Similar to the “first computing means” term of claim 33, Defendants argue that the "transformer" term in claim 4 is indefinite, and thus renders claim 4 invalid, if M does not equal N. Defendants argue that, like independent claim 33, dependent claim 4 is invalid because the specification does not provide structure corresponding to the "M" chips per code function. Similar to its previous findings, the Court finds that changing N to M for certain terms is not an impermissible broadening of the claims during reissue. The Court finds that M need not equal N, and conversely, the Court is not convinced that M cannot be a different number than N. Thus, the Court rejects Defendants' arguments that claims 2, 4, 12, and 33 reciting the term "M" is invalid if M does not equal N. The Court further rejects Defendants' argument that this dependent claim is broader than claim 1 by eliminating the fixed numerical relationship between the number of data symbols and chips per code. The Court finds that the ordinary meaning of the term "transform" is to change in form, appearance, or structure; a mathematical quantity obtained from a given quantity by an algebraic, geometric, or functional transformation. Wi-LAN proposes a definition for the term "transformer" that is consistent with the ordinary meaning of that term, while Defendants do not provide a definition and only argue that M must equal N. The Court finds that while a transformer can be a device that performs an N-point transform, it may not necessarily be limited to such a device. The parties have not disputed the meaning of other claims that use the terms "transformer" or "transforms." Thus, the Court construes the term "transformer" to mean "a device that performs transforms."

2. A transformer having a primary side and a secondary side.

At the hearing, O2 offered a compromise construction of this term and Samsung accepted it. The court adopts that construction and defines this term to mean "a device, which when used, will raise or lower an incoming voltage, having a side receiving the incoming voltage, and a side outputting the raised or lowered voltage."

E. Transformers

The parties dispute the meaning of the term "transformers" that appears in Claim 3 of the '130 Patent. Use of these transformers in the claimed high-frequency phase shifter unit is important because one of its advantages over prior art is its simplification of power sharing. (See id., Col. 2, ll. 45-48.) Claim 3 claims "[t]he phase shift assembly as claimed in claim 1, wherein the first and second connection lines comprise transformers which share power in a predefined manner between the tapping sections of the at least first and second stripline sections." (Id., Claim 3, Col. 6, ll. 23-27.) Further, Claim 2 claims that "the at least first and second stripline sections have different impedance values." (Id., Claim 2, Col. 6, ll. 20-23.) However, both parties agree that the transformers themselves do not share power. (See Kathrein's Claim Construction Br. 12 ("transformers . . . permit power sharing"); RYMSA's Claim Construction Br. 27 ("A [t]ransformer itself does not share power . . . ").) Thus, the Court's construction of this term within the context of Claim 3 shall reflect this concession.

The Court agrees with RYMSA that Kathrein's definition of transformers, when read in the context of Claim 3, is unhelpful
because it merely repeats other language of the claim. (See Pl.'s Claim Construction Br. 12; '130 Patent, Claim 1, Col. 5, ll. 61-67 & Col. 6, ll. 1-19; id., Claim 3, Col. 6, ll. 24-27.) “The phase shift assembly as claimed in claim 1, wherein the first and second connection lines comprise [the connection lines permit power sharing between the tapping sections] . . . which share power in a predefined manner between the tapping sections of the at least first and second stripline sections.” (Defs.' Claim Construction Br. 28 n.3.)

RYMSA argues that the claim and the specification show that transformers are "portions of the connection lines that are specifically designed for controlling the transmission of electrical signals." (RYMSA's Claim Construction Br. 27-28.) First, with regard to RYMSA's interpretation that transformers are "portions of the connection lines," the Court does not find support for that construction in the intrinsic evidence. It is clear that the transformers may be the entire connection lines because Claim 3 states that the first and second connection lines themselves are transformers. (See '130 Patent, Claim 3, Col. 6, ll. 23-27 ("wherein the first and second connection lines comprise transformers"); RYMSA's Claim Construction Br., Ex. 2 at 46 ("the transformers are the connections 31a and 31b").) Because the transformers can be the entire connection lines, and not merely a portion thereof, the Court will, in part, use the term "devices" in this particular instance because the parties have not provided an alternative, more accurate, term.

Second, with regard to RYMSA's construction that the transformers "are specifically designed for controlling the transmission of electrical signals," RYMSA points to the specification that states:

"Suitable selection of the characteristic impedances and suitable regions of the connections 31a and 31b between the corresponding tapping points 29 as well as tapping points 27a and 27b, respectively, now allows the power to be shared at the same time between the dipole radiating elements 1a and 1d, on the one hand, and the further pair of dipole radiating elements 1b and 1c."

('130 Patent, Col. 5, ll. 8-14.) However, this language does not establish that transformers "control" anything. (See '130 Patent, Claim 3, Col. 6, ll. 22-27; RYMSA's Claim Construction Br., Ex. 2 at 46, 51.) Rather, in the context of the specification, the transformers (connection lines 31a and 31b) transfer electrical signals and match impedance values between a source of energy (center tap 29) and a load (tapping point 27a and corresponding dipole radiating elements 1b and 1c or tapping point 27b and corresponding dipole radiating elements 1a and 1d). Because the transformers enable power to be shared between the tapping sections of the at least first and second stripline sections and because each stripline section has a different impedance value, the transformers necessarily must match the impedance values between the source and the tapping section of each stripline section.

Accordingly, the Court holds that a clearer, more accurate construction of "transformers" is "devices that transfer electrical signals and match impedance values." Thus, in the context of Claim 3, and given the parties' agreement that transformers do not themselves share power but enable the sharing of power, the definition reads: "The phase shift assembly as claimed in claim 1, wherein the first and second connection lines comprise . . . [devices that transfer electrical signals and match impedance values] which . . . [permit the sharing of power] in a predefined manner between the tapping sections of the at least first and second stripline sections.”

---

7. Transforming

The term “transforming” means converting each of the color characters to monochromatic characters by replacing the pixels in the color character that represent the foreground colors with the corresponding color pattern masks for those colors and by replacing the pixels in the color character that represent the background colors with the corresponding color pattern masks for those colors.
The parties agree that a transistor is an active semiconductor device with three terminals: a source, a drain, and a gate. Although Quality's opening brief on claim construction is silent on the issue, in its opposition to Pericom's opening brief Quality contends that the singular term "transistor" covers a product with multiple transistors connected in parallel if the aggregate dimensions of the channels in each transistor add up to the specific channel width and length dimensions required by the patent claims.

Pericom counters that where the word "transistor" is used in the claims only a single transistor is meant. In doing so, Pericom focuses primarily on the plain language of the claims and specifications. Pericom asserts that no ambiguity is present in the plain language of the claims and the specifications, and that the patent as a whole indicates that only a single transistor with the specified dimensions is covered. Pericom also makes several arguments based on the prosecution history of the '062 patent.

--- Footnotes ---

1 Among its many arguments, Pericom suggests that the use of the article "a" before the term "transistor" and all parts of the transistor establishes that these elements are singular. See North American Vaccine v. American Cyanamid Co., 7 F.3d 1571 (Fed.Cir. 1993), cert. denied, 511 U.S. 1069, 128 L. Ed. 2d 365, 114 S. Ct. 1645 (1994), in which the court in fact stated that it is "generally accepted in patent parlance that 'a' can mean one or more." Id. at 1576 (citing Robert C. Faber, Landis on Mechanics of Patent Claim Drafting 531 (3d ed. 1990)). Nonetheless, the court found "no indication in the patent specification" that the inventors intended the term to have anything but its singular meaning. Id. The court further stated that "while such an interpretation [i.e., a plural meaning] might make sense as a theoretical concept, it has no support in the specification." Id. Similarly, the specifications and accompanying diagrams of the '062 patent provide no indication that the inventor intended the term "a transistor" to encompass several transistors connected in parallel.

Pericom also uses the prosecution history to support its argument. Pericom states that dependent claims 4 and 10 which originally described two transistors arranged in parallel were rejected by the examiner because they were anticipated by the prior art. Rather than appeal the examiner's decision, Quality dropped the claims. See Ex. D (File History, '050 Application) at D-19 (Original Claim 4) (emphasis added); Ex. D (File History, '050 Application) at D-20 (Original Claim 10) (emphasis added). Not mentioned by Pericom is the fact that one of the examiner's objections to the claim was that the transistors were in fact connected in "inverse parallel," because their conductivity is opposite each other, rather than in parallel as stated in the claim. Heit Opp. Decl., at Ex. H. Although the claim was rejected because anticipated by the prior art, the original claim did not describe the exact configuration in contention, and therefore the rejection of this claim is not relevant. The rejection of claim 10 is not relevant because Claim 10 involved transistors that were two different types, so even though they were arranged in parallel they could not make up a transistor of the same type.

--- End Footnotes ---

Quality argues that a transistor is often made up of many smaller transistors arranged in parallel, aggregated to meet particular dimensions, and that the resulting device is then referred to as a single transistor. According to Quality, the addition of each smaller transistor is like adding lanes to a road. Although the width is increased, the road is still referred to in the singular. In support of this argument, Quality provides a definition of "transistor" found in The New IEEE Standard Dictionary of Electrical and Electronics Terms, quotes the deposition of the device's inventor, David C. Wyland, and quotes the Declaration of Richard D. Crisp, an expert in the field.

The IEEE definition of "transistor" provided by Quality sheds no light on its contention that a "transistor" can be comprised of several smaller transistors arranged in parallel: "an active semiconductor device with three or more terminals. It is an analog device." Quality also offers the testimony of Wyland and Crisp to bolster its conclusions. For instance, Wyland, the device's inventor, states in his deposition:

When you have two physical structures on a -- two physical transistor structures that are individual transistors when they are separated, if they're the same type made on the same process, when you connect them, gate to gate, source/drain to source/drain, source/drain to source/drain, they become a single transistor. And this is the way transistors are commonly made.
Field effect transistors having a channel width greater than 100 to 200 microns are conventionally constructed in the manner described by Mr. Wyland. A semiconductor layout designer will design a transistor by laying out in parallel multiple transistor structures of the same type until the desired dimensions are obtained. This is well known in the art.

Despite Quality's assertions to the contrary, the meaning of the term "transistor" as used in the '062 patent is unambiguous in light of the patent and prosecution history. Nothing in the patent or the prosecution history indicates that "a" transistor may consist of several transistors connected in parallel. For instance, the patent specification precisely defines the meaning of the channel length and width in reference to a single transistor, and points to Figures 3 and 4, which depict a MOS type transistor as a single device with one source, one drain, and one gate as well as a single channel, with a single channel width and a single channel length. '062 patent at 3:36-49. The specification clearly states that:

As shown in FIGS. 3 and 4, the channel length of a MOS type transistor is the distance L between the source and drain regions of the transistor while the channel width is the dimension W of the transistor . . . Another common definition of the channel length is the width of the gate that overlaps the active region of the transistor between the source and drain. Another common definition of the channel width is the length of the gate overlapping the active region of the transistor between the source and drain.

'062 patent, at 3:38-49. Given the diagrams and the language of the specification, it does not appear possible for the "active region" of a transistor as depicted in the diagram to include the separate connections between two or more transistors connected in parallel.

Although Quality correctly suggests that terms of art commonly known in the industry should not be defined in the patent, Spectra-Physics, Inc. v. Coherent, Inc., 827 F.2d 1524, 1534 (Fed.Cir. 1987), cert. denied, 484 U.S. 954, 98 L. Ed. 2d 372, 108 S. Ct. 346 (1987), something more than simple assertions provided by the inventor and a single expert are required to create or establish the presence of an ambiguity. Surprisingly, apart from the IEEE definition, Quality provides no documentary evidence showing that transistors are "commonly made" in this manner. For instance, if the channel lengths and widths of several transistors simply "add up" to the desired channel length and width when the transistors are connected in parallel, an elementary electrical engineering textbook would surely state such a simple linear relationship. The court finds it difficult to believe that a "common" occurrence such as the one Quality asserts here is not presented as part of some text or manual on circuit design.

Furthermore, the lack of ambiguity in the meaning of the term "transistor" makes reliance on the presented extrinsic evidence, such as the testimony of the Quality's expert and the device's inventor, inappropriate. As stated by the Vitronics court, expert testimony should only be used as a last resort when the claim language, the prosecution history and the specifications do not remove an ambiguity in the meaning of a term. Vitronics, 90 F.3d at 1583. As noted by the Bell court, the testimony of the inventor is entitled to little or no consideration since it is often a "self-serving, after-the-fact attempt" to broaden the scope of his or her patent. Bell, 132 F.3d at 706. Such is the case here, especially given the unsupported contentions of the device's inventor. Both the schematic drawings provided by Wyland and the testimony of Wyland and Crisp "inject a new meaning into terms that is inconsistent" with what is set forth in the '062 patent. See Bell, 132 F.3d at 706.

Finally, a similar dispute arose in Miles Laboratories Inc. v. Shandon Inc., 997 F.2d 870, 876 (Fed.Cir. 1993), cert. denied, 510 U.S. 1100, 127 L. Ed. 2d 232, 114 S. Ct. 943 (1994). Miles involved a claim for a tissue processing treatment that facilitated the viewing of specimens under a microscope. The plaintiff's claim described a "cabinet" containing the various parts of the apparatus. The claims, specification and drawings all disclosed a single cabinet whereas the accused infringer's
The court therefore construes the term "transistor" as used in the '062 patent to comprise only a single transistor with a source, drain and a gate.

"Transit Traffic"

Peerless proposes the following construction of "transit traffic": "Traffic between one telecommunications carrier and another such carrier, transmitted by a third carrier." NT agrees with this construction but would add to the end of the sentence "in a local region regardless of any other transport of the call." The key disagreement then, is whether "transit traffic" includes the long distance portion of the call. NT admits that the term as used in the industry has the broader definition proposed by Peerless. However, NT argues that the context of the '708 Patent makes clear that transit traffic means traffic within a local region.

When the phrase is considered in the context of the '708 Patent, "transit traffic" is intended to be limited to traffic within a local region. As NT points out, every relevant example and embodiment in the '708 Patent shows that the invention relates only to the segment of a call that occurs within a local region. Therefore, the Court, particularly considering the phrase in the context of the intrinsic record, construes "transit traffic" as "traffic between one telecommunications carrier and another such carrier, transmitted by a third carrier in a local region regardless of any other transport of the call."

The primary differences between the parties' constructions as to the term "transition times" is whether the "transition" is for a voltage waveform "across a primary winding" and whether "transition of a voltage waveform" means a "change from one voltage state to another."

SynQor argues that the language around the term "transition times" in the asserted claims states that the relevant transition is of a voltage waveform "of a primary winding," and that including that language in the disputed "transition times" term is not helpful. SynQor argues that unasserted claims of the patents-in-suit refer to "transitions times" of voltages for power MOSFET switches, not a primary winding, and thus Defendants' proposal is incorrect to add the "across a primary winding" language. SynQor argues that "transition" is a common English word, just like "change," and Defendants' proposal adds nothing of substance to the construction. Defendants argue that SynQor's proposed construction is deficient because it refers to a transition of "a voltage waveform" without identifying which waveform should be considered in determining the recited times. This generic reference to a "voltage waveform" implicitly suggests that any voltage waveform can be considered when determining the "transition times" required by the claims. Defendants argue that their construction is mandated by the claims because they are clear that the only voltage waveform relevant for determining the recited "transition times" is the voltage waveform across "a primary winding."

The Court finds that the claim language at issue requires that the voltage waveform of the primary winding has (i) a fixed duty cycle and (ii) transition times which are short relative to the on-state and off-state times of the controlled rectifiers. Thus, the Court agrees with the Defendants that the language "across a primary winding" is necessary and appropriate, because it is clear from the claims that the only voltage waveform relevant for determining the recited "transition times" is the voltage waveform across "a primary winding." Like in the previous term, the Court rejects Defendants' insertion of the language "voltage stage" when such a limitation appears unnecessary and not based on the claims or the specification. The term "transition" itself generally means to change. Thus, rather than repeating the word "transition" as SynQor proposes in its construction, the Court finds that the term "change" proposed by Defendants is accurate. Thus, the Court construes the term "transition times" to mean "time periods during which a change of a voltage waveform occurs across a primary winding."
7. The term "TRANSLATION CIRCUITRY" (claim 6) means "electrical components that make the sensor and meter electrically and physically compatible." This translation circuitry must be a part of the sensor probe.

Q. Translator/Translating

Visto suggests that the term "translator" means "software routines or code that convert information or data in one format to information or data in a second format." Seven contends that the term means "a global translator that translates between a global format and a Format A or between the global format and a Format B, but not directly between Format A and Format B or vice versa, and residing outside a corporate firewall."

This term is found only in the '708 patent. Seven, through its argument, incorporates the word "global" into this term and dictates where in the system the translator must be located. Seven relies heavily on a statement in the prosecution history in which the patentee distinguished a prior art reference (Smith) by describing claims 1 and 17 of the '708 as providing a "system and method for synchronizing two versions of a workspace element across a network using a global translator." According to Seven, the applicants limited the scope of the word translator to a "global translator" as exemplified by the preferred embodiment.

The court's review of the prosecution history reveals that the patentee did not limit the claim term in the manner Seven proposes. Read in context, the statement made in the prosecution history reflects an attempt to distinguish the Smith reference on the grounds that Smith failed to include the second store limitation contained in claims 1 and 17. As such, the court adopts Visto's definition of "translator" to mean "software routines or code that convert information or data in one format to information or data in a second format." Likewise, the term "translating" as used in various claims of the '708 Patent is defined to mean "converting information of data in one format to information or data in another format."

A. "transmission"! "transmitting away" /"transmission . . . to a select destination"

The term "transmission" appears in various forms including "transmission away"; "transmitting away" and "transmitting . . . to a select destination." These terms appear in a total of eleven claims in all of the Burst patents. Claim 1 of the '995 Patent is indicative.

1. An audio/video transceiver apparatus comprising: input means for receiving audio/visual source information;

   compression means, coupled to said input means, for compressing the said audio/video source information into a time compressed representation thereof having an associated time period that is shorter than a time period associated with a real time representation of said audio/video source information;

   random access storage means, coupled to said compression means, for storing the time compressed representation of said audio/video source information; and

   output means, coupled to said random access storage means, for receiving the time compressed audio/video source information stored in said random access storage means for transmission away from said audio/video transceiver apparatus.

'995 Patent at 10:58-11:7. The parties agree that "transmission" should be understood as "sending."
The first issue in dispute is where the information is sent when the patent uses the term "transmitting away" or "transmitting . . . to a select destination." Burst contends that the information is sent to an external device. Apple disputes this construction, asserting that the inventor disclaimed sending information to an external device when he distinguished his patent from the Izeki prior art. Apple's argument turns on its particular understanding of the depiction of the reproduction device in Figure 1 of the Izeki patent. See U.S. Patent No. 4, 974,178 at Fig. 1 ("Izeki patent"). Apple contends that the dotted line surrounding the reproduction device in the Izeki patent indicates that it is external to the Izeki apparatus. The court is unwilling to conclude that Izeki teaches transfer of information to external devices based on this dotted line. In fact, Figure 1 of the Izeki patent includes a printer which is commonly considered an external device and it is not outlined with dotted lines. Id. In addition, the prosecution history of the Burst patents shows that the inventor distinguished the invention from Izeki by arguing that the Izeki prior art "is simply not concerned with transmitting audio/video information away from the apparatus to one or more receivers." Id., '705 File History, Brown Decl, Exh. L at APBU 652. The inventor contended that the Izeki prior art is an apparatus for editing and storing audio/video source information within the apparatus and without external transmission. Izeki Patent at 1:10-15. Therefore, Burst did not disclaim sending information to external devices.

Apple argues that the proper construction of "transmitting away" should be "sending information to a remote location," attempting to distinguish between sending information to devices that are local and devices that are remote. However, the term "remote" injects further ambiguity into the claim construction, and Apple offers no test to distinguish between devices that are local and devices that are remote, stating only that the difference is a matter of degree. Though the term "remote" is used in the patents, it is not used universally in association with transmission and should not be a limit on the term "transmission." Compare '995 Patent at 10:14-20 (using term "remote"), with id. at 11:3-8 (not using term "remote").

The second issue is whether the construction of "transmission" should be limited to sending information to devices capable of playback. Burst argues that the patent teaches transfer of information between transceiver devices that are capable of playback, relying on language in the '995 patent specification. The key language discussed by Burst appears in the '932 Patent specification: "The VCR-ET can receive/transmit a video program . . . from/to a variety of sources . . For example, a video program may be communicated at an accelerated rate from the first VCR-ET to a second VCR-ET . . . " '932 Patent at 8:18-23 (emphasis added). This language does not support Burst's contention; it indicates that transferred information may be to a device capable of playback, but not that it must. The court is unwilling to adopt such a limitation. Burst further contends that when the patent refers to transmission time it is relative to the duration of real-time playback of the audio/video source information. See, e.g., '995 Patent at 7:60-66. Burst suggests that this reference implies that the device receiving the information must be capable of playback. This conjecture is insufficient to limit transfer of information solely to devices capable of playback.

Accordingly, the court finds that "transmission" means "sending", and "transmitting away" or "transmission . . . to a select destination" means "sending information to an external device".

DTL contends that this limitation is not a means-plus-function limitation under § 112, P 6 and should be construed as "a transmitter." Cingular states that if the court does not consider the limitation to be a means-plus-function limitation, the term should be construed as "a transmitter in the form of an amplifier, amplifier driving a light emitting diode, or solid state diode laser and a transmit interface."

This term substantially reproduces the dispute regarding the meaning of "digital signal processing." For the same reasons discussed above, Claim 18 recites no structure to perform the "transmission means" function. Thus, the claim must be construed as a means-plus-function limitation.

DTL states that function is "transmitting the sequence of groups of digital bits to a location remote from the transducer means" whereas Cingular contends that the function is "transmitting the sequence of groups of digital bits output from the analog-to-digital converter means to a location remote from the transducer means." As with the "digital signal processing
means," the parties agree that the transmission means must transmit the sequence output from the analog-to-digital conversion, though it need not receive that sequence output from the analog-to-digital conversion means directly. The court finds that the function is "transmitting the sequence of groups of digital bits that are received, directly or indirectly, from the analog-to-digital converter means to a location remote from the transducer means."

DTL contends that the corresponding structure is "a transmitter, amplifier or radio transmitter, and equivalents thereof" Cingular proposes that the corresponding structure is "a transmitter in the form of an amplifier, amplifier driving a light emitting diode, or solid state diode laser and a transmit interface that changes the sequence of groups of digital bits into a format suitable for transmission such as a Yamaha part number YM3613B, or a substantially equivalent structure in existence as of September 1991."

The court again turns to the specification of the '799 patent to determine the appropriate structure corresponding to the "transmission means." According to the specification, structure for the "transmission means" includes a transmitter (col. 5, l. 66-67), an amplifier (col. 5, l. 68), an amplifier driving a light emitting diode or solid state diode laser (col. 6, ll. 8-9), and a radio transmitter (col. 6, l. 10).

Cingular argues that the corresponding structure must provide for a transmitter that includes a transmit interface, such as a Yamaha part number YM3613B disclosed in '799 col. 7, ll. 53-59. Cingular points to col. 5, ll.65-67, which states that "the output of the transmit interface is connected to a transmitter." Cingular's argument is unavailing. Figure 3 makes clear that the transmit interface 112, is a separate structure from the transmitter 116. The specification makes it clear that the data is converted by the transmit interface prior to transmission. "The A/D converter output data 110 is converted to a standardized form suitable for transmission by a transmit interface 112." '799 patent, col. 5, ll. 60-62. The transmit interface is not clearly linked to the function recited in Claim 18, and unless the structure is clearly associated with the claimed function, it cannot be corresponding structures for purposes of § 112, P 6. See Omega Engineering, Inc. v. Raytek Corp., 334 F.3d 1314, 1332 (Fed. Cir. 2003). Accordingly the court finds that the corresponding structure is "a transmitter, an amplifier, an amplifier driving a light emitting diode or solid state diode laser, a radio transmitter, or equivalents thereof."

**4564**

"Transmission channels" used in claims 9, 10, 24, and 25.

This disputed term appears in claim 9, which is dependent on claim 1, and in claim 10, which is dependent on claim 9.

9. The information transmission system of claim 1, wherein said transmitter transmits said data packets using multiple transmission channels.

10. The information transmission system of claim 9, wherein . . . said transmitter transmits data packets containing at least selected portions of said video program materials on at least one of said multiple transmission channels and primarily non-video information on at least one other one of said multiplicity of transmission channels;

The term also appears in almost identical language in claim 24, which is dependent on claim 16, and in claim 25, which is dependent on claim 24.

One of ordinary skill in the art would understand that, depending on the context, "channel" as used in the field of data transmission could have two meanings. Sometimes "channel" is used to refer to a band of frequencies of a determined width, measured in megahertz. (MHz). This is the way "channel" is commonly used when referring to common T.V. or radio channels. DirecTV argues that these claims should be limited to this construction.

But multiple "channels" can be carried on a single frequency using a technique called time division multiplexing ("TDM"). In this process, a transmission path (a frequency) is divided into time slots to carry data from several sources at the same time. For example, data from each of three sources is divided into a series of short pieces or "frames" each of which will fit into a time slot. The first piece of data from the first source is transmitted in the first time slot. The first piece of data from the second and third data sources follow in time slots two and three respectively. This sequence is repeated for the second, third and succeeding pieces of data from each source. In effect all three sources of data are transmitted on one path, but in
different, time differentiated "channels."

Finisar argues that "transmission channels" as used in these claims, encompasses both kinds of "transmission channel." The various technical dictionaries and references noted in the parties' briefs describe "channel" in both ways. But, contrary to Finisar's arguments, just because a word can be used in two or more ways, does not mean that it was. The issue is: what is meant by "transmission channels" in these particular claims?

This issue illustrates the tension between understanding the meaning of a claim term in the context of the specification, and incorporating limitations from a disclosed embodiment into the claims. In this case, more than one embodiment is described in the specification. The preferred embodiment is a single channel implementation, and at least one other embodiment is a multiple channel implementation. Several of the dependent claims appear to be directed specifically to a multiple channel implementation. But, although the specification describes at least two embodiments, the terms "channel," and "transmission channel" are consistently used to describe a band of frequencies. In fact, the specification distinguishes between a time division multiplexed "time slot" and a "channel" or "transmission channel."

The specification identifies the one-channel implementation as the "preferred embodiment." 505 patent, col. 4, 11. 65 -- col. 5, 11. 1-2. The specification indicates that satellite transmission channels can be used for different geographical areas. 505 patent, col. 5, 11. 2-5, and it refers to a "single satellite channel," suggesting a single band of frequencies rather than a single TDM time slot in a band of frequencies. 505 patent, col. 5, 11. 23-26. When "multiple transmission channels" are used, the subscriber stations "change the transmission channel being monitored" (' 505 patent, col. 7, 11. 27-36), and the satellite receiver must be told which channel should be selected (' 505 patent, col. 12, 11. 29-36). Bandwidth in a single channel transmission system may be subdivided into tiers, with 25% of the available bandwidth being reserved. 505 patent, col. 13, 11. 67 -- col. 14, 11. 37. The "bandwidth of a channel" (' 505 patent, col. 14, 11. 36) may be subdivided by TDM, suggesting a distinction between channel and TDM time slot.

This suggestion is much more explicit when the specification describes video programming, described as "a classic problem in that it tends to occupy large amounts of bandwidth." 505 patent, col. 16, 11. 46-48. The specification states that "in the preferred embodiment most video programming is transmitted on a separate channel." 505 patent, col. 16, 11. 54-56. This sentence is useless surplusage if "separate channel" refers to TDM. Of course the video programs have to be separated from other data. If only one frequency divided "channel" is being used, there would be no way to transmit the video programs separately, other than with TDM.

The specification then states that on this "separate channel" it would be "possible to use time multiplexing so as to transmit six video programs . . . simultaneously." 505 patent, col. 16, 11. 57-60. One of ordinary skill in the art would know that TDM could be used to transmit several programs on one frequency "channel" so there would have been no need to refer to the "separate channel" if it did not mean another frequency.

Claims 10 and 25 are clarified, when read in the context of the portions of the specification discussed above. Both of these claims describe transmitting video programming on "at least one of said multiple transmission channels" and transmitting "primarily non-video information on at least one other one of said multiplicity of transmission channels." 505 patent, col. 19, 11. 66 -- col. 20, 11. 3 and col. 23, 11. 7-12. What is the purpose of these dependent claims if "transmission channels" refers to TDM?

Hence, although the term "channel" may, in some contexts, apply to a time multiplexed slot on a band of frequencies, the specification of the 505 patent clearly distinguishes between a time multiplexed slot and a band of frequencies, with the latter being referred to as a "channel" or "transmission channel." n4 Therefore this claim term will be defined as follows.

"transmission channels" means "paths for transmitting electronic signals which are differentiated by their frequencies."

n4 The Court need not decide whether the term "channel" would properly apply to a TDM time slot in another context.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

n4 The Court need not decide whether the term "channel" would properly apply to a TDM time slot in another context.
5. Differential Input and Transmission Line

The last element of Claim 1 reads "driver means including low pass filter means having a differential input coupled to the current output for impressing an analog voltage onto a transmission line." '269 Patent at 7:1-4. With respect to the differential output, the parties now appear to agree that the term refers to the driver means and not the low pass filter means, thus the court accepts that construction.

The parties do dispute what transmission line includes. Seeq contends that it should be interpreted to include "any alternative transmission media which exhibit lossy characteristics, including twisted pair wire or radio frequency." Level One asserts that a transmission line refers to communication over a physical connection such as a line, a wire or a cable and that ether is not a lossy media. The court agrees that even though distortion may occur with radio transmission, the term transmission line suggests a physical media and it does not logically apply to radio frequency. While the '269 patent states that it "relates generally to problems in data communication systems having a lossy transmission media," '269 Patent at 1:7-9, it more specifically addresses "conventional transmission lines, such as twisted-pair cable" later in the specification. '269 Patent at 1:29-30. Accordingly, the court construes transmission line to encompass lossy physical media, such as lines, wire and cable.

"Transmission times" as used in two claim terms:

11b. "transmission scheduler reserves transmission times for transmitting portions of said information database requested by subscribers." Used in claim 37; and

11c. "said transmitting step including transmitting said requested portions of said information database during said reserved transmission times." Used in claim 44.

The parties agree that "reserving transmission times" means setting aside transmission times. Again the question is whether or not time has to be reserved in direct response to a request. This would imply that time was reserved only if a subscriber called in and requested certain information. That may be one embodiment, but, as DirecTV agrees, the "reserved" phrases used in the claims do not explicitly state that any action will be "in response to" subscriber request. DirecTV Brief, p. 29.

As with the earlier phrases, the plain language of the claim phrase simply provides that transmission time is set aside for transmitting data requested by subscribers. Nothing in this language limits the "request" to any particular type, nor does the language prohibit transmission of data during "unreserved" times. As pointed out above, data "requested" by a subscriber may be included in the basic subscriber service. 505 patent, col. 5, 11. 45-65.

This term will be defined as follows:

"Transmission times" are "reserved" by setting aside time for transmitting portions of the information database that are requested by subscribers.

1. Transmission system

The Court lets stand its previous definition of "transmission system" to mean an assembly of elements, hardware and software, that function together to convert items of information for storage in a computer compatible form and subsequent transmission to a reception system.
The Court addresses the definition of the phrase "transmission system" because it is a limitation on the method disclosed in Claim 19.

The parties dispute the proper construction of the phrase, "transmission system" as previously defined by the Court and as used in Claim 19. In the July 12 Order, the Court construed the phrase "transmission system," as it is used in apparatus Claims 1, 17 and 27 of the '702 Patent and in Claims 1-18 of the '992 Patent. Based on the arguments in the briefs and presentations made during the June and September hearings, the Court reconceives its definition of "transmission system."

When the meaning of a term is sufficiently clear in the patent specification, that meaning shall apply. Multiform Desiccants, Inc. v. Medzam, LTD., 133 F.3d 1473, 1477 (Fed. Cir. 1998) (citing Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388 (Fed. Cir. 1992)). "This rule of construction recognizes that the inventor may have imparted a special meaning to a term in order to convey a character or property or nuance relevant to the particular invention. Such special meaning, however, must be sufficiently clear in the specification that any departure from common usage would be so understood by a person of experience in the field of the invention." Multiform Desiccants, Inc., 133 F.3d at 1477.

In the July 12 Order, the Court treated "transmission system" as a term with a special meaning, namely, "an assembly of elements, hardware and software, that function together to convert items of information for storage in a computer compatible form and subsequent transmission to a reception system." (July 12 Order at 27-28.) The Court's July 12 definition recognizes that by "transmission system" the patentee meant something more than an apparatus which "transmits." The Court finds that the definition given in the July 12 Order recognizes some but not all of the components of what the patentee meant by the phrase "transmission system."

The phrases "transmission system" and "reception system" are coined terms. The inventions disclosed in the '992 Patent are audio and video transmission and receiving apparatuses and methods which operate over conventional communication channels, but ones in which a user remotely controls what material is transmitted and when it is played back. To accomplish this objective, the patentee disclosed an apparatus with interconnected components for preparing the audio and video information for user access and transmission, which the patentee coined as a "transmission system."

When the patentee acts as his or her own lexicographer, the court looks to the intrinsic evidence for a definition of the words and phrases used in a claim. Vitronics Corp., 90 F.3d at 1582. In the specification of the '992 Patent, the patentee defines the components of the "transmission system" as follow:

To achieve the objects in accordance with the purposes of the present invention, as embodies and described herein, the transmission ... system for providing information to remote locations comprises source material library means prior to identification and compression; identification encoding means for retrieving the information for the items from the source material library means and for assigning a unique identification code to the retrieved information; conversion means, coupled to identification encoding means, for placing the retrieved information into a predetermined format as formatted data; ordering means, coupled to the conversion means, for placing the formatted data into a sequence of addressable data blocks; compression means, coupled to the ordering means, for compressing the formatted and sequenced data; compressed data storing means, coupled to the compression means, for storing as a file the compressed sequenced data received from the compression means with the unique identification code assigned by the identification encoding means; and transmitter means, coupled to the compressed data storing means, for sending at least portion of a specific file to a specific, one of the remote locations.

('992 Patent, Col. 2:25-48.)

In specifying the components of "transmission system" the patentee uses a "structural tag plus means." Under this format, once a given means-plus-function component is introduced, the patentee may make subsequent references to the same structure by using the structural "tag" followed by the word "means," e.g., "After compression processing by compressor
116, the compressed audio and/or video data is preferably formatted and placed into a single file by the compressed data storage means 117." ('992 Patent, Col. 10:24-26). An apparatus claim which is in mean-plus-function format is limited to the corresponding structure in the specification and its equivalents. A method claim containing a preamble which requires that the steps be performed by an apparatus, is limited to that apparatus and any other apparatus identified in the specification for performing the specified step. Claim 19 is limited to the "transmission system" and "receiving system" disclosed in the specification.

In the July 12 Order, the Court defined some of the structures of the components of the "transmission system." Incorporation of those structures does not import preferred embodiments into a claim. The "transmission system" and "receiving system" and methods for using them to distribute audio and video information as described in the specification are the inventions in the '992 Patent. They are not preferred embodiments; they are the inventions themselves. When the embodiment is described as the invention itself, the claims are not entitled to a broader scope than the embodiment. Modine Manufacturing Co., v. United States International Trade Comm., 75 F.3d 1545, 1551 (Fed. Cir. 1996) (abrogated on other grounds by Festo Corp. v. Shoketsu Kinzoku Kogyo Kabushiki Co., 234 F.3d 558 (Fed. Cir. 2000), rev'd by 535 U.S. 722, 122 S. Ct. 1831, 152 L. Ed. 2d 944 (2002)).

The specification includes drawings of the "transmission system" described as follows:

**FIGS. 1a - 1g are high level block diagrams showing different configurations of the transmission ... system of the present invention.**

('992 Patent, Col. 3:50-53.)

***

**FIGS. 2a and 2b illustrate detailed block diagrams of preferred implementations of the transmission system 100 of the present invention.**

('992 Patent, Col. 5:59-61.) It is clear from the specification that the patentee intended "transmission system" to mean a particular assembly of elements depicted in the drawings and described in the specification. These elements are configured in such a fashion to fulfill the purposes of storing, retrieving and identification encoding, formatting, ordering, compressing, storing in a compressed data library, and transmitting information.

Further, in describing the components of the transmission system, the specification states which components are "coupled to" one another. The Court has previously defined "coupled to" to mean "directly connect to or attached to." (July 12 Order at 24.) The specification that a particular component be coupled to another is significant because it means that in order for information to proceed from one component to another, it must follow the same sequence. It also means that each interconnected component is essential because information can only be transferred to an interconnected component.

As used in Claim 19 of the '992 Patent, the Court construes the phrase "transmission system" to mean:

*An apparatus which comprises the following interconnected components: a source material library means, an identification encoding means, a conversion means, an ordering means, a compression means, a compressed data storing means (as illustrated in the block diagram labeled Figure 2a), and a compressed data storage means and a transmitter means (as illustrated in the block diagram labeled Figure 2b). The corresponding structure for each means is the structure identified in the specification for performing the recited function.*
5. "transmit/transmitting information regarding the acceptance and rejection of the onsite and remote auction bids"

The parties dispute the meaning of "transmit/transmitting information regarding the acceptance and rejection of the onsite and remote auction bids" as that term is used in Claims 1 and 3. AMS proposes that the claim term means simply "transmit[ting] facts or data regarding the acceptance and rejection of bids submitted by onsite and remote auction bidders." In contrast, Defendants propose that the term be construed to mean "send[ing] four types of information relating to auction bids: (1) information regarding the acceptance of remote bids, (2) information regarding rejection of remote bids, (3) information regarding the acceptance of onsite bids, and (4) information regarding the rejection of onsite bids."

In support of Defendants' argument that this claim term unambiguously refers to the transmission of four types of information, Defendants proffer three basic arguments. First, defendants argue that the use of the conjunctive in the claim term itself unambiguously requires the transmission of four types of information. Second, Defendants point to the specification, arguing that in order to "instill[] confidence of all parties . . . in the integrity of the process" (612 patent col.2, II 46-52), transmission of four types of information is necessary. Finally, Defendants note that during prosecution the inventors cancelled claims which employed the disjunctive and described the transmission of information about the acceptance or rejection of bids, and substituted the conjunctive form which eventually issued as Claims 1 and 3. Defendants argue that in light of this change in claim language during prosecution, the Court must give effect to that distinction.

In contrast, AMS argues that Defendants' proposed construction is overly restrictive, and that nothing in the claim language, specification, or prosecution history requires the transmission of four distinct types of information. The Court agrees. From the basic grammatical construction of the claim term, the Court sees no reason why four distinct types of information are required, and Defendants do not point out any reason why a single type of information can not relate to both acceptance and rejection of bids. Accordingly, the term "transmit/transmitting information regarding the acceptance and rejection of the onsite and remote auction bids" shall mean "transmit[ting] facts or data regarding the acceptance and rejection of bids submitted by onsite and remote bidders."

"Transmit channels"

Cisco's proposed construction is "logical channels of data transmitted out of a network." Alcatel's proposed construction is "logical channels of data transmitted to the customer premise equipment."

Essentially, the same dispute exists regarding the construction of "transmit channels" as for "egress traffic of a network." Alcatel claims that it is limited to traffic directed towards customer premise equipment, and Cisco claims that there is no such limitation. Again, Alcatel cites to various points in the specification where the term transmit channels is used in connection with references to customer premises equipment. See, e.g., Valizadeh, at 2:60-3:10. However, as before, the plain language of the claims indicates that "transmit channels" is not limited to data transmitted to the CPE. The term "transmit channels" is used in claims 1, 6, 7, and 12. However, the term is not explicitly referred to in connection with customer premise equipment in claims 1 and 12, but is referred to in such a way in claim 6. 11 Furthermore, the specification itself notes that "[t]he queuing and servicing schemes described herein may be readily adapted to any system wherein additional granularity is desired for ensuring fairness when data received from multiple receive channels is to be transmitted over a single transmit channel." Id. at 3:20-24.

11 Claim 7 is dependent on claim 6.
Thus, as before, Alcatel seeks to limit the claim language based on the preferred embodiment, and seeks to read into one claim a limitation included in another claim, which are both at odds with the general principles of claim construction.

Nevertheless, the principles of claim construction also require that the Court interpret the claims in light of the specification. See Netword, LLC v. Centraal Corp., 242 F.3d at 1352 ("The claims are always construed in light of the specification, of which they are a part."). Accordingly, in the same manner that the specification makes clear that "egress traffic" is not merely traffic exiting any "network," neither are "transmit channels" simply "logical channels of data transmitted out of a network," as Cisco suggests. Instead, transmit channels are used to transmit data to the slower network (such as customer premise equipment). See, e.g., Valizadeh, at 1:58-65, 2:60-67, 3:11-34, 3:45-55, 6:3-5, Fig. 2.

Therefore, the Court construes "transmit channels" as "logical channels of data transmitted to a network operating at a slower data rate."

**2. transmit control**

The term transmit control appears in Claim 1, for example:

Control means responsive to said monitor means for automatically transferring transmit control to the first microphone and disabling said second microphone such that transmission cannot occur through said second microphone when audible sounds are generated at said first microphone and for enabling said second microphone to transmit only when audible sounds are not generated at said first microphone.

Claim 1(e); see also, Claims 13(b) or 18(f). Plaintiff argues that "transmit control" means: "the power to regulate or exercise influence over a telephone line; in other words, control over the transmission of sound over the telephone line." This definition is not contested by defendants. Because the term is not defined in the claims, specification or prosecution history, the words are given their ordinary construction by the Court. Thus, the Court defines "transmit control" as used in the 501 patent to mean that "one microphone is given control." This definition applies to all the claims of the 501 patent.

**R. "receiving a transmitted reservation request"**

Claims 5 and 17 refer to a computer and a communications module that are used for "receiving a transmitted reservation request." (col. 27, ll. 36-37,44-45; col. 30, ll. 62-63.) The Defendants maintain that the disputed phrase is simply part of the limitation associated with the means-plus-function analysis of "communications module." Not only does this argument ignore the fact that "receiving a transmitted reservation request" is not always paired with communications module, but the Court has already determined that communications module is not properly construed in means-plus-function terms. The Court has previously construed "reservation request." "Receiving" and "transmitted," two commonly understood words, do not require construction.

**4. Terms Which Depend on the Construction of "transmitted symbol" and "received symbol"**

Disputed terms [17] to [22] of the '322 Patent will be analyzed together as they largely depend on the Court's construction of the terms "transmitted symbol" and "received symbol." Four terms are found in the last two steps of the method recited in Claim 1. The steps are:

[19] implementing said change at the transmitter in response to a [17] transmitted symbol having a symbol count
matching said value; and

[20] implementing said change at the receiver in response to a [18] received symbol having a symbol count matching said value.

'322 Patent, col. 12, 11. 5-10. Two terms are also found in Claim 20. This claim reads as follows:

20. A transmission system using multicarrier modulation, comprising:

a transmitter including a modulator for modulating multiple carriers each with an individually allocated number of data bits per transmission symbol, the transmitter including a [17] [21] transmitted symbol counter for counting transmitted symbols and a control unit for updating a number of data bits allocated to a carrier at a time dependent upon a count of the transmitted symbol counter; and

a receiver including a demodulator for demodulating the carriers to derive the allocated numbers of data bits from the multiple carders, the receiver including a [18] [22] received symbol counter for counting received symbols and a control unit for updating a number of data bits derived from a carder at a time dependent upon a count of the received symbol counter.

The parties dispute the construction of the two steps appearing in Claim 1. Based on the parties' proposed constructions, the issue is whether a "transmitted symbol" and "received symbol" must be entirely or completely transmitted or received, or simply be in the process of being transmitted or received. Plaintiff argues that the term "implementing said change at the transmitter in response to a transmitted symbol having a symbol count matching said value" requires two elements: 1) the change occurs after a symbol is "entirely transmitted," and 2) the change must be caused by that transmission. 16 (Pl.'s Opening Br. at 22-25). Plaintiff submits that the use of the phrase "in response to" supports such an interpretation. Further, Plaintiff contends that the tense of the word "transmitted," that is past tense, signifies that the act of transmission must have been completed before a change is effectuated. (Id. at 23).

Additionally, Plaintiff refers to portions of the specification to support its interpretation. For example, Plaintiff refers to the specification which describes Figure 3 in the patent. It states: "the transmitter control unit 36 includes the counter 38, which it increments immediately after the transmission of each symbol, and the receiver control unit 48 includes the counter 50, which it increments immediately after the reception of each symbol." '322 Patent, col. 7, 11. 10-14 (emphases added). Plaintiff asserts that this disclosure, in addition to the claim language, indicates that "it is the transmission of the symbol itself that . . . instigates cause for the change." (Pl.'s Opening Br. at 24). Logically, Plaintiff submits, these factors necessitate a construction that requires the "complete transmission" of a symbol.

In contrast, Defendants argue that in the context of the claims, and in light of the specification, a "transmitted symbol" is simply a symbol "being transmitted." (Chart at 6). Defendants claim that Plaintiff is attempting to import various limitations by equating "in response to" with "entirely after." Defendants argue that the ordinary meaning of the term "in response to" should be adopted. Based on a competent dictionary reference, Defendants define the word "response" as "[a] reaction, as that of an organism or mechanism, to a particular stimulus." WEBSTER'S II NEW COLLEGE DICTIONARY 945 (1995). Further, Defendants argue that the ordinary meaning of "transmit" means "to move data from one location to another location." THE NEW IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS 1406 (1993). Combining these definitions, Defendants propose that the term should be construed as "implementing a change at the transmitter or receiver in reaction to symbols that are eventually transmitted." (Defs.' Reply at 17). Defendants assert that neither the intrinsic evidence nor the ordinary meanings of the words require the limitation that the symbol be "entirely
transmitted" before a change can be implemented.

Although the Court agrees with Plaintiff that the terms "transmitted" and "received" are drafted in the past tense, the Court concludes that the specification describes a dynamic or pipeline process in which symbols are being transmitted and received at any given time. The specification describes various radios, bridges, and routers to provide a wireless communication link to the programmed computer. The plain language of the claim does not rule out the possibility that a symbol may still be in the transmitter and be considered a "transmitted symbol." The same reasoning applies to the construction of "received symbol." Therefore, the Court will adopt Defendants' construction of "transmitted symbol" and "received symbol," and will adopt the ordinary meaning of the phrase "in response to."

Accordingly, the Court concludes: 1) [17] "transmitted symbol" means "a symbol that is in the process of being transmitted which may or may not be in the transmitter"; 2) [18] "received symbol" means "a symbol that is in the process of being received which may or may not be in the receiver"; 3) [19] "implementing said change at the transmitter in response to a transmitted symbol having a symbol count matching said value" means "a change is effectuated at the transmitter in reaction to symbols that are in the process of being transmitted that have a symbol count matching said value"; 4) [20] "implementing said change at the receiver in response to a received symbol having a symbol count matching said value" means "a change is effectuated at the receiver in reaction to symbols that are in the process of being received that have a symbol count matching said value"; and 6) [22] "received symbol counter for counting received symbols" means "a counter that counts symbols that are in the process of being received."
another" and "to send out (a signal) either by radio waves or over a wire." Pl. App. Ex. 48 at 475; Pl. App. Ex. 49 at 500.
Based on the dictionary definitions, Papyrus alleges that there is no requirement for direct transmission without intermediate processing or storage, as commonly understood. Pl. MHSP vol. 1 at 81.

NYSE, however, contends that the specification contains no disclosure regarding the sending of signals to some intermediate device between the first device and the second device. Def. Br. 24. As a result, NYSE ask the court to construe the term and phrase as meaning "directly sending between the identified devices without use of an intermediate network." Def. PCCO 3. Specifically, NYSE seeks to distinguish between transmission from the HHD to the programmed computer and communication from the programmed computer to the network system. According to NYSE, when the patent refers to a router and a network, it describes the connection between the booth clerk back into the network system, and the router is only involved when there is communication with entities other than the booth clerk and the floor brokers. See Markman Hr'g Tr. vol. 2 at 14-15. In contrast, NYSE alleges that phrase "direct transmission" refers to "data packet[s] fly[ing] directly from one computer to the other." Id. at 17. Moreover, in direct transmission, the data packet does not go back into the network through the router. Id.

To support its position, NYSE relies on both the patent language and the prosecution history. In citing the specification, NYSE repeatedly emphasizes the phrase "from a first device to a second device." See '877 Patent col.6 ll.42-43. The specification also states that "[a]ll data packets that are to be transmitted, either from the [base station] or the HHD, are handled by the routine illustrated in Fig. 15." Id. col.28 ll.2-4. Because the data packet is "placed in [the] outbound queue" in step 740 and is transmitted in step 742, NYSE alleges that there is no discussion of indirect transmission in the preferred embodiment. Def. Br. 25.

With regard to the prosecution history, NYSE argues that Papyrus defined the "transmitting" term and phrase during prosecution of the '362 Patent, which issued from the same initial application as the '877 Patent. Def. Br. 25; Def. MHSP 121. NYSE also alleges that "Papyrus amended its claims to expressly recite direct transmission . . . [by] add[ing] language that called for transmitting a data packet from a first individual to a second floor broker." Markman Hr'g Tr. vol. 2 at 18. Further, the prosecution history would lead a competitor to reasonably believe that Papyrus had disavowed indirect data transmissions, and therefore function as a disclaimer. Def. Br. 27; see Omega Eng'g, Inc., v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003) ("As a basic principle of claim interpretation, prosecution disclaimer promotes the public notice function of the intrinsic evidence and protects the public's reliance on definitive statements made during prosecution.").

"When multiple patents derive from the same initial application, the prosecution history regarding a claim limitation in any patent that has issued applies with equal force to subsequently issued patents that contain the same claim limitation." Biovail Corp. Int'l v. Andrx Pharms., Inc., 239 F.3d 1297, 1301 (Fed. Cir. 2001) (quoting Elkay Mfg. Co., 192 F.3d at 980). In addition, "a statement made by the patentee during prosecution history of a patent in the same family as the patent-in-suit can operate as a disclaimer." Verizon Servs. Corp. v. Vonage Holdings Corp., 503 F.3d 1295, 1306 (Fed. Cir. 2007).

In this case, during the prosecution of the '362 Patent, Papyrus specifically explained the process of direct transmission in order to overcome prior art. 17 See Pl. App. Ex. 32 at 314. Following the June 7, 2001 amendment, the PTO examiner rejected the application because "the features upon which applicant relies (i.e., direct transmissions from one floor broker to another) are not recited in the rejected claim(s)." Office Action in Application Serial No. 09/668,184 (Aug. 27, 2001), Pl. App. Ex. 34 at 325. Papyrus again amended the patent application to expressly recite direct transmission. See Amendment in Application Serial No. 09/668,184 (Feb. 21, 2002), Pl. App. Ex. 35 at 328 ("transmitting the data packet from the first device to the assigned network address of the second handheld device"). To explain its proposed changes, Papyrus stated that "[t]he amendments to [C]laim 7 directly address the arguments in Applicants' prior Amendment since the amended [claim] expressly recites direct transmissions from one individual to another." Pl. App. Ex. 35 at 331. The examiner subsequently concluded that the closest prior art discloses a method of order management which fails to anticipate or render obvious the direct transmission from HHD to HHD. Pl. App. Ex. 37 at 340-41.

--- Footnotes ---

17 The amendment states that:

[t]he claimed arrangement enables direct data transmission between and among floor brokers . . . In contrast, Gutterman et al. has all data transmissions directed through the same electronic order entry system and provides no flexibility to allow
direct data transmissions from one floor broker to another.

Amendment in Application Serial No. 09/668,184 (June 7, 2001), Pl. App. Ex. 32 at 314 (emphasis added).

Although NYSE is correct in noting that the '362 Patent used "transmitting" to mean direct communication between HHDs, the prosecution of the '362 Patent Claim 7 does not limit the '877 Patent Claim 1 because the two claims use different language. Ventana Med. Sys. v. Biogenex Labs., Inc., 473 F.3d 1173, 1184 (Fed. Cir. 2006) (suggesting that statements made by inventor during continued prosecution of related patent application should not limit claim scope where patent-in-suit includes different claim language than later-prosecuted claim). The latter does not require direct transmission between two HHDs, but rather, transmission from a programmed computer to a HHD and from a HHD back to the programmed computer. See '877 Patent col.32 ll.29-31, ll.35-36. Given the different language in the claims, it would be inconsistent to apply the same construction to the term "transmitting" as it appears in the two patents. Moreover, because the claim language does not require direct transmission and because the specification calls for the use of radios and ethernet bridges, the court may not adopt a construction that builds in or precludes direct transmission. See '877 Patent col.8 ll.34-39; Fuji Photo Film Co., 386 F.3d at 1106. Accordingly, the court finds that both the term "transmitting" and the transmitting step mean "sending from one place to another."

6. "transmitting" or "transmit"

The parties dispute the meaning of the terms "transmitting" of claim 21 and "transmitted" of claim 24. Echostar argues that nothing in the plain and ordinary meaning of "transmit" requires any particular method of transmission, whereas IPPV argues that "transmitting" is limited to the sending of information by propagating a signal from the first location to the second, and does not include the sending of information by mail.

In support of its construction, IPPV points to a portion of the specification stating that "with the increased interest and activity in the field of subscription or pay video transmission of all types (e.g. broadcast and cable subscription television, long distance satellite transmission, television transmission of textual information, etc.), there has arisen a need for more secure transmission of high quality video information." IPPV argues that the examples set forth in this passage indicate that the mail service is not a type of "transmission" in the context of the invention.

Echostar argues in response that U.S. Patent No. 4,405,942 and the '217 patent, both Block patents, refer to transmissions and include mail as a method of transmission. IPPV therefore contends that the inventors knew that "transmitting" included use of the mail service, yet failed to expressly exclude mail as a method of transmission in claims 21 and 24.

When viewed in the context of claim 21, it is clear that "transmitting" refers to the transmission of a signal. The claim refers to "transmitting the encrypted television program signal to a receiver station" and "transmitting said control signal with said program signal." Program and control signals cannot be transmitted through the mail. The court also recognizes that the examples provided in the specification, broadcast and cable subscription television, long distance satellite transmission and television transmission of textual information, are all methods of sending a signal. The court therefore concludes that "transmitting" of claim 21 means the propagation of a signal from the first location to the second, and does not include the sending of information by mail. To be consistent throughout the patent, the court assigns the same meaning to "transmitted" of claim 24.

A. "transmission"! "transmitting away" /"transmission . . . to a select destination"

The term "transmission" appears in various forms including "transmission away"; "transmitting away" and "transmitting . . .
to a select destination." These terms appear in a total of eleven claims in all of the Burst patents. Claim 1 of the '995 Patent is indicative.

1. An audio/video transceiver apparatus comprising: input means for receiving audio/visual source information;

   compression means, coupled to said input means, for compressing the said audio/video source information into a time compressed representation thereof having an associated time period that is shorter than a time period associated with a real time representation of said audio/video source information;

   random access storage means, coupled to said compression means, for storing the time compressed representation of said audio/video source information; and

   output means, coupled to said random access storage means, for receiving the time compressed audio/video source information stored in said random access storage means for transmission away from said audio/video transceiver apparatus.

'995 Patent at 10:58-11:7. The parties agree that "transmission" should be understood as "sending."

The first issue in dispute is where the information is sent when the patent uses the term "transmitting away" or "transmitting . . . to a select destination." Burst contends that the information is sent to an external device. Apple disputes this construction, asserting that the inventor disclaimed sending information to an external device when he distinguished his patent from the Izeki prior art. Apple's argument turns on its particular understanding of the depiction of the reproduction device in Figure 1 of the Izeki patent. See U.S. Patent No. 4, 974,178 at Fig. 1 ("Izeki patent"). Apple contends that the dotted line surrounding the reproduction device in the Izeki patent indicates that it is external to the Izeki apparatus. The court is unwilling to conclude that Izeki teaches transfer of information to external devices based on this dotted line. In fact, Figure 1 of the Izeki patent includes a printer which is commonly considered an external device and it is not outlined with dotted lines. Id. In addition, the prosecution history of the Burst patents shows that the inventor distinguished the invention from Izeki by arguing that the Izeki prior art "is simply not concerned with transmitting audio/video information away from the apparatus to one or more receivers." Id., '705 File History, Brown Decl, Exh. L at APBU 652. The inventor contended that the Izeki prior art is an apparatus for editing and storing audio/video source information within the apparatus and without external transmission. Izeki Patent at 1:10-15. Therefore, Burst did not disclaim sending information to external devices.

Apple argues that the proper construction of "transmitting away" should be "sending information to a remote location," attempting to distinguish between sending information to devices that are local and devices that are remote. However, the term "remote" injects further ambiguity into the claim construction, and Apple offers no test to distinguish between devices that are local and devices that are remote, stating only that the difference is a matter of degree. Though the term "remote" is used in the patents, it is not used universally in association with transmission and should not be a limit on the term "transmission." Compare '995 Patent at 10:14-20 (using term "remote"), with id. at 11:3-8 (not using term "remote").

The second issue is whether the construction of "transmission" should be limited to sending information to devices capable of playback. Burst argues that the patent teaches transfer of information between transceiver devices that are capable of playback, relying on language in the '995 patent specification. The key language discussed by Burst appears in the '932 Patent specification: "The VCR-ET can receive/transmit a video program . . . from/to a variety of sources . . ." '932 Patent at 8:18-23 (emphasis added). This language does not support Burst's contention; it indicates that transferred information may be to a device capable of playback, but not that it must. The court is unwilling to adopt such a limitation. Burst further contends that when the patent refers to transmission time it is relative to the duration of real-time playback of the audio/video source information. See, e.g., '995 Patent at 7:60-66. Burst suggests that this reference implies that the device receiving the information must be capable of playback. This conjecture is insufficient to limit transfer of information solely to devices capable of playback.

Accordingly, the court finds that "transmission" means "sending", and "transmitting away" or "transmission . . . to a select destination" means "sending information to an external device".

4579

b. Do UEI's remote control devices transmit "in sequence a plurality of response command signals?"

UEI contends the phrase "transmit in sequence a plurality of response command signals" in claims 1 and 6 should be read to mean that the remote control device, without any intervening action on the part of the user, must be capable of transmitting more than one response command signal in response to a single key press. In support of this claim construction, Cook testified that this language describes an action in which the process is initiated by the user. The device on that action transmits in sequence a plurality of signals; that is, the device transmits a series or a large number of response command signals. He testified that the flow chart in Figure 5 shows this, as it describes a process whereby the user presses a learn button and then presses a category button. The unit then automatically continues to send command signals until the user releases the learn button.

Philips responds by again arguing that the flow chart in Figure 5 is simply a preferred embodiment and that nothing in the words of the claim requires that the signals be sent continuously without any user intervention. Philips contends that while the language of the claim is satisfied if the user holds down a button to send consecutive signals, it is also satisfied if the user presses two buttons alternatively, causing consecutive signals to be sent (as UEI's devices do).

In support of this proposed construction, that claims 1 and 6 do not claim a device that automatically scrolls through the library of codes, Philips notes that it has a separate claim that does claim an automatic search through the library of codes. Claim 9 reads:

9. Apparatus as set forth in claim 8, wherein said first user operable selector means comprises a keyboard having an 'identify' key: and

wherein said first user operable selector means generates said "identify" command during depression of said identify key and a "terminate" command terminating said transmission of said plurality of response command signals upon release of said identify key. (emphasis supplied)

Claim 9's specific identification of a device that automatically scrolls through a library of codes does suggest Philips's proposed construction is correct. Therefore, the words "transmitting in sequence a plurality of response command signals" in claims 1 and 6 should not be construed to provide for an automatic transmitting of a plurality of response command signals. Rather, these words are broad enough to include a user transmitting in sequence one at a time a plurality of response command signals, as the user does in UEI's step and set method.

4580

1. Claim 12 requires sending the executable software with the email message

The first step required by claim 12 of the '688 Patent is "transmitting said e-mail message and executable software associated with said e-mail message from said first computer using said first e-mail platform to said second computer using said second e-mail platform." '688 Patent col. 10:60-63. PostX claims that Sigaba wrongly reads a "limitation of transmitting executable software with the e-mail message" into the claim. PostX argues that, from prosecution history
through patent issuance, "associated with" was the chosen term to express the requirement that executable software is also transmitted from the sender to the recipient. Pl.'s Opp'n at 12:5-7. PostX warns the Court not to commit error in its consideration of prosecution history, arguing that using the prosecution history to interpret "what is meant by a word in a claim is not to be confused with adding an extraneous limitation . . . , which is improper." Intervet Am., Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 1053 (Fed. Cir. 1989) (internal citation omitted).

The Court finds that it need not add extraneous limitations in order to find that Sigaba's interpretation of the claim is correct. In the context of the patent, "with" and "associated with" both suggest conjunctive meanings. In other words, "associated with" has elsewhere in the patent described something being sent "with" something else. See e.g., '688 patent at col. 6:30-32. Further, throughout the specification, there is ample evidence that the e-mail and the executable software together are sent to the e-mail recipient; the transmission of "embedded" executable software, for example, appears integral to the novelty of the PostX product. See e.g., '688 Patent title, col. 1:1-5 ("EMAIL PROGRAM CAPABLE OF TRANSMITTING, OPENING AND PRESENTING A CONTAINER HAVING DIGITAL CONTENT USING EMBEDDED EXECUTABLE SOFTWARE"); col.1:8-12 ("The present invention relates to . . . using embedded executable software."); col. 1:66 - 2:5, see also 2:6-8 ("the executable software that is transmitted as part of the E-mail message . . ."); 2:16-18; 4:4-12; 6:66-7:5.

In Sigaba's technology, the "e-mail sender's computer does not transmit any software with the e-mail." Chakraborty Decl., P 3 (emphasis in original). According to Sigaba's Senior Vice President of Engineering and Operations, Sayan Chakraborty, the disputed software does not at any point or within any embodiment allow for this feature as claimed in the '688 patent. The disputed technology, therefore, fails to meet the limitation of claim 12. Accordingly, the Court can at this point dispose of the case as the failure to meet any one limitation justifies summary judgment. See Intellicall, Inc., 952 F.2d at 1389. However, the Court will address the additional arguments for which parties provided extensive briefing.

4581

D. Transmitting surface

Claims 1 and 25 recite "a transmitting surface on the tip of the waveguide." The term "transmitting surface" is recited again in the 90% clauses. AMS proposes "surface through which electromagnetic radiation is transmitted from the tip in the targeted lateral direction" as a construction for "transmitting surface." LP proposes a construction limited to the embodiments disclosed in the specification, which is predicated on its argument that "transmitting surface" and the 90% clauses are means-plus-function terms. For the reasons previously stated, the Court concludes that "transmitting surface" is not a means-plus-function term. The Court finds no basis in the specification or prosecution history for limiting "transmitting surface" to the embodiments disclosed in the specification. See Phillips, 415 F.3d at 1323.

Beginning with the claim language itself, claim 1 recites "a transmitting surface on the tip of the waveguide." and "a reflecting surface on the tip of the waveguide for internally reflecting electromagnetic radiation . . . in a direction lateral to the propagation direction toward a particular area on the transmitting surface." Claim 25 recites "a transmitting surface on the tip of the waveguide" and "a reflecting surface on the tip of the waveguide for internally reflecting electromagnetic radiation . . . in a second propagation direction toward the transmitting surface." Claim 1 further recites that "greater than about 90% of electromagnetic radiation reflected by the reflecting surface is incident on the particular area . . . for transmission through the transmitting surface," while claim 25 further recites that "at least 90% of all electromagnetic radiation reflected by the reflecting surface is incident on the transmitting surface . . . for transmission through the transmitting surface." In short, the claim language indicates that electromagnetic radiation reflected by the reflecting surface is transmitted through the transmitting surface, which is on the tip of the waveguide, in a lateral or second propagation direction.

The specification describes electromagnetic radiation as being transmitted "through" or "out" the transmitting surface. See, e.g., '699 Patent col.5 ll.3-6, col.5 ll.66-68, col.6 ll.48-51, col.9 ll.39-43. The specification also indicates that electromagnetic radiation is transmitted through the transmitting surface in a desired lateral direction or second propagation direction and that the second propagation direction is the desired lateral direction. 8 See, e.g., '699 Patent col.2 ll.21-23, col.8 ll.42-46, col.8 ll.59-68, col.9 ll.39-44. As a result, the specification confirms that electromagnetic radiation is transmitted through the transmitting surface in a desired lateral direction.
8 AMS uses the term "targeted" rather than "desired" in its proposed construction. The Court discerns no difference between "targeted" and "desired," but adopts "desired" based on its use in the specification.

LP seeks to limit "transmitting surface" to the outside surface of an optical fiber's core cladding based on the prosecution history of the '699 Patent. After allowing claim 1, the patent examiner rejected original claim 26 as anticipated by Payne. The examiner maintained that Payne disclosed a transmitting surface on the tip of the waveguide. In response, the applicant amended original claim 26 to recite that the waveguide had "a glass cladding extending to a distal end of the tip" and stated in the context of describing one embodiment of the invention that the "transmitting surface includes a portion of the cylindrical outside surface of the core cladding." When taken in context, the applicant's statement does not constitute the "clear and unmistakable" surrender required for prosecution disclaimer. See Bayer AG v. Elan Pharm. Research Corp., 212 F.3d 1241, 1252 (Fed. Cir. 2000).

The Court construes "transmitting surface" as "surface through which electromagnetic radiation reflected by the reflecting surface is transmitted from the tip in the desired lateral direction." 9

9 LP contends that construing "transmitting surface" in terms of transmission "through" the surface ignores the 90% clauses, which recite that electromagnetic radiation is "incident on" the particular area or transmitting surface. Given the unambiguous language in the claims and specification indicating that electromagnetic radiation is transmitted "through" the transmitting surface, this argument is unpersuasive.

LP makes several collateral arguments with respect to the construction of "transmitting surface." First, LP contends that the accused product does not contain a transmitting surface because the surface interfaces in the accused product are removed by fusing. "[A] trial court should certainly not prejudge the ultimate infringement analysis by construing claims with an aim to include or exclude an accused product or process." Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1322, 1326-27 (Fed. Cir. 2006). The Court declines to determine if the accused product includes a transmitting surface at this time.

Second, LP asserts that AMS's proposed construction is suspect because AMS proposed three different constructions of "transmitting surface" during litigation of the '699 Patent in the United States District Court for the District of Massachusetts. LP also maintains that AMS represented to the Massachusetts court that the transmitting surface was on the surface of the optical fiber. The portions of AMS's Massachusetts brief cited by LP as establishing that the transmitting surface is on the surface of the optical fiber, however, simply describe specific embodiments of the invention, and LP has not identified which of the proposed Massachusetts constructions are inconsistent with AMS's proposed construction in this action or indicated that it has relied on the Massachusetts constructions. See SanDisk Corp. v. Memorex Prods., Inc., 415 F.3d 1278, 1290-92 (Fed. Cir. 2005) (explaining when judicial estoppel arises in the context of claim construction).

Moreover, the Court "has an independent obligation to determine the meaning of the claims, notwithstanding the views asserted by" the parties here or in other proceedings. See Exxon Chem. Patents, Inc. v. Lubrizol Corp., 64 F.3d 1553, 1555 (Fed. Cir. 1995). Accordingly, the Court independently construes the terms here.

Third, LP contends that the patent claims require one, and only one, transmitting surface. The Federal Circuit has repeatedly emphasized the general rule that an indefinite article "a" or "an" in the context of patent claims carries the meaning of "one or more" in open-ended claims containing the transitional phrase "comprising." Baldwin Graphic Sys., Inc. v. Siebert, Inc., 512 F.3d 1338, 1342 (Fed. Cir. 2008). "The exceptions to this rule are extremely limited: a patentee must 'evince a clear intent' to limit 'a' or 'an' to 'one.'" Id. Here, "transmitting surface" was introduced using "a" in claims reciting "comprising" as the transitional phrase. In the absence of language in the claims, specification, or prosecution history necessitating a departure from the general rule, the Court construes "a transmitting surface" to permit one or more transmitting surfaces.
A. "Transmitting Surface" (Independent Claims 1, 7, and 25)

The court finds "transmitting surface" to mean "surface through which electromagnetic radiation is transmitted in the lateral direction."

The primary dispute between the parties over this term relates to the location of the transmitting surface. Defendants urge a construction that locates the "transmitting surface" on the outer surface of a round core cladding on the waveguide. They point to figures included in the patent (the '699 Patent Figs. 1-4 and 9) that show a transmitting surface located on the outside of the cladding but beneath any glass cap or transparent adhesive or other materials that lie on the outside of the cladding.

Defendants' limiting construction must be rejected because it would exclude an embodiment of the patent. A definition that excludes an embodiment of the patent is unlikely to be correct or "would require highly persuasive evidentiary support." Vitronics, 90 F.3d at 1583. The '699 Patent describes an embodiment of the patent in which a "transparent tube" is attached to the tip of the probe with adhesive. In Figure 12, the "transmitting surface" is located on the external surface of the transparent tube and not simply on the outside of the core cladding. Because this embodiment of the '699 Patent describes a transmitting surface located elsewhere than on the core cladding, Defendants' proposed definition is too restrictive.

2 This court's construction of the term "transmitting surface," though worded somewhat differently, is in line with Judge Eriksen's, in the sense that it rejects Defendant's more restrictive language. See Laser Peripherals, 2009 U.S. Dist. LEXIS 95387 at *25-*27.

A. "A Transmitting Terminal"

For the following reasons, this court construes the claim term "a transmitting terminal" in claims 1 and 9 to mean:

One or more devices that transmit a WDM optical signal.

The term "a transmitting terminal" is in claims 1 and 9 in the following context: "a transmitting terminal transmitting a wavelength division multiplexed (WDM) optical signal having a variable number of channels associated with different wavelengths." ('681 patent, col. 22:5-8; col. 22:54-57.)

Within the '681 patent's specification, transmitters are represented both as a single device and as a combination of devices. Specifically, Figure 25 illustrates "a transmitter (Tx) transmits a SV light beam to a receiver (Rx), were an SV light beam is light that is wavelength-multiplexed with a main signal." ('681 patent, col. 19:40-44.) So, a transmitting terminal, as represented by the transmitter Tx, can be a single device. Figure 1 of the '681 patent, however, depicts:

a conventional fiber optic communication system which uses wavelength division multiplexing to transmit, for example, four channels through a single optical fiber. Referring now to FIG. 1, transmitting units transmit individual carriers having wavelengths [lambda] 1- [lambda] 4, respectively. Each carrier is modulated with information and represents an individual channel. The different carriers are multiplexed together by an optical multiplexer into a wavelength-multiplexed optical signal. The wavelength-multiplexed optical signal is transmitted through an optical fiber to an optical demultiplexer.

('681 patent, col. 1:44-55; see Fig. 1.) Moreover, the conventional fiber optic communication system of Figure 1 explains
The dispute between the parties centers on whether claim 6, the only claim at issue, by its terms requires the data transmission path from the selected server back to the client to bypass the load balancer. Claim 6 provides (emphasis added to highlight the disputed claim limitation):

6. A computer-implemented method of servicing requests for resources from a client by nodes containing different resources, the computer-implemented method comprising the steps of:

   making a connection and setting up a session between the client and a load balancer at a web site for servicing requests from clients;

   waiting for a URL request from the client once the load balancer has made the connection with the client;

   receiving the URL request from the client and decoding the URL request to determine a requested resource;

   comparing an identifier for the requested resource to identifiers for resources located on a plurality of nodes and determining a first subset of the plurality of nodes which contain the requested resource and a second subset of the plurality of nodes which do not contain the requested resource;

   assigning the URL request to an assigned node in the first subset of the nodes which contain the requested resource, by determining the assigned node to be a server in the first subset of the nodes which is least busy processing requests, wherein the assigned node is not in the second subset;

   transferring the connection and the session setup to the assigned node containing the requested resource by storing packets received from the client when establishing the connection and by transmitting the packets to the assigned node after the URL request is received;

   reading the requested resource on the assigned node and transmitting the requested resource to the client,

   whereby the assigned node is selected based on a location of the requested resource determined from the URL request and load balancing is performed among nodes having the requested resource and the connection is transferred from the load balancer to the assigned node by re-transmitting the packets to the assigned node.

The key phrase "transmitting the requested resource to the client" lies at the heart of the dispute. The district court construed the phrase to mean "transmitting outbound data packets from the server directly to the client using the connection with the client which was transferred to the server, causing the outbound data to bypass the load balancer." (Emphasis added.) In other words, the district court held that claim 6 requires the bypass feature.

In the accused devices, Alteon's Web Switch products running WebOS software, all data transmitted from the selected server to the client passes through the load balancer. Under the district court's construction, the accused devices could not infringe claim 6. Accordingly, the patentee Resonate stipulated that it could not prevail under the district court's construction of the disputed limitation; a judgment of noninfringement was entered.

Resonate timely appeals the final judgment entered by the district court. Alteon supports the district court's construction and judgment, and in addition has filed what it denominates as a cross-appeal. In its cross-appeal Alteon states that, in the event we disagree with the district court's construction of the phrase "transmitting the requested resource to the client," and the
matter is returned to the district court for possible trial before a jury, we should "supplement" the court's construction of two additional limitations in claim 6--"making a connection" and "transferring the connection."

DISCUSSION

A.

The single issue raised on appeal by Resonate is the correctness of the district court's claim construction of the disputed phrase in claim 6. Claim construction is a matter of law over which we exercise independent review. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456 (Fed. Cir. 1998) (en banc).

As always, we begin our claim construction analysis with the language of the claim. There is a "heavy presumption" that the terms used in claims "mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art." Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1201 (Fed. Cir. 2002). After identifying the ordinary meaning of a disputed claim term, we turn to the patent's written description and drawings to determine whether that meaning is inconsistent with the patentee's use of the term, Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001), for example whether the patentee has specially defined the term or otherwise limited the scope of the claim. SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1344 (Fed. Cir. 2001).

However, the written description is not a substitute for, nor can it be used to rewrite, the chosen claim language. Though understanding the claim language may be aided by the explanations contained in the written description, it is important not to import into a claim limitations that are not a part of the claim. For example, a particular embodiment appearing in the written description may not be read into a claim when the claim language is broader than the embodiment. Electro Med. Sys., S.A. v. Cooper Life Scis., Inc., 34 F.3d 1048 (Fed. Cir. 1994). In addition to the written description, prosecution history may be relevant to the claim construction process because statements made by a patentee during prosecution also may affect the scope of the claimed invention. Rexnord, 274 F.3d at 1343.

The disputed language in claim 6--"transmitting the requested resource to the client"--specifies nothing regarding the transmission path over which the requested data must be sent. It merely requires the requested resource to be transmitted from the "assigned node" (the server identified as the "least busy processing requests" from among those that contain the requested resource) to the client that initiated the request. The limitation contains no language regarding the load balancer's involvement in the transmission of the requested resource to the client; by its terms, the limitation fails to specify whether data must pass through or bypass the load balancer. Thus, based on the plain language of the disputed limitation, any transmission path from the selected server to the client appears to be within the scope of claim 6. The question then becomes whether there is sufficient reason--in the other language contained in the claim, in the written description, or in the prosecution history--to read into the claim the further limitation that the data must bypass the load balancer on its return to the client.

The district court based its claim construction primarily on its observation that every other step of claim 6 is described in detail, including every interaction between the client, load balancer, and assigned server. From this, the court inferred that if the requested data passed through the load balancer on its way to the client, that step would have been detailed in the claim as well. Because the limitation simply requires the server to transmit the requested resource to the client, the district court held that the language implies that the load balancer is bypassed.

The district court's 'level of detail' analysis does not withstand close scrutiny. The patentee's apparent choice not to specify a transmission path from the server to the client led the district court to add a limitation that the requested resource be transmitted directly to the client. But patentees are not required to claim each part of an invention with the same amount of detail; indeed, such a rule likely would prove unworkable. Courts may not rewrite claim language based on what has been omitted from a claim, and the district court's attempt to do so here was legal error. See K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1364 (Fed. Cir. 1999) ("Courts do not rewrite claims; instead, we give effect to the terms chosen by the patentee."); Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 396 (Ct. Cl. 1967) ("Courts can neither broaden nor narrow the claims to give the patentee something different than what he has set forth.").

Alteon argues that the district court's reading of the plain language of the claim is correct when the claim is considered as a whole. According to Alteon, bypassing the load balancer is the natural consequence of other limitations set forth earlier in
the claim. While it is true that a disputed claim limitation is construed in the context of other words and limitations in the claim, see Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 2003 U.S. App. LEXIS 13861, 2003 WL 21488142, at *1 (Fed. Cir. 2003), that canon of claim construction does not help Alteon here.

Most of the steps set out in claim 6 relate to the process of selecting a server based on the resource requested by the client. After the initial step of "making a connection" between the client and load balancer, the claim includes several steps detailing the server selection process, followed by the step of "transferring the connection" to the selected server. These steps constitute the 'delayed resource-binding' aspect of the invention; a connection between the client and a server is not made until the load balancer determines which server should receive the client's request. Only the final step of claim 6 involves transmitting the requested resource back to the client.

The crux of Alteon's argument is that once the connection is transferred to the server, transmission of data from the server to the client must occur over that connection, and use of that connection must necessarily cause the data to bypass the load balancer. This line of reasoning is flawed. First, nothing in claim 6 requires that the requested resource be transmitted to the client using the transferred connection. Second, and the issue focused on by the parties, is that even if data transmitted from the server to the client uses the transferred connection, no language in the claim indicates that data transmitted via the transferred connection necessarily bypasses the load balancer.

Alteon fills in the missing language by arguing that a proper understanding of the term "connection" in the TCP/IP context requires that the transferred connection must bypass the load balancer. We agree with Resonate that Alteon's view is overly narrow for at least two reasons. First, as the district court correctly held, nothing in the language of claim 6 requires the connection to be defined in terms of TCP/IP. In holding that a connection is established by the exchange of information uniquely identifying the connection, the district court accepted a portion of Alteon's proposed construction, to which Resonate eventually acceded. The court, however, declined to restrict its construction to the specific unique information Alteon argues is required by a TCP connection.

Second, even if it is proper to consider the TCP/IP context when construing the term "connection," there is no basis for limiting the interpretation to the particular TCP connection Alteon proposes. As Resonate correctly points out, the written description of the '660 patent teaches that TCP/IP can be modified to achieve desired routing of data packets. Therefore, even if one interpreted the term "connection" in the context of TCP/IP, it would be improper to restrict the meaning to any particular implementation of TCP/IP. We conclude that the language of claim 6, both the disputed phrase and the other language of the claim, does not require data transmitted from the server to the client to bypass the load balancer.

The next question to be addressed is whether the written description limits the scope of the claim. Alteon argues that the written description establishes that the claimed invention must include the bypass feature to avoid the potential bottleneck at the load balancer when large files are transmitted from the server to the client via the load balancer. In support of its position, Alteon refers us to several passages in various parts of the written description, including the abstract, "Background of the Invention," and "Summary of the Invention" sections, all of which discuss the bottleneck problem. In response, Resonate cites portions of the written description, including a section entitled "Advantages of the Invention" and an overview of the inventive method in the "Summary of the Invention" section, from which any mention of bypass is conspicuously missing.

Alteon accuses Resonate of ignoring bypass as one of the main inventive features by selectively citing parts of the written description. Resonate responds by criticizing Alteon for focusing on the bypass feature to the exclusion of the other main aspect of the invention, arguing that the key novel feature of the invention is the delayed resource-binding, which allows for content-based load-balancing and eliminates the need to mirror content on the multiple servers comprising a web site's server farm. The bypass feature, Resonate contends, is an additional inventive aspect, not included within the particular terms of claim 6.

The issue at this point may be stated thus: when the written description sets out two different problems present in the prior art, is it necessary that the invention claimed, and thus each and every claim in the patent, address both problems? We conclude that on the record in this case, the answer is no. While not explicitly mentioning the prior art problem of having to store complete copies of the web site's content on multiple servers, claim 6 contains provisions that refer to the solution to this problem: the preamble language indicating that the nodes (servers) contain different resources, and the steps relating to the delayed resource-binding aspect of the invention. The claim does not, however, make any reference to the bottleneck
problem or to the bypass solution of that problem. Therefore, without explicit claim language relating to the bottleneck problem, we see no reason why the invention as recited in claim 6 must include the bypass feature described in the written description as a solution to that problem. See Honeywell, Inc. v. Victor Co. of Japan, 298 F.3d 1317 (Fed. Cir. 2002) (holding that claimed invention did not need to solve both problems in the prior art when claim included language addressing only one problem).

Alteon also relies on the "Detailed Description" portion of the written description and the preferred embodiment contained therein for support of its position that claim 6 must include the bypass feature. It is undisputed that in the preferred embodiment of the '660 patent, data transmitted from the server to the client bypasses the load balancer. Indeed, the "Detailed Description" section contains a subsection entitled "Outgoing Data Bypasses Load-Balancer." However, as noted earlier, limitations may not be read into a claim from a preferred embodiment when the claim language is broader than that embodiment. See Electro Med. Sys., 34 F.3d at 1054. In this case, claim 6 is broader than the preferred embodiment because, as discussed, there is no language in claim 6 relating to the bottleneck problem or the bypass solution of that problem. Therefore, we conclude that the bypass feature, though shown as part of the preferred embodiment and discussed in the written description as a solution to the potential bottleneck problem in the prior art, is not properly a limitation of claim 6.

Nor is this conclusion undercut by anything in the prosecution history. The only argument in that regard that Alteon makes is that the examiner required the inventors to combine both the steps of delayed load-balancing and transferring the connection before he allowed the patent to issue. Even if this statement is true, which Resonate disputes, it is irrelevant because the thrust of Alteon's argument stands on its contention that bypass is an inevitable result of transferring the connection, an argument we have rejected. Therefore, we see nothing in the prosecution history to alter our conclusion that claim 6 does not require that data, transmitted from the server to the client, bypass the load balancer.

P. "transmitting the proposed reservation time to the PCD"

"Transmitting" is the only word in this disputed phrase that has not been construed. The ordinary meaning of "transmit" is "to send out." Webster's Third New International Dictionary (Unabridged) 2429 (1976). Thus, as proposed by the Plaintiff, "transmitting the proposed reservation time to the PCD" means "sending the proposed reservation time to the PCD."

A. Claim Construction

On February 16, 2006, the Court held a claims-construction hearing in this matter. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The Court considered the '136 Patent and prosecution history, the parties' Markman briefs, the applicable law regarding, inter alia, claim construction, indefiniteness, and means-plus-function claims, and the argument of counsel. On May 25, 2006, this Court rendered a claims-construction order (Doc. #292), which construed the terms as following:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Construed Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Debit Card&quot;</td>
<td>&quot;a prepaid card for exchange of value&quot;</td>
</tr>
<tr>
<td>n2&quot;ID information [stored on the debit card]&quot;</td>
<td>&quot;encrypted data, excluding the card number, stored on the debit card in the form of merchant ID, store ID, or terminal ID&quot;</td>
</tr>
<tr>
<td>&quot;Terminal&quot;</td>
<td>&quot;a point-of-sale apparatus, which&quot;</td>
</tr>
</tbody>
</table>
includes a central processing unit, a card reader, a keypad, and a communications interface

"ID information [stored on the terminal]" "data stored on the terminal in the form of merchant ID, store ID, or terminal ID"

"Stored thereon prior to the transaction" "stored on the terminal prior to the consumer presenting the debit card to the merchant"

"Relates . . . in a predetermined manner" "prior to a transaction, ID information stored on the debit card and ID information stored on a terminal are capable of being matched"

"Matching" and "Matched" "determining whether ID information stored on the debit card and corresponding ID information stored on the terminal are equal or identical"

"Retrieving via the terminal" "locating and returning, by means of the terminal, ID information and a card number stored on the debit card"

"Computer" and "Computer means" "a data processing device"

"Transmitting to a computer" "sending by means of a signal path to a computer"

"Validation" and "Valid" "indication of whether the ID information stored on the debit card matches the corresponding ID information stored on the terminal"

"Computer means disposed remotely" "a computer that is located apart from a terminal and connected to the terminal by a signal path"

"Card reader means" "a device, included as part of a terminal, used for retrieving ID information from a debit card"

"Communication means" function "transmitting the ID information stored on the debit card and the ID information stored on the terminal to the computer means"

"Communication means" structure "a modem or a signal path"

"Selected from a group of ID information" (Claim 2) "chosen from one of the following ID information"
n2 "ID," as used throughout this opinion, in whatever context, is shorthand for "identification."

4587

7. Transmitting . . . to said device

The court adopts a construction of "transmitting . . . to said device" which is similar to the one adopted by Judge Brewster. The court construes this phrase to mean "transmitting information directly to the device without re-transmission of the information by an intermediate processor."

4588

8. "transmitting to a user remote access device at least one specific voice message linked to a specific one of said received first signals"

Klausner argues this term needs no construction apart from the construction of "user remote access device." Vonage proposes "the telephone answering device plays back the voice message to the user remote access device over the single telephone link between the telephone answering device and user remote access device."

Among other things, Vonage proposes that this phrase requires "play back" by the telephone answering device. While "play back" of a voice message may be one action taken to accomplish the transmission of the voice message, the concept of "play back" does not appear to be inherent in the word "transmitting," nor does Vonage point to anything in the intrinsic record, aside from a specific embodiment described in the specification, suggesting otherwise. The Court declines to incorporate details of a disclosed embodiment into a claim term in the absence of clear direction otherwise from the intrinsic record. See, e.g., Varco, L.P. v. Pason Sys. USA, Corp., 436 F.3d 1368, 1373 (Fed. Cir. 2006) ("In examining the specification for proper context . . . this court will not at any time import limitations from the specification into the claims."). Vonage also argues the requirement of using a "single telephone link" between the telephone answering device and the "user remote access device." That argument has been addressed above.

4589

III. Claim Construction -- The ' 505 patent, Claim 25

The disputed phrase appears in Claim 25. Claim 25 is a method claim which is dependent on Claim 24, which itself is dependent on Claim 16. Claim 25 is set out below with the disputed phrase in bold.

25. The information transmission method of claim 24, wherein said information database includes video program materials as well as non-video information; said transmitting step transmits data packets containing at least selected portions of said video program materials on at least one of said multiple transmission channels and transmits primarily non-video information on at least one other one of said multiplicity of transmission channels; and at a multiplicity of said subscriber stations, receiving and storing video program materials.

The court previously defined "transmission channels," as used in claims 24 and 25 as "paths for transmitting electronic signals which are differentiated by their frequencies."

Finisar's proposed definition is:
"Transmits information that constitutes more non-video than video on at least a second transmission channel, i.e., there is information that constitutes more non-video than video on at least a second transmission channel."

DirecTV's proposed definition is:

"The transmission capacity of one other of the transmission channels is mostly used to transmit non-video information."

The parties seem to have similar definitions of "primarily" -- DirecTV uses "mostly" and Finisar uses "more." But the court still must determine: "Mostly" what? "More" what? At first glance one might say "mostly" or "more" "non-video information." But how is that measured? Col. 5, 11.23-26 describes the data stream on a single channel as being transmitted at the rate of 1.5 megabytes per second in "fixed size 10KB (kilobyte) data packets having a maximum size of 10,000 bytes." Figure 6 diagrams a data packet. Each data packet has an identifier, a function code, error detection codes and "a set of data" of any size up to the maximum chosen for the system. See ' 505 patent, col. 10, 11. 48-51. But, while a data packet has a fixed maximum size, there is no limit to how little information it contains.

Finisar first argued that one simply counts up the number of data packets labeled or identified as containing non-video information and compares that to the number of data packets labeled or identified as containing video information. Nothing in the claim or specification indicates that transmitting primarily non-video information simply means having more empty data packets with an identifier of "non-video."

At the first Markman hearing, the parties analogized data packets to train cars. Here, an analogy would be to train cars labeled as containing a particular grain, say rice. If more cars were labeled "rice" than were labeled "wheat," (or alternatively if more cars actually contained some rice) then the train would carry mostly rice. So how does one compare fifty cars, each carrying a cup of rice with one caboose carrying fifty bushels of wheat? Could that train be said to "primarily" carry rice? Simply counting the labels on data packets, irrespective of their contents, renders "primarily" ineffective.

Finisar also argued that a transmission channel, which "transmits primarily non-video information" could be a frequency, which carried a great deal of video information, so long as there was some information (i.e., some data packets) on that frequency that contained "more non-video than video." This is contrary to the wording of Claim 25. The claim is dependant on Claim 24, which requires a method using "multiple transmission channels." Claim 25 requires the information database to contain "video program material as well as non-video information." "Data packets containing at least selected portions of said video program materials" must be transmitted on one of the multiple channels. The method of claim 25 "transmits primarily non-video information" on at least one other channel. If, as Finisar argues, all that is required is that some data packets on this other channel have more non-video than video information, then why is "primarily" included in the phrase? What distinguishes the "one other channel" from the first? One data packet a year which has mostly non-video information?

Continuing the parties' analogy, Finisar's construction would be like saying a train with a car carrying a ten pound bag of rice and ten cars each with fifty bushel baskets of wheat, carried "primarily" rice, because one car did. The word "primarily" would be superfluous. The court cannot assume that a word in a claim was included accidentally, or that it has no meaning. Whether the information transmitted by the patented method is measured in data packets, bytes, or in transmission times, or by some other recognized unit of measurement, Claim 25 requires one of the multiple channels to carry more non-video information than video information. Therefore this claim term will be defined as follows:

        "transmits primarily non-video information on at least one other one of said multiplicity of transmission channels" means: "most of the information which is transmitted on at least one of the frequencies is non-video information."

GO BACK

4590

15. Transparent

This term is present within claims 16 and 26 of the '727 patent. The plaintiff argues for a construction of "the support of upper layer protocols so that a remote device and a host server may communicate directly according to their respective
The defendants propose "to perform in a manner that is invisible to, and of no concern to a user." Based on the pertinent portions of the specification, the defendants' construction is proper, and the court adopts it.

7. (Substantially) Transparent

Defendants' Proposed Construction: "Substantially transparent" means transmitting light without appreciable scattering in a manner such as ordinary window glass so that objects placed behind the placard are clearly distinguishable.

Plaintiff's Proposed Construction: Leave undefined.

The Court's Claim Construction For Transparent: "Transparent" means transmitting light without appreciable scattering in a manner such as ordinary window glass so that objects placed behind the placard are clearly distinguishable.

Claim 2 states as follows:

2. The method of claim 1 wherein the provided placard is substantially transparent and printing is applied to one of the faces under the coating of said one of the faces.

MPT argues that "transparent" should not be defined because its common English meaning is clear. The problem with this argument is that the industry definitions provided by Defendants and incorporated into Defendants' proposed construction are entirely consistent with the Court's understanding of the common English meaning of transparent. The technical references state as follows:

"TRANSPARENT Transmitting light without appreciable scattering so that objects beyond are clearly distinguishable." (TLM p. 63).

"TRANSPARENT LABEL A pressure sensitive label whose face material, adhesive and protective coatings, transmit light so that objects can be seen through it." (TLM p. 63).

"Transparent - The ability of a material to transmit light without any appreciable scattering. Objects viewed through transparent materials are clearly distinguishable and are therefore also described as 'clear' or 'glass clear'" (Fairley p. 214).

"Transparent label - Pressure-sensitive label in which the face material, adhesive and any protective coating transmit light and through which objects can be clearly seen. A transparent label on a clear bottle will allow the color, nature and volume of the contents of a bottle to be viewed through the label. See also 'No-label look'." (Fairley p. 215).

Transparent has a well established meaning in the art and a person of ordinary skill in the art would recognize that meaning in the language of Claim 2. However, the Court recognizes that Claim 2 describes a substantially transparent placard. Neither party has attempted to explain to the Court how a substantially transparent placard differs from a transparent placard. Thus, the Court adopts Defendants' definition, but only for the term "transparent."

1. Transparent Light Scattering Materials

The term Transparent Light Scattering Materials is a portion of the specification of the 619 patent. Specifications are utilized in determining the claim language of the patent. This Court defines Transparent Light Scattering Materials, when taken in conjunction the fact that it is not the only means for combining, and read with the patent language, as material that is transparent, such as, but not limited to, glass, epoxy, liquid, or gas, including air.
resistivity lower than the active layers." Claim Construction Order, slip op. at 16-19. Epistar does not challenge or propose an alternative to this construction. It argues instead that the inventors disclaimed the use of ITO in the window layer.

To prevail, Epistar must establish the inventors "demonstrate[d] an intent to deviate from the ordinary and accustomed meaning of a claim term by including in the specification expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002). With respect to Epistar's arguments that the inventors disavowed the use of ITO during the prosecution history, Epistar must also overcome a heavy presumption that claim terms carry their full ordinary and customary meaning, unless it can show the patentee expressly relinquished claim scope. Omega Eng'g v. Raytek Corp., 334 F.3d 1314, 1323 (Fed. Cir. 2003). For the following reasons, Epistar's arguments fall short of these standards.

Epistar argues that the Commission erred in permitting "transparent window layer" to encompass a current spreading window layer of ITO because "the very purpose of the '718 patent was to address problems with . . . the use of ITO." The specification of the '718 patent states:

The techniques proposed for minimizing the current crowding problem in AlGaInP LEDs have not been completely satisfactory . . . . Another technique is to use a transparent front electrical contact such as an indium-tin oxide instead of metal. Such transparent electrical contacts have high resistivity and lead to high series resistance in the device. Because of such shortcomings, it is desirable to provide a technique for distributing current from the front contact to the active p-n junction so that light is emitted more uniformly throughout the junction and device efficiency is enhanced.

'718 patent col.1 ll.57-59; col.1 l.67-col.2 l.8 (emphasis added). Although "transparent front electrical contact" and "transparent window layer" are separate structures, nowhere does the '718 patent specification or prosecution history state or suggest that ITO should not be used as a transparent window layer.

The ALJ correctly determined that the '718 patent does not disclaim the use of ITO as a window layer:

The Administrative Law Judge confirms that he does not find a clear disavowal of the use of ITO as a transparent window layer in the specification of the '718 patent. The specification does describe two unsatisfactory techniques proposed for minimizing the current crowding solution which include the modification of the front contact. One of those techniques involved the replacement of a metal front electrical contact with ITO. The Administrative Law Judge does not find, however, that a statement in the background section that the use of ITO was not "completely satisfactory" as a front contact is a disclaimer that ITO does not fall within the scope of the claimed "transparent window layer," which serves a distinct function in an LED.

The '718 patent's discussion of ITO addresses the "current crowding" problem, by using a transparent contact that permits more light to escape than an opaque metal contact. '718 patent col.1 l.67-col.2 l.3. A transparent contact does not block the light generated under the contact. Although current crowding still occurs, the use of a transparent contact, such as ITO, diminishes the problems of a metal contact.

In any event, this technique is not relevant to the '718 patent, which does not modify the front contact to solve the current crowding problem. Instead, the invention keeps the opaque "metal electrical contact" 25 but adds a "transparent window layer" 24 beneath it. Id. The claims and specification of the '718 patent consistently treat these two structures as separate and distinct elements. See, e.g., id., col.2 l.66-col.3 l.13 (claims 1 and 6 discussing metal electrical contact 25 and transparent window layer 24 in Figure 2).

In LizardTech, Inc. v. Earth Resource Mapping, Inc., this court held that where two steps (or structures) are "entirely different concepts and procedures" and identified as separate steps in the claims, no skilled artisan could reasonably construe them as a single element. 424 F.3d 1336, 1342-43 (Fed. Cir. 2005) (excluding the "altogether distinct process of taking a DWT [discrete wavelet transform]" from the scope of the claim term "maintaining updated sums of DWT coefficients"). As in LizardTech, the transparent front electrical contact is "entirely different" from the transparent window layer. Id.
Even if the patent specification did disparage the use of ITO as a window layer, this criticism does not rise to the level of a disavowal. Disavowal requires "expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Teleflex, 299 F.3d at 1325. A patentee's discussion of the shortcomings of certain techniques is not a disavowal of the use of those techniques in a manner consistent with the claimed invention.

For example, in Micro Chemical, Inc. v. Great Plains Chemical Co., the patentee explained in the background section of the patent that a prior art device using the "weigh dump method" was too slow and too inaccurate. 194 F.3d 1250, 1260 (Fed. Cir. 1999). The patent did not assert that the "weigh dump method" itself was the reason for the inaccuracies or slowness. Id. This court ruled that the patentee did not disavow the use of the "weigh dump method," even if the claim were construed as a step-plus-function claim under 35 U.S.C. § 112, P 6. Micro Chem., 194 F.3d at 1259-60.

Moreover, this case does not present an instance where an inventor distinguishes an invention over the prior art in an unmistakable disavowal of those prior art features. In Phillips, this court recognized that in certain cases, "the specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor." 415 F.3d at 1316. In such cases, this court interprets the claim more narrowly than it otherwise would to give effect to the inventor's intent to disavow a broader claim scope. Id.; Honeywell Int'l, Inc. v. ITT Indus., Inc., 452 F.3d 1312, 1319-20 (Fed. Cir. 2006); SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1342-44 (Fed. Cir. 2001). By the same token, this court also recognizes that disparaging comments alone do not necessarily show a manifest or express disavowal of the criticized subject matter. See, e.g., Ventana Med. Sys., Inc. v. Biogenex Labs., Inc., 473 F.3d 1173, 1180-81 (Fed. Cir. 2006) (finding that general comments distinguishing the prior art were not sufficient to limit the term "dispensing" to "direct dispensing"); In re Am. Acad. of Sci. Tech. Ctr., 367 F.3d 1359, 1365-67 (Fed. Cir. 2004) (finding descriptions of the deficiencies of using mainframe computers did not exclude mainframes from the term "user computer" because the specification as a whole did not express a clear disavowal of that subject matter). In this case, the single, passing reference to ITO as a relatively unsatisfactory transparent electrical contact in the specification does not disavow the use of ITO as a transparent window layer.

Epistar argues that the '718 patent "cannot be construed to encompass ITO [because] the patent does not actually disclose a means of using it," i.e., the use of ITO in the transparent window layer is not enabled in the '718 patent specification. See, e.g., Genentech, Inc. v. Novo Nordisk A/S, 108 F.3d 1361, 1365 (Fed. Cir. 1997) ("To be enabling, the specification of a patent must teach those skilled in the art how to make and use the full scope of the claimed invention without undue experimentation.") (internal citations omitted)). This court has also held that "[a]n applicant is not required to describe in the specification every conceivable and possible future embodiment of his invention." Cordis Corp. v. MedtronicAve Inc., 339 F.3d 1352, 1365 (Fed. Cir. 2003); see also Spectra-Physics, Inc. v. Coherent, Inc., 827 F.2d 1524, 1534 (Fed. Cir. 1987) ("If an invention pertains to an art where the results are predictable, . . . a broad claim can be enabled by disclosure of a single embodiment . . . and is not invalid for lack of enabling simply because it reads on another embodiment of the invention which is inadequately disclosed.") (internal citations omitted)).

Because ITO as a transparent conductive layer was already known to those of skill in the art, the '718 patent specification did not need to make further enabling disclosures about its prior art uses. See, e.g., Spectra-Physics, 827 F.2d at 1534 ("A patent need not teach, and preferably omits, what is well known in the art."). Epistar acknowledges that methods of fabricating transparent ITO layers were known in the art with its discussion of the Lawrence patent that discloses an ITO current spreading layer, i.e., "transparent electrode." Accordingly, this court finds that the ALJ did not err in construing "transparent window layer."

2. "trap sequence number" Used in Claims 6 and 25.

Cisco initially proposed that this term should be construed as "a value associated with a trap that can be used to determine the order in which the trap has been sent." Telecordia suggested "a number associated with a trap that indicates the order in which the trap is sent." In its reply brief, Cisco agreed that "number" could be substituted for "value."

The parties agree that a "trap" is "an unsolicited message, notification, or other communication generated by a network element to indicate an event or status of the network element." This comports with the commonly understood meaning of
the term in this field of technology. See William Stallings, SNMP, SNMPv2 and CMIP: The Practical Guide to Network Management, p. 133 (1993) Exhibit E of Cisco's Opening Claim Construction Brief, [Doc. # 49, Attachment # 5, p. 3 of 3]; Exhibit 8 of Telcordia's Responsive Claim Construction Brief, [Doc. # 57, Attachment # 8, p. 8 of 9]. (defining "trap" as an unsolicited message). Nothing in the claims and specification indicates an intent to ascribe anything but its ordinary meaning to the term.

The specification states that each trap includes "a trap sequence number (TSN)." '656 patent, col. 4, ll. 40-41. A trap sequence number is an example of a "state variable." See '656 patent, col. 6, ll. 44-50. What both parties seem to miss in their respective briefs is that each network element may be sending traps to the network manager, each labeled in sequence. See '656 patent, col. 4, ll. 24-26. For example, if there were three network elements, there could easily be three traps with a sequence number of five. Telcordia's suggestion of a number which indicates the order in which the trap is sent is incomplete because the number five does not really tell the network manager very much. Likewise, Cisco's initial proposal is insufficient, because the number five, by itself, is not enough to determine where the trap falls in the sequence coming from a particular network element.

The trap sequence number is only useful in conjunction with the numbers associated with other traps sent by the same network element. For instance, Method 200 of the patent is described as beginning when a trap is received "from a particular network element 16." '656 patent, col. 8, ll. 49-51. (emphasis added) The trap includes a trap sequence number (TSN). '656 patent, col. 8, ll. 56-57. As part of Method 200, that number is compared with an expected TSN, and the result of the comparison determines what action is taken. '656 patent, col. 8, ll. 60 - col. 9, ll. 10.

Based on this analysis, and the agreements of the parties at the hearing, the court will define this term as follows:

"Trap sequence number" means "a number associated with a trap from a particular network element, which can be, and is, used to determine the order in which that trap has been sent with respect to other traps from the same network element."

D. Traversing

<table>
<thead>
<tr>
<th>Leader's Construction</th>
<th>Facebook's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Searching</td>
<td>Navigation by the user</td>
</tr>
<tr>
<td></td>
<td>according to a specific path or route</td>
</tr>
</tbody>
</table>

The term "traversing" appears in Claims 17 and 18. Both Leader's and Facebook's proposed constructions of the term "traversing" are closely related to their proposed constructions of the term "ordering," discussed above. Leader contends that its proposed construction is correct because one of ordinary skill in the art would understand "traversing" to mean "searching." (D.I. 179, at 10-11.) Further, Leader contends that the claim language describes "a process where the system searches for, and locates, the different data that is associated with the user environments" (id. at 11), directly supporting its proposed construction. Facebook similarly argues that one of ordinary skill in the art would understand "traversing" to mean "navigation by the user according to a specific path or route." (D.I. 191, at 33.) Facebook contends that the claim language requires that the user environments "be navigated according to a specific path or route as defined by their ordering." (Id.) Additionally, Facebook essentially makes a claim differentiation argument, contending that the patentee used the term "searching" in other claims and portions of the specification, and thus, "traversing" should not be construed as synonymous with "searching." (Id. at 33-34.) Leader responds that it can agree that "traversing" means "navigating," but that Facebook's proposed construction reads in two unsupported limitations: that the navigation must be "by a user," and "according to a specific path or route." (D.I. 196, at 9.)

The Court initially concludes that Facebook's proposed limitation- that "traversing" must be done "by the user"- is not supported by the claim language. In relevant part, Claim 17 claims "[a] computer-implemented method of managing data, comprising computer-executable acts of: . . . traversing the different arrangements of the user environments with one or more of the applications based on the ordering information to locate the data associated with the user environment." '761 patent, col. 22:12-13, 31-34 (emphasis added). Dependant Claim 18 claims "[t]he method of claim 17, the act of traversing
is performed using a webslice that includes traversal information for locating the data associated with a given user environment." '761 patent, col. 22:35-38 (emphasis added). By the plain language of Claims 17 and 18, the act of "traversing" does not require a certain action to be taken by a user, but rather is a "computer-executable act[]." '761 patent, col. 22:13. Facebook has not pointed to anything in the specification to support a construction of "traversing" which requires some action by the user. 2

2 Ironically, a portion of the specification which might be read to support Facebook's position that "traversing" must be done "by the user" provides as follows: "the data content is indexed to facilitate searching for the content in a number of different ways in the future by the user of other users." '761 patent, col. 3:50-53. However, Facebook maintains that "searching" and "traversing" are not synonymous. Because Leader has agreed that "traversing" can mean "navigating," the Court will not undertake an unnecessary analysis of whether "traversing" also means "searching."

The Court concludes, however, that "traversing" must be done "according to a specific path or route," as Facebook contends. Claim 18 clearly provides that "traversing" is an act performed for "locating the data associated with a given user environment." '761 patent, col. 22:35-38; see also Claim 17, '761 patent, col. 21:31-34 ("traversing . . . to locate the data associated with the user environments"). The manner in which data associated with the user environments is located is provided for by the Claims. According to Claim 17, "traversing" is done "based on the ordering information." '761 patent, col. 22:32-34. According to Claim 18, "traversing" is done "using a webslice [i.e., routing algorithm] that includes transversal information." '761 patent, col. 22:36-37. Transversal information, in turn, includes "at least a collection ID, a user environment ID, and a routing path to the location of the environment data." '761 patent, col. 22:40-41. Therefore, the act of "traversing" is more than merely "navigating" to locate data associated with the user environment- the navigation must be performed in the manner or path specified by the claim language. Accordingly, the Court adopts, in part, Facebook's proposed construction, and concludes that "traversing" means "navigation according to a specific path or route."

4596

(4) tree topology network

This term appears in only the presently asserted claims of the '395 patent. Similar to "star-topology network," the patentee defined the breadth of the term "tree topology network." The specification states, "[t]he system could also be arranged in a tree structure where one hub 44d is connected to others (44c 44f) as depicted e.g. in FIG 3B." '395 Patent, col. 3, ll. 24-26. The court is unwilling to adopt such strong limiting language asserted by Dell absent sufficient support from the specification.

The court defines "tree topology network" as follows: "a network configuration with a hub connected to other hubs in a tree-like structure."
from a "succession of N outputs from the trellis encoder . . . ." '627 patent, 4:20. According to the plaintiff, multiple outputs correspond to a separate state change and, therefore, a single state transition cannot be a limitation.

The defendants argue that a trellis state transition occurs only when the encoder has moved on to the next symbol. According to the defendants, the "succession of outputs" referenced by the plaintiff refers to subset identifiers which are generated in parallel while the encoder operates on the data. Subset identifiers collectively determine the trellis encoded symbol. The defendants argue that nothing in the intrinsic evidence suggests that these outputs are the result of multiple state changes in the trellis encoder.

The plaintiff's argument is correct. A trellis encoder working on a multiple bit word produces a succession of subset identifiers which collectively make up the trellis encoded symbol. See '627 patent, 5:1-30. The subset identifiers are then supplied to another encoder, e.g., a four-dimensional QAM encoder, which outputs a stream of signal points comprised of interleaved streams of trellis encoded channel symbols. Id. The plaintiff's construction of this term is correct, and the court adopts it.

III. "TRELLIS ENCODING ONES OF THE AGGREGATED BITS TO IDENTIFY, FOR EACH OF THE PLURALITY OF SYMBOLS, A RESPECTIVE SUBSET FROM WHICH THAT SYMBOL IS TO BE CHOSEN" ('154 patent, Claim 1)

As a preliminary matter, the July 20 Order appears to have caused some consternation on the part of Broadcom, which suggests that its proposed construction of this term may have been misunderstood by the Court. This concern is misplaced: The Court arrived at its holding through careful consideration of Broadcom's argument that each group of trellis-encoded bits is used to identify a single symbol subset. To the extent that confusion arose from the Court's citation to col. 14, ll. 22-31 of the '154 patent, the Court reiterates its interpretation of this specification as "disclaiming potential limitations of the subset-identification process on the basis of the specified embodiments of that process." Agere, 2004 WL 1658530, at *40, 2004 U.S. Dist. LEXIS 14187, at *144-45. In other words, the Court did not cite this specification as a direct contradiction of Broadcom's construction, but rather as a manifestation of the patentee's express intent to include as many embodiments of the subset-identification process as possible within the language of the claim term, thereby indicating that Broadcom's proposed limitation of the term to its embodiments was improper. Nonetheless, the Court, acknowledging that its claim construction included potentially confusing language regarding "successive identification of symbol subsets," clarifies that this holding was intended to indicate only that the instant term's ambiguity must, as discussed above, be broadly construed to include the possibility of identifying of multiple subsets per group of trellis-encoded bits.

In light of this clarification, the Court finds that the construction proposed by Agere, "trellis encoding some of the aggregated bits to identify one or more subsets from which one or more symbols is to be chosen," is consistent with the July 20 Order. This construction could, however, be interpreted to imply incorrectly that more than one symbol subset may be associated with a particular symbol. Thus, the Court adopts a slightly modified version of Agere's proposed construction:

"trellis encoding some of the aggregated bits to identify one or more subsets, from each of which one symbol is to be chosen."

14. "trench[es]" 4TThe term "trench" appears in three 229 patent claims as part of "trench capacitor" and in eleven 148 patent claims as part of "trench capacitor, " "capacitor trench, " "trench mask" and "said trench[es]." Three different constructions are offered for "trench[es]." UniRAM proposes that "trench[es]" means "a recess in the surface of a substrate." Jt Cl Const, Ex B at 29-30. TSMC requires that this recess be "deep," and MoSys additionally requires that the recess be in the "active area" of the substrate and that "the initial etching into the substrate is nearly perpendicular to the substrate surface." Id.

At no point do the claims or specification suggest that the initial etching must be nearly perpendicular. Moreover, the patents never indicate that the trench must be deep. On the contrary, the specification suggests that the storage capacitor for
the invention is smaller than that of prior art DRAM cells. 229 patent at 4:15-19, 17:46-50. Moreover, although MoSys and TSMC assert that figures 16(d) and 18(a) depict deep trenches, "the mere fact that the patent drawings depict a particular embodiment of the patent does not operate to limit the claims to that specific configuration." Anchor Wall Systems, Inc v Rockwood Retaining Walls, Inc, 340 F3d 1298, 1306-07 (Fed Cir 2003).

Accordingly, the court adopts UniRAM's definition of "trench(es)" as "a recess in the surface of the substrate."

15. "trench capacitor"

"Trench capacitor" appears in three claims in the 229 patent and nine claims in the 148 patent. The parties briefed this term together with the term "trench." The issue is whether a trench capacitor is formed wholly or partially within a trench. UniRAM argues that a trench capacitor includes a lateral component that is outside of the trench and connects to a transistor. UniRAM Br at 45. MoSys and TSMC instead contend that the lateral component is not part of the trench capacitor, which they assert must be formed wholly within the trench. MoSys Br at 43; TSMC Br at 33, n22. MoSys also asserts that UniRAM's proposed construction is too broad and includes non-trench capacitors such as a stacked capacitors, which only have a small portion within a shallow recess in the substrate. MoSys Br at 42-43.

The court agrees with MoSys and TSMC that a "trench capacitor" does not include the lateral components. In a section beginning with the "following advantages are obtained according to this invention," the patent states that "three edges of the trench capacitor are defined by field oxide" and the fourth edge "is defined by mask." 229 patent at 20:24-29. Accordingly, the trench capacitor cannot include the lateral components, which lie on top of the field oxide and do not share the same four edges as the trench. Figs 14(g), 18(b). And although the court does not limit the term "trench capacitor" to this particular embodiment, the court notes that the patent does not clearly indicate that a trench capacitor includes components outside of the trench. Moreover, UniRAM's broad definition creates ambiguity because the boundaries between the trench, lateral components and top electrode are unclear. Accordingly, the court adopts a modified version of TSMC's definition of "trench capacitor" that fits with the construction of "trench" above: "A capacitor formed entirely within a recess in the surface of a substrate."

1."a plurality of trenches"

This term appears in claims 1, 3 and 16 of the '715 patent. Toshiba does not believe "a plurality of trenches" requires construction but alternatively suggests the term means "more than one groove." Jt Cl Const, Ex C at 1. Hynix argues that the term means "a plurality of recessed areas in which the upper boundary of each trench is defined by the top surface of the material that is removed to form the trench." Id. Hynix appears to refer to the "recessed areas" as "trenches" even within its own definition; hence, the court gathers that the crux of Hynix's construction is construing a "trench" as being bounded "by the top surface of the material that is removed to form the trench."

The specification teaches that a trench is formed by removing material from the substrate. '715 patent at 2:60-67, 4:49-52, 15:9-12, 21:1-8. After the trench is formed, it may be eliminated or have its depth reduced by removing other material comprising the trench's side walls. Id at 4:57-68 (removal of nitride film). Hynix defines "trench" based on its original dimensions; that is, Hynix contends that a trench extends up to the top surface of the material originally removed to create the trench. But if a trench's side walls are later reduced, Hynix's definition leads to an anomaly in which a "trench" exists in a volume of space above its surrounding material. Hynix has not shown that a person of ordinary skill in the art would expect this counterintuitive result, which contravenes the ordinary understanding that a "trench" is defined by its depth relative to the surface at any given time.
Accordingly, the court rejects Hynix's construction and the court declines to construe this straightforward term.

4602

F. "triangulation"

The term "triangulation" is used in claim 31 of the '763 patent: "wherein the positional data is acquired using a system selected from the group consisting of a global positioning system and triangulation." This term is found in the specification: "The first step in the registration process, block 102 is to determine the exact geographic location, block 201 of the communications device via either GPS, block 202, signal strength, block 203, Loran, block 204, triangulation or other similar location means." ('763 patent, 11:34-39) (emphasis added). EMSAT and LBS argue that "triangulation" covers "a method of calculating an unknown point, used by position determining systems such as LORAN, by forming a triangle having the unknown point and two known points as the vertices." On the other hand, Centennial asserts the following construction: "a method of calculating the location of an object by determining the angles from the object to two points having known locations."

The defendant argues that triangulation requires determining angles. Several dictionary definitions support Centennial's argument. See Navigation Dictionary 260 (2d ed. 1969). In its strictest sense, triangulation differs from trilateration, which measures distances instead of angles. Dictionary.com, http://dictionary.reference.com/browse/trilateration. But in the field of mobile phone location, rather than navigation or surveying, the defendant conceded that "triangulation" has a broader connotation that includes distance measurement.

Although the court is persuaded that "triangulation" as a generic concept might conceivably encompass GPS, the '763 patent explicitly refers to GPS as separate and distinct from triangulation. Claim 31 states that the mobile unit's position "is acquired using a system selected from the group consisting of a global positioning system and triangulation." Likewise, the specification explains, "The preferred means for establishing exact geographic location (EGL) is a satellite communication system such as discussed in the incorporated material. However, other means, including, but not limited to, triangulation and the like, can be used ..." ('763 patent, 16:50-54) (emphasis added). GPS is disclosed a means for determining exact geographic location that uses satellites. ('763 patent, 9:24-26). Thus GPS is different from triangulation. As such, the court construes "triangulation" to mean "a method, distinct from GPS, of calculating an unknown point by measuring the distance or angles of two or more reference points."

4603

C. Triangulation Calculation

The Court concludes that there is no significant disagreement between the parties as to the definition of triangulation calculation. For the purposes of this case, the Court adopts the definition of triangulation set forth in The Photonics Dictionary, with the further understanding that triangulation calculation involves the use of trigonometric principles.

4604

Claim 21 of the '015 patent reads as follows:
21. An apparatus for measuring an object, comprising:

- two ultrasonic transducer means, each having an emitter and a receiver associated therewith and oriented in substantially mutually perpendicular relationship to define a two-dimensional field of greater extent in each dimension than that of the largest object to be measured, said ultrasonic transducer means each being aimed across said field to measure a mutually perpendicular dimension of said object;

- a third ultrasonic transducer means having an emitter and a receiver associated therewith for measuring a third dimension of said object in a direction substantially mutually perpendicular to said first two measured dimensions;

- trigger means for selectively activating each of said transducer means to take a dimensional measurement when said object is in proximity thereto;

- timer means for determining travel time between the generation of an ultrasonic wave by each emitter and the receipt of said wave by its associated receiver after reflection from said object;

- correlation means for correlating said travel times to linear distances;

- computing means for determining the dimensions of said object from said linear distances; and

- data collection means for collecting said dimensional measurements.

('015 patent, col. 14, l. 61 -- col. 15, l. 21.)

Here, the "trigger means" claim element does not recite sufficient structure to perform the undisputed function of selectively activating, and Data Trak does not dispute and has not presented evidence to overcome the presumption that this is a means-plus-function limitation. As to the corresponding structure disclosed in the specification for carrying out the function, Quantronix contends that "trigger means for selectively activating each of said transducer means to take a dimensional measurement when said object is in proximity thereto" should be construed to comprise either a beam, a sensor, a timer, a footswitch, a software command or equivalents thereof. Quantronix points to the '015 patent specification, which provides in part as follows:

Given that orientation of movement, photocell 22 and retroreflector 24 are preferably mounted substantially in lateral alignment with sensors 14 and 16 so as to trigger a measurement when the leading edge of a large object 28 or a small object 26 interrupts the light beam between photocell 22 and reflector 24. Photocell 22 may be any commercially available photocell, preferably operating in the infrared polarized light range. Proximity sensors of various types, including but not limited to magnetic or capacitive, may also be employed.

('015 patent, col. 4, ll. 9-19.) Quantronix also points to the following portion of the specification:

Sensor 12 is triggered by the interruption by an object of the beam 23 between photocell 22 and retroreflector 24 (FIG. 5) in the instance of unit 10, and by the operator in the case of unit 110. Process controller 180, in response to photocell 22, produces a trigger signal, sent to pulser 202 and counter/timer 204, causing pulser 202 to transmit an activation signal to sensor 12 and counter/timer 204 to start counting. If static measurement unit 110 is being controlled, pulser activation may be triggered by a timer, footswitch, software command or other suitable means via unit 180. The pulser signal causes sensor 12 to transmit an ultrasonic signal burst toward the object to be measured.

('015 patent, col. 9, ll. 27-40.) In addition, Quantronix cites to the following portion of the Summary of the Invention:

[T]he measuring . . . operations may be triggered and data accumulated and processed by computer means; bar code or other optical character recognition via an optical character recognition reader decodes identification of the objects measured to automatically correlate measurements to a specific package[.]

('015 patent, col. 2, l. 67 - col. 3, l. 5.) Again, Data Trak does not dispute Quantronix's construction.
Although neither party entered the '015 patent's prosecution history as evidence for this motion, the parties represented at oral argument that there is nothing in the prosecution history that would assist the Court in claim construction and that the Court had everything that it would need in front of it to make a determination for the purposes of this motion. Relying on the parties' representations, and upon thorough consideration of the available intrinsic evidence, the Court agrees with Quantronix and construes "trigger means," for the purposes of this motion, to comprise either a beam, a sensor, a timer, a footswitch, a software command or equivalents thereof.

In addition, neither party entered the '392 patent's prosecution history as evidence for this motion either. And the parties similarly represented at oral argument that there is nothing in the prosecution history that would assist the Court for the purposes of ruling on the present motion.

Cygnus asserts that in the '964 patent, "triggered" is used in the ordinary English sense of initiated or precipitated. Defendants admit that "[t]he term 'triggered' is not defined in the specification" but argue that "triggered" should be limited to "(a) a matching of the incoming direct inward dial number (DID) with the assigned/stored DID number and (b) the subscriber hanging up." Defendants overlook that the specification uses "trigger" in another context in a manner consistent with Cygnus's interpretation and inconsistent with their own:

"Triggered" therefore merely means "initiated or precipitated."

Defendants argue that claim 1 of the '027 patent is invalid because the term "triggered" is indefinite, not enabled, and no written description in the specification supports claim 1's use of the term. However, given the constructions of "triggered" and "DID number," claim 1 is not indefinite and provides that "the center dials the callback number of the subscriber when the DID number is initiated, i.e., sent by the terminating LEC. Defendants' motion for summary judgment that the use of "triggered" renders claim 1 of the '027 patent invalid under § 112 is denied.

Defendants argue that "triggering signal(s)" and "triggering activity" are also not capable of construction. Defendants argue it is not possible to construe these terms in light of the patent's use of similar terms-"triggering event signal," "triggering activity signal," and "triggering event." Defendants concede that on its face a "triggering event signal" is a signal indicating a triggering event and, likewise, a "triggering activity signal" is a signal indicating a triggering activity.

The claims use the terms "triggering event" and "triggering activity" synonymously. The claims also use the terms "triggering signal," "triggering event signal," and "triggering activity signal" synonymously. Claims 7-14 are the best
example of this. In claim 7, the motion detector sends the controller "triggering signals." Col. 13:21-22, 25-26. The camera in claim 7 operates in at least two modes. In the first mode, the controller activates the camera mechanism upon receipt of a "triggering signal" from the motion detector. Col. 13:20-22. In the second mode, the controller increases the activity counter but does not activate the camera mechanism when it receives a "triggering signal" from the motion detector. Col. 13:22-26. In claim 8, which depends from claim 7, in the first mode, the controller both activates the camera mechanism and increases the activity counter when a "triggering activity" occurs. Col. 13:27-30. Thus, it is a "triggering activity" that initiates the "triggering signal." In claim 14, which depends from claims 13 and 7, the controller is programmable to ignore "triggering event signals" sent by the motion detector until a predetermined amount of time has passed. Col. 13:45-48. Since claims 7 and 13 do not require the controller to act on any "triggering event signals," such signals must be the "triggering signal" of claim 7. Thus, "triggering event signal" and "triggering signal" must be the same. Further, since "triggering activity" initiate the "triggering signal," "triggering activity" must also initiate "triggering event signals."

Other claims also illustrate this interchangeability. In claim 15, the motion detector sends the controller a "triggering activity signal." Col. 13:53-55. In claim 18, which depends from claim 15, information about a "triggering activity" is stored when the controller receives a "triggering signal" from the motion detector. Col. 14:1-3. Thus, claims 15 and 18 use "triggering activity signal" and "triggering signal" synonymously. Similarly, in claim 20, the controller stores a "triggering activity" upon receipt of a "triggering signal" from the motion detector. Col. 14:14-21.

In claim 21, the activity counter is programmable to display a predetermined number of "triggering events." Col. 14:33-35. In the pause state, the controller ignores any "triggering event signals" received from the motion detector for a predetermined time. Col. 14:36-39. Thus, in claim 21, "triggering events" cause "triggering event signals."

Claim 26 uses "triggering signal" and "triggering event signals" synonymously. In claim 26, the controller receives a "triggering signal" from the motion detector and acts upon the signal. Col. 15:12-19. The controller is also programmable to ignore any "triggering event signals" from the motion detector until a predetermined time has passed. Col. 15:19-23.

The specification supports the synonymous use of the terms. The Summary teaches that in the first mode of one embodiment, the motion detector sends a "triggering signal" to the controller and the controller then activates the camera mechanism. Col. 1:44-47. In the second mode of this embodiment, the controller activates the activity counter but not the camera mechanism when a "triggering activity" occurs. Col. 1:47-50. In another embodiment, the motion detector sends a "triggering activity signal" to the controller. Col. 1:51-57. In this embodiment, the camera's shutter button is located external to the housing allowing a manual activation of the camera. Col. 1:55-57. In a third embodiment, which includes a digital camera mechanism, the motion detector sends a "triggering signal" to the controller. Col. 1:58-64. The distinguishing feature of these embodiments is not the use of a "triggering signal" as opposed to a "triggering activity signal"; rather, it is clear from these descriptions of the embodiments that the drafter used "triggering signal" and "triggering activity signal" interchangeably.

In the Detailed Description, the specification teaches that, in one embodiment, the motion detector sends a signal to the controller when a "triggering event" occurs. Cols. 4:34-36, 8:2-4. A motion detected by the motion detector is one example of a "triggering event." Cols. 4:36-37, 8:4-5. Upon receiving the signal indicating the "triggering event," the controller sends signals to the flash and the camera mechanism. Cols. 4:37-40, 8:5-9. In another embodiment, the LCD display can be used as an activity counter to display the number of "triggering activities" detected by the motion sensor. Col. 8:17-19. In that instance, when the motion detector is triggered, it sends a "triggering signal" to the controller, which then increases the activity counter by one. Col. 8:19-22.

In the pause state, the motion detector sends a "triggering signal" to the controller, and the controller increases the activity counter by one. Col. 8:30-34. The controller then goes into a pause state and ignores the motion detector for a period of time. Col. 8:34-35. "This prevents a single motion activity from causing an inordinate amount of triggering signals." Col. 8:35-37. In the pause state, the controller ignores any "triggering events" of the motion detector for a predetermined amount of time. Col. 8:34-35. In another embodiment, the controller can be programmed to ignore a "triggering activity" during flash charging or film removal. Col. 9:2-5. The controller can also be programmed to go into the pause state after each "triggering event." Col. 12:3-4.

It is clear from the claims and specification that "triggering event" and "triggering activity" are synonymous, as are "triggering signal," "triggering event signal," and "triggering activity signal."
mean "signals sent from a motion detector in response to activity detected by the motion detector" and "triggering signal" to mean "one or more signals sent from the motion detector in response to activity detected by the motion detector." The Court construes "triggering activity" to mean "activity that is detected by the motion detector."

4607

1. Claim 1

Terms and phrases within subsections (b), (d), and (e) of Claim 1 require construction. Claim 1(b) states:

...triggering the activation of a high voltage and current generator in response to said sensed presence, said generator coupled between said high voltage electrode and said reference electrode, said triggered generator being activated for a predetermined time period.

There are two terms in Claim 1(b) that require construction: "triggering" and "predetermined time period."

With respect to the "triggering" term, Agrizap argues that triggering is defined as "any manner of initiating, actuating or causing activation of a high voltage and current generator in response to the sensed presence, such as through hardware, software or any combination thereof." (Agrizap's Reply Br., at 8). Woodstream argues that Agrizap's definition of "triggering" is unsupported by the patent and does not consider the term in the context of Claim 1(b). Woodstream's proposed construction is: "the sensed presence of a pest results in an immediate and irreversible triggering of the high voltage and current generator without regard to any verification of the sensed presence. " (Woodstream's Reply Br., at 7). In response, Agrizap argues that the triggering is neither immediate nor irreversible because after the pest makes contact, the invention allows for a delay to prevent triggering based on the momentary presence of a pest. According to the specification, when a pest makes contact, a voltage drop on the triggering mechanism occurs and there is a delay of the rising voltage to ensure that the timer is not activated by a momentary presence of a pest. (636 patent, col. 8, lines 21-36).

This Court will construe the "triggering" term as:

the sensed presence of a pest results in an immediate and irreversible triggering of the high voltage and current generator.

As Woodstream argued, the triggering is immediate and irreversible upon sensing the pest. The specification supports this conclusion. See Phillips, 415 F.3d at 1315 (stating that specification is single best guide for determining meaning of disputed term). The specification states that "[g]ood contact must be established before [the] current will be large enough to trigger a timing circuit." (636 patent, col. 4, lines 32-36). Furthermore, the specification states that after the voltage drop, "Capacitor 10 creates a time constant which delays the rising voltage on TTRIG 99 to ensure that the timer is not activated by a momentary presence of a pest." (636 patent, col. 8, lines 32-36). Thus, the triggering of the activation of the generator does not occur until after the delay of the rising voltage in the triggering mechanism. Once this delay has occurred, the generator is triggered immediately and there is no indication in the patent that it can be reversed.

GO BACK

4608

The same is true as to the construction of "trinary code generator for generating a three-valued or trinary code responsive to the variable binary code." Lear's construction focuses on the conversion from a "binary number generated by the binary code generator into the first trinary code." Such a construction impermissibly limits the claim to conversion from a binary number to a trinary code. As we noted above, the claims never limit the initial binary code to a "binary number," instead leaving the term open to encompass other numerical and character languages, including trinary code. Therefore, we construe "a trinary code generator for generating a three-valued or trinary code responsive to the variable binary code" to mean "a processor programmed to generate a trinary code in response to the variable binary code."

GO BACK
2. truncated exponential biphasic [multiphasic] waveform

Claim 8 of the '212 Patent recites the delivery of electrical energy to a patient in a "truncated exponential multiphasic waveform." n10 Philips asserts that this phrase should be construed as "a defibrillation shock having at least two truncated exponential phases of opposite polarity." Cardiac Science contends that this term should be construed as "a waveform that is delivered in at least two phases, is interrupted prior to delivery of all energy, and ignoring change of phase and time between phases, has a continuous exponential shape." Thus, although the parties agree that each phase must be truncated and exponential in shape, the parties dispute whether the two phases must constitute one continuous exponential curve. In other words, the parties dispute whether if the second phase was flipped over, the second phase would start where the first phase ended (absent the interphase period), and continue with the same slope.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

n10 The term "truncated exponential biphasic waveform" appears in Claims 50 and 58 of the '454 Patent. That Patent, entitled "Electrotherapy Method and Apparatus," was issued on March 4, 1997. The claims at issue read as follows:

50. The method of claim 47 wherein the discharging step comprises the step of discharging the energy source across the electrodes to deliver electrical energy to the patient in a truncated exponential biphasic waveform.

58. A method for applying electrotherapy to a patient through electrodes attached to an energy source the method comprising the following steps

charging the energy source to an initial level prior to detecting a need to apply a shock to a patient,

determining the need to apply a shock to a patient,

charging the energy source to a second level greater than the initial level

discharging the energy source across the electrodes to deliver electrical energy to the patient in a truncated exponential biphasic waveform.

('454 Patent at c. 14, ll: 43-46; c. 16, ll: 1-12.) The '454 Patent is a continuation-in-part of the parent of the '212 Patent, and the '454 Patent provides no additional guidance with respect to the term at issue. Consistent with the parties' arguments, the Court will construe these claims consistently, the only difference being that the term "biphasic" applies to two phases, and the term "multiphasic" applies to at least two phases.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

The Court finds that the truncated exponential multiphasic (or biphasic) waveform need not be continuous. First, both the '212 and '454 Patents depict the truncated multiphasic (biphasic) wave form represented in Figure 1 as a preferred embodiment of the waveform, not ruling out that other waveform configurations may fall within the scope of the invention. In fact, both the '212 and '454 Patents refer to implantable defibrillators that use truncated exponential biphasic waveforms. Of the examples cited, the inventors refer to U.S. Patent No. 4,800,883 (the "Winstrom Patent"). Undisputedly, the waveform of the Winstrom Patent is noncontinuous. (See Axtell Ex. 70 (Winstrom Patent) at sheet 8, Fig. 8c.) In addition, a preferred embodiment of the '454 Patent describes removing a resistor from the circuit during delivery of a shock. ('454 Patent at c. 14, ll: 43-46; c. 16, ll: 1-12.) Cardiac Science recognizes that a variation in either capacitance or resistance can change the shape of the curve. (Cardiac Science, Inc.'s Mem. of Law on Claim Construction for Additional Claim Terms from Philips' Patents at 17-18.) When a resistor is removed from the circuit, the resistance of the circuit will change, thus resulting in a noncontinuous waveform. Cardiac Science's proposed construction would read out a preferred embodiment, which is rarely proper without strong evidentiary support. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996).
For these reasons, the Court construes the term "truncated biphasic (multiphasic) exponential waveform" as "a defibrillation shock having two (at least two) truncated exponential phases of opposite polarity."

"Trusted time source" appears in each disputed patent claim (536 Patent: 1,6; 709 Patent: 1,17). The defendants contend that the phrase "trusted time source" means "a non-resettable and tamper-proof real time clock that is installed on or as part of the computer of a user who desires to time-stamp a digital data field" (Doc. 62 at 14). The plaintiff argues that the phrase "trusted time source" means simply "a source from which a time value that is trustworthy may be obtained" (Doc. 60 at 12). However, the latter definition contradicts the patents' express identification of a "local source of trusted time" as an important aspect of the invention. One of the express objectives of the plaintiff's invention is to "provide such systems, apparatus, methods, and articles of manufacture for time-stamping digital data files, which do not continually rely on a remote trusted source of time" (536 Patent at 14:14-18; 709 Patent at 14:2-6).

The plaintiff's proposed construction also contradicts the express teachings of the patents' specifications. In attempting to distinguish his invention over existing prior art, the patentee expressly defines a "trusted time source" as "a real time clock, which is not resettable, is independent of any system clock of the PC, and is installed locally relative to the PC" (709 Patent, Abstract). A patentee may act as his own lexicographer to specially define a word or phrase used in his patent. Markman v. Westview Instruments, Inc., 52 F. 3d 967, 979-80 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). If a patentee provides a definition to distinguish his invention over prior art, he may not later attempt to recapture the disclaimed meaning. Astrazeneca AB v. Mutual Pharmaceutical Co., 384 F.3d 1333, 1340 (Fed. Cir. 2004).

Further, both patents repeatedly distinguish the patented invention over prior art on the basis that conventional DTS used a time source remote from the user. In distinguishing his invention from conventional DTS, the patentee states "because the DTS is located remotely relative to the user, there is no way to provide a digital time-stamp locally at the user's site" (536 Patent at 11:58-67; 709 Patent at 11:64-67). "It would be much more desirable to provide systems and methods of time-stamping digital data files locally and without continuing reliance on a remote time source" (536 Patent at 13:36-43; 709 Patent at 13:23-30). This crucial distinction throughout the patent between a "remote" versus a "local" time source necessarily informs any construction of "trusted time source."

Finally, the plaintiff's urged construction of "trusted time source" as "a source from which a time value that is trustworthy may be obtained" (Doc. 60 at 12) is mere tautology and would render the patent indefinite. Because a "trustworthy" time value may vary widely with context, the plaintiff's proposed construction fails to provide the public adequate notice (as required by law n2) of the patentee's claimed invention. If "one of ordinary skill would not know from one [context] to the next whether a particular composition standing alone is within the claim scope or not . . . [t]hat is the epitome of indefiniteness." Geneva Pharms., Inc. v. GlaxoSmithKline PLC, 349 F.3d 1373, 1384 (Fed. Cir. 2003). The law requires definiteness "to guard against unreasonable advantages to the patentee and disadvantages to others arising from uncertainty as to their rights." General Electric Co. v. Wabash Appliance Corp., 304 U.S. 364, 369, 58 S. Ct. 899, 82 L. Ed. 1402, 1938 Dec. Comm'r Pat. 813 (1938); Athletic Alternatives Inc. v. Prince Mfg. Inc., 73 F.3d 1573, 1581 (Fed. Cir. 1986).

n2 35 U.S.C. § 112 requires a patentee to include "one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention." 35 U.S.C. § 112, P 2 (2006).

In sum, the patents' express identification of a "local source of trusted time" as an important aspect of the invention (536 Patent at 14:14-18; 709 Patent at 14:2-6), the patentee's express definition of a "trusted time source" (709 Patent, Abstract), the patent's repeated disavowal of a remote time source as used in prior art (536 Patent at 11:58-67, 13:36-43; 709 Patent at 11:64-67, 13:23-30), and the requirement of definiteness disfavor decisively the construction urged by the plaintiff. Accordingly, "trusted time source" means "a real time clock, which is not resettable, is independent of any system clock of
the PC, and is installed locally relative to the PC." n3

n3 This definition comports with the patents' prosecution history. Indeed, during prosecution of the 536 Patent, the U.S. Patent and Trademark Office amended the applicant's claims. The amendment expressly requires a "trusted time source" that is local to the user's PC (Doc. 99). Likewise, the examiner's "Notice for Allowability" for the 709 Patent explains that the "trusted time source" is installed on or as part of the user's PC (Doc. 99).

4611

2. "tuning said TV signals to a specific program"

TiVo argues no construction is needed for these terms, or, if construed, should mean "adjusting the system to receive signals at a particular frequency or a particular program." See TiVo's Op. Br. at 7-8; '389 patent at col. 3:37-46; TiVo's Markman Slides at 61-68.

EchoStar argues these terms should be defined as "using a tuner to select a radio frequency bandwidth that carries exactly one television program at a time." EchoStar's Opening Br. at 8-9; EchoStar's Response Br. at 15; EchoStar's Slide Presentation at 54-58.

The specification does not explicitly define "a specific program." The claim term "a specific program" does not appear in the specification. Based, however, on its use in the claims, the Court finds that one of ordinary skill in the art would understand "a specific program" to mean "a specified frequency range." The Court finds that the claim term "tuning" was used according to its plain meaning in the '389 patent and does not require further construction.

Therefore, the Court defines "tuning said TV signals to a specific program" as "tuning said TV signals to a specified frequency range."

GO BACK

4612

"Tunnel"

Cisco's proposed construction for "tunnel" is "path between a client and a network through an intermediary." Alcatel's proposed construction is "communication using encapsulation of packets."

Cisco argues that its proposed construction is the meaning of the term "tunnel" understood by one of ordinary skill in the art in 1996. See Leifer '019 Report, at 10. Alcatel does not dispute that one of ordinary skill in the art would have understood a "tunnel" to exist between a client and a network through an intermediary, but argues that such a definition also applies to connections other than tunnels. See Lazar '019 Decl., at P 49. Alcatel contends that a communication through a tunnel is accomplished in this patent by encapsulating the packets being sent over the tunnel. While this may be true, the claim language does not use the term tunnel to describe the means by which information is delivered over the tunnel, but is obviously referring to the tunnel itself, which is a path, not a communication method. For example, in claim 9, the term tunnel is used in the following manner: "forwarding the encapsulated link level protocol through the tunnel." Valencia, at 16:15-16 (emphasis added). The encapsulation requirement is separately referenced in the claim, and the "tunnel" is referred to as the path through which the encapsulated information is sent.

Nevertheless, as is clear from the claim language and the specification, the "tunnel" in this patent is referring to a communication link between a remote client and the local network. See, e.g., Valencia, at 4:6-9, 4:31-34, 16:35-36, Figs. 2-3. Therefore, the Court construes the term "tunnel" as "communication path between a remote client and a local network"
Cisco's proposed construction for this term is "path between a client and a network through an intermediary by which link level (layer 2) information is sent." Alcatel's proposed construction is "communication using encapsulation of packets according to the layer 2 forwarding protocol."

Both sides essentially restate their proposed constructions for the term "tunnel" while incorporating their respective notions of the definition of layer 2 forwarding protocol. As seen from the claim language, a "layer 2 tunnel" is no more than a "tunnel" operating according to a "layer 2 forwarding protocol." See Valencia, at 16:37-40, 59-67.

Therefore, in accordance with the Court's construction of the terms "tunnel" and "layer 2 forwarding protocol," the Court construes the term "layer 2 tunnel" as "communication path between a remote client and a local network through an intermediary, operating according to a layer 2 forwarding protocol."

2. Transmitting Registration Requests With Tunnel Identifier in a Key Field of a Tunnel Header

Starent also argues that summary judgment is appropriate because the ST products do not transmit registration requests with tunnel identifiers in a key field of a tunnel header. Our conclusion that the ST products do not use tunnel identifiers also disposes of this issue because if the ST products do not have tunnel identifiers then the ST products cannot transmit registration requests with tunnel identifiers in a key field of a tunnel header.

However, assuming, arguendo, that the ST products do use tunnel identifiers, we must determine whether the ST products transmit registration requests with the tunnel identifier in a key field of a tunnel header. First, the terms "tunnel header of a registration request" and "key field in the tunnel header" require claim construction. Starent asserts that a "tunnel header of a registration request" ("tunnel header") is the portion of a tunnel packet with information needed to route the registration request. Starent asserts that a "key field in the tunnel header" ("key field") means a specific field for identification located in the portion of a tunnel packet with information needed to route a registration request. UTStarcom argues that the "tunnel header" is the portion of a data packet containing the information used to identify the end points of the tunnel. UTStarcom argues that a "key field" is a specific field for identification located in the portion of a data packet containing the information used to identify the end points of the tunnel.

In regard to the term "tunnel header of a registration request," Starent finds support for its proposed claim construction in both the specification and the prosecution history. Specifically, the specification states that "[i]n tunneling, packets or frames from one network are placed inside frames (‘encapsulated’) of another network. The encapsulated frames may include a header with sufficient routing information to transmit the encapsulated frame from a source to a destination." (Def. St., Tab 2, ’905 patent, col. 1, ll. 34-38.) During prosecution, UTStarcom amended all of the independent claims to include the limitation that the tunnel identifier was "in a key field of a tunnel header" of both "the registration request sent to the home agent" and "data packets from the home agent." (Def. St., Tab 3, Prosecution History, February 15, 2006 Response to August 15, 2005 Final Office Action and January 10, 2006 Advisory Action at 2 (FH-0079).) In the Summary of the Claimed Invention section of the Office Action Response, UTStarcom stated that:

The foreign agent then tunnels this registration request to the mobile node's home agent. Before doing so, the foreign agent inserts the assigned tunnel identifier into a key field in a tunnel header that the foreign agent uses to tunnel the registration request to the home agent. When the foreign agent receives a registration reply tunneled from the home agent, that reply also has that tunnel identifier in a key field in the tunnel header.
In defense of its claim construction, UTStarcom simply states that "[g]iven the subject matter of the '905 patent and the detailed discussion of tunneling and the GRE tunneling protocol in the specification … one of ordinary skill in the art would understand the term 'tunnel header' to mean 'the portion of a data packet containing the information used to identify the end points of the tunnel.'" However, UTStarcom does not make any arguments or point to any specific evidence, intrinsic or extrinsic, to support its proposed claim construction. It only points to Dr. Olivier's unsupported, conclusory declaration that a "tunnel header" is the portion of a data packet containing the information used to identify the end points of the tunnel. We cannot consider such unsupported and conclusory assertions regarding the definition of a claim term in our claim construction analysis. Phillips, 415 F.3d at 1318.

Furthermore, UTStarcom's proposed claim construction is at odds with the intrinsic evidence. UTStarcom's construction is so broad that the "tunnel header" does not necessarily have to be in the header, nor tunneled. However, in the Summary of the Claimed Invention section of an Office Action response, UTStarcom stated:

Thereafter, when the foreign agent receives packets tunneled from the home agent for the mobile node, those packets will be encapsulated in a tunnel header having the tunnel identifier in a key field.

(Def. St., Tab 3, Prosecution History, February 15, 2006 Response to August 15, 2005 Final Office Action and January 10, 2006 Advisory Action at 14 (FH-0091)). This passage clearly indicates that the tunnel header is not part of the data packet, but instead, it is added during encapsulation.

UTStarcom argues that we should not adopt Starent's claim construction because its claim construction is technically impossible and would render the claims nullities. Specifically, UTStarcom argues that Starent's claim construction requires the registration request to be tunneled but that in actuality registration requests are not tunneled because a tunnel is not created when the registration request is sent. Instead, UTStarcom argues that "transmitting the registration request to the home agent with a tunnel identifier in the 'tunnel header' of the data packet, plus the home agent's responsive transmission using the same tunnel identifier, create the tunnel for further communication between the mobile node and the home agent." (Pl.'s Br. Opp'n Summ. J. 8-9) UTStarcom dismisses the express statements it made during prosecution that "the foreign agent . . . tunnels [the] registration request" and that the "foreign agent receives a registration reply tunneled from the home agent" as "inartful phrasing" and "loose and possibly incorrect language." ((Pl.'s Br. Opp'n Summ. J. 8; Pl.'s Sur-Reply Br. Opp'n Summ. J. 7) We agree with Starent that UTStarcom, as the patentee, should bear the consequences of its inartful phrasing. (Def.'s Reply Br. Supp. Summ. J. 7); see Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1425 (Fed. Cir. 1997) (imposing the "higher cost of careful prosecution on patentees" instead of "on the public at large"). Furthermore, we do not have to reject Starent's claim construction simply because it would be impossible to practice the invention under such a construction. See Chef America, Inc. v. Lamb-Weston, Inc., 358 F.3d 1371, 1374 (Fed. Cir. 2004) (affirming claim construction even though such construction would produce a nonsensical result).

UTStarcom also argues that it should not be bound by its statements from the prosecution history because those statements were not disavowals of claim scope, were not definitions of the claim terms nor were they attempts to avoid prior art. (Pl.'s Sur-Reply Br. Opp'n Summ. J. 7) However, as the Federal Circuit has explained, "the prosecution history can often inform the meaning of the claim language by demonstrating how the inventor understood the invention." Phillips, 415 F.3d at 1317. Here, the prosecution history demonstrates that UTStarcom understood the invention to tunnel registration requests from the foreign agent to the home agent and to tunnel registration replies from the home agent to the foreign agent. UTStarcom had the opportunity to be more careful in its choice of words and to correct its "inartful phrasing." It did not do so. In fact, it used the same language on two separate occasions during prosecution. We can only assume that UTStarcom meant exactly what it said.

For the above stated reasons, we construe "tunnel header" to be the portion of a tunnel packet with information needed to route the registration request. UTStarcom's and Starent's proposed constructions of "key field" are very similar. The only notable difference between the two constructions is that UTStarcom argues that the key field is located in a portion of a data packet whereas Starent argues that it is located in a portion of a tunnel packet. 6 Given our construction of "tunnel header" that embraces the concept of a tunnel packet, we adopt Starent's construction of "key field." Therefore, we construe the "key field" to be a specific field for identification located in the portion of a tunnel packet with information needed to route a
 registration request.

6 UTStarcom argues that the term "tunnel packet" - as opposed to "tunnel" or "data packet" - has no recognized meaning in
the art. However, UTStarcom does not provide any support for this assertion. Therefore, we find this distinction meritless.

GO BACK

4615

1. "Tunnel Identifier"

Starent argues that summary judgment is appropriate because the ST products do not contain a tunnel identifier when
performing GRE tunneling. The parties dispute the meaning of the term "tunnel identifier." We must first determine the
meaning of the term "tunnel identifier" and then determine whether the ST products contain a tunnel identifier under the
term's proper meaning. AK Steel Corp., 344 F.3d at 1238.

UTStarcom asserts that the Court should adopt the plain meaning of the term "tunnel identifier" and broadly construe the
term to mean an indicator used to identify a particular tunnel. Starent, on the other hand, asserts that when the tunnel
identifier is read in light of the specification and prosecution history, it should be construed more narrowly to mean an
indicator such as an integer that specifies a tunnel, but does not use addresses.

We agree with Starent that a reading of the term tunnel identifier in light of the specification and prosecution history
requires the term to be construed more narrowly to mean an indicator such as an integer that specifies a tunnel, but does not
use addresses. The abstract of the '905 patent explicitly states that "(t)he tunnel identifier is independent of (i) a home
address of the mobile node and (ii) an address of a home agent for the mobile node." (Def. St., Tab 2, '905 patent, at (57).)
The abstract has been held to be "a potentially useful source of intrinsic evidence as to the meaning of a disputed claim
term. Tate Access Floors, Inc. v. Maxcess Techs., Inc., 222 F.3d 958, 966 n.2 (Fed. Cir. 2000). UTStarcom even admits that
"[t]he Abstract may indeed be probative evidence for claim construction." (Pl.'s Sur-Reply Br. Opp'n Summ. J. 5) But,
UTStarcom asserts that the abstract "is no more probative than the rest of the specification and the plain meaning of the
claim language." Id. UTStarcom, however, does not cite any case law to support this assertion. As will be seen below, the
abstract is but one factor in our determination of the proper claim construction. We choose not to give greater weight to the
abstract than to any other evidence found in the intrinsic record of the patent and its prosecution history.

The body of the specification also supports the construction that a tunnel identifier does not use addresses because the
specification refers to the tunnel identifier and the addresses as distinct items. The specification specifically states:

At step 210, the home agent saves the tunnel identifier and sends a registration response to the PDSN. The registration
response may include the IP address of the mobile, the IP address of the home agent and authentication information using
which the mobile node can authenticate the home agent. The registration response may include other types of information,
as well. The home agent may fill a field in the header (e.g., the key field in a header) with the tunnel identifier and sends
[sic] the data packets to the PDSN.

(Def. St., Tab 2, '905 patent, col.4, ll. 37-45) This passage demonstrates that the tunnel identifier is distinct from the
addresses of the mobile node and the home agent. If, as UTStarcom claims, the tunnel identifier included addresses, it
would be redundant for UTStarcom to separately mention the tunnel identifier and the addresses of the mobile node and the
home agent in the above passage. Therefore, we interpret the above passage to require the tunnel identifier and the addresses
of the mobile node and the home agent to be mutually exclusive.

A review of the prosecution history further supports the interpretation that the tunnel identifier does not use addresses. The
United States Patent and Trademark Office ("USPTO") rejected the originally filed independent claims as being anticipated
by U.S. Patent No. 6,466,964 ("Leung") under 35 U.S.C. § 102(e). (Def. St., Tab 3, Prosecution History, January 11, 2005
Office Action at 2 (FH-0178).) Specifically, among other reasons, the USPTO stated that "Leung anticipates determination
of a tunnel ID" and "Leung anticipates assigning a tunnel ID." (Id. at 3 (FH-0179), 5 (FH-0181).) In response to this rejection, UTStarcom amended the claims to state that "the tunnel identifier is independent of (i) a home address of the mobile node and (ii) an address of a home agent." (Def. St., Tab 3, Prosecution History, April 29, 2005 Response to January 11, 2005 Office Action at 5 (FH-0157).) In the Remarks section of the Office Action Response, UTStarcom argued that Leung did not teach a tunnel identifier that was independent of the addresses of the mobile node and the home agent:

In Leung, and in Mobile IP generally, both the mobile node's home address and [home agent ("HA")]] address are needed to uniquely identify the correct mobile node to which to route packets, because two mobile nodes connected to the same [foreign agent ("FA")]] could have identical home addresses, which each has a different HA.

…

Claim 1, in contrast, is directed to a method where the tunnel identifier that is used to identify the connection to the mobile node is independent of the mobile node's home address and HA address. This identifier, perhaps just a simple integer, is merely extracted from packets sent from the HA to the FA . . . without the FA needing to extract both the home address and the HA address . . . As such, with the method of claim 1, the connection to the mobile node can be identified more quickly (i.e., a "PDSN Fast Tunnel Lookup").

(Id. at 16 (FH-0167).) This amendment to the claims and accompanying arguments clearly indicate UTStarcom's intention to narrow the claim scope to include a tunnel identifier that is independent of the mobile node's home address and the home agent address.

The USPTO rejected UTStarcom's amendments as being anticipated by U.S. Patent No. 6,856,624 ("Magret") under 35 U.S.C. § 102(e). (Def. St., Tab 3, Prosecution History, August 15, 2005 Final Office Action at 2 (FH-0125).) In response to this rejection, UTStarcom withdrew its previous claim amendment, which required the tunnel identifier to be independent of the mobile node and home agent addresses. (Def. St., Tab 3, Prosecution History, October 17, 2005 Response to August 15, 2005 Final Office Action at 2 (FH-0104).) However, in the Remarks section of the response, UTStarcom did not explain the reason for the withdrawal nor did it attempt to reclaim a broader interpretation of the term "tunnel identifier." In fact, contrary to any inference that may be drawn from the withdrawal of the amendment to the claim, UTStarcom reiterated the arguments it had made in its previous response and stated "Leung . . . teaches using both a mobile node's home address and home agent address to identify a connection to a mobile node." (Id. at 12 (FH-0114).) Therefore, UTStarcom continued to distinguish the Leung prior art on the ground that it used addresses in the tunnel identifier.

UTStarcom further maintained a consistent interpretation of "tunnel identifier" in its combined response to the August 15, 2005 Final Office Action and January 10, 2006 Advisory Action. In that response, UTStarcom argued:

Leung contains no advance beyond the standard Mobile-IP practice of uniquely identifying a mobile node using a combination of the mobile node's home address and home-agent address.

…

While the present invention involves a fast lookup using the tunnel identifier to directly access the tunnel table, which is indexed by tunnel identifiers, Magret teaches . . . the necessity to search the visitor cache for an entry having a value that matches the temporary IP address in that extra tunnel header.

…

Leung contains no teaching that goes beyond the standard Mobile-IP practice of maintaining a visitor list and searching that visitor list for a matching combination of home address and home-agent address . . . Again, there is no indication in Leung that that value is anything other than a reference number that the foreign agent uses as shorthand for the home-address/home-agent-address combination that the foreign agent actually uses to identify connections to mobile nodes.

- 4840 -
UTStarcom argues that its withdrawal of the claim amendment rendered the amendment and the supporting arguments a nullity. The Federal Circuit has stated that "[a]lthough a disclaimer made during prosecution can be rescinded, permitting recapture of the disclaimed scope, the prosecution history must be sufficiently clear to inform the examiner that the previous disclaimer, and the prior art that it was made to avoid, may need to be re-visited." Hakim v. Cannon Avent Group, PLC, 479 F.3d 1313, 1318 (Fed. Cir. 2007). Here, UTStarcom made no attempt to reclaim the disclaimed meaning of the term "tunnel identifier." Therefore, the withdrawal did not act to nullify the narrower definition of the term. Even if the withdrawal acted to render the amendment and the supporting arguments a nullity, UTStarcom made identical arguments limiting the scope of the term in subsequent responses, thereby reviving the claim limitation.

--- Footnotes ---

4 However, UTStarcom is unable to direct us to any case law that supports this assertion.

--- End Footnotes ---

UTStarcom also argues that we should adopt its broader definition of tunnel identifier because "[u]nder the doctrine of claim differentiation, the express recitation of the GRE tunneling protocol in dependent claim 4 is evidence that the broader, independent claims are not so limited, and encompass the use of other standard tunneling protocols and the full range of associated headers and possible tunnel identifiers." (Pl.'s Br. Opp'n Summ. J. 7) The doctrine of claim differentiation creates a "presumption that an independent claim should not be construed as requiring a limitation added by a dependent claim." Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380 (Fed. Cir. 2006). "[T]his doctrine is not a rigid rule but rather is one of several claim construction tools." ICU Medical, Inc. v. Alaris Medical Systems, Inc., 558 F.3d 1368, 1376 (Fed. Cir. 2009). The court can choose to not apply this doctrine in its claim construction analysis, even if the result would lead to some redundancy. Netcraft Corp. v. eBay, Inc., 549 F.3d 1394, 1400 n.1 (Fed. Cir. 2009) (finding plaintiff's claim differentiation arguments unpersuasive when several references in the specification suggested that the term should be construed more narrowly); see also Nystrom v. Trex Co., 424 F.3d 1136, 1142-43 (Fed. Cir. 2005) (construing a term more narrowly because that construction was supported by the specification and prosecution history even though the doctrine of claim differentiation suggested that the term should be construed more broadly). We are not persuaded by UTStarcom's claim differentiation argument because the specification and prosecution history provide overwhelming support in favor of Starent's proposed claim construction.

--- Footnotes ---

5 Dependent claim 4 depends from claim 2 and states that "each of the data packets includes a header and the header is a Generic Routing Encapsulation (GRE) header."

--- End Footnotes ---

UTStarcom also argues that its proposed claim construction is supported by the specification. Specifically, UTStarcom points to the following passage: "The tunnel identifier may be assigned randomly or non-randomly. The tunnel identifier may be in any form, for example, an integer. Other examples of tunnel identifiers are possible." (Def. St., Tab 2, '905 patent, col.5, ll. 43-46.) UTStarcom uses this passage to claim that "[t]here are no words or expressions of manifest exclusion or restriction in the patent to justify limiting the plain meaning of the term 'tunnel identifier.'" (Pl.'s Br. Opp'n Summ. J. 6-7) However, we are not persuaded by this single passage to adopt UTStarcom's proposed claim construction because as discussed above, there are several instances in the specification and prosecution history where UTStarcom limited the scope of the term "tunnel identifier."

Based on the references in the specification and arguments presented during prosecution, we construe the term "tunnel identifier" to mean an indicator such as an integer that specifies a tunnel, but does not use addresses.

GO BACK

4616

As to the terms "turn-on period," "turn-off period," "turn-on delay period," "turn-off delay period," the Court sees little substantive difference between the parties' constructions and, therefore, adopts Power-One's proposals as the more helpful to the jury. The specification of the '999 patent states that a "delay period" is a "period of time to wait," which would comport with the plain and ordinary meaning of the term. '999 patent, col. 2:31-32. Both parties include this aspect in their proposed constructions. Thus, the Court construes these terms as "the time to wait from an event before turning on an output," "the time to wait from an event before turning off an output," "the time to wait from an event before turning on an output," and "the time to wait from an event before turning off an output," respectively.

As to the terms "turn-on data" and "turn-off data," the '999 patent specification discusses turn-on and turn-off data at col. 2:14-24. In particular, the specification states "[e]xamples of output timing parameters include when to generate the output (e.g., sequencing data, turn-on data), when to stop generating the output (e.g., termination data, turn-off data), the slew rate of the output (e.g., slew rate data), etc." At col. 4:33-52, the '999 patent specification recites and discusses exemplary values of "turn-on data" and other data. In these cases, the "turn-on data" specifies when the output is to be generated. The Court finds that Power One's proposed construction is too broad, while Artesyn's proposed construction is unnecessarily limiting. Accordingly, the Court will construe "turn-on data" to mean "data indicating when to generate an output," and the Court will construe "turn-off data" to mean "data indicating when to stop generating an output."

### PART THREE

The Disputed Claims

Avocent contends that ClearCube's accused products infringe claim 1 of the '997 patent, and claims 1, 6, and 16-18 of the '919 patent. n31 Claim 1 of the '997 patent, and claims 1, 16, and 18 of the '919 patent, are independent claims. Claim 6 of the '919 patent is dependent on claim 1, and claim 17 of the same patent is dependent on claim 16. Claim 1 of the '997 Patent recites:

1. A system for transmission of analog color video signals between a source of said signals and a video monitor, being at spaced locations, comprising: n32

   a plurality of computers, each providing, as a set, said color video signals;

   a switch receiving said sets of said color video signals, each with respect to a common reference, from said computers and providing a selected said set of said color video signals as an output;

   a signal transmitter at a first location responsive to said output of a set of said color video signals, said transmitter, including n33 an amplifier for each said color video signal of one of said sets for providing a color video signal output and wherein n34 at least a high frequency portion of each said color video signal has been amplified as a direct function of frequency and providing both an inverting and non-inverting signal, available as an output;

   a plurality of video transmission circuits, each said circuit having first and second ends, respectively, one circuit for each of said color video signals of one of said sets and each said circuit having an input responsive to an output of said transmitter at said first end, and each said circuit having a responsive signal output at said second end;

   a signal receiver at a second location responsive to each of said transmitted signal outputs and color video signal at said second end, including an amplifier for each said color video signal for providing a discrete color video signal with respect to a common reference; and

   signal means responsive to said receiver for providing each said color signal, each with respect to a common reference, to an analog color video monitor. n35

Claim 1 of the '919 Patent recites:

- 4842 -
1. An extended-in-length computer video communications link for transmitting computer video signals comprising:
   a source of computer video signals including red, green, and blue video signals,
   a video transmitter comprising a plurality of amplifiers, one of each said amplifiers for each of said red, green, and blue video signals, each said amplifier comprising:
   a signal input for receiving a one of said red, green and blue video signals,
   frequency sensitive compensating circuitry responsive to a said video signal so that said amplifier provides a first video signal that increases in amplitude with increasing frequency at a first output and a second video signal that is an inverse of said first video signal at a second output,
   a twisted pair of conductors for each said amplifier, with first and second conductors of said twisted pair coupled at one end to respective said first and second outputs of said amplifier,
   an adapter for each of said twisted pair of conductors, each said adapter coupled to an opposite end of a respective one of said twisted pair of conductors, each said adapter receiving said first video signal and said second video signal and providing a respective said video signal as a single ended output, and further configured to provide a ground reference potential for said transmitter at said adapter, whereby need for a reference ground conductor between said transmitter and said adapter is eliminated. n36

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n31 Doc. no. 1 (complaint); see also doc. no. 125 (Avocent Huntsville's Summary and Background of the Technology Embodied in the Claims of the Patents-in-Suit), at 1.

n32 The word "comprising" is a term of art in Patent law that means the claim includes all of the elements that follow in the body of the claim statement, but does not exclude additional, unrecited elements. See, e.g., Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327-28 (Fed. Cir. 1999). Claims that use "comprising" are sometimes referred to as "open claims." See, e.g., Vivid Techs. v. American Science & Eng'g, 200 F.3d 795, 811 (Fed. Cir. 1999).

n33 The word "including" is another term that, like "comprising," signals the claim statement encompasses all of the elements that follow, but does not exclude additional, unrecited elements. See Robert C. Faber, LANDIS ON MECHANICS OF PATENT DRAFTING § 7 (4th ed. 1999).

n34 The word "wherein" is another term of Patent art that customarily signals the claim includes all the elements that follow, but does not necessarily exclude additional, unrecited elements. See id.

n35 '997 patent, col. 13 & line 14 through col. 14 & line 15. A copy of the '997 patent is located, among many other places in the record, at doc. no. 79 (Avocent's Combined Memorandum), Ex. A(2).

n36 '919 patent, col. 18, lines 12-41. The '919 patent is located, among many other places in the record, at doc. no. 79 (Avocent's Combined Memorandum), Ex. A(1).

Claim 16 of the '919 Patent recites:

16. A computer video signal communications system for selectively coupling sets of R, G, B computer color video signals from one of a plurality of computers to a separately located color monitor, said system comprising:

   a transmitter including:

   switching means for selectively providing a said set of said color video signals from a selected said computer, and

   a first signal format converter responsive to each said color signal of a said set of color signals from said switching means for converting a signal format of each said color signal from single ended format to a balanced format;

   a plurality of sets of twisted pair conductors, each set of said conductors having a first end and second end, with a said first end of each of said sets of conductors receiving a discrete color video signal from said transmitter;

   a receiver coupled to said second ends of said sets of said twisted pair conductors and including:

   a plurality of second signal format converters for converting a said balanced format of each said discrete color video signal from each said set of conductors from balanced to unbalanced format; and

   signal means responsive to unbalanced format signals from said receiver for coupling color video signals to a color video monitor. n38

Claim 18 of the '919 Patent recites:

18. A computer video signal communications system for selectively coupling a set of R, G, and B computer color video signals from one of a plurality of computers to a separately located color monitor, said system comprising:

   a transmitter including:

   switching means for selectively providing said set of said color video signals from a selected said computer, and

   a first signal format converter responsive to each said R, G and B color video signal for converting a signal format of each said R, G and B color video signal from single ended format to a balanced format;

   a set of twisted pair conductors for each said balanced format R, G, and B color video signals, each said set of twisted pair conductors having a first end and a second end, with a said first end of each of said sets of twisted pair conductors
receiving a discrete one of said balanced format R, G, and B color video signals from said transmitter;

a receiver coupled to said second ends of said sets of twisted pair conductors and including:

frequency compensation means for boosting a frequency response of each said R, G and B color video signal directly as a function of frequency;

a plurality of second signal format converters for converting said balanced format of each said R, G and B color video signal from each said set of twisted pair conductors from balanced to unbalanced format; and

signal means responsive to said unbalanced format signals from said receiver for coupling said R, G and B color video signals to a color video monitor. n40

PART FOUR

Claim Construction Decisions

A claim construction hearing was held on February 22 and 23, 2006. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 372, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996) (holding that the first issue in any patent infringement case is that of "claim construction": the interpretation of words used in a patent's claim, "the portion of the patent document that defines the scope of the patentee's rights"); see also, e.g., Rockwell International Corporation v. United States, 147 F.3d 1358, 1362 (Fed. Cir. 1998) ("The first step in any invalidity or infringement analysis is claim construction.") (citations omitted. The memorandum opinion and order entered on March 15, 2006, set forth this court's interpretation of the following, disputed, claim terms. n41

"Twisted pair" wiring, which is used in the '919 patented invention to conduct analog video signals, may be either "shielded" or "unshielded."

The term "amplifier," as it is claimed in both the '997 and '919 patents, was defined as "a circuit (or a device when connected in a circuit) that draws power from a source other than the input signal and provides an output signal that reproduces the essential features of the input signal."

The term "discrete," as it is used in the claims of both patents, simply means that a color video signal (e.g., red) is separate or distinct from the other two color video signals (e.g., green and blue).

Finally, the phrase "for said transmitter," as recited in claim 1 of the '919 patent, was construed as meaning "from the signals received from the transmitter."

8. Two way interactive communication
The term "two way interactive communication" appears in the preamble of claims 35, 36, 37 (by virtue of its dependency on claim 35), and 38 (by virtue of its dependency on claim 36) of the '774 patent. The plaintiff's proposed construction is "a non-simultaneous exchange of information or commands (handshake) between a host computer and a remote user station." The defendants propose "connection which assigns an upstream channel to a single remote link adapter." The court has considered the arguments of the parties and construes the term "two way interactive communication" to mean "a bi-directional exchange of information or commands between a host computer and a remote computer."

C. "Type Information"

The invention parses a hypermedia document and learns the location of at least a portion of some object. '906 Patent, col. 18, ll. 13-18. This object has "type information" associated with it, and this type information is utilized by the browser to identify and locate the executable application. '906 Patent, col. 18, ll. 18-22. What does type information mean?

1. The Claim and Specification

The claim language suggests that type information provides a clue to the browser to assist it in identifying and locating the executable application. Microsoft seeks to exclude from the scope of "type information" any tag that simply tells the browser which application to use. In its view, type information is limited to data types. For example, according to Microsoft, type information cannot be "WinAmp," it must be ".mp3." If the type information tells the browser what application to use, then the browser has very little left to do in identifying and locating the application. But nothing in the claim language says there has to be a challenge for the browser; if the author of the hypermedia document being parsed wants to make it easy for the browser, and tell it what application to use, so be it. Identifying an application will often convey information as to the type of object involved. For example, identifying the application x-vis conveys that the object is a three-dimensional image; this gives the browser some idea of the character of the object. The claim says type information is associated with the object -- both application names and data types can be associated with objects and both can convey useful information to the browser for it to use in identifying and locating the executable application. Neither possibility is foreclosed by the claim language.

The specification squarely supports this view. The inventors gave examples of type information in the form of the HTML TYPE element of an EMBED tag: "Examples of values for the TYPE element are 'application/x-vis' or 'video/mpeg'. The type 'application/x-vis' indicated that an application named 'x-vis' is to be used to handle the object..." '906 Patent, col. 13, ll. 2-5. Thus, type information could be either the application itself (x-vis) or the data type (video/mpeg).

Microsoft argues that to simply identify an application no longer "associates" type information with the object and thus would read "associated with" out of the claim language. I disagree. There is no evidence that association is a term of art, and I give it a plain and ordinary meaning. Association requires only some connection between the object and the type information; type information does not have to be integrated into the object to be associated with it. In the example used in the specification, by identifying x-vis as the TYPE element of the EMBED tag, the hypermedia document is associating x-vis with the object, which is identified by the HREF element, also within the EMBED tag. 14 '906 Patent, col. 12, l. 54 - col. 13, l. 18. That is all the claim language requires.

2. The File History

Microsoft says the embodiment in the specification is wrong; the inventors disavowed such a construction of type information in the course of prosecuting the patent. Microsoft acknowledges that this reading would mean that the inventors did not claim one of the embodiments in the specification. It is plausible that during a lengthy prosecution history, patentees
fail to update the specification language as they amend the claims. However, in this case, as noted above, I do not find the specification's example of x-vis as the TYPE element to contradict the ordinary meaning of the claim language. Cf. Novo Nordisk of North America, Inc. v. Genentech, Inc., 77 F.3d 1364, 1369 (Fed. Cir. 1996) (claim language "unquestionably" does not cover specification language). Moreover, given that the primary example used by the patentees in describing the invention, indeed the invention's apparent origin, is the ability to automatically invoke x-vis to allow embedded interaction with 3-D embryo images, I find it difficult to read that embodiment out of the claim. See Vitronics, 90 F.3d at 1583 (interpreting claim to exclude preferred embodiment is rarely correct). To reach such a conclusion, the file history must be "highly persuasive." Id.

a. The Khoyi Patent

At the time of the examiner's rejection based on Khoyi, the claim language said (emphasis added):

wherein said first distributed hypermedia document includes an embed text format that specifies the location of an object external to the first distributed hypermedia document and that specifies type information utilized by said browser to identify and locate an executable application….

The examiner found that Khoyi teaches the ability to "invoke a corresponding object manager (a program external to the document) in response to an invocation request to process and control the object" and teaches "links specifying the object and type." File History, Paper # 12, p. 3 (emphasis added). The applicants amended the claim to read (emphasis added):

wherein said first distributed hypermedia document includes an embed text format… that specifies the location of at least a portion of an object external to the first distributed hypermedia document, wherein said object has type information associated with it utilized by said browser….

File History, Paper # 14, p. 2. Microsoft says this amendment, by adding "associated with" overcomes the Khoyi prior art by implying that type information must be data type. There is no substantive discussion in the File History (from either the applicants or the examiner) relating this amendment to Khoyi. 15 There is no discussion of how this amendment changes, if at all, the meaning of type information. Given the tenor of Paper # 14, which notes the limitations of Khoyi, one could read the amendment to be an attempt to broaden, not narrow, the claim. Perhaps the amendment signals to the examiner that this invention can do more than Khoyi -- it does not use type information in a Khoyi-like manner specified by the source document, but is more flexible. In any event, given the ambiguous nature of the amendment's relationship to Khoyi, I think it insufficient to mandate a claim construction that excludes a preferred embodiment stated in the specification.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

15 Professor Felten testified that, as he read the file history, the applicants never distinguished Khoyi based on how type information was used. Felten Direct Examination, October 25, 2000, Tr. at 102. Professor Dunsmore testified that he was not sure why the applicants made the amendment, but that he assumed the change would help in acceptance by the examiner. Dunsmore Direct Examination, October 26, 2000, Tr. at 233.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

b. The Koppolu Patent

Microsoft next argues that the applicants, in their response to the Koppolu-based objection, revealed an intent to disavow type information as a simple application identifier. Koppolu-OLE, according to the applicants, used a binary pointer mechanism and an operating system registry to identify objects with containee server applications. File History, Paper # 19, p. 9. This CLASSID system, not the compound document's text, is used to determine object type. 16 Id. I do not read this to be an explicit disavowal of the possibility that the '906 browser reads a named application as a type associated with an object; instead I read this reference to distinguish a method of using numerical identifiers and platform-dependent registries to perform the association. See II.D., infra.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
A CLASSID is a 32-bit number that is a unique identifier for a particular component. Michael Wallent Direct Examination, October 25, 2000, Tr. at 169. The Windows operating system maintains a database registry of CLASSIDs, linking the 32-bit numbers with their corresponding application. Without recourse to this registry, the CLASSID is essentially meaningless.

Similarly, the applicants' discussion of the cross-platform benefits of the '906 invention does not disavow the possibility that applications are identified as type information. See File History, Paper # 19, pp. 21, 25. The applicants were not addressing type information, they were saying their invention is better than OLE because it is not platform-dependent: the invention vests more functionality in the hypermedia document and browser than allowed in the OLE system, according to the applicants. Id. Microsoft says it is a logical inference that, since OLE uses the CLASSID architecture, and since that platform-dependent system is generally equivalent to simply naming an application to use with certain objects, the inventors must have been disclaiming this more general approach. I disagree.

In both Paper Nos. 14 and 19, the applicants addressed objections based on prior art, but there is no explicit discussion of how the type information language overcomes the objection. While Microsoft makes plausible arguments by drawing inferences from the file history, I cannot say the history is anything but ambiguous. Given that the claim language supports a construction of type information that includes naming an application, and given that the specification's preferred embodiment explicitly embraces such a form of type information, I reject a reading of the claim that hoists ambiguous file history above the claim and specification.

III. Conclusion

A. An "executable application," as used in the '906 Patent, is any computer program code, that is not the operating system or a utility, that is launched to enable an end-user to directly interact with data.

B. "Type Information" may include the name of an application associated with the object.

A. USB (UNIVERSAL SERIAL BUS)

The '788 patent specification states:

The present invention relates generally to a USB (Universal Serial Bus) to VGA (Video Graphics Array) converter, and in particular to a USB-to-VGA converter connectable between a USB port of a computer and a VGA display device.

Id. at 1:6-9. The parties dispute the meaning of "USB" and propose the following constructions:

<table>
<thead>
<tr>
<th>Term</th>
<th>DisplayLink's proposed construction</th>
<th>MCT's proposed construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB</td>
<td>Universal Serial Bus, the technology described in the Universal Serial Bus Specification Revision 2.0 and its predecessor revisions.</td>
<td>USB has an ordinary and customary meaning to a person of ordinary skill in the art. USB generically refers to any serial bus specifications which support USB based display signals from the host computer and which are compatible with any USB port/plug.</td>
</tr>
</tbody>
</table>

MCT asserts that the term "USB" refers to any serial bus that supports USB and has a compatible USB port or plug. MCT
asserts that a person of ordinary skill in the art would associate the term "USB" by its unique and characteristic plug. DisplayLink argues that the term "USB" as used in the patent refers to a specific standard rather than to any serial bus specification that is compatible with any USB port/plug. Additionally, DisplayLink asserts that that standard is Universal Bus Specification Revision 2.0 and any prior versions of that standard because these were the specifications that existed and were known at the time of the filing of the '788 patent.

Claim terms should be construed based on how that claim term was understood by a person of ordinary skill in the art at the time of the invention. SmithKline Beecham Corp. v. Apotex Corp., 403 F.3d. 1331, 1338-39 (Fed. Cir. 2005). The parties dispute whether a person of ordinary skill in the art would have understood at the time of the alleged invention that the term "USB" meant a technology utilizing a distinctive port/plug or a bus that complied with a particular industry standard. USB technology was developed in an effort to create a standardized universal port for connecting peripheral devices to a personal computer. 3 Tr. at 18:21-24. Intel introduced the first version of USB, version 1.0, in 1995. Id. at 19:2-3. In 1999, Intel introduced a second USB version, version 1.1. Id. at 19:7-8. This technology was fast enough to run such peripherals as a keyboard, mouse, modem, or printer. Id. at 19:18-22. In April of 2000, Intel released USB 2.0, which had sufficient speed to run a monitor. Id. at 19:10-12. Thus, with USB 2.0, users were able to attach all of their peripherals to their PC using the standard USB interface. Id. at 19:24-20:8.

--- Footnotes ---

2 DisplayLink’s expert, Alan H. Jones, Ph.D., asserts that a person of ordinary skill in the art as it relates to the ’788 patent would have "at least (1) a degree in electrical engineering or computer science and (2) experience in hardware design, including (a) work on the concepts of timing, data throughput, and how the device will need to interact with the intended system and (b) implementing devices that comply with well-known industry standards such as the USB and VGA standards." Jones decl. at P 23. MCT’s expert, Paul S. Min, Ph.D., submits that a person of ordinary skill in the art would have "a minimum of Bachelor of Science degree in Electrical Engineering, Computer Science, or Computer Engineering, and one year experience in the electronics industry." Min decl. at P 23. The court’s construction of the terms in dispute does not depend on whose definition of a person of ordinary skill in the art is adopted. It does not appear that the proposed persons of ordinary skill would construe the disputed language differently.

3 As used herein, references to the "Tr. at    “ refer to page and line numbers of an uncertified transcript of the claim construction hearing held on May 13, 2008.

--- End Footnotes ---

At the hearing, MCT’s electrical engineering expert, Paul S. Min, Ph.D., agreed that the term "USB" is defined by an industry accepted standard. Tr. at 44:7-9. Further, Dr. Min agreed that if a person of ordinary skill in the art wanted to design a system that implemented the USB standard, he or she would turn to the most recent available USB standard. Id. at 44:14-17; 46:10-17. Currently, this standard is contained in the Universal Serial Bus Specification Revision 2.0. Id. at 19:10-12.

In its claim construction brief, MCT states that:

It is common for a computer system to be attached to peripheral devices such as inkjet and laser printers. These devices usually have a cable that attaches on one end of the computer. One way these devices connect to a computer is through a USB port on a the computer. The USB port and USB cable are built based upon an industry accepted USB standard. USB is generically understood in the field to refer to USB without any reference to particular versions of the standard.

MCT Br. 23-24. Thus, MCT itself recognizes that a person of ordinary skill in the art would understand the term "USB" to reference an industry accepted standard, not the shape of a port/plug. Accordingly, the court agrees with DisplayLink that the term "USB" refers to a type of serial bus that meets the requirements of the industry standard.

The parties also dispute whether the term "USB" as used in the ’788 patent is limited to the technology described in the Universal Serial Bus Specification Revision 2.0 and its earlier versions. 4 DisplayLink asserts that the term as used in the ’788 patent must be limited to the 2.0 specification and any earlier version because "[i]t is no way to know whether or not 'future' versions of the USB standard will [be] substantially similar to or substantially different from the versions that existed at the time of the ’788 patent application was filed." DisplayLink Br. at 5.

--- 4849 ---
4 The most current USB specification is version 2.0.

The '788 patent is silent as to a particular USB standard. However, a person of ordinary skill in the art understood USB to be the technology disclosed in the 2.0 specification (or the earlier versions) and what they would necessarily look to in order to design a USB compliant product. Dr. Min testified that in relation to the term "USB controller" the device communicated according to a USB standard. Asked what he meant by "USB standard," Dr. Min explained that at the time of filing the '788 patent specification, the latest available standard in 2001 (one year before the filing date of the '788 patent) "would have been what a person of ordinary skill in the art would look at" to determine what the USB standard meant. Min Dep. 106:21-107:9. The parties do not dispute that this standard was USB 2.0.

However, at the hearing the parties noted that USB 3.0 is set to be released in the near future. MCT seeks to have a construction that would cover this future version. Display Link objects. Since it is impossible to know what that standard specification will include, the question as to whether the patent will read on a serial bus using a future revision of the USB standard is not ripe for decision.

Accordingly, the court construes the term "USB" as follows:

"USB" is an abbreviation for "Universal Serial Bus," which is a computer standard technology described in Universal Serial Bus Specification Revision 2.0 and the prior versions of this standard. The court does not reach the issue of whether the term as used in the patent is compatible with possible future versions of the USB specification.

The parties propose the following constructions of the term "USB based display signals":

<table>
<thead>
<tr>
<th>Term</th>
<th>DisplayLink's proposed construction</th>
<th>MCT's proposed construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB based display signals</td>
<td>USB encoded display signals</td>
<td>USB signals containing display information</td>
</tr>
</tbody>
</table>

The parties dispute, to the extent the court understands the distinctions made by the parties, is whether USB based display signals include USB signals that merely contain some display information (MCT's position) or whether the display signal itself must be in a USB encoded format (DisplayLink's position).

The plain language of the claims suggests that USB based display signals are USB encoded. To interpret USB based signals as referring to any USB signal containing display information would seem to read "based" out of the term being construed. Both parties' experts appear to agree that USB display base signals are USB encoded. Jones decl. at PP 45-46;
MCT argues that USB based display signals may include such control or packet information as required by the USB standard. DisplayLink does not disagree to the extent the USB standards requires certain control or protocol information, such information would be included in USB based display signals. The court construes USB based display signals as follows:

"USB based display signals" are USB encoded display signals.

D. USB CONTROLLER

The USB controller of the '788 patent refers to the device positioned between the USB port of a host computer and the bridge of the USB-to-VGA converter. '788 patent Fig. 1. The parties propose the following constructions:

<table>
<thead>
<tr>
<th>Term</th>
<th>DisplayLink's proposed construction</th>
<th>MCT's proposed construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>USB Controller</td>
<td>Component(s) that controls the receipt, storage, and routing of USB encoded data.</td>
<td>Device that communicates with the computer according to the USB standard and communicates with the bridge in the signal form understood by the bridge.</td>
</tr>
</tbody>
</table>

MCT argues that DisplayLink's construction introduces words "receipt, storage, and routing" of USB "encoded data" and those requirements are not supported by the specification or prosecution history. DisplayLink argues that MCT's proposed construction does not give any meaning to the claim term. Further, DisplayLink asserts that its proposed construction, including the terms "receipt, storage, and routing," is supported by the claims and the specification. DisplayLink argues that the USB controller is not a passive device that simply receives data and sends on signals. Rather, the USB controller is an active device that controls the receipt, storage, and routing of the USB encoded data.

Claim 1 of the '788 patent claims "a USB controller disposed external to the computer for receiving exclusively therethrough USB based display signals from the computer, the USB controller issuing a bus command." Id. at 4:60-65. The '788 patent specification describes the USB controller as a device that is "connectable to a USB port 210 of a host computer 200 for receiving USB based display signals from the host computer 200." Id. at 2:27-29. The USB controller is connected to a bridge that receives USB based signals from the USB controller. Id. at 2:26-30. The specification states that the bridge contains a first-in-first-out ("FIFO") controller that "issues control instructions to the USB controller" to forward signals from the host computer to the FIFO controller. Id. at 2:54-59.

At the hearing, DisplayLink's counsel stated that the key dispute it has with MCT's proposed construction of the term is that MCT's proposed definition changes the controller function to a device that merely communicates. Tr. at 112:1-7. DisplayLink asserts that the controller is actually doing the control function. Tr. at 111:22-23. MCT indicated that its main objection to DisplayLink's proposed construction is DisplayLink's inclusion of the term "encoded." Tr. at 112:17-19. In response to the parties' proposals, the court suggested that the term "USB controller" be construed as a device that receives a USB display signal, holds it until it receives a bus command, and then forwards the USB display signal out on a FIFO basis. The parties did not voice specific objection to this proposed construction. Tr. 112:1-23. The court believes that its proposal...
is consistent with the patent disclosure. Accordingly, the court construes the term "USB Controller" as follows:

"USB Controller" is a device that receives a USB display signal, holds it until it receives a bus command, and then forwards the USB display signal out on a FIFO basis.

17. "data to be permanently stored in memory in an unalterable fashion" ('409 patent, claim 8)

AVID argues that the term should be construed as "data to be stored in memory in a non-volatile manner and in such a way that the data cannot be changed." According to AVID, the claim and the specification use the word "permanently" in conjunction with both "unalterable" and "alterable." Therefore, AVID states that "permanently" must mean that the data is stored in a non-volatile manner (i.e., in non-volatile memory), such that it is retained in the absence of power.

The Defendants propose a construction of "data to be permanently stored in memory in a manner that does not permit the data to be altered after it is initially stored therein." The Defendants argue that the disputed phrase is used in Claim 8 in relation to two steps: (1) "receiving data to be permanently stored in memory in an unalterable fashion, said data being known as unalterable data;" and (2) "storing said unalterable data in an unalterable memory."

The Court agrees with AVID's proposed construction and adopts it. The phrase means "data to be stored in memory in a non-volatile manner and in such a way that the data cannot be changed."

18. "an unalterable memory" ('409 patent, claim 8)

AVID argues that the term should be construed as "memory wherein the stored data cannot be changed." According to AVID, the specification at 1:64-68, 2:7-12, and 7:10-17 supports what it argues is the plain meaning of the term.

The Defendants propose a construction of "a first type of memory whose content cannot be changed because of the nature of the first type of memory." The Defendants argue that the term "unalterable memory" has no accepted meaning in the art. However, according to the Defendants, the specification teaches at 7:10-13 that the laser PROM "contains data which uniquely identifies the tag and is unalterable because of the nature of the laser PROM." The Defendants argue that the specification thus serves to define this term as it is used in the claims. The Defendants also submit an alternative construction: "a non-reprogrammable type of memory in which the data is written once and cannot be changed."

After carefully considering the parties' proposed constructions, the Court construes the term to mean "a memory in which the data is written once and cannot be changed."

8. "occurring under the direction of the auctioneer"

The parties dispute the meaning of the term "occurring under the direction of the auctioneer" appearing in Claims 1 and 2. When read in context with the language of the remainder of this claim, and in view of the inventors' extensive efforts to differentiate the control aspect of their invention from that of time-based systems discussed above, the occurrence of non-time based events must occur under the complete control of the auctioneer. Therefore, the term "occurring under the direction of the auctioneer" shall mean "occurring under the complete control of the auctioneer."
DISCUSSION
Analysis of patent infringement starts with “construction” of the claim, whereby the court establishes the scope and limits of
the claim, interprets any technical or other terms whose meaning is at issue, and thereby defines the claim with greater
precision than had the patentee. Although the construction of the claim is independent of the device charged with
infringement, it is convenient for the court to concentrate on those aspects of the claim whose relation to the accused device
is in dispute. On appeal the Federal Circuit is required to construe the claim de novo; thus we do so without deference to
the rulings of the trial court. See generally Cybor Corp. v. FAS Technologies, Inc., 138 F.3d 1448, 46 USPQ2d 1169 (Fed.
Cir. 1998) (en banc).

B. The Term "Immediately"

As noted above, the district court construed "immediately" to require the activation of the blocking flange simultaneously
with removal from the patient. The court decided that this term imposed a limitation upon claims where it appeared in the
preamble, as well as upon two claims where it did not literally appear.

In this case, both the RE '885 patent's specification and prosecution history clearly indicate that the invention is focused on
ensuring the protection of the healthcare worker, patient, and bystanders by safely covering the needle at once upon removal
from the patient. The "Summary of the Invention" section of the RE '885 patent is particularly instructive:

The present invention addresses [the needlestick hazard] problem confronting the healthcare industry and is designed
specifically to eliminate needlestick injuries of the type described in connection with blood collection. To this end, there is
provided a new and improved system which . . . shields the blood-contaminated needle simultaneously with its removal
from the donor . . . whereby the probability of an exposed contaminated point being in any injury-causing proximity to a
medical worker is virtually nil . . . .

RE '885 patent, col.2 ll.52-62 (emphasis added). The summary is of course not wholly dispositive. See Rambus Inc. v.
Infineon Techs. AG, 318 F.3d 1081, 1094 (Fed. Cir. 2003) ("While clear language characterizing 'the present invention' may
limit the ordinary meaning of claim terms, such language must be read in context of the entire specification and the
prosecution history." (internal citations omitted)). There is nothing in the RE '885 patent specification, though, that speaks to
the needle being rendered safe at any time other than the moment of removal from the patient. Furthermore, the prosecution
history provides additional support for the district court's conclusion. During prosecution of the related '347 patent, the
examiner rejected MBO's application in view of U.S. Patent No. 5,026,356, issued to Smith. In response, MBO
distinguished its invention from and criticized the Smith patent:

Please note that in Smith . . . the needle 60 may be fully withdrawn from the patient's flesh by an inattentive or rushed
operator in exactly the [unsafe] state, with the needle point and needle end portion fully exposed and hazardous for
needlestick and contamination! It is required in Smith as a specific manipulative effort that the operator personally bodily
move the [needle guard] forward . . . which may be overlooked in rushed or harried treatment conditions . . . .

Reply Letter to Alexander, Examiner, In the Patent Application of Blecher et al., S.N. 07/972,013, at 8 (Nov. 15, 1993). The
clear implication is that the MBO invention, in contrast to Smith, does provide assurance that the needle will be made
instantly safe upon withdrawal from the patient. Prosecution arguments like this one which draw distinctions between the
patented invention and the prior art are useful for determining whether the patentee intended to surrender territory, since
they indicate in the inventor's own words what the invention is not. See Medtronic, Inc. v. Guidant Corp., 465 F.3d 1360,
1373 (Fed. Cir. 2006) ("A surrender can occur by argument as well as by amendment.").

The patentee here has clearly indicated via the specification and the prosecution history that the invention provides, as an
essential feature, immediate needle safety upon removal from the patient. It is therefore appropriate to construe the claims
so as to ensure that they, too, require that feature. The construction of the term "immediately" to mean "simultaneously with the needle's withdrawal from the patient" is correct. Where that term appears in a claim preamble, it is "necessary to give life, meaning, and vitality to the claim," and may be used as a limitation. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999) (quotation marks omitted).

Reissue claims 32 and 33 do not contain the word "immediately," but the district court nonetheless used its construction of that term to limit the claims. We sympathize with the district court's choice, since we agree that safety at once upon removal from the patient is an essential element of the invention as described by MBO. However, we cannot endorse a construction analysis that does not identify "a textual reference in the actual language of the claim with which to associate a proffered claim construction." Johnson Worldwide Assocs., Inc. v. Zebo Co., 175 F.3d 985, 990 (Fed. Cir. 1999); see also Renishaw PLC v. Marposs S.p.A., 158 F.3d 1243, 1248 (Fed. Cir. 1998) ("[I]t is manifest that a claim must explicitly recite a term in need of definition before a definition may be associated with the claim."); E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988) (finding it improper to impose "a limitation read into a claim from the specification wholly apart from any need to interpret what the patentee meant by particular words or phrases in the claim").

In this case, we are reviewing only certain disputed terms of the claim construction and lack the power to construe other terms not disputed by the parties. None of the disputed terms that are found in claims 32 or 33 can reasonably be construed to impose the simultaneous-safety requirement upon those claims. The district court's grafting of the "immediately" limitation into claims 32 and 33 is error. 2

--- Footnotes ---

2 We express no view on whether claims 32 and 33 as construed would invoke the recapture rule.

--- End Footnotes ---

11. uniaxial medium ('412 patent)

Claim 3 of the '412 patent, in which this term is found, recites:

A cell according to claim 2, wherein the two polarizing means are crossed rectilinear polarizers and wherein the compensating medium is uniaxial medium of negative optical anisotropy having an axis of symmetry parallel to the homeotropic direction and an extraordinary axis parallel to said axis of symmetry.

CEA requests that the court construe the entire phrase "uniaxial medium of negative optical anisotropy" as a single claim term while Samsung argues that "uniaxial medium" and "negative optical anisotropy" should be separately construed.

CEA's proposed construction is of "uniaxial medium of negative optical anisotropy" is "a new type of birefringent, manufactured, plastic material having optical properties of a product resulting from the process disclosed in the specification and illustrated in figures 4 and 5." As an alternative, should the court construe that phrase as two claim terms, CEA's proposed construction of "uniaxial medium" is "a birefringent medium wherein the extraordinary index exceeds an ordinary index or vice versa."

Samsung's proposed construction of "uniaxial medium" is "a type of birefringent material wherein the values of two of the principal optical indices (called the ordinary indices) are equal to each other and the third optical index (called the extraordinary index) has a different value."

The court determines that "uniaxial medium" and "negative optical anisotropy" will be separately construed. Samsung's proposed construction of "uniaxial medium" is adopted.

CEA's construction of "uniaxial medium" would read on its construction of "biaxial medium" and must be rejected. 35
Samsung's proposed construction of "uniaxial medium" is both distinguishable from its proposed construction of "biaxial medium" and supported by the specification. Describing figure 1, the specification recites "[t]his nematic liquid crystal layer is also a positive optical anisotropy uniaxial medium, the extraordinary index NeCl of said medium exceeding its ordinary index NoCl." 36 Figure 1 uses the same identifier, NoCl, for both of the ordinary indices of the liquid crystal layer demonstrating that each are equal to the other. The specification continues by specifying that "[c]ompensating plate 16 is a negative optical anisotropy uniaxial medium, the extraordinary index Ne1 of said medium being below its ordinary index No1." 37 Figure 1 uses the same identifier, No1, for both of the ordinary indices of the compensating plate, again demonstrating that each are equal to the other. The description of a biaxial medium, by contrast, makes clear that each of the three indices have different values: "[e]ach plate 20 or 22 is a biaxial medium having two principal indices N1o and N2o with values close to one another and a third index N3e below N1o and N2o, the weak index axis N3e being parallel to the homeotropic direction." 38

Therefore, the court adopts Samsung's proposed construction: "a type of birefringent material wherein the values of two of the principal optical indices (called the ordinary indices) are equal to each other and the third optical index (called the extraordinary index) has a different value."

3. Unified execution of multiple media data streams

The plaintiff proposes that "unified execution of multiple media data streams" be construed to mean "processing two or more different types of media data streams by the same execution unit." On the other hand, the defendants submit that the disputed phrase means "operating on two or more media data streams in parallel, all at the same time with the same processor, without external specialized processors." The parties' primary dispute is whether media data streams are processed "in parallel," "all at the same time," and "without external processors." The defendants correctly note that the general purpose media processor claimed in the patents was an improvement over the combination of prior art specialized processors; however, the court does not read the claim language or the specification to exclude all use of external processors. What is required is that the media processor has the capability of processing two or more different types of media data streams by the same execution unit. The court is persuaded that the plaintiff's proposed construction is correct. Accordingly, the court construes "unified execution of multiple media data streams" to mean "processing two or more different types of media data streams by the same execution unit."

2. Unified media data streams

The court construes "unified media data streams" to mean "combined media data streams of different types."

1. "Uniform file-locking semantics"/"Uniform locking semantics"

<td>&quot;A set of lock modes, each combining an access mode and a deny mode, into which lock requests from multiple protocols are translated.&quot;</td>
<td>&quot;[A] set of [file-] locking rules that can be applied in the same way to requests using diverse [file-server] protocols.&quot;</td>
</tr>
</tbody>
</table>

Sun further contends that the preambles in which this term appears are limiting. 13

--- Footnotes ---

13 NetApp concedes that the preambles in which the term appears are limiting. NetApp also abandoned its argument that the term need not be construed at all. 14 The bracketed portions of NetApp's construction apply to "uniform file-locking semantics" but not to "uniform locking semantics."

--- End Footnotes ---

The dispute centers on whether the semantics are lock modes, which must have an access mode and deny mode as Sun contends, or whether uniform file-locking semantics are rules that are applied in the same way to diverse protocols, as NetApp contends. NetApp argues that the claims show that "uniform [file-] locking semantics" are rules, not lock modes. As NetApp notes, claim 1 provides that the uniform file-locking semantics include a list of steps for taking particular actions in response to particular requests. The rules in this claim, according to NetApp, are that the system will grant an opportunistic lock in response to a message using the first protocol, and break the lock in response to a message using the second protocol. '351 patent at Claim 1. The rules allow clients using different protocols to work together to access the same data without corrupting it. Ganger Decl. P 45.

This claim language strongly indicates that the semantics are a set of rules composed of certain predetermined steps that mandate certain responses to certain events. While Dr. Brandt claims that these actions taken by the file server are functions or actions taken by that server, rather than a set of rules, see Supp. Brandt. Decl. P 23, requiring a certain action in response to a given event is more accurately characterized as a "rule" as NetApp argues, as opposed to a function. Claim 1, for example, discusses "steps for enforcing a uniform file-locking semantics." The semantics are the rules that are "enforced" in order to mandate certain actions in response to certain events. In addition, the use of the word "enforce" in the patent title and in the patent abstract indicates that the semantics are rules. The steps outlined as the uniform locking semantics cannot be accurately described as merely a "set of modes," as Sun argues. 15

--- Footnotes ---

15 NetApp also notes that U.S. Patent No. 5,668,958, cited on the face of both patents, states: "The API also comprises the rules or semantics of behavior of the file system i.e. the effects of various file system requests on objects in file system repository." Sun argues that this merits less weight than evidence of the patentee's own words. It is also is unclear whether or not the semantics are more properly categorized as rules or effects in the '958 patent. Therefore, while this reference in the '958 patent mildly supports NetApp, it is not particularly persuasive.

--- End Footnotes ---
Turning to the specification, the patent generally contemplates translating the various types of lock requests received from the file server protocols into uniform file-locks, each containing an access mode and a deny mode:

The file server 110 uses a uniform file-locking semantics so as to model file-locking aspects of any requested operation from any file server protocol in the same way. The uniform file-locking semantics identifies a uniform set of file-locks, each including an access-mode for the requesting client device 130 and a deny-mode for all other client devices 130.

'351 patent at 7:38-44.

NetApp argues that this aspect of the preferred embodiment shows that the "uniform file-locking semantics" identifies the "uniform set of locks," but the former is not equated with the latter. Ganger Decl. P 47. In addition, the uniform file-locking semantics model file-locking in the same way, i.e., uniformly, for any protocol, according to Dr. Ganger. The uniform file-locking semantics do so by providing uniform rules regarding locking, including (1) how requested lock modes are determined for any request from a client using any particular protocol and (2) how requested lock modes are compared to existing lock modes to decide whether to allow or deny a given request. Ganger Decl. P 47. The Court agrees with NetApp, as the above passage demonstrates that the locking semantics are not the same as lock modes. Rather, the semantics identify a set of file-locks, which include certain modes (access and deny modes). These semantics are a set of rules or commands that can be applied in the same way to different requested operations.

Dr. Brandt argues that the same passage shows that the uniform locking semantics establish a uniform representation of file-locks on the server, which consists of a set of lock modes, each including an access mode and deny mode. Brandt Supp. Decl. PP 20-21. This portion of the specification indicates that the set of file-locks which are identified by the uniform file-locking semantics include an access mode and a deny mode. See '351 patent at 4:52-56 (defining "lock mode" as the combination of an access mode and a deny mode). Dr. Brandt argues that no other embodiment, other than this teaching of a uniform file-locking semantics having an access mode and a deny mode, is taught or suggested in the specification. Brandt Decl. PP 70-71. While this portion of the specification uses lock modes having an access mode and deny mode, these lock modes are not utilized in this way for every aspect of the invention.

Specifically, the invention describes three separate aspects of the invention: (1) one in which the uniform file-locking semantics protect against data corruption; (2) another one in which the common internet file system (CIFS) client device can obtain an oplock and the network file system (NFS) and network lock manager (NLM) devices 16 are allowed to request to break the oplock; and (3) a third aspect in which the CIFS client device can obtain a "change-monitoring lock." See '351 patent at column 2. The patents disclose an application of uniform locking semantics in which lock modes are not involved at all — the ability of a CIFS client device to obtain a "change-monitoring" lock on a file directory. This type of lock gives notice when a directory is changed by CIFS or non-CIFS devices. '351 patent at 2:51-59. For example, this "change-monitoring" lock provides notice when a directory is created, deleted, or files are renamed or moved. Id. Such a lock is not exclusive, does not prevent access to a file, and cannot properly be explained in terms of access modes and deny modes. Ganger Decl. P 49. Lock modes are not even mentioned in the description of change-monitoring locks in the specification. '351 patent at 14:20-15:6 (noting that the change monitoring lock specifies both the name of the changed file and the type of change). Yet "uniform file-locking semantics" are used when granting change-monitoring locks. See, e.g., claims 6 and 85. While Sun maintains that the access and deny lock modes constitute the uniform language of these patents, the fact that the change monitoring lock cannot be expressed in mere access and deny modes severely undermines Sun's proposed construction.

16 The background of the invention explains that in the prior art, there are multiple diverse file server protocols, each with differing semantics for file operations. The NFS protocol does not provide semantics for file-locking. The CIFS protocol has an extensive mandatory file-locking semantics. And, while NFS is often augmented by a NLM protocol, NFS treats NLM locks as advisory only.

Sun counters that lock modes are involved in granting a change-monitoring lock, as that process involves receiving a file open request. '351 patent at 14:30-35. In order to determine whether such a request should be allowed, the CIFS open
request must be translated into a uniform lock mode, containing an access mode and deny mode. Id. at 9:37-10:33; Brandt Supp. Decl. PP 18-19. However, while lock modes may be used in granting a change-monitoring lock, the patent does not address what lock mode exists once the change-monitoring lock is in effect. Sun concedes that the patent is silent on this point, but argues that the mode would likely be a deny-none mode. The patent does not support Sun's conclusion, however, and a deny-none mode itself would not provide change notification to a client. Furthermore, the specification notes that the "file-lock" is converted on the open directory to a change-monitoring lock. '351 patent at 14:38-39. When the change-monitoring lock is in effect, therefore, there is no specified lock mode.

Sun's reliance on Respironics, Inc. v. Invacare Corp., 303 Fed. Appx. 865, 871 (Fed. Cir. Dec. 16, 2008) is inapposite, as in that unpublished case, the patent had only one embodiment, in which the pressure magnitudes at issue were "predetermined." Limitation of the claim term at issue in Respironics was supported by the patent's only embodiment. Here, by contrast, one of the three aspects of the invention -- the change-monitoring lock -- does not appear to utilize the uniform lock modes proposed by Sun when carrying out its change notifying function.

As to NetApp's proposed construction, Sun argues that it is flawed because the specification does not teach that the uniform file-locking semantics are applied in the same way to requests using different protocols. In particular, the patent specification describes how the uniform file-locking rules are applied differently to requests from different CIFS, NFS, and NLM protocols. Brandt Decl. PP 74-75; '351 patent at columns 6-13 (outlining differences between application of the rules for CIFS, NFS, and NLM requests). For example, NLM and CIFS byte-range lock requests are handled differently. With respect to NLM, "[i]f the file server 110 is checking for conflicts between existing file -locks or byte range locks, and a new request for a NLM byte-range locks, the . . . locks are cross-indexed against a lock mode equivalent to the new NLM byte-range lock request. For the purpose of comparing with existing file -locks, the file server 100 treats newly requested NLM byte-range locks as having deny-mode deny-none, and as having access-mode read-only for nonexclusive locks . . . and access-mode read-write for exclusive locks." By contrast, "CIFS byte-range lock requests are only checked against byte-range locks because they require a prior CIFS file open operation at which existing file -locks were already checked." Brandt Decl. P 75 (quoting '351 patent at 11:32-38, 12:25-28).

NetApp counters that Sun fails to distinguish between: (1) the locking rules, which apply uniformly to locking requests by each client, no matter what protocol that client uses; and (2) the variation among clients as to which type of locking request a particular client might make. The background of the invention itself notes "that it is desirable to provide a method and system for enforcing file-locking semantics among client devices using multiple diverse file server protocols," which is achieved in the invention by using a "uniform set of file-locking semantics." '351 patent at 1:60-67. In the preferred embodiment, specific file-locking semantics of the CIFS protocol are implemented to allow NFS client devices to interoperate with CIFS client devices. Id. at 2:1-5. And, as noted above, the preferred embodiment states that the file server "uses a uniform file-locking semantics, so as to model file-locking aspects of any requested operation from any file server protocol in the same way." Id. at 7:38-44 (emphasis added). For example, in a system providing for opportunistic locks, the uniform locking semantics are applied in the same way to all requests for opportunistic locks. However, not all clients may be able to request opportunistic locks. Ganger Decl. P 56. As the summary of the invention describes the invention: "uniform file-locking semantics provides that the file server determines, before allowing any client device to read or write data, or to obtain a new file -lock or byte-range lock, whether that would be inconsistent with existing locks, regardless of originating client device and regardless of originating file server protocol or file-locking protocol for those existing locks." '351 patent at 2:21-27.

As NetApp itself acknowledges, "clients using diverse protocols may make different types of requests and therefore trigger different subsets of the rules." NetApp Markman Hearing Slide 93. In other words, the same subset of "rules" do not apply to all requests from all protocols. In addition, the initial translating steps are different for different protocols. For example, both CIFS and NFS protocols issue read requests. For CIFS read requests, the lock mode of the request is compared only against the access mode acquired when the file was opened, after file open time. '351 patent at 4:35-45. On the other hand, for NFS read requests, the lock mode of the request is compared against the lock mode of any pre-existing file or byte-range locks. Id. at 6:27-30, 6:46-50, 11:26-30. NetApp's proposed construction, which states that the rules are applied "in the same way," is therefore somewhat misleading. In addition, the semantics do more than just translate the requests, as they also compare requests. See Sun Reply Brief at 10:18-22 (citing '351 patent at 9:37-10:33) (describing method by which CIFS open request is translated into a uniform lock mode and the requested lock mode is compared with the mode of any preexisting locks to determine whether file access may be granted). In other words, the rules govern file-locking aspects of the request, rather than just translate those requests.
In light of the above, the Court proposes construing "uniform file-locking semantics/uniform locking semantics" as "[a] set of [file] locking rules that consistently govern [file]locking aspects of any request, even though the requests use diverse locking protocols." While this is a proposed construction, the parties may only comment if they find a mistake or ambiguity in the wording, as opposed to disagreeing with the Court's reasoning, and they must do so within ten days of the date of this Order.

4632

(1) Unique. The term "unique" is included in each of the above-listed claims; the parties disagree on its meaning. Defendants construe "unique" to mean "random and non-repeating within an election." Plaintiff defines the term as "a random or pseudo-random number (alphanumeric character or symbol) or number randomly chosen from a unique sequence of numbers." The dispute appears to be that, according to Plaintiff, the term "unique" does not require randomization, and, according to Defendants, it does. All parties agree that the term includes non-repeating.

Plaintiff's position is bolstered by the language of Claim 71 describing "identifier for the voting session" as "unique, randomized, and does not identify a voter." The language of the patent therefore demonstrates that unique and random are two different and separate qualities. For example, numbers 1, 2, and 3 can be randomly assigned to 100 people, but all those assigned a number 1 cannot be found to hold a unique number.

As noted above, a dictionary is permissible extrinsic evidence in claim construction as long as the dictionary definition does not conflict with the definition of the term as used in the patent language. See Interactive Gift Express, Inc., 256 F.3d at 1332 n.1. Unique is not necessarily a technical term. When used as an adjective, it is defined as "[o]f which there is only one; one and no other; single, sole, solitary." Oxford English Dictionary, http://www.oed.com/cgi/entry (last visited August 15, 2007).

For the foregoing reasons, the Court agrees with Plaintiff's proposed construction of the term "unique."

4633

3. "A unique audio data signal in IP protocol representing a specific audio condition to be monitored." Used in Claim 1(b).

Claim 1(b), with disputed term in bold, reads:

[the system comprising] at least one audio sensor adapted for monitoring a selected audio condition associated with the commercial transport for generating a unique audio data signal in IP protocol representing a specific audio condition to be monitored.

E-Watch argues this phrase means "an audio signal of a monitored area or object, transmitted in IP protocol together with information for distinctively identifying the audio signal, such as the source and date/time of the audio signal, or together with information for distinctively identifying a sound." March Networks proposes "a specific data signal in IP protocol representing an event that is able to be sensed audibly, and which indicates the occurrence of the event." The specification's description of the use of an audio signal is similar to the description of the visual signal discussed above. See '692 patent, col. 14, l. 45 - col. 15, l. 6. Accordingly, the analysis of this claim element is the same as for the previous claim element, and the court will construe it in a similar fashion, as follows:

"A unique audio data signal in IP protocol representing a specific visual condition to be monitored" means: "Information:

- a. which is transmitted in a protocol compliant with the internet;

- b. is about a condition, which can be heard, and which has been chosen to be observed; and
c. which distinctly identifies the condition being observed.

Claims 3 and 31 are dependent on Claim 1. They are set out below with the disputed terms in bold:

3. The system of claim 1, wherein said sensor is a commercial transport based sensor adapted for monitoring a specific on-board based condition on the commercial transport.

31. The system of claim 1, wherein said sensor comprises an image sensor device for generating an image signal.

1. Unique Authorized Information

Claims 1-12, 15 and 16 all refer to "unique authorized information" associated with individual objects. n59 As CIAS concedes, n60 neither the claims nor the specification define the term explicitly. n61

n60 See CIAS Mem. at 14.

n61 See generally '422 Patent.

CIAS argues that there was no need to define the term, as "unique authorized information" was "intended to and does carry its common and ordinary meaning. The information associated with each object is unique to that object, and it is information that has been authorized by the system." n62 In other words, "unique authorized information" incorporates any data so designated by the counterfeit detection system - even "a picture of Mickey Mouse with a moustache." n63

n62 CIAS Mem. at 14.

Alliance makes two arguments in favor of a more limited definition. It first contends that the specification requires that the term be construed as referring "merely to a small 'authorized' subset of a larger set of 'valid' numbers." n64 As a matter of logic, the "unique authorized information" selected by the system for a given set of objects will be a subset of all possible information that could be so selected. There is no support in the specification, however, for the initial selection of a set of "valid" information from which the "unique authorized information" is then distilled. Alliance points to one section of the specification that, in describing the particular embodiment of casino chips, suggests that casinos, as a practical matter, will need to reserve some coded information for future use. n65 This description of the potential pragmatic needs of one embodiment of the invention, however, cannot be read as a limitation on the claim term itself. n66

n64 Alliance Mem. at 13-14.

n65 See '422 Patent at 7:36-55, 15:57-63.
Alliance next contends that the inventors disclaimed multi-part information from inclusion in "unique authorized information" during re-examination of the '422 patent. During re-examination, the inventors cited Shoshani, another counterfeit detection patent, as prior art that had not been cited during initial prosecution. n67 The inventors described Shoshani as "teaching away from the use of serial numbers alone [because they provide inadequate counterfeit protection]."

According to the '422 inventors, Shoshani provides objects with an associated pair of numbers. One number of the pair is a serially-selected identification number, and the other number of the pair is a randomly-selected control number. A master list of the associated pairs of numbers is stored in mass memory. When an object's pair of numbers is scanned, the device compares that pair with pairs of numbers stored in the mass memory, and discrepancies are indicated. Shoshani teaches the use of a pair of numbers, and not either serial numbers alone or randomly-selected numbers alone. n69

CIAS argues that Shoshani actually is distinguishable as prior art because "it does not detect when information relating to code elements machine read from a similar object is the same as information previously read from a similar object." n70 This argument, however, is misplaced, as the issue is not whether the '422 patent should have issued over Shoshani on re-examination, but rather whether the inventors disclaimed multi-part numbers from their patent. Other possible differences between the '422 patent and Shoshani that were not discussed by the inventors at that time are therefore of no present moment.
Again, while this may be an accurate description of how Shoshani actually works, the question here is what the inventors disclaimed during re-examination. The inventors there characterized Shoshani differently, stating that it "teaches the use of a pair of numbers, and not either serial numbers alone or randomly-selected numbers alone." n72 They did not state that Shoshani used the two numbers separately, but instead implied that the patent used them together, as opposed to "serial numbers alone or randomly-selected numbers alone." The inventors requested re-examination because of their failure to disclose Shoshani as prior art during the initial prosecution, n73 and so the context of their description of Shoshani was their interest in distinguishing it from the '422 patent. With that framework in mind, the implication of the inventors' description is that they understood and claimed the '422 patent, in contrast to Shoshani, to use either serial numbers alone or randomly-selected numbers alone. n74

n72 Request for Re-Examination at 4 (emphasis added).

n73 See id. at 2-4.

n74 See Phillips, 415 F.3d at 1317 ("Like the specification, the prosecution history provides evidence of how the [] inventor understood the patent. Furthermore . . . the prosecution history was created by the patentee in attempting to explain and obtain the patent.").

Despite being secondary to the specification, prosecution history can demonstrate "how the inventor understood the invention and whether the inventor limited the invention in the course of prosecution, making the claim scope narrower than it would otherwise be." n75 A competitor, "reading the prosecution history, would reasonably conclude" that the '422 inventors had restricted their claims to information of a single type and thus had given up multi-type information. n76 On the basis of the re-examination statements of the inventors in distinguishing Shoshani, therefore, the term "unique authorized information" excludes information other than serial information alone or randomly-selected information alone.

"The '422 patent claims 'unique authorized information . . . comprised of machine readable code elements coded according to a detectable series. The claim language has no exclusion of multi-part information. To the contrary, use of the word "comprised" expressly means that the 'unique authorized information' may include something in addition to the detectable series." n77

In other words, Claim 1's description of "unique authorized information" includes not just machine readable elements coded according to a detectable series, but also any additional information that the system selects. Thus, argues CIAS, multi-part or -type information is included.

n77 CIAS Mem. at 15-16.
As an initial matter, this argument does not address the re-examination history detailed above, as the Claim 1 language is original to the initial prosecution and so subject to the inventors' disclaimer during re-examination. Accordingly, even if CIAS were correct as to the language in Claim 1, the conclusion would remain the same.

Further, despite the Court's invitation, n78 CIAS was unable to locate binding case law holding that "comprised of" is an open-ended term, rather than a limiting one. Instead, both parties' searches, as well as the Court's, indicate that there is no consensus in the Federal Circuit as to the meaning of this phrase. n79 In the absence of such precedent, of any indication in the patent itself as to the phrase's meaning, and of any external evidence offered by the parties, the Court adheres to the ordinary and customary meaning of "comprised of" as a limiting description of composition. n80 This construction preserves the distinction between "comprised of" and "comprising," the latter of which in fact is a patent term of art when used in a transitional phrase, meaning "including, but not limited to." n81

n80 See, e.g., Apotex, 376 F.3d at 1343 ("Apotex's spray dried solution creates an amorphous 'co-precipitate' comprised of 90% CA, 9% sorbitol, and 1% zinc chloride by mass.").

n81 See, e.g., Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327-28 (Fed. Cir. 1999).

Accordingly, the Court construes "unique authorized information" to mean information associated with each object, unique to that object and authorized by the '422 patent's system, but excluding information other than serial information alone or randomly-selected information alone.

A. Ref. No. 2 "Unique, randomly assigned identifying number" and "Unique identifier"

These terms/phrases are recited in Claims, 1, 17, 20, and 22 of the '787 Patent. Plaintiff proposes the following construction: "A random or pseudo-random number (or alphanumeric character or symbol) or number randomly chosen from a unique sequence of numbers which can be used to correlate the voting selections stored in a tangible medium with the voting selections stored separately from the tangible medium in the voting apparatus's memory." Defendants propose the following construction: "A random or pseudo random number (or alphanumeric character or symbol) or number randomly chosen from a unique sequence of numbers assigned to a particular voting session which the voter takes away at the end of the voting session to enable the voter to identify her voting record from among the voting results published for that particular election."

The language in Claim 1 provides that the randomly assigned identifying number is printed on a paper that is "human readable," "optically readable," or both. (Defs. Ex. 3, Col. 27, ll. 51-55.) Further, the printed paper is provided to "verify [] the voting selections made during the voting session that are printed on the printed paper." (Id. Col. 27, ll. 56-58.) That piece of paper is called a receipt in the specifications of the patent. (Id. Col 6, ll. 14-15.) "At the conclusion of a voter's voting session, voting machine VM stores the voting record of a voting session and the voting session identifier associated therewith by its processor in its internal memory or memories and provides same to local printer LP which provides . . . a tangible record PR, e.g., in the form of a printed receipt PR, to the voter." (Id. Col. 6, l. 66-Col. 7, l. 4) (emphasis added). The specifications further advise that the voter may use the voting session identifier on the receipt to check the voting record and confirm his or her vote. (Id. Col. 7, ll. 48-50.) On the other hand, the patent specifications also teach that the individual voting record may "alternatively" be stored in the non-volatile memory built-in within smart card, hard computer disk, or "any other suitable electronic media, optical media or . . . electronically or optically readable media . . . both within
the voting machine or in the smart card." (Id. Col. 22, ll. 1-7, 12-17.)

The foregoing language does imply that the printed paper can be retained by the voting machine or retained by the voter, but the language is not as clear on this issue as that in the '209 Patent, discussed below. Because the language in the '787 Patent is the same as that in the '730 Patent already litigated in this Court, and because the '787 Patent is a continuation of the '730 Patent, the Court is obligated to follow precedent and, adopting its earlier reasoning, construes these terms as it construed the same terms in the '730 Patent. See Avante Int'l Tech., No. 4:06cv0978 TCM, Doc. 276 at 8-13.

There does not appear to be a dispute about the interchangeable use of the terms "voting session identifier" and "unique identifier" or "unique randomly assigned identifying number." Support for these positions is replete within the patent specifications and in the abstract. (See Defs.' Brief at 13, 14.)

Accordingly, the Court construes the above terms/phrases as follows:

A random or pseudo random number (or alphanumeric character or symbol) or number randomly chosen from a unique sequence of numbers assigned to a particular voting session which the voter takes away at the end of the voting session to enable the voter to identify his/her voting record from among the voting results published for that particular election.

2. UNIQUE IDENTIFICATION / UID

Reference is first made to "unique identification" in Claim 3. Elsewhere, the claims refer to a UID, however the parties agree (as does the Court) that the phrase "unique identification" means the same thing in the Patent as the acronym "UID."

Plaintiff appropriately cites to a portion of the specification where the drafter provides a clear and specific definition of UID. At column 6, lines 39-42, we are told that "for ease of expression, the identification assigned to a given license file . . . at a given node . . . at a particular time is referred to as the UID." The definition is found within the description of the license transfer embodiment; however, it appears also to pertain to the license pool embodiment. Of course, the definition at column 6, lines 39-42 is itself referential and to be fully understood must therefore be read in conjunction with the specification's description of the "identification assigned to a given license file: "The operating system . . . assigns an identification to each license file . . . . In connection with the installation program at the local node, the assigned identification is unique to the license file . . . that was stored on the local node at a particular time." (Patent 6:33-39).

The phrase "installation program" does not appear in the claims, however, and incorporation of this term into the definition of "UID" would start a snowball effect resulting in the incorporation of a great deal of the specification not appropriate to a non-means-plus-function element. A relevant understanding of the term "installation program" for purposes of defining "UID" thus is simply that one exists on each node and it must be able to distinguish the UID of any license file within its bailiwick from every other license file it may encounter. Therefore, the drafters description of "UID," while specific, merely conforms to plain meaning. That is, a UID must identify each license file such that it will not be confused with any other license file then in existence.

A UID is data assigned to a LICENSE FILE which is different from the data assigned to any other LICENSE FILE then in existence with which the first mentioned LICENSE FILE otherwise may be confused.
is peculiar to or which only relates to a single transaction." Id. at 5.

6 In reaching his proposed construction of "UTID," the magistrate judge rejected the parties' proposed constructions of the term. Plaintiffs asked the magistrate judge to construe "unique transaction identifier" or "UTID" as "information that, at any given time and a particular step of the transaction, allows a party to positively identify the transaction." Visa urged the magistrate judge to construe "unique transaction identifier" or "UTID" "as a data string that is generated by the originator of the transaction and is not repeated within the originator, recipient and transaction administrator systems (i.e. unique) and that is specifically constructed, designated and used for the purpose of establishing both the identity and the validity of a particular transaction."

1. Visa's Objections to Magistrate Judge's Recommended Construction of UTID

Visa has filed objections to the magistrate judge's proposed definition of "unique transaction identifier" or "UTID." Visa contends that the term "information," as used by the magistrate judge in his recommended claim construction, does not fully capture the characteristics of an "identifier," as used in the '878 patent, and risks allowing the jury to confuse the UTID with the information that makes up the transaction itself. Def. Obj. to Second Report at 5. Visa contends that both the '878 claims and the specification indicate that the UTID must be a data string, which is distinct from the transaction information itself. Id. at 6. Visa urges the court to construe "unique transaction identifier" or "UTID" as: "a data string peculiar to or which only relates to a single transaction initiated by an originator, and which specifically identifies the transaction." Def. Obj. to First Report at 2. Alternatively, if the court disagrees with the term "data string," Visa asks the court to insert "symbol," "code," "label," or "text string" in place of the word "information" in the magistrate judge's recommended definition. Id. at 4. Visa also states that these definitions can be combined to read "a symbol, code or label, which also communicates the nature and function of the UTID described in the specification and prosecution history." Id.

Visa also asks the court to incorporate the magistrate judge's definition of "unique," namely, "peculiar or which only relates to a single transaction," into the definition of "unique transaction identifier." Def. Obj. to Second Report at 10. According to Visa, "[t]his modification will ensure [that] the Magistrate Judge's intended meaning is clearly captured in the construction and [will] limit the potential for misinterpretation in subsequent proceedings." Def. Obj. to First Report at 3.

To support its proposed construction that the UTID is a "data string" distinct from the transaction information itself, Visa points to both the intrinsic and extrinsic evidence. Visa references independent claim 27 and dependent claim 28 which specifically describe the "UTID" as a number, and use the word "number" interchangeably with "identifier." Def. Obj. to Second Report at 6-7 (quoting claims 27, 28). "[C]laims 27 and 28 describe sending the 'unique transaction identifier' to the transaction administrator and then subsequently forwarding that same 'unique transaction number' to the originator, where it is compared with other 'unique transaction identifiers.'" Id. at 7. Visa also explains that independent claim 31 and dependent claim 32 use the word "number" synonymously with "identifier." Visa provides the court with excerpts from both claims:

Claim 31 (excerpt):

... generating in response to the second e-mail message a third e-mail message from the transaction administrator to the originator requesting validation of the unique transaction identifier, the third e-mail message including the unique transaction identifier;

... comparing the unique transaction number from the third e-mail message to the other unique transaction numbers generated by the originator to determine if the originator generated the transaction order; and completing the transaction based upon the results of the comparison.

Claim 32 (excerpt):

The method of claim 31 wherein the step of completing further comprises the steps of: notifying the transaction administrator if the originator generated the unique transaction number based on the results of the comparison[.]

- 4865 -
Id. at 20 (quoting claims 31 and 32) (Visa's emphasis). Based on this evidence, Visa contends the court should construe the UTID as a number. Visa also emphasizes Plaintiffs' admission that in claims 27, 28, 31 and 32, the UTID must be a number. Id. at 7 (citing Pl. Reply to Def. Obj at 3 n.2). Visa contends that "[u]nder applicable law as explained in Phillips and elsewhere, if the 'unique transaction identifier' means a number in some claims, then it must also mean a 'number' in all other claims." Id. (citing Dayco Prods., Inc. v. Total Containment, Inc., 329 F.3d 1358, 1371 (Fed. Cir. 2003) ("If a claim term appears in more than one claim it should be construed the same in each."). Finally, Visa contends that the specification expressly distinguishes the UTID from the transaction information, explaining that the UTID is created, processed and transmitted in addition to the transaction data. Id. at 8. (Visa's emphasis). Visa provides the following examples from the specification:

The electronic transaction includes details of the transaction such as descriptions of the item(s) that the client desires to purchase, credit card or check payment information, information on other types of payment by means of which the item(s) will be purchased, and a unique transaction identifier that has been generated by the originator and is uniquely associated with the particular purchase transaction.

'878 patent, col. 3 lines 12-19 (emphasis added).

The originator 50 validates the transaction by comparing at step 95 the UTID with a list 100 generated by the processor 70 of the originator listing the UTID associated with each transaction generated by the originator and notifying the transaction administrator 60 of the results. The list 100 also includes the details of the transaction (amount; parties, etc.) associated with the UTID which must also be validated by the originator 50.

'878 patent, col. 5 lines 14-21; see also '878 patent, col. 5 lines 65-67 ("Along with the confirmation request, the merchant 55 transmits the UTID, credit card number and data concerning the purchase order to the CA 60."); col 7 lines 3-5 ("The CA 60 then sends the credit transaction information along with an associated UTID or a rejection of authorization back to client 50 at step 210."); col. 10 lines 64-67 ("Included within the e-mail message . . . are the unique transaction identifier [and] purchase order data such as item, amount and delivery address[]"). Visa also refers the court to Figure 4 of the '878 patent, which separately identifies the UTID, "transaction content," and "relevant information." See Ex. A to App. A to Def. Obj. to Second Report. Additionally, in the Petition to Make Special, VIMachine stated that: "a unique transaction identifier is generated by an originator, and ultimately, the electronic commerce transaction and its associated identifier are returned to the originator to provide for validation." Based on the totality of the above-referenced intrinsic evidence, along with numerous other similar references to the UTID as something separate and apart from the details of the transaction, Visa summarizes its argument as follows: "If the UTID could be the transaction information itself, there would be no need to describe it as something that is included in addition to the details of the transaction." Def. Obj. to Second Report at 8 (original emphasis).

In addition to the intrinsic evidence, Visa supports its proposed construction of "UTID" with various technical dictionaries. Visa cites a computer dictionary which defines "identifier" as "[g]enerally, any text string used as a label, such as the name of a procedure or a variable in a program, or the name attached to a hard drive or floppy drive. Compare descriptor." Id. at 9 (citing Computer Dictionary, Microsoft Press, 1991); see also id. (citing Modern Dictionary of Electronics, R. Graf, 6th ed. 1984) (identifier is "1. A symbol the purpose of which is to identify, indicate, or name a body of data. 2. a mnemonic code used to identify or name an item of data or data format in a computer."). Visa has also provided the court with the testimony of its expert, Dr. Michael I. Shamos, whose testimony at the claim construction hearing regarding how "unique transaction identifier" would be understood by one of skill in the art, was in keeping with the technical dictionary definitions. See App. A to Def. Obj. to First Report at 10-16.

2. Plaintiffs' Response to Visa's Objections

Plaintiffs oppose Visa's proposed modifications to the magistrate judge's recommended construction of the term "unique transaction identifier" or "UTID." Plaintiffs contend that the "UTID [is] simply information that enable[s] a customer to identify a transaction as uniquely his." See Pl. Reply to Def. Obj. to Second Report at 3. "There is no requirement in the specification or claims that the UTID be a contiguous alphanumeric string; rather the specification and claims teach that the UTID can include transaction content, such as the purchase price." Id. Plaintiffs argue further that UTID is never referred to as a "number" in the specification, nor is the word "string" used in the specification or claims.
3. Discussion

Given this intrinsic evidence of record, and the teachings of Phillips, supra, the court determines that the magistrate judge's recommended construction of "unique transaction identifier" or "UTID," insofar as it includes the term "information," is too broad and potentially confusing to the jury. "[I]nformation which specifically identifies an individual transaction initiated by an originator" (see First Report at 5) as the definition of "UTID" could well lead a jury to confuse the "UTID" with the information that makes up the transaction itself. Such a definition would be inconsistent with the intrinsic evidence. The intrinsic record referenced above (including the specification, claims and prosecution history) amply illustrates that the UTID is not merely the transaction information itself, though transaction data can be included in the UTID. The '878 specification clearly distinguishes the UTID from the "information" that constitutes the transaction ('878 patent, col. 3 lines 12-19); the "details of the transaction" ('878 patent, col. 5 lines 14-21); the "data concerning the purchase order" ('878 patent, col. 5 lines 65-67); the "purchase order data" ('878 patent, col. 6 lines 5-9); the "credit transaction information" ('878 patent, col. 6 lines 5-9); the "relevant transaction data" transmitted by the originator ('878 patent, col. 10 lines 58-60); and "item, amount and delivery address" ('878 patent, col. 10 lines 64-67). Figure 4 of patent '878 shows the UTID as different from the "relevant information" or "content" of the transaction itself. As stated by the Federal Circuit in Phillips, "The specification is always highly relevant to the claim construction analysis. Usually it is dispositive; it is the single best guide to the meaning of a disputed term." Phillips, 415 F.3d at 1315. In the Petition Statement, Plaintiffs similarly separated the "electronic commerce transaction" from its "associated identifier."

Although the court agrees with Visa that the recommended term "information" is too broad and risks confusing the jury, the court rejects Visa's argument that the UTID must always be a number. As Plaintiffs correctly argue, that the UTID is a number in certain claims (27, 28, 32, 32) does not make it a number in all claims. See Pl. Reply to Def. Obj. to Second Report at 3 n.3 ("[W]hile it appears that the UTID in [claims 27, 28, 31 and 32] must be a 'number,' there is no reason to import that limitation to any of the other claims. If the drafter had meant to write claims that required a unique transaction 'number,' he would have used that formulation since he obviously knew how to do so.").

7 Defendants cite to Phillips to support their argument that because the UTID is a number in certain claims it must be a number in all claims. See Phillips, 415 F.3d at 1314 ("Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claim."). The court agrees with Plaintiffs that Visa's invocation of this principle from Phillips is misleading. As stated by Plaintiffs: "There are two different claim terms at play here. In claim 27, for example, there is claimed a 'unique transaction number.' The fact that, in that claim, the UTID is a 'number' does not mean that it has to be a number in all other claims. Two different phrases are at play[,] not a single phrase - the second being more restrictive in claiming a 'number.'" Pl. Reply to Def. Obj. to Second Report at 5 n.6.

In sum, for the reasons stated directly above, the court sustains that portion of Visa's objections relating to the magistrate judge's choice of the word "information" as part of his recommended construction of the claim term "unique transaction identifier" or "UTID." Visa proposes that the court replace the word "information" with "data string," or, alternatively, "code," "symbol," "label," or "text string." Having considered these terms, and the ultimate purpose of the construction, which is to inform the jury of the meaning of claim terms, the court determines that the terms "code or label" best capture the meaning of "identifier," when viewed in light of the intrinsic and extrinsic evidence. 8 Merriam-Webster's Collegiate Dictionary defines "code" as "a system of signals or symbols for communication" or "a system of symbols (as letters or numbers) used to represent assigned and often secret meanings." See Merriam-Webster's Collegiate Dictionary 239 (11th ed. 2004); see also The New Oxford American Dictionary 330 (2001) (code is "a system of words, letters, figures, or other symbols used to represent others"). Merriam-Webster's Collegiate Dictionary defines "label" as "a descriptive or identifying word or phrase[]." See Merriam-Webster's Collegiate Dictionary at 239.

8 Extrinsic evidence in the form of definitions of the word "identifier" from technical dictionaries supports the court's decision to sustain Visa's objection to the magistrate judge's use of the word "information" in his construction of the claim
term "unique transaction identifier" or "UTID." See Def. Obj. to Second Report at 9 (citing Computer Dictionary, Microsoft Press, 1991); see also id. (citing Modern Dictionary of Electronics, R. Graf, 6th ed. 1984) (identifier is "1. A symbol the purpose of which is to identify, indicate, or name a body of data. 2. A mnemonic code used to identify or name an item of data or data format in a computer."). See generally Phillips, 415 F.3d at 1318 ("Because dictionaries, and especially technical dictionaries, endeavor to collect the accepted meanings of terms used in various fields of science and technology, those resources have been properly recognized as among the many tools that can assist the court in determining the meaning of particular terminology to those of skill in the art of the invention."). Similarly, testimony of Visa's expert regarding the meaning of "unique transaction identifier" to one skilled in the art also supports the court's decision. See App. to Def. Obj. to First Report at 10-16; see generally Phillips, 415 F.3d at 1318 ("[E]xtrinsic evidence in the form of expert testimony can be useful to a court for a variety of purposes, such as to provide background on the technology at issue, to explain how an invention works, to ensure that the court's understanding of the technical aspects of the patent is consistent with that of a person of skill in the art, or to establish that a particular term in the patent or the prior art has a particular meaning in the pertinent field."). The court is mindful, however, that "while extrinsic evidence can shed useful light on the relevant art, . . . it is less significant than the intrinsic record in determining the legally operative meaning of claim language." Id. at 1317 (internal citations and quotations omitted). Further, "undue reliance on extrinsic evidence poses the risk that it will be used to change the meaning of claims in derogation of the indisputable public records consisting of the claims, the specification and the prosecution history, thereby undermining the public notice function of patents." Id. at 1319 (citation and internal quotations omitted). Here, the court has carefully examined the intrinsic record, as instructed in Phillips, which is the court's primary source for claim construction. Unlike the court in Texas Digital, which adopted the dictionary definition divorced from the intrinsic record, this court has only secondarily consulted the extrinsic evidence, recognizing it is entitled to far less weight. See generally id. at 1319.

The court, however, overrules Visa's request that the court insert the magistrate judge's definition of "unique," namely, "peculiar to or which relates to a single transaction," into the definition of "UTID" in place of "which specifically identifies an individual transaction." The court agrees with Plaintiffs that it is "difficult to see what the difference is or why it is material." See Pl. Feb 27, 2006 Reply to Def. Obj. at 6. The magistrate judge's recommended definition of "unique transaction identifier" or "UTID" more than sufficiently conveys a sense of uniqueness that a jury will understand. Absent a clear need to change the magistrate judge's proposed construction, the court will not substitute an equivalent phrase in its stead.

In sum, after careful review of the magistrate judge's findings and conclusions, Visa's objections, record, legal briefing, and applicable law, the court determines that the magistrate judge's proposed construction of "unique transaction identifier" or "UTID" in patent '878 is correct in part. Specifically, the court rejects that portion of the magistrate judge's recommended definition that uses the word "information," and replaces that term with "code or label." The court accepts the remainder of the magistrate judge's proposed definition. Accordingly, the court construes "unique transaction identifier" or "UTID" in patent '878 to mean: "a code or label which specifically identifies an individual transaction initiated by an originator."

2. "A unique visual data signal in IP protocol representing a specific visual condition to be monitored." Used in Claim 1(a).

Claim 1(a), with disputed term in bold, reads:

[the system comprising] at least one visual sensor adapted for monitoring a selected visual condition associated with the commercial transport for generating a unique visual data signal in IP protocol representing a specific visual condition to be monitored.

E-Watch proposes "an image of a monitored area or object, transmitted in IP protocol together with information for distinctively identifying the image, such as the source and date/time of the image, or together with information for distinctively identifying an object or condition in the image." March Networks suggests "a specific data signal in IP protocol representing an event that is able to be sensed visually, and which indicates the occurrence of the event."
March Network, therefore, argues that the signal being transmitted must be a specific signal such as an alarm in response to an event. That is described at col. 12, ll. 18-21. But the specification also describes the system monitoring an aircraft, with the signal transmitting information such as the tail number and G.P.S. location data, so that the signal identifies a specific aircraft at a specific location and time. See ‘692 patent, col. 12, ll. 41-43; ’692 patent, col. 13, ll. 1-8. Just because the signal in one of the embodiments is a specific alarm does not mean that the entire claim should be so limited. The court construes this claim term as follows:

"A unique visual data signal in IP protocol representing a specific visual condition to be monitored" means: "Information:

a. which is transmitted in a protocol compliant with the internet;

b. is about a condition, which can be seen, and which has been chosen to be observed; and

c. which distinctly identifies the condition being observed."

C. "Screen Identification (ID)" and "Uniquely Identifying"

"Screen identification (ID)," or screen ID, is not sufficiently defined in the claim language to reveal the format in which it is generated. In the specification of the '961 patent, however, the language repeatedly uses the term "screen ID number" in describing the concept, revealing that the format of the screen ID is a number. This is consistent with the specification's discussion of the background of the invention where, in discussing the problem of the prior art, the applicant asks the reader to "consider two possible screen IDs, 123 and 890," both of which are numbers. '961 Pat. at col. 2, ll. 23-24.

Lansa argues that the term "screen identification (ID)" is a number which is devoid of any independent meaning from its meaning associated with the algorithm, and is used solely for identifying a screen. However, no such limitation is provided by either the language or the intrinsic evidence. The only direct support Lansa argues for its position that the screen ID must be a number which is "otherwise meaningless" is a conclusory assertion by a technical expert. However, such extrinsic evidence need not be considered by this Court, particularly where it is unsupported and is not being used to resolve an ambiguous technical term. See Vitronics, 90 F.3d at 1584.

Lansa further contends that, when considered in conjunction with the term "uniquely identifying," screen ID must refer to something other than the data received from the incoming data screen. However, this interpretation is not supported by either the claim language or the intrinsic evidence. The fact that the screen or image must be uniquely identified, i.e. identified as the only one of its kind, in no way implies that it cannot be uniquely identified from information downloaded in the incoming data. The term "uniquely," as used in the claim language, quite simply means one of its kind, and is simply used to qualify the term "screen ID," a number which identifies the screen or image.

a. Definition of "Unistroke Symbols"

I. Symbols Comprised of Entirely Single "Unistroses"

Palm argues that each and every alphabetical symbol must be created by a single, unbroken stroke in order to be a "unistroses" alphabet. The Graffitii alphabet uses various symbols, including the "X" and several accented letters, which clearly require two separate strokes to form the symbol. Thus, Palm argues that Graffitii is not a "unistroses" alphabet. Xerox argues that the Graffitii "X" is actually a "unistroses" symbol which requires two separate strokes to form. They also argue that Graffitii does have an operation mode which includes a symbol for "X" that is formed with only one pen stroke. Finally, Xerox argues that only claims 10 and 11 require an entire alphabet of individual unistroke symbols, while claims 1-9 and 12-16 require that only some, not all, of the symbols be unistrokes.
During the re-examination proceedings before the PTO, the patent examiner noted in his May 24, 1999 Interview Summary that "applicant's representatives also clarified that the claimed invention does require all hand-written unistroke symbols to be a single stroke. Although multi-stroke symbols as entered, for example, using a "soft-key" arrangement are not excluded, the claimed unistroke recognition method/system pertains to symbols consisting of only a single stroke." (May 24, 1999 PTO Interview Summary, p. 3). The patent specification specifically defines the term "unistroke" as "a single, unbroken stroke." ( '656 Patent, col. 2, line 46).

I find that the definition of "unistroke symbols" does not require an entire alphabet of single-stroke symbols. Rather, as Xerox argues, only claims 10 and 11 require an entire alphabet. However, as the PTO Examiner recognized, Xerox's claimed recognition method/system pertains only to symbols consisting of a single stroke - i.e. "unistroke" symbols.

ii. Graphical Separation

Palm argues that the '656 claims do not cover a symbol set where there is a substantial graphical overlap between any pair of the symbols - i.e. where two symbols share similar x,y graphical coordinates and, therefore, can be easily mis-interpreted by the computer due to handwriting sloppiness. Palm argues that Graffiti's Roman alphabetical-like symbols are not well "graphically separated" because some symbols (like "O" and "Q" or "R" and "B") are so similar. They share nearly identical x-y coordinates with only minor variations when graphed by the computer.

Xerox argues that graphical separation of symbols is not a limitation of the '656 patent's claims. This interpretation is inconsistent with the patent's specification and with the prosecution history. The specification of the patent clearly indicates that graphical separation of symbols is a defining characteristic of "unistroke symbols".

In the "Summary of the Invention," the patentee notes that "to relax the graphical constraints on the precision of the handwriting that is required for accurate computerized interpretation of handwritten text, the text is written in accordance with this invention using symbols that are exceptionally well separated from each other graphically." ( '656 Patent, col. 2, lines 35-39).

In the "Background of the Invention" section, the inventor recognizes that "the characters of ordinary Roman alphabets are not reliably distinguishable from each other in the face of rapid or otherwise sloppy writing….Accordingly, it will be evident that the performance of the interpreted text entry system could be improved if all text was entered using characters that are well separated from each other in 'sloppiness space.'" ( '656 Patent, col. 1, lines 54-64). He went on to explain that this sloppiness space notion can best be understood by recognizing that each alphanumeric symbol is defined by some number of features (say, d features). Thus, each symbol normally resides at a unique point in a d-dimensional space which is referred to herein as 'sloppiness space.' From this it follows that the amount of overlap, if any, that occurs in the positioning within this d-dimensional space of the normal variants of the symbols of a given alphabet determines how well separated those symbols' are in sloppiness space. If there is little, if any overlap between the variants of different symbols, the symbols are 'well separated from each other in sloppiness space.'

( '656 Patent, col. 1, line 65 - col. 2, line 9). Finally, in the "Conclusion" portion of the specification, the patentee notes that "the unistroke symbols are readily discriminable from each other, even when imperfectly formed." ( '656 Patent, col. 6, lines 57-58).

Furthermore, during the original prosecution of the '656 patent, Xerox distinguished the Whitaker prior art from Unistrokes on the basis of "graphical separation," arguing that the Whitaker symbols were not well separated graphically (pointing to the Whitaker symbols for "7" and "15"), noting that "there is substantial overlap between the graphical specifications for certain of the symbols". (Xerox January 23, 1996 Information Disclosure Statement, p. 3, para. 2).

During the re-examination proceedings before the PTO, Xerox also clarified that one of the features of "Unistrokes" is that "unistroke symbols are single stroke symbols (representing alphanumeric characters or specified functions) that are sufficiently well separated from each other graphically so that definitive recognition can occur after each such symbol is written, e.g. immediately upon pen-up, without requiring the system to wait for possible additional strokes." (Patent Owner's Summary of May 24, 1999 Personal Interview with Examiners, p. 2).
Moreover, although not a part of the '656 patent prosecution history, it is interesting to note that PTO Examiner Larry Prikockis, the same PTO Patent Examiner who allowed the '656 patent to come out of re-examination, on the same day, reviewed Palm's application for a patent on Graffiti and specifically distinguished the '656 patent, stating that

it is agreed that Goldberg [the '656 patent] teaches and claims a set of input symbols that are graphically well separated, and teaches away from a set of input symbols based substantially on the Roman alphabet which are not graphically well separated from each other.

(November 18, 1999 Graffiti PTO Examiner's Interview Summary).

Even in the context of this litigation, Xerox has acknowledged that some "graphical separation" is a defining element of "unistroke symbols". For instance, Thomas Webster, the Xerox patent attorney who prosecuted the '656 patent, testified during his deposition, that three or four elements went into defining a "unistroke symbol":

it's a symbol; secondly, that it's a unistroke; thirdly, that it's designed for entering text into a computer for handwriting recognition; and fourthly, the different ones of these symbols differ sufficiently graphically from each other that they can be recognized as soon as the symbol is completed….

(Deposition Transcript of Thomas Webster March 30, 1999 Deposition, p. 14) (emphasis supplied).

Thus, I find that the definition of "unistroke symbols" includes a "graphical separation" limitation such that symbols must be well separated from each other graphically so that unambiguous recognition of symbols can occur immediately upon completion of the symbol, even when imperfectly formed.

iii. Definitive Recognition of Unistroke Symbols

Palm argues that the definition of "unistroke symbols" requires that the computer recognize a symbol definitively and finally as soon as the user lifts his or her pen. Palm argues that Graffiti does not employ "definitive recognition" because Graffiti only tentatively recognizes certain symbols immediately upon pen lift, but must wait to see whether the user will add an additional stroke to change the meaning of the symbol before definitive recognition can occur. In other words, a Graffiti user can add a subsequent stroke to a Graffiti symbol and change the computer's interpretation of the symbol. For example, the Graffiti user can make a stroke for the symbol for "A", lift the stylus, then add a second stroke which changes the "A" symbol to an "M" symbol, and the computer will correctly change its recognition of the A to an M. Palm argues that, in Unistrokes, the computer recognizes and interprets a symbol immediately upon pen lift and the symbol cannot subsequently be changed or modified by the addition of another stroke.

Xerox argues that Palm's interpretation of "definitive recognition" as requiring final, unalterable recognition upon pen-lift is based upon faulty claim construction. Xerox argues that in the context of "unistroke symbols" being defined as "sufficiently well separated from each other graphically so that definitive recognition can occur after each such symbol is written, e.g. immediately upon pen-up," the term "definitive recognition" requires only that each symbol can be "unambiguously differentiated" from the other input symbols in the system. Xerox points to the patent specification, which teaches that a unistroke symbol may be used for control functions (such as mode shifts) ( '656 Patent, col. 3, lines 40-63). Thus, Xerox argues, the claim term "unistroke symbols" permits, but does not require, the system to reach a final, unalterable recognition after pen lift.

Xerox's proposed interpretation of "definitive recognition" is inconsistent with the interpretation it urged during the prosecution history. During the re-examination proceedings before the PTO, Xerox clarified that one of the features of "Unistrokes" is that "unistroke symbols are single stroke symbols (representing alphanumeric characters or specified functions) that are sufficiently well separated from each other graphically so that definitive recognition can occur after each such symbol is written, e.g. immediately upon pen-up, without requiring the system to wait for possible additional strokes." (Patent Owner's Summary of May 24, 1999 Personal Interview with Examiners, p. 2) (emphasis supplied).

In fact, Xerox distinguished the prior-art Sklarew patent on a similar basis during re-examination of the '656 patent. Xerox distinguished the Sklarew system on the basis that it was designed to accommodate multi-stroke symbols as well as single stroke symbols and, therefore, did not implement the '656's claimed combination of unistroke symbols and symbol
independent delimiting. The Sklarew method of computerized handwriting recognition requires the computer to wait approximately .5 seconds after a stroke has been entered to recognize the stroke as a character in order to allow the user sufficient time to add an additional stroke to complete the symbol if necessary. The PTO agreed with Xerox, finding that "while the prior art such as the Sklarew patent (US 4,972,496) distinguishes strokes by a symbol independent delimiter (pen up/pen down transition), the prior art is typically designed to accommodate multi-stroke characters as well, so this operation does not equate to a symbol delimiter." (PTO Notice of Intent to Issue Reexamination Certificate, p.2-3).

Moreover, while not a part of the '656 prosecution history, it is again interesting to note the comments of PTO Examiner Larry Prikockis (who conducted the '656 re-examination) with regard to distinguishing the '656 prior art during a PTO review of Graffiti:

Goldberg (the '656 patent) teaches and claims a system that always reaches a final recognition upon pen-up after each stroke (i.e. every symbol is finally recognized upon pen-up and none can be modified by subsequent strokes), as opposed to [the] claimed invention [Graffiti], Sklarew, and other prior art of record where some strokes initially recognized as one character may be modified by subsequent (i.e. "post-character") strokes….Examiner and applicant's representatives also agreed that Goldberg teaches away from a system or process of interpretation of handwritten text that is capable of changing the result of a recognition based on a previous stroke to a different recognized character based on a subsequent stroke (as distinguished from simple editing).

(November 18, 1999 Graffiti PTO Examiner's Interview Summary).

I find that the definition of "unistroke symbols" requires definitive recognition of a symbol immediately upon delimitation - e.g. immediately upon pen lift. I further find that "definitive recognition" does not simply refer to "unambiguous differentiation," but rather requires that the computer be capable of making a final, unalterable interpretation (recognition) of the symbol immediately upon delimitation (e.g. pen lift) without requiring the system to wait for possible additional strokes.

In considering the definition of "unistrokes," the trial court properly looked to the plain meaning of the claims, the specification, and the prosecution history of the '656 patent. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996). The specification defines the term "unistroke" as "a single, unbroken stroke." '656 patent, col. 2, l. 46. In addition, only claims 10 and 11 require an entire alphabet. We therefore agree with the district court that the definition of "unistrokes" itself does not require an entire alphabet.

The only reference to graphical separation in the independent claims is found in claim 10, which states "some of said unistroke symbols have graphical specifications that differ from each other essentially only on the basis of their respective stroke direction parameters." '656 patent, col. 8, ll. 37-40. During reexamination, Xerox clarified that "unistroke symbols are single stroke symbols (representing alphanumeric characters or specified functions) that are sufficiently well separated from each other graphically so that definitive recognition can occur after each such symbol is written, e.g., immediately upon pen-up, without requiring the system to wait for possible additional strokes." Xerox additionally distinguished United States Patent No. 4,972,496 ("Sklarew patent") on the basis that it was designed to accommodate multi-stroke symbols as well as single stroke symbols, and, therefore, did not implement the '656 patent's claimed combination of unistroke symbols and symbol independent delimiting. The term "unistroke symbols" therefore requires sufficient graphical separation for the computer to definitively recognize a symbol immediately upon delimitation or pen lift.

Defendants seek to construe the term "unit" as "a device, separate from the computer system, that is designed to be easily installed and removed from the apparatus in the mobile environment." Keystone's proposed construction is: "A device or
collection of components, separate from the computer system." The parties dispute two points of construction of this term: 1) whether a "unit" can be a "collection of components" and 2) whether a "unit" is "designed to be easily installed and removed from the apparatus in the mobile environment."

On the first issue, Keystone argues the specification repeatedly refers to a "unit" as a "collection of components," and supports its proposed construction. See '123 Patent, 6:38-7:44, 8: 19-9-54, and Fig. 7. Further, it argues that because the "unit" has a variety of actions it can perform (e.g., receiving a wireless signal, processing the signal, communicating with the computer system, etc.), the unit must have a variety of components it uses to accomplish those actions. The Court finds that there is sufficient support in the specification to construe the term "unit" as a collection of components.

On the second issue, defendants argue that the intrinsic record overwhelmingly confirms that "unit" should be limited to devices designed "to be easily installed and removed" in the mobile environment. They note that the parties agree that the line replacement unit claimed in the parent '592 patent must be modular and easily replaceable in the field. They contend that this limitation should be read consistently for the term "unit" in the '123 patent. Defendants also contend that both the specification and the prosecution history support a construction of "unit" as a modular, easily replaceable device. Specifically, defendants point to an office action response wherein the inventor argued to the examiner that the "unit" can be "disconnected from a first computer system and . . . connected to a second computer system." See '123 File History, Response to Non-Final Office Action, at SIR013355 (June 24, 2005). They further point to Mr. Hindman's arguments to the examiner about the theft deterrent feature of the "unit," which defendants argue would be pointless unless the unit could not be removed from the first computer and used in a second computer.

Keystone argues that the claims of the '123 Patent use the term "unit" broadly as compared to the claims '592 patent. It attempts to differentiate the term "line replacement unit" used in the '592 patent from the term "unit" in the '123 patent, arguing that by not using the words "line replacement" to modify "unit" in the claims of the '123 patent, the inventor clearly intended a different meaning. Keystone argues that equating the meanings of the two terms would render the words "line replacement" meaningless. However, "claim differentiation is not a 'hard and fast rule of construction,' and cannot be relied upon to 'broaden claims beyond their correct scope'" Wenger Mfg., Inc. v. Coating Mach. Sys., Inc., 239 F.3d 1225, 1233 (Fed. Cir. 2001). The specification and prosecution history of the '123 patent make it clear to the Court that the inventor intended the "unit" to be easily replaceable, notwithstanding the doctrine of claim differentiation. See Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1370 (Fed. Cir. 2007) ("the written description and prosecution history overcome any presumption arising from the doctrine of claim differentiation"); Versata Software, Inc. v. Sun Microsystems, Inc., No. 2-06-CV-358, 2008 U.S. Dist. LEXIS 63645, 2008 WL 3914098, at *5 (E.D. Tex. Aug. 19, 2008).

Based on the discussion above, the Court construes the term "unit" as "a device or collection of components, separate from the computer system, that is designed to be installed and removed from the apparatus in the mobile environment."

11. Multi-precision arithmetic unit

The parties largely agree on the construction of "multi-precision arithmetic unit" with one exception. The plaintiffs contend that the "multi-precision arithmetic unit" is "a unit that can perform addition, subtraction, multiplication, division, and other integer and floating point arithmetic operations on data streams of varying sizes." The defendants object to the plaintiff's proposed construction on two grounds. First, the defendants contend that the term "unit" refers to a defined circuit block, and not circuitry distributed across the media processor, as the plaintiff argues. Second, the defendants further contend that the language "other integer and floating point arithmetic operations" should not be included in the construction. Thus, the defendants propose the following construction of "multi-precision arithmetic unit" -- "a unit that can perform addition, subtraction, multiplication, division, and other arithmetic operations on data streams of varying sizes." The 840 patent provides as follows:

Many of the logic blocks themselves can also replaced [sic] with a single multi-precision arithmetic unit, which can be internally partitioned under software control to perform addition, multiplication, division, and other integer and floating point arithmetic operations on symbol streams of varying widths while sustaining the full data throughput of the memory hierarchy.
Based on the cited portion of the specification, the court is persuaded that the plaintiff's construction is correct and adopts it. The court declines to further define "unit" to require a single circuit block.

As a threshold matter, the parties dispute whether the term "computing unit" is subject to means-plus-function treatment. Plaintiff argues that the term "computing unit" does not qualify as a means-plus-function limitation under § 112, ¶ 6. First, Plaintiff notes that the absence of the term "means" triggers a presumption against application of § 112, paragraph 6. See Lighting World, 382 F.3d at 1358. Second, Plaintiff cites to LG Elecs., Inc. v. Bizcom Elecs., Inc., 453 F.3d 1364 (Fed. Cir. 2006), overruled on other grounds by, Quanta Computer, Inc. v. LG Elecs., Inc., 553 U.S. 617, 128 S. Ct. 2109, 170 L. Ed. 2d 996 (2008), in support of its argument that the term "computing unit" is not subject to § 112. In LG Electronics, the Federal Circuit held that the term "control unit" was subject to the presumption against means-plus-function treatment and held that the presumption was not overcome because the claim itself "provide[d] sufficient structure, namely 'a CPU and a partitioned memory system,' for performing the stated function, 'controlling the communication unit.'" Id. at 1373. Plaintiff contends that the description of the term "computing unit" as being a "commercially available personal computer or workstation," and "includ[ing] at least one processor and at least one data memory," is sufficient to determine that "computing unit" is a not a means-plus-function limitation. Plaintiff argues that these descriptions in the specification contain sufficient structure for the term "computing unit" to preclude application of § 112, ¶ 6.

Defendants respond that the means-plus-function treatment applies to "computing unit" because the claims provide no structure other than to describe the relevant function. Defendants emphasize that the following descriptions of the "computing unit" relate strictly to the functions which the "computer program product" performs as executed by the "computing unit":

1. evaluates destination call reports;
2. associates recognized identification codes;
3. records an input time of each destination call report with a statement of the boarding floor as well as the desired destination floor;
4. compares the distance between the boarding floor and the actual position of the elevator car;
5. computes the distance between the boarding floor and the destination floor;
6. considers the actual user presence and computes possible intermediate stops;
7. performs an optimization and ascertains for each destination call report a conveying result, denoting the most favorable elevator for conveying the passenger;
8. records a recognition time of a recognized identification code;

- 4874 -
(9) compares a recognized identification code with the identification address of stored user profiles;
(10) records the destination floor.

(See Defs.’ Opening Markman Br. 20-21.) Defendants contend that only the functions performed are described in the Patents-in-Suit and that no explanation is provided as to the structure that performs the recited functions, thereby triggering application of § 112, P 6.

Defendants also distinguish LG Electronics on the ground that in that case the claim itself provided a sufficient and definite structure, i.e., a CPU and a partitioned memory system, whereas here the claims themselves lack any analogous description of the structure of the "computing unit."

The Court concludes that the presumption against means-plus-function treatment applies as the term "computing unit" does not use the term "means," see York Prods., 99 F.3d at 1574, however, this presumption is overcome because the claim language itself does not provide sufficient structure to perform the recited function. See Apex, 325 F.3d at 1373. Again, Plaintiff cites only to the language in the specification, rather than the claim language itself, as describing the structure for the function of the "computing unit."

The Court agrees with Defendants that the instant case is distinguishable from LG Electronics. In LG Electronics, the Federal Circuit found that "control unit" was not a means-plus-function limitation because "[t]he claim itself provide[d] sufficient structure, namely ‘a CPU and a partitioned memory system,’ for performing the stated function, ‘controlling the communication unit.’" 453 F.3d at 1372. Unlike LG Electronics, Plaintiff here concedes that nothing in the claim language itself provides the corresponding structure, rather Plaintiff relies on the description provided in the specification. As explained above, in determining whether the means-plus-function presumption is overcome, courts look to the language of the claims themselves to discern whether sufficient structure is provided. See Altiris, 318 F.3d at 1376 (collecting cases). Thus, the Court finds that because the presumption has been overcome and that the claim language itself does not recite sufficient structure to perform the claimed function, means-plus-function treatment is warranted.

Having determined that means-plus-function treatment is appropriate here, the Court must examine the specification in order to: (1) identify the claimed function; and (2) determine the corresponding structure in the written description which performs that function. See Omega Eng'g., 334 F.3d at 1322.

As to the first question, the Court has identified the function of the "computing unit" as follows: (1) generating a destination signal to the modernizing device (‘861 Patent, claim 1); (2) evaluating the destination call reports (‘861 Patent, claim 11); (3) associating destination floors with recognized identification codes (‘861 Patent, claim 11; 465 Patent, claim 1); and (4) outputting a destination signal for one of the destination floors associated with one of the identification codes. (‘861 Patent, claim 11; ‘465 Patent, claim 1).

As to the second question, the Court finds that the means-plus-function limitation is indefinite as the required corresponding structure is not disclosed for the claimed function. The Federal Circuit has established that computer-implemented inventions with means-plus-function claiming are subject to a specific test - the particular structure disclosed in the specification must be more than a general purpose computer microprocessor. See Aristocrat Techs. Austl. Pty Ltd. v. Int'l Game Tech., 521 F.3d 1328, 1333 (Fed. Cir. 2008) ("Aristocrat II") (for cases involving functional claims concerning computer-implemented inventions, the Federal Circuit has "consistently required that the structure disclosed in the specification be more than simply a general purpose computer or microprocessor"). More specifically, "[i]n a means-plus-function claim in which the disclosed structure is a computer, or microprocessor, programmed to carry out an algorithm, the disclosed structure is not the general purpose computer, but rather the special purpose computer programmed to perform the disclosed algorithm." WMS Gaming, Inc. v. Int'l Game Tech., 184 F.3d 1339, 1349 (Fed. Cir. 1999). In other words, it is insufficient for the patentee to merely point to a "computer" or "microprocessor," rather it is necessary that the particular algorithms that carry out the claimed function be disclosed in order to fulfill the "structure" requirement under § 112, P 6. 9

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

9 An algorithm consists of a specified series of instructions intended to be implemented as a computer program.
Here, the specification provides that the computing unit may be "for example, a commercially available personal computer or a workstation," which may "include[] at least one processor and at least one data memory." (‘465 Patent, col. 6:20-24.) The specification further states that the computing unit is capable of "execut[ing] at least one computer program product for the evaluation of destination call reports or for the association of recognized identification codes with destination floors." (Id. col. 6:27-30.) Furthermore, the explanation of "computer program product" contained in the specification recites only the functionality of the "computer program product," e.g., explaining that the "computer program product" receives destination call reports and/or identification codes, converts identification codes into destination floors, and performs optimization algorithms to assign an elevator car to each user. (Id. col. 6:35-7:50.)

Importantly, however, neither the "computer program product" nor the underlying algorithm used to perform the optimization process is disclosed in the specification. See Harris Corp. v. Ericsson Inc., 417 F.3d 1241, 1253 (Fed. Cir. 2005) ("A computer-implemented means-plus-function term is limited to the corresponding structure disclosed in the specification and equivalents thereof, and the corresponding structure is the algorithm."). Plaintiff contends that a sufficient algorithm is disclosed in the specification because the "optimization" algorithms performed by the "computer program product" to determine the most favorable elevator for conveying each user were well-known in the art at the time of the filing, citing to U.S. Patent No. 4,718,520 (providing a description of a computer algorithm for performing destination dispatch optimizations). 10 The Federal Circuit, albeit in an unpublished decision, recently addressed a similar argument in Encyclopaedia Britannica, Inc. v. Alpine Electronics, Inc., 355 F. App'x 389 (Fed. Cir. 2009).

10 Importantly, Plaintiff has failed to cite to any evidence, including expert testimony, other than the preexisting patent in support of its argument that a person of ordinary skill in the art would understand the optimization process claimed by the computing unit. Cf. AllVoice Computing PLC v. Nuance Communications, Inc., 504 F.3d 1236, 1245-46 (Fed. Cir. 2007) (relying on expert testimony explaining the scope of the algorithm expressly disclosed in patent in order to give meaning to the claim terms and finding that sufficient structure existed from the perspective of "an ordinarily skilled artisan").

In Encyclopaedia Britannica, the Federal Circuit rejected the patentee's argument that the specification disclosed sufficient corresponding structure for a computer-based means-plus-function element because a person of ordinary skill in the art would recognize that the specification inherently discloses a class of algorithms for retrieving the necessary information from a database on a general purpose computer. Id. at 393. The court emphasized that a contention that sufficient corresponding structure was present when the specification implicitly disclosed to a person of ordinary skill in the art a class of algorithms is not supported by existing case law. Id. at 394. Instead, the court explained that a patent "must explicitly disclose an algorithm in the specification for performing the claimed function for a computer-implemented invention to have sufficient corresponding structure" for the claimed limitation. Id. at 394. Furthermore, the Federal Circuit, citing Aristocrat II, rejected the patentee's alternative argument that the specification need not disclose any algorithm where the computer function being performed is well known. Id. at 395. Based on the patentee's failure to disclose an underlying algorithm, the court found that the patent was indefinite. Id. at 396.

Although Encyclopaedia Britannica is not binding, the Court finds it to be a well-reasoned opinion and will adopt it for purposes of resolving the issue before the Court. The Court finds that Plaintiff has failed to demonstrate that the specification describes the term "computing unit" with sufficient structure in order to avoid indefiniteness. The Patents-in-Suit are devoid of any disclosure as to the algorithm used by the computing unit vis-a-vis the "computer program product" to perform the "optimization" function. The absence of an underlying algorithm is fatal to Plaintiff's proposed construction. Therefore, the Court finds that the term "computing unit" is indefinite for failure to set forth sufficient algorithmic structure associated with the contested means-plus-function clauses.

2. "Evaluation unit"/"Evaluation unit for asking when . . . , whether . . . ."
IPCom neatly says that the '751 Patent's evaluation unit is simply a microprocessor. Chart at 4. Therefore, it does not agree with HTC that this claim limitation is written as a means-plus-function element subject to paragraph 6 of 35 U.S.C. § 112. HTC argues that the function is ambiguous because it is subject to multiple interpretations due to grammatical errors, and its structure is indefinite for failure to disclose such structure in the specification.

Again, the Court concludes that IPCom presents the much more compelling and logical construction, given the Claim, the specification and what would be known to one skilled in the art. "[A] claim term that does not use 'means' will trigger the rebuttable presumption that § 112 ¶ 6 does not apply . . . the presumption flowing from the absence of the term 'means' is a strong one that is not readily overcome." Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004).

Here, the claim does not use the term "means" and HTC has not rebutted the presumption that it is not a means-plus-function term. Moreover, even if it were such a term, the specification describes the corresponding structure. Figure 2 of the '751 Patent shows a mobile station (5) with a transceiver (65), and evaluation unit (60), antenna (70), and subscriber identity module (SIM) card (75). '751 Patent, Fig. 2. The evaluation unit connects to the transceiver and accesses the SIM card. Id. at 5:4-10 ("The transceiver unit 65 is also connected to an evaluation unit 60, which accesses an access authorization card 75, such as a SIM card.") It has memory, id. at 6:60, and performs the steps set forth in Figures 4a-4c of the Patent, determining for example whether certain data is in the received signals, obtaining a value from the SIM card or memory, drawing a random number, and comparing values. Id. at 8:63-10:10. This description of the evaluation unit and its interaction with other components reveals that it is a microprocessor. Thus, the Court construes "evaluation unit" to mean a "microprocessor."

5. "unit having a persistent unique hardware identification used to restrict access to data received at the unit via the wireless signal" (Claim 1)

Keystone proposes a lengthy construction of this term: "A number, code or other location independent identifier (such as a serial number) that identifies a specific piece of hardware and does not identify any other piece of hardware of the same type, and once assigned to that specific piece of hardware does not change, and is employed in the process of preventing retrieval of all or part of user requested data from the data that actually arrived at the unit by way of the wireless signal." Defendants' proposed construction is "a non-volatile number or bit pattern that is unique to a particular unit is provided to the computer system so that the computer system makes a determination whether it will accept data from the unit that was received from a wireless signal."

The parties dispute four issues of construction of this term (1) whether the computer system plays some role in verifying the persistent unique hardware identification; (2) whether the persistent unique hardware identification can ever change; (3) whether the restricted data must be "user requested;" and (4) whether the hardware identification is unique within a given context or unique as to the world.

On the first issue, Keystone argues that the claim language in no way requires the computer to make a verification based on the hardware identification. It points to the fact that the claims simply read "used to restrict access to data received at the unit." Therefore, Keystone argues that while the computer system may make the determination in one embodiment of the system, there is no requirement that this always be the case. It contends that the computer system alone, the unit alone, or a combination of both should be able to make this determination.

Defendants respond by arguing there is no support in the patent for anything other than the computer system doing this verification. First, they note that the claim language itself recites the "cooperation" between the unit and the computer system in receiving data and thereby determining access restriction. Further, defendants note that specification makes clear that "if the proper address signature is not provided to the mobile computer system in the main assembly 3, data access can be restricted." I See '123 Patent, 7:29-33. Additionally, they point to prosecution history wherein the inventor differentiated prior art by pointing to the hardware identifier that is provided to the computer system in this invention. See '123 File History, at SIR0133317 (Sept. 13, 2004); see also id. at SIR0133420 (Oct. 13, 2005).
The Court agrees with defendants that the claim language, specification and prosecution history all demonstrate that the inventor intended the computer system to make the determination of whether access to a unit should be restricted based on the unit's identifier. Although it may be theoretically possible, there is no support in the patent whatsoever to show that the unit itself could authenticate itself and determine that the computer should receive the wireless signal from it, or that this verification can be done by the computer and the unit in tandem. Although it is improper to read a limitation from the specification into the claims, it is also an established axiom that claims must be read in view of the specification, of which they are a part. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004). As defendants point out, the only portion of the specification that discloses this aspect of the invention clearly refers only to "the proper address signature [being] provided to the mobile computer system." '123 Patent, 7:29-33. The inventor highlighted this aspect to the Examiner, explaining that it is the computer system that verifies the hardware identification of the unit. See '123 File History, at SIR013355 (June 24, 2005) ("This feature of the present invention allows the unit to identify itself to the computer system according to a persistent unique identification. By way of example, the persistent unique identification can be used by the computer system to ensure that only registered units are operating with computer system . . . .") (emphasis added). Plaintiff's arguments that the unit itself or the unit in combination with the computer system can perform this verification are not persuasive.

On the second issue, the parties argue that the interpretation of the term, "persistent." Defendants contend that the identifier must simply be non-volatile and persist through any power loss to the unit. They also argue that this identifier can be "intentionally changed." In support, they point to prosecution history wherein the inventor defined "a persistent unique identification" as "i.e., one that does not typically change over time." See '123 File History, at SIR013355 (June 24, 2005). Hence, they contend that it was not the understanding of the inventor that this identifier never changes. They propose that the hardware identification be construed by the Court as being simply non-volatile, but changeable.

Keystone responds that defendants attempt to limit the hardware identification to a type of non-volatile memory when there is no such limitation defined in the patent specification. It argues that persistent should be defined to be location-independent and unchanging once assigned. The Court agrees with the plaintiff on this point. There is no reason to read in a requirement that the persistent identifier be changeable. The Court however adopts the language used by the inventor to define "persistent" during the prosecution of the patent. See Pfizer, Inc. v. Teva Pharm.s USA, Inc., 429 F.3d 1364, 1373 (Fed. Cir. 2005) (finding that absent contrary intrinsic evidence, "i.e." defines the meaning of a term).

The third issue is whether the data being restricted is only "user requested" data. Keystone argues that while data is continuously received at the unit, only the data requested by the user is restricted based on the hardware identification. Plaintiff's arguments to read in such a restriction are not persuasive. The Court finds that all received data can be restricted.

The final issue on this term is if the unique hardware identification needs to be unique to the world. Defendants argue that the intrinsic record is silent as to the meaning of unique, and therefore the understanding of the term in the art should be adopted. This they contend is "one of a kind within a given context." Keystone argues that defendants improperly import this limitation based on prior art asserted by the defendants to invalidate the claims. They note that the specification refers to passwords and hardware unit codes, along with a HEX word address, as being an address signature of the unit. The Court finds that there is no reason to limit this identifier as being unique only within a given context, rather than being unique globally.

Based on the issues resolved above, the Court construes this term as: "A number, code, bit pattern or other location independent identifier that identifies a specific piece of hardware and does not identify any other piece of hardware of the same type, and once assigned to that specific piece of hardware does not typically change, and is provided to the computer system so that the computer system makes a determination whether it will accept data from the unit that was received from a
wireless signal."

GO BACK

4647

We also agree with the Commission that the proper construction of the limitation "a unitary, electrically conducting member carrying a pair of spaced electrical contacts" must give meaning to "unitary." The plain meaning of the term "unitary," which modifies "electrically conducting member," denotes a single, continuous structure. The specification and prosecution history confirm that this plain meaning is appropriate in the context of this claim limitation. See Phillips v. AWH Corp., 415 F.3d 1303, 1316 (Fed. Cir. 2005) (en banc).

For example, the specification teaches that "unitary" refers to the nature of the member's physical structure, not just its electrical relationship with the two contacts. Similarly, the Summary of the Invention describes the member as being "rigid" and "in the nature of a buss bar." '398 patent col.1 ll.56-61. Both descriptions refer to the member's physical characteristics; both imply a single structural unit. Additional description in the summary, which explains how the member moves and interacts with other parts of the device, also reveals that the inventor only contemplated a single structural unit. See e.g., id. col.1 l.62-col.2 l.13.

Contrary to P&S's arguments, this requirement of a unitary structure does not improperly confine the claim scope to a buss bar, or a member cast from a single die or molded from a single piece of metal. A unitary structure may contain layers or be formed by an additive process, so long as the resulting product has the physical character of a single unit. Since the claim language requires that a unitary member carries the pair of electrical contacts, the Commission correctly construed the term to require that both electrical contacts are disposed on the same unitary member.

GO BACK

4648

II.

Herstein contends that the district court failed to properly construe the meaning of the term "unjoined," and that the term should be considered to mean "operational without any separate connection." Claim 1 is representative and provides in relevant part:

1. In a microwave assembly comprising a pair of microwave components and a stripline type of connecting device for electrically interconnecting said components . . . said stripline connecting device comprising:

(a) elongated interconnecting structure for microwave transmission having conductive terminal portions at opposite ends thereof, said terminal portions having lateral faces respectively contacting but unjoined to the projecting end portions of the conductors of said microwave components . . .

'981 patent, col. 10, ll. 41-68.

Herstein further argues that the soldering of the connections in the accused device is not necessary to its operation and that infringement cannot be avoided by the addition of the solder. In Herstein's view, the connection in the accused device should, therefore, be considered to be "unjoined."

Although the district court stated that it "need not engage in a lengthy analysis in construing the claim because there is no dispute as to the meaning of the word 'unjoined' in the relevant claim limitation," Herstein v. Comtek Federal Systems, Inc., Memorandum and Order No. 98-CV-3556 (CBA) at 11 (E.D. N.Y. October 27, 1998) (Herstein I), the court, in its thorough opinion on the infringement issues, carefully considered Herstein's arguments and reviewed the patent's written description and prosecution history in considerable detail. It concluded that the soldered connections in the accused device were not "unjoined" as that term is used in the patent. See id. 1

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
In finding no infringement under the doctrine of equivalents, the court considered two prior art references, Lehrfeld and Logan, and concluded that "joined" connections had been relinquished.

A district court's construction of disputed claim terms is a question of law subject to plenary review on appeal. See Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc). We give disputed claim terms their ordinary and accustomed meaning, within the context of the claim, unless (1) a different meaning is clearly set forth in the written description or the prosecution history; or (2) the meaning of the term is unclear from the context of the claim. See Johnson Worldwide Assoc., Inc. v. Zebco Corp., 175 F.3d 985, 989-90, 50 U.S.P.Q.2D (BNA) 1607, 1610 (Fed. Cir. 1999). Claim construction is independent of the device charged with infringement. See Pall Corp. v. Hemasure, Inc., 181 F.3d 1305, 1308, 50 U.S.P.Q.2D (BNA) 1947, 1949 (Fed. Cir. 1999).

A review of the written description of the '981 patent and its prosecution history reveals that the term "unjoined" is not specifically defined. However, the claim term is used in the context of the interconnecting structure having "conductive terminal portions with lateral faces respectively contacting but unjoined to the projecting end portions of the conductors of [the] microwave components." The term "unjoined" does not appear to be so ambiguous that one of skill in the art must look elsewhere in the patent for its meaning. See Johnson Worldwide Assoc., Inc. v. Zebco Corp., 175 F.3d 985, 990, 50 U.S.P.Q.2D (BNA) 1607, 1611 (Fed. Cir. 1999) (citing Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187, 48 U.S.P.Q.2D (BNA) 1001, 1005 (Fed. Cir. 1998)). Based on the claim language alone, the district court's comment that there is no dispute as to the meaning of the term "unjoined" is appropriate.

Herstein contends that the term "unjoined" should be considered to have a special meaning, i.e., "operational without any separate connection." We, therefore, consult the patent specification and prosecution history to determine whether Herstein's asserted construction of the term "unjoined" is revealed or otherwise appropriate. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996).

Both the patent and the prosecution history provide guidance. The patent is directed to a microwave assembly technique that, inter alia, is free from the disadvantage of soldered connections that do not allow easy replacement of components. See '981 patent, col. 1, ll. 35-68, and col. 2, ll. 1-22. The written description provides further that the "connection between the components is achieved by mechanical clamping. Neither cement nor solder is required for the connection. Component removal and exchange can be performed simply by unclamping and reclamping the housing portions, and this can be done without damage to the leads or tabs." Id., col. 6, ll. 58-64. Finally, the patent provides that "the mechanical clamping utilized in the test fixture leaves the components' leads clean, and reassembly in the final subsystem is extremely simple." Id., col. 8, ll. 51-54. It is clear from this language that one of the salient features of the invention is the ease of connection and disconnection of components.

The prosecution history is also informative. In response to the PTO's rejection of the claims as unpatentable over two prior art references - Lehrfeld and Logan - the claims were amended to add the term "unjoined." The Lehrfeld reference did not employ mechanical clamping, but instead used solder or adhesively bonded joints to achieve its connections. In distinguishing Lehrfeld, it was argued that the invention was distinctive because of its use of mechanical clamping and because the terminal portions of the invention's connecting structure and the projecting ends of the microstrip conductors were unjoined.

The Logan reference employed mechanical clamping and solder in the relevant connections. It was distinguished because the connections were joined and did not allow the feature of the invention of quick connection and disconnection of the microwave components, which was achieved by the invention's unjoined mechanical clamping.

Based on the claim language, the written description and the prosecution history, we conclude, as did the district court, that the term "unjoined" means a connection that employs mechanical clamping and which is not soldered.

Herstein contends, however, that the addition of solder to the accused device was unnecessary and that the accused device was operational and literally infringed the '981 patent before the solder was added.
2 Although Herstein argues that MicroKim conceded that the solder was added to the connections in order to avoid infringement, the record does not bear this out.

The district court fully considered this argument and specifically ruled that:

where one element of the relevant claims is that the device be "unjoined," the accused device clearly does not include all elements of the claims. Defendants have not merely "added" an additional element. They have added a feature that the claims of the '981 patent expressly do not include.

Herstein I at 13 (emphasis in original).

As previously discussed, the term "unjoined" when properly construed means a connection that is not soldered. In MicroKim's accused device the relevant connections are soldered during manufacture. The accused device does not meet all the limitations of the '981 patent claims and, therefore, does not literally infringe.

4649

B. "Unknown Destination"

Fortinet proposes construing "unknown destination" as an unspecified destination, while PAN advocates construing it to mean a destination that has not yet been determined. In other words, the parties dispute whether "unknown" refers to: (1) the fact that the communication does not identify a specific final destination intended by the sender, as Fortinet contends, or (2) the fact that the system receiving the communication has not yet determined where the communication will ultimately be sent, as PAN contends. The court agrees with Fortinet.

Neither the claim language, nor the specification provide much guidance as to the meaning of "unknown destination." The claims discuss a process by which the system receiving the communication determines where the communication will ultimately be sent, but they do not clarify whether the claimed invention encompasses the process for making such determinations when the sender of the communication has requested a specific final destination. The specification is also unhelpful, as the phrase "unknown destination" is never used, much less defined, in the specification.

The prosecution history, however, makes clear that an "unknown destination" is an unspecified destination, meaning the communication does not identify a specific final destination intended by the sender. "The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution." Southwall Techs. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995). During the prosecution of the '272 Patent, the examiner had initially rejected the majority of the claims as anticipated by United States Patent No. 5,757,904 ("Anderson reference"). The applicant sought to distinguish the disclosed invention from the prior art Anderson reference by arguing that the Anderson reference "relate[s] to situations in which the caller has already specified the destination by requesting a specific person." Dkt. No. 47 Ex. B at PAN000178. In an interview with the examiner, the applicant "identified the difference, non-specific requests, between the disclosed invention and Anderson. Examiner suggested that the claims be amended to recite 'unknown destinations' for overcoming the prior art of record." Id. at PAN000231. Based on this conversation, the applicant amended the claims to recite the "unknown destination" limitation in order to overcome the Anderson prior art. Id. at PAN000226. Hence, the patentee has expressly limited the scope of the claims to situations where the sender has not made a specific request regarding the intended final destination for the communication. The court therefore construes "unknown destination" as an unspecified final destination.

1 The court adds the word "final" to Fortinet's proposed construction in order to clarify that the claims encompass situations where the sender has identified a general or intermediary destination, such as the number of a customer service hotline, but
has not identified the intended final destination, such as a particular individual or department.

--- End Footnotes ---

4650

Claim Element 1h

wherein the web page is accessible from the second user point via an unlisted universal resource locator, and users at the second user point are provided with at least one user ID and user password

The parties disagree on the meaning of "unlisted universal resource locator."

Dell proposed: "an internet address not commonly accessible." Dell further proposed that the remaining terms should be construed according to their ordinary meanings.

Lucent proposed: "the web page containing the customized information is accessible from the second user Internet point by inputting a confidential URL not available through a web search that, along with at least one user ID and user password, has been previously provided to the second user Internet point."

The court construes "unlisted universal resource locator" as follows:

"an internet address not purposefully made available for discovery through a web search or otherwise."

4651

6. ferromagnetic (claims 1, 2); magnetic material pins (claim 5); unmagnetized magnetic material (claim 8)

Fargo ferromagnetic: of or relating to a class of substances characterized by abnormally high magnetic permeability, definite saturation point, and appreciable residual magnetism and hysteresis

magnetic material pins: pins made of a magnetic material

unmagnetized magnetic material: magnetizable material that is not permanently magnetized

Iris ferromagnetic: a material that exhibits ferromagnetism, but is not magnetized

magnetic material pins: pins made of a material that is capable of being magnetized, but is not magnetized

unmagnetized magnetic material: material that is capable of being magnetized but, in the absence of an applied external magnetic field, is not magnetized

--- Footnotes ---

n5 Iris offered this proposed construction at oral argument.

--- End Footnotes ---

The focus of Iris's arguments regarding these terms is that, within the context of the patent, they all refer to material that is capable of being magnetized, but is not magnetized. Iris highlights evidence in the prosecution history where the applicant sought to distinguish prior art on the basis that the supply rolls have "no magnets." (Fink Aff., Ex. C, pt. 4, at C61-C62.) The
document states:

Claim 11 [issued Claim 8] is specific to the positioning of the identifier indicia, using an unmagnetized magnetic material. This feature is very important, again, from a pollution control standpoint, because there are no magnetic materials that are utilized on the roll, but yet the reliability of a magnetic sensor can be utilized using one stationary detector of the present invention.

* * *

With the present invention the magnetic material pins are cheap, they are non-polluting, and since there are no magnets, there are no plurality [sic] requirement. They can be placed on the supports or inserted into the apertures without regard to polarity.

The doctrine of prosecution disclaimer prevents a patentee from recapturing a specific meaning that it disclaimed during prosecution. Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1323 (Fed. Cir. 2003). The disclaimer must have been clear and unambiguous for the doctrine to apply. Id. at 1324. Fargo argues that there is no clear and unmistakable disavowal of the ordinary and customary meaning of "magnetic material pins." The problem with Fargo's argument, however, is that its proposed construction for "magnetic material pins" is "pins made of a magnetic material." Yet the prosecution history clearly indicates that the "invention" has "no magnets." Neither Fargo's arguments nor its proposed definition help explain how "material" that is "magnetic" is nevertheless not a "magnet."

At oral argument, Iris offered a new definition for "unmagnetized magnetic material" to counter any objection that its previous definition might have excluded the pins in the patent because they are briefly magnetized as they pass through the magnetic field that is part of the sensor. The resulting definition, "material that is capable of being magnetized but in the absence of an applied external magnetic field is not magnetized," is a better definition than Fargo's because it avoids the ambiguity of the word "permanent." In light of the prosecution history indicating that the supply rolls have "no magnets," the Court will adopt this definition for "unmagnetized magnetic material" and a similar definition for "magnetic material pins:" "pins made of material that is capable of being magnetized but in the absence of an applied external magnetic field is not magnetized." In so doing, the Court is aware that it is defining different terms to have essentially the same meaning. Although a patentee's use of different terms normally indicates that it intended those terms to carry different meanings, a reading of the patent and prosecution history does not reveal what that difference might be in this case, and Fargo's objections to Iris's proposed definitions ignore the clear statement in the prosecution history regarding the lack of magnets.

Finally, in light of that same prosecution history, the Court will adopt Iris's definition of "ferromagnetic," modified as follows: "a material that exhibits ferromagnetism, but, in the absence of an applied external magnetic field, is not magnetized." Because Iris concedes that Fargo's definition of "ferromagnetic" is correct "in the abstract," the Court will adopt Fargo's definition of "ferromagnetic" insofar as it is necessary to define the word "ferromagnetism" in Iris's definition of "ferromagnetic."

B. Ref. No. 7 "Wherein the unique voting session identifier is unrelated to a particular voter's personal identity."

This phrase is recited in Claim 1 of the '730 Patent.

Plaintiff proposes the following construction: "The unique voting session identifier consists of a random or pseudo-randomly chosen number." Defendants, on the other hand, argue that the term does not require a construction separate and apart from the definition of unique and voting session identifier as set forth in the previous claim.

The patentee on several occasions informs us that the voting session identifier cannot be associated with the personal identify of the voter. (See Col. 16, ll. 58-59; Col. 8, ll. 43-45; Col. 8, ll. 55-58; Col. 8, ll. 65-67; Col. 10, ll. 47-49; Col. 20, ll. 11-20; Col. 20, ll. 25-30; Col. 24, ll. 1-7.) Based upon the discussion in the previous claim, it appears to the Court that the inventor was concerned about the anonymity of the voter as related to the voting session identifier. Therefore, this feature should be included in the construction of this term.
For the foregoing reasons, the Court has construed the term in Ref. No. 7 as follows: "The unique voting session identifier consists of a random or pseudo-randomly chosen number which is unrelated and untraceable to the voter's identity."

II. DISCUSSION

During the briefing on claim construction for the term "unrequested," Beneficial offered the proposed construction of "not requested by the user" whereas Defendants proposed "not sent in response to a signal from a user's computer." In the Court's claim construction order, the Court rejected Defendants' proposal and construed the term "unrequested" to mean "not requested by the user." The Defendants ask the Court to reconsider its construction of the term "unrequested" in view of Beneficial's remarks to the USPTO. Defendants request that the Court construe the term "unrequested" to mean "just appears and is not in response to any immediately previous user input."

Defendants contend that the patentee's arguments to the USPTO during reexamination contradict the arguments made by Beneficial during the claim construction hearing before this Court. Defendants argue that Beneficial wants the term
"unrequested" to mean one thing in this litigation to prove infringement and to mean something else before the USPTO to preserve validity. At the claim construction hearing, Plaintiff provided to the Court an example of what it considered to be an "unrequested advertisement." The example showed the user inputting a query into a Google search engine and receiving a web page in immediate response to this input. The web page contained results of the search performed by the search engine together with an advertisement. Even though the web page containing advertisement was sent in immediate response to the user inputting the query, Plaintiff characterized the advertisement on that web page as "unrequested." Defendants argue that this example of the "unrequested" advertisement at the claim construction hearing is substantively indistinguishable from the advertisement disclosed in Internet Week that Plaintiff argued is not "unrequested" to the USPTO.

Beneficial argues that it did not expressly define the term "unrequested" in the reexamination. Rather, in arguing to the USPTO that the asserted prior art reference did not teach a system that provided "unrequested" advertising, Beneficial argues that it merely provided the Examiner with an example of one type of advertisement that would be an advertisement that was not requested by the user. Beneficial also argues that the example of an unrequested advertisement that it presented to the USPTO is consistent with its proposed claim construction to this Court and refutes the construction proposed by the Defendants during claim construction. Beneficial also argues that its arguments to the USPTO do not constitute the clear and unambiguous disavowal of claim scope that would be required to overcome a construction compelled by the ordinary meaning of the claim language and the specification.

In distinguishing the prior art during reexamination, the patentee provided an example of "unrequested advertising" as "advertising that just appears and is not in response to any immediately previous user input, e.g. a pop-up ad." The Court finds that the patentee was not merely giving an example of an unrequested advertisement, but was defining the term "unrequested" in its attempt to distinguish the prior art. By distinguishing the claimed invention over the prior art during the reexamination, Beneficial has taken a position on how the term "unrequested" should be construed. The Court rejects Defendants' contention that the remarks during reexamination support Defendants' proposed construction during claim construction. However, while the example of "unrequested advertising" made during reexamination is not directly inconsistent or contradictory with the Court's construction, it is certainly a narrowing of the Court's construction for the term "unrequested." Further, the Court finds that Beneficial's arguments to the Examiner that the prior art is not "unrequested," in which the search engine returns both the search results and a banner advertisement in response to a user's search query, is contradictory to its arguments to this Court that a web page responsive of Google search results combined with an advertisement is "unrequested."

The Federal Circuit is clear that a claim is to be interpreted by the prosecution history of the patent, which includes arguments made during any reexamination. See CIAS, 504 F.3d at 1362-63; CVI/Beta, 112 F.3d at 1158. The Court rejects Beneficial's arguments that this Court should ignore the arguments and remarks made to the USPTO during reexamination, particularly in light that its arguments to the USPTO are contradictory to arguments it made to this Court. The Court will not allow Beneficial to make arguments as to the interpretation of claims in this Court and then to make contradictory arguments to the USPTO in distinguishing the prior art without any effect on the scope of the claim. Defendants propose that this Court adopt verbatim Beneficial's arguments during reexamination that "unrequested" should mean "just appears and is not in response to any immediately previous user input." The language "just appears" is not particularly helpful in the construction of the term, and thus the Court rejects Defendants' proposal that includes this language. The Court finds that the term "unrequested" should be construed to mean "not in response to any immediate previous input by the user."

IV. CONCLUSION

The Court finds that the construction for the term "unrequested" should be modified in light of Beneficial's remarks and arguments to the USPTO during reexamination of the '366 patent. The Court adopts the construction set forth in this opinion for the "unrequested" term in the '366 patent. The parties are ordered that they may not refer, directly or indirectly, to each other's claim construction positions in the presence of the jury. Likewise, the parties are ordered to refrain from mentioning any portion of this opinion, other than the actual definitions adopted by the Court, in the presence of the jury. Any reference to claim construction proceedings is limited to informing the jury of the definitions adopted by the Court.
5. "Ordinary Unresolved Pointer"

While the parties agree that "ordinary unresolved pointers" are always resolved by high-level language routines, IBM reads into the term the further requirement that an "ordinary unresolved pointer" is an unresolved pointer that is not converted into a resolved pointer after the address of its target is determined. Data General, on the other hand, maintains that an ordinary unresolved pointer could be (but is not necessarily) resolved once by a high-level language routine and then converted into a resolved pointer.

Proper claim construction of the term "ordinary unresolved pointer" requires an understanding of several related terms, of which the definitions are undisputed. The parties agree that a "pointer" is a data item that represents the address of a target data item. A "resolved pointer" contains the target's address. An "unresolved" pointer does not contain the target's address, but instead, contains data from which that address may be determined.

Claim 10 recites in relevant part:

… said data items include ordinary unresolved pointers, each one of said ordinary unresolved pointers representing a represented address of said addresses and containing said data items from which said represented address may be derived.…

The term "ordinary unresolved pointer" is not a term commonly used in computer engineering, and thus, this Court must look beyond Claim 10 to the Common Specification to construe the term. The Common Specification distinguishes between two kinds of unresolved pointers, "ordinary unresolved pointers" and "associative pointers":

The subclasses of unresolved pointers are ordinary unresolved pointers and associative pointers. The difference between the two kinds of unresolved pointers is the manner in which they are resolved. Ordinary unresolved pointers are always resolved by high-level language routines, while associative pointers are resolved the first time they are used in a Process 610 and a domain by high-level language routines, but are subsequently resolved by means of a table called the Associated Address Table (AAT). This table is accessible to microcode, and associative pointers may therefore be more quickly resolved than ordinary unresolved pointers.

'602 Specification, col. 327, l.60 - col. 328, l. 4. The parties agree that, as the Common Specification unambiguously states, ordinary unresolved pointers are always resolved by "high-level language routines."

Data General maintains that an ordinary unresolved pointer could be resolved once by a high-level language routine and then be converted into a resolved pointer. According to Data General, Claim 10 simply requires that the pointer resolution sequence return the target's address but is silent as to whether or not the unresolved pointer is overwritten with the resolved pointer.

This Court was persuaded by Professor Graham's testimony that the replacement of an unresolved pointer with a resolved pointer is conceptually distinct from determining the target of the unresolved pointer. (Graham T. 3/19). The computer can access the target data item without overwriting the unresolved pointer, but at the cost of having to determine again the target address should it encounter the pointer again in the same program. For reasons of efficiency, a computer might overwrite a pointer so that it can go directly to the target data item if it encounters the pointer again in the same run, without the need to resolve the pointer again. Claim 10, Data General argues, does not speak to whether the computer performs this optional step.

In IBM's view, however, the language of the Common Specification supports its proposed construction, namely, that an ordinary unresolved pointer is never converted into a resolved pointer upon the determination of the address of its target. IBM further argues that Data General's construction is inconsistent with the language in the Common Specification.

First, IBM asserts that Data General's contention that an ordinary unresolved pointer could be resolved once and then converted into a resolved pointer contradicts the statement in the Common Specification that "ordinary unresolved pointers are always resolved by high-level language routines." IBM contends that if Data General's position were correct, then an ordinary unresolved pointer would be "resolved by high-level language routines" only the first time it was used. Thereafter,
on subsequent uses of the pointer, no resolution would be required. Thus, such a pointer would not "always" be "resolved by high-level language routines."

IBM's argument is without merit. If a computer replaced an unresolved pointer with a resolved pointer, after determining the target's address, that pointer will no longer be unresolved when encountered again in the same program. Thus, replacing an ordinary unresolved pointer with a resolved pointer is not inconsistent with the statement in the Common Specification that an ordinary unresolved pointer is an unresolved pointer that is "always resolved by high-level language routines" because a particular ordinary unresolved pointer disappears when it is replaced with a resolved pointer.

Second, IBM argues that Data General's proposed construction contradicts the statement in the Common Specification that "associative pointers may therefore be more quickly resolved than ordinary unresolved pointers." IBM contends that if, according to the system Data General envisions, a particular ordinary unresolved pointer were overwritten with a resolved pointer, the next time the processor encountered that pointer it would be "resolved" more quickly than an associative unresolved pointer, which would still have to be looked up in the Associated Address Table.

This argument is similarly unavailing. Again, the critical weakness in IBM's argument lies in the fact that an ordinary unresolved pointer would disappear were it replaced by a resolved pointer. If a particular ordinary unresolved pointer were overwritten with a resolved pointer, the next time the processor encountered that pointer, it would no longer be an ordinary unresolved pointer. The notion that a resolved pointer is "resolved" faster than an associative pointer in no way contradicts the Common Specification language that "associative pointers may therefore be more quickly resolved than ordinary unresolved pointers."

Thus, as outlined above, Data General's interpretation does not appear to be inconsistent with the language in the Common Specification. Data General's expert, Professor Finkel, highlights an example in the Common Specification where an unresolved pointer is resolved and then overwritten. (Finkel T. 1/109-10). That portion of the Common Specification which describes the resolution and overwriting of unresolved pointers by software lends credence to Data General's proposed construction while undermining that of IBM.

The Dynamic Linker then obtains the UID of Procedure Object 608 from EOS, uses the UID and offset information contained in the Binder Area location to locate Procedure 602's gate, places the pointer to the Gate at the location occupied by the unresolved pointer in the Static Data Block, and returns the pointer to the pointer-to-descriptor microcode. The microcode is now able to convert the pointer to a descriptor….

'602 Specification, col. 331, l. 66 - col. 332, l. 5.

3. "unscrambling circuit"

The plaintiffs assert that the term "unscrambling circuit" requires no further construction. Joint Claim Construction Brief, Exh. B. Defendant EchoStar argues it means a circuit that restores a scrambled analog signal to its unscrambled condition. The DIRECTV defendants argue an "unscrambling circuit" is the entire electronic circuit that restores a scrambled analog signal to its unscrambled condition.

I have construed "scrambling" to apply to both analog and digital signals. I have construed "unscrambling" to mean restoring a modified signal to its unmodified condition.

The DIRECTV defendants argue that the term should be construed to include "the entire circuit that unscrambles the signal . . . to clarify that the claim language itself dictates that the circuit include both 'key elements,' and perhaps other elements that do not satisfy the 'key elements' limitation." Defendant DIRECTV . . . Principal Opening Brief On Claim Construction, at p. 57. I do not understand the plaintiff to disagree.

I construe the term "unscrambling circuit" to mean the entire circuit that restores a modified signal to its unmodified condition.
10. Claim 10: "unswitched" "Unswitched is construed to mean "the mode in which the bypass is off or not utilized."

A. Untrusted Network

The parties agree that the patentee explicitly defined the term "untrusted network" in the specification of the '416 Patent. However, they disagree as to whether the patentee's definition comprises one or two sentences. The relevant part of the specification reads:

"As used herein, an untrusted network is defined as a public network with no controlling organization, with the path to access the network being undefined and the user being anonymous. A client-server application running over such a network has no control over the transmitted information during all the phases of transmission."

('416 Patent, col. 3, ll. 59-64). Plaintiff contends that "untrusted network" is defined by only the first sentence, whereas Defendants contend that the patentee intended "untrusted network" to be defined by both sentences. (D.I. 266, pg. 25; D.I. 305, pg. 26; D.I. 268, pg. 39; D.I. 306, pg. 17). Defendants contend that the patentee clearly intended to limit the scope of the term "untrusted network" to "control" over transmitted information, and that desired scope is only apparent when both sentences are read together. (D.I. 268 at 39).

After reviewing the claim language and the specification, the Court concludes that the second sentence explains how an untrusted network acts upon a client-server application, while the first sentence contains the patentee's definition of the term. Accordingly, the Court agrees with Plaintiff, and construes "untrusted network" to mean "a public network with no controlling organization, with the path to access the network being undefined and the user being anonymous."

4. '769 Patent Claim 1, 11, 23, 35, 43: "updated billing rate parameters"

Claim 35 describes the apparatus for updating the call rating device. The claim includes four elements; only one sub-element of the fourth element is in dispute.

"means transmitting from the rate provider to the call rating device the updated billing rate parameters when the rate provider determines that an update is required."

The parties dispute the meaning of the term "updated billing rate parameters." The term "updated billing rate parameters" appears in Claims 1, 11, 23 and 43 as well, and has the same meaning as it has in Claim 35. 12

12 No particular or definite means for transmitting is described by this language. The element is therefore a "means-plus-function" claim governed by paragraph 6 of section 112. The only part of the claim that is actually limited by the specification, however, is the means itself. The function that the means performs is fully described in the claim itself. The function of the claim is therefore not limited by the specification, although the specification is a useful aid in interpreting the claim.
According to the claim, the apparatus would be required to transmit "from the rate provider to the call rating device the updated billing rate parameters." MediaCom contends that the term should be construed to require transmission of entire new rate tables whenever the rate provider determines that an update is proper. Rates maintains that the claim requires modifications to the database of the call rating device in order to make current the information stored there, but does not require transmission of entire new rate tables.

The meaning of the disputed term is not obvious from the context of the claim. The specification explains that "billing rate parameters could include the rates for local and long distance calls, and the rates of various carriers in some instances." Col. 3, Lns. 19-21. The billing rate parameters are compiled in a "rate table" that is stored in the "current rate table storage" and the separate "new rate table storage" components of the call rating device. Col. 3, Lns. 24-31. Similarly, the rate provider stores billing rate parameters in a (typically larger) "rate table storage" device. There is no question that the billing rate parameters are stored in the form of tables, as MediaCom argues.

The specification does not say, however, that the information is transmitted in the form of tables, as MediaCom urges the Court to conclude. MediaCom points to Col. 4, Lns. 58-59, "the rate table is replaced (block 105) if changes are required." This language reveals that the new table entirely replaces the current table within the call rating device once the new table becomes effective. 13 It does not reveal, however, how the data are transmitted from the rate provider to the call rating device in the first instance. Similarly, the specification refers to a "newer rate table" becoming available within the rate provider device, Col. 6, Lns. 19-20, but does not discuss transmission. The only discussion concerning transmission of billing parameters refers to a "block of data" or "block of information" being retrieved and sent. Col. 5, Ln. 11, 28; Col. 6, Lns. 2-19. The specification contemplates that an update might require the transmission of more than one such block, based on a determination of whether more data is needed to update the database. Col. 6, Lns. 6-19.

Absent some other clear indication in the specification, there is no reason to conclude that the "updated billing rate parameters" must be transmitted in the form of complete rate tables. Thus the claims encompass transmission of the complete new tables, or, in the alternative, additions, deletions, or modifications to the existing rate tables.

--- Footnotes ---

13 The reason two storage areas are required within the call rating device is that new billing information may become available before the new rates actually go into effect. By using two different tables, the device can be updated as soon as the new rates are publicized, but continue to refer to the old rates as long as they remain in effect.

--- End Footnotes ---

5. "updated secret state"

Step (b) of the process provides: "applying at least said selected transformation operation to said internal secret state to produce an updated secret state." For convenience, the Court will refer to step (b) as the "applying step." In the applying step, the parties dispute the construction of the phrase "updated secret state." In particular, the dispute is over whether an exemplary "mathematical function" disclosed in the written description 4 should be included in the construction. Defendant would like to import the limitation that the "transformation operation" is a "mathematical function."

--- Footnotes ---

4 (See '092 Patent, Col. 4:35-39.)

--- End Footnotes ---

The ordinary and customary meaning of "to update" is "to change." Nothing in the specification, including the claim, indicate that the inventor intended to limit "updated secret state" to the exemplary mathematical function disclosed in the written description. Therefore, the Court finds that the ordinary and customary meaning attributed to the term "updated secret state" by those skilled in the art should be applied.
Accordingly, the Court construes the phrase "updated secret state" to mean: a changed secret state.

D. Updating

The patentee has used several terms in the patent claims that have similar connotations, including "storing" and "maintaining," both of which could be used to suggest the idea of "keeping." Another set of terms vulnerable to confusion is "maintaining" and "updating," either of which could encompass the concept of revising something. To discern the actual meaning in the Hill patent for any of these terms requires careful scrutiny of the context in which the term is used, and consideration of the broader context of the patent itself. The Court has just defined "maintaining" as "keeping the most current information available," which then must be distinguished from the word "updating." Although both terms involve the idea of incorporating revisions, "maintaining" refers to keeping information in a certain state or condition, while "updating" refers to the actual process of bringing data, files, or programs up-to-date.

In the Hill patent, "maintaining" is used only in connection with data or programs on the main computer, and it implies a volitional act, whereas "updating" occurs only with respect to the data or programs on the remote computer, and implies a system-generated activity. The file history makes this point in remarks about an amendment made to "more particularly point out" that constant data stored on the remote computer is a subset of the product information data in the electronic catalog. See Plf's Ex. 93, Tab 9, at 5. When discussing the product selection process, the patentee described the updating of constant data on the remote computer as "automatic." Id. at 6. Specifically, the patentee declared that "the customer never has to request an update of constant data." Id. These passages are in response to an Official Action dated May 23, 1994, in which the examiner rejected claims 1-6, 9-19, 22, 24-29, 32-64, 66-71, and 73-74, based on obviousness in light of prior art. Id., Tab 7 at 3. The examiner had noted that the Waite patent taught the "inherent step" of storing and maintaining a main revision status in the main computer to indicate the revision level of constant data stored therein. Id. at 4. In this prior art reference, such information was necessary to allow a remote user to request the correct revision level of a particular product. Id. It was in response to these objections that the patentee represented in his invention updating of constant data on the remote computer was never at the request of the customer. Thus, the prosecution history supports a finding that "updating" involves the idea of an automatic process.

The patent also describes "updating" as a process of transmitting revised data or programs from the main computer to the remote computer, while "maintaining" refers to action taken only at the main computer. In a network of computers, when there is a main or host computer and one or more remote computers, a hierarchy is created. See Tr., Vol. I at 25-26, 34. By only referring to the process of "updating" as a transmission of information from the main computer to the remote, the Hill patent recognizes that hierarchy. See Id. at 28, 34. Updating involves an automatic transmission of portions of the revised data or programs from the main computer (where the latest program revisions and all data is maintained) down the hierarchy to the remote computer (where such things are only stored). The Court finds that "updating" is also distinguishable from "maintaining" by these features -- the locus of each activity within the network hierarchy and the automatic nature of the process of "updating."

According to Hill, the ordinary definition for "updating" is simply "bringing up to date," and although technical definitions may be found, they are consistent with this proposed ordinary definition. The technical definitions presented at the hearing include, "in database management, a fundamental data manipulation that involves adding, modifying, or deleting data records so that data is brought up-to-date." Webster's New World Dictionary of Computer Terms. Hill's expert testified that this is the meaning that would be understood by one of ordinary skill in the art. Tr., Vol. I at 78-79. Similarly, another technical dictionary defines "update" as, "to change a system or a data file to make it more current." Microsoft Press Computer Dictionary. Compuserve's proposed definition includes several other elements: "bringing up to date all of the constant data files of the electronic catalog stored on the remote computer by transmitting in a single transmission containing the constant data files necessary for synchronization so that a complete copy of all of the most current constant data files are [sic] stored on the remote computer." Def's Brf. at 25.

In support of this definition, Compuserve cites passages from the description of the preferred embodiment relating to the step of comparing the remote and main program and constant data revision statuses. '490 Patent, Col. 18, ll. 47-51. The passages refer to a process in which "all the updated files are compressed into a single update file" and sent from the main.
computer to the remote computer. Id., ll. 59-62. The "single update file is then downloaded" onto the customer's computer in
response to an update request. Id., ll. 62-64. From this, Compuserve concludes that the claim term "updating" must mean the
process of transmitting all updated files, which have been compressed into a single update file, and that "all" means every
constant data file for the entire electronic catalog system that has changed since the last time the remote computer accessed
the catalog.

In another passage, the circumstances are discussed under which the constant data and software on the customer's computer
are more than one revision level behind those on the main computer. In that case, "all of the files for all of the revisions that
the customer requires to become updated are compressed into a single file and downloaded." '490 Patent, Col. 19, ll. 26-31.
Compuserve deduces from this passage further support for its contention the patent requires that all of the changed constant
data be transmitted to the remote computer and synchronized. Def's Brf. at 27. At no point does Compuserve address the
language in the actual claims, or attempt to construe the term "updating" in that context. Nor does Compuserve refer to the
summary of the invention in the specification for any guidance as to the meaning of this claim term.

Based on the cited passages alone, the Court is not satisfied that Compuserve has demonstrated that the patentee created a
"special and particular definition" for "updating" that is more specific than the ordinary technical or dictionary meanings. In
fact, Compuserve's proposed definition specifically refers to constant data, whereas the claims use "updating" in connection
with both constant data and program files. It also imports the "single transmission" limitation found in the preferred
embodiment into the definition of a broader claim term, which is improper. See '490 Patent, Col. 18, ll. 59-62; Mantech, 152
F.3d at 1374; SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1121 (Fed. Cir. 1985). For these reasons, the Court will not
adopt the single transmission of all constant data element of the proposed definition of the defendant.

This decision, however, does not end the inquiry. Both parties have presented arguments about whether "updating" means
that all of the revised data and program files on the main computer must be sent each time updating occurs. Compuserve
contends that updating means transmitting all of the current constant data files on the main computer to the remote.
Hill opposes Compuserve's definition by arguing that the word "all" does not appear in the claim language, and that adding
it to the definition of updating would thus be improper. According to Hill, the only revised data used for the updating step is
the data needed for the specific task to be performed. This argument misses the point. It is the word "updating" that the
Court must construe, and the question is whether that term should be defined to include the limitation that all revised data
and program files on the main computer be included with each update. Answering that question requires the Court to further
examine the claims and the specification for relevant textual clues.

In the summary of the invention, the constant data updating step is described as including the step of "determining updated
portions of the constant data stored in the main computer that are different than the constant data stored in the remote
computer," transmitting those "updated portions," and "replacing portions of the constant data stored on the remote
computer with the updated portions . . . received from the main computer." '490 Patent, Col. 3, ll. 64-67, Col. 4, ll. 1-5
(emphasis added). In another passage, the patentee refers to the method of "automatically" updating a program on a remote
computer. Id., Col. 4, ll. 22-24. A part of that method includes the step of "updating portions of the program" in the remote
computer that are different from the program in the main computer. Id., ll. 35-37 (emphasis added). A similar pattern of
language is used for an illustration of the updating step, each time referring to portions of data that vary from the data on the
remote computer. Id., Col. 4, ll. 40-48. What this language does is point the way to a determination of what data will be
included in an update: the data that is different from what is stored on the remote computer.

Such a limitation is born out in parallel language in the claims. Specifically, Claim 1's updating step calls for updating the
constant data in the remote computer "with constant data maintained in the memory of the main computer that is different
from the constant data stored in the memory of the remote computer." '490 Patent, Col. 22, ll. 5-8 (emphasis added). In
Claim 15, the updating step uses similar language, updating "with constant data stored in the memory of the main computer
that is different from" that stored in the remote computer. Id., Col. 23, ll. 45-48 (emphasis added). Although these passages
suggest that Hill's argument about the transmission of less than all revised files might be correct, their significance in
relation to the meaning of the claim term "updating" cannot be understood without consideration of other language in the
claims.

When a transmission of data relating only to the specific task to be performed by the remote computer is described in the
specification or the claims, the modifier "related to" is used. For example, Claim 1 calls for "transmitting variable data
related to the at least one product" from the main to the remote computer. '490 Patent, Col. 22, ll. 9-11 (emphasis added).
Further, in Claim 15's transmitting step, the method calls for transmitting "variable data related to the selected product" from the main to the remote computer. Id., Col. 23, ll. 49-50 (emphasis added). The integrating step in Claim 15 uses similar language to represent this concept. It requires "integrating constant data stored in the memory of the remote computer associated with the selected product with the variable data . . . ." Id., Col. 23, ll. 51-53 (emphasis added). In Claim 1, the integrating step requires "integrating constant data related to the at least one product . . . ." Id., Col. 22, ll. 12-13 (emphasis added). By using this modifier in the patent claims to indicate the intent to limit the operation being performed to the data needed for the specific task initiated by the customer, the patentee demonstrated that he did not intend to so limit the operation performed on data without the modifier. Thus, Hill's contention that "updating" means transmitting less than all of the revised files or data from the main computer to the remote is not supported in the context of the claims.

Having said this, the question of whether the claim term "updating" should be defined to limit it to a transmission of all the revised data or files on the main computer would seem to be answered. It is not. The reason for this is that the question of whether all or only a portion of the revised files would be transmitted during updating is answered in the claim itself, and the answer need not become a limitation in the definition of the term "updating." As the Court has noted, the claim language makes clear that the constant data or programs from the main computer to be used for updating the remote computer will be those that are different from the constant data or programs stored in the remote computer. Because the constant data stored in the remote computer is a "subset of information data related to the at least one product," it is conceivable that only a subset of all the revised data on the main computer would be transmitted during an update.

By limiting the claim term with respect to how much constant data would be transmitted, the Court would effectively remove that possibility from the claimed invention. That is not necessary. The Court has not accepted the invitation of the parties to interpret the scope of the claim at this point in the litigation. Rather, it is accepting the Markman invitation to define the individual claim term. It is in the interpretation of the scope of the entire updating step that the Court will address the issue of whether all revised data or files must be transmitted, not during the Markman process of construing individual claim terms.

When construed in the context of the other steps in the method claim and the specification, the word "updating" cannot be defined as including a limitation that all revised constant data on the main computer be sent with each transmission. Nor is it adequately defined for purpose of this patent by the phrase "bringing up to date." Thus, the Court finds that the term "updating" should be defined as "an automatic process of adding, modifying, or deleting data records or program files to bring the remote computer up-to-date." This definition is consistent with the cited technical dictionary definitions, and "stays true to the claim language and most naturally aligns with the patent's description of the invention." See Renishaw, 158 F.3d at 1250.

Step 4

The parties dispute the proper construction of Step 4, which provides for "updating, without input from each customer, each customer profile in accordance with the content profiles of the data sources actually accessed by that customer to automatically update each customer's actual preferences for said predetermined characteristics." Amazon construes Step 4 as "modifying, without the user taking an overt action, the mathematical values forming the customer profile to agree with the mathematical values forming the content profiles of the data feeds accessed by the user to reflect the users actual relative interests in the predetermined characteristics." As an initial matter, Amazon's proposed construction must fail to the extent it includes its constructions of "customer profile," "content profile," and "data sources." The Court rejects these constructions. Because Amazon relies on its flawed construction of "customer profile" and "content profile" to construe the phrase "customer's actual preferences for said predetermined characteristics," that construction must too be rejected. The remaining key phrase in dispute is "updating, without input from each customer."

--- Footnotes ---

5 Amazon asserts inconsistent constructions of the claim term "updating." Amazon's claim chart construes "updating" as "modifying with current information," while Amazon's motion construes "updating" as "modifying." Compare Def. Mem. at 23 ("modifying with current information, without the user taking an overt action") with Def. Mem. at 24 ("the entire clause
means . . . 'modifying, without the user taking an overt action'). The court assumes Amazon intends the construction asserted in its motion, rather than in its claim chart.

6 As explained above, neither "customer profile" nor "content profile" solely relate to "predetermined characteristics." Claim 43 is instructive. Both "customer profile" and "content profile" appear in the claim language, but the phrase "predetermined characteristics" is noticeably absent. Thus, Amazon may not imply "predetermined characteristics" into "customer profile" and "content profile."

Amazon asserts that "updating, without input from each customer" means "modifying, without the user taking an overt action." Amazon directs the court to a general purpose dictionary, the patent prosecution history, and its expert witness' declaration about usage in the field of art. Webster's Dictionary defines "update" as "to bring up to date." The prosecution history reveals the inventors described this updating feature as updating customer profiles "without any customer having to take any overt action such as filling out a new questionnaire or requesting that the customer profiles be updated." Def. Mem., Ex. 6 at 26 (AMZN 001679). Amazon's expert attests that the proposed construction is consistent with the understanding in the field; others have referred to this as "modification," a process that requires "modifying the weights for characteristics in the customer profile to be more like the weights for the same characteristics in the content profiles of items the user has implicitly indicated a preference for (e.g., programs watched)." Def. Mem. at 23 (citing Resnick Deci., P 61).

In contrast, Pinpoint construes "updating, without input from each customer, each customer profile in accordance with the content profiles of the data sources actually accessed by that customer to automatically update each customer's actual preferences for said predetermined characteristics" as "the claimed method is able to update the customer's preferences without the customer taking direct action to tell the system how it should update the customer's actual preferences." Pinpoint agrees with Amazon's construction of "updating, without input from each customer," but proposes a different construction using "simpler language."

Pinpoint's construction is flawed in its simplicity. Its proposed construction of Step 3 fails to include many key terms, such as "customer profile," "content profile," and "predetermined characteristics." Nor may the court entirely adopt Amazon's proposed construction as it relies upon rejected constructions. The court restricts claim construction of Step 3 to the phrase "updating, without input from each customer." The proper construction of this phrase is Amazon's: "modifying, without the user taking overt action." See Pl. Opp. Mem. at 20 (construing the claim term "updating" in Claim 41 as "modifying"); Def. Mem., Ex. 6 at 26 (AMZN 001679) ("without any customer having to take any overt action"). 7 The court construes Step 3 as "modifying, without the customer taking an overt action, each customer profile in accordance with the content profiles of the data sources actually assessed by that customer to automatically update each customer's actual preferences for said predetermined characteristics." Vitronics, 90 F.3d at 1582.

7 The court substitutes the term "customer" in place of the term "user" advanced by Amazon to ensure consistency. The plain language of the '257 patent refers to the term "customer," not "user."

5. upgrade microprocessor

A microprocessor which operates at a faster speed than the first microprocessor

This term is defined in the following specification language.
One way to increase the performance of a personal computer system is to replace the microprocessor in the system with a higher speed microprocessor operating on a higher clock rate, . . .

('981 Patent Col 1:19-22)

This definition is also fully supported by the following dictionary definition.

Microsoft Computer Dictionary (4th ed. 1999) upgrade: n. The new or enhanced version of a products; v. To change to a newer, usually more powerful or sophisticated version.

10. "Upon"

Testing in Claim 8 comprises, inter alia, "performing predetermined operations which provide a predetermined expected response from the removable article upon the existence of correct alignment and electrical contact." As with "when," the parties dispute whether the response must be given "as soon as" the existence of correct alignment and electrical contact is detected or whether the response is given "on condition that" alignment and contact are detected, against without a temporal limitation.

The ALJ determined that "upon" had no temporal component. ID at 51 n.18. The Commission did not review that decision.

This Court finds that for many of the same reasons that "when" is construed in its temporal sense, "upon" must also mean "as soon as." Like "when," the term "upon" has as an ordinary meaning either construction. To determine which prevails, attention must be given to the purpose of the claim in question. See Renishaw, 158 F.3d at 1251-52. As a dependent claim, Claim 8 shares independent Claim 1's purpose in the testing step "to facilitate the rapid placement in contact because as soon as this has been done, the process stops." Col 2, Ins 23-24. Because "stopping . . . when" requires a rapid response to the existence of correct alignment and electrical contact so too does the predetermined expected response to those conditions require a rapid response to provide for rapid stopping.

4. The term "upon" in claim 34 requires no construction;

2. "Upon completion of scanning" is construed to mean "after either a single or the first in a series of film-based medical images is scanned, status information is displayed to the user."

6. Upon confirmation of availability of said funds, accepting said order, generating an electronic record n7

n7 This term is also used in Claim 1 of the '364 Patent.
DE argues that the phrase means "following confirmation of availability of said funds, accepting said order, generating an electronic record." Dell contends that the correct construction is "immediately following confirming that funds are available the transaction program accepts the order and generates the electronic record."

Dell's use of the word "immediately" is based upon a dictionary definition of "upon," but this use of extrinsic evidence, as noted in Phillips v. AWH, carries the danger of "focusing the inquiry on the abstract meaning of words rather than on the meaning of claim terms within the context of the patent." 415 F.3d 1303, 1321 (Fed. Cir. 2005). Dell also relies upon the prosecution history, claiming that the applicant tried to distinguish the '020 Patent from prior art during the prosecution by stating that "the initiation of electronic title generation upon confirmation of available funds greatly expedites the overall process, thereby overcoming one of the major disadvantages inherent to conventional international transactions." Prosecution History Files for Patent '020, at DET05098. Dell contends that this statement clearly indicates that DE intended for "upon" to be construed as "immediately following," otherwise the process would not be "greatly expedited." If this were the case, DE could not argue for a broader temporal limitation because it would have narrowed the claim term during prosecution to distinguish the invention from prior art. See Spectrum Int'l v. Sterilite Corp., 164 F.3d 1372, 1378 (Fed. Cir. 1998). DE contends that the point of novelty was the cause and effect relationship, however, where generation of a record would be based upon confirmation of funds, rather than the timing of the electronic record. The prior art, which lacked an integrated system, took many days to complete the generation of an electronic record. The process could still be expedited, therefore, without generation of a record "immediately following" the confirmation of available funds. The court finds DE's interpretation of the prosecution history to be consistent with the language of the claim and the specification, and does not find that the applicant "clearly and unambiguously disclaimed or disavowed any interpretation during prosecution in order to obtain claim allowance." Salazar v. Procter & Gamble Co., 414 F.3d 1342, 1344 (Fed. Cir. 2005). The court therefore declines to adopt a construction that requires the generation of a record to immediately follow the confirmation of available funds.

The other area of dispute is whether the transaction program itself must accept the order and generate an electronic record. The words of the specification support DE's claim that a retail vendor can use an external program to accept the order. See '020 Patent, col. 7, ll. 19-21; col. 9, ll. 31-34 ("the same processing center can then send a confirmation for the respective customer order to the vendor ... by accessing the vendor order system."). As Dell suggests, however, the transaction program must be used to either generate an electronic record automatically or the vendor will use the system to generate an electronic record. This meaning is supported by the specification, which provides that "once electronic funds (or other authorization) are transferred to the vendor (step 161) from a local clearing house, the vendor will utilize a connection to the transaction system of the present invention to generate an electronic title." '020 Patent, col. 10, ll. 15-27.

Based on the foregoing, the court construes the phrase, "upon confirmation of availability of said funds, accepting said order, generating an electronic record," to mean "following determination that the funds are available, confirming acceptance of the order and generating an electronic record."

4668

L. "Upon Connection with the Destination" (073 and '766 Patents)

This term appears in independent claims 1, 18, and 36 of the '073 patent and in every independent claim (claims 1, 11, and 21) of the '766 patent. Yodlee believes that the Court does not need to construe this term, while CashEdge proposes "[c]onnecting the user and the user's appliance to the destination." The difference between the two parties' constructions is that CashEdge believes that end user's computer must actually connect to the target website, while Yodlee believes that an intermediary computer may be the computer that actually connects.

The Court agrees with Yodlee that this term need not be construed. The Court agrees with Yodlee that "upon connection to the destination" refers to the portal's connection to the destination. CashEdge's attempt to read a limitation into this term is not supported by the evidence. CashEdge points, first, to the prosecution history, in which Yodlee apparently stated "the user and the user's appliance actually have access to the URL destination WEB page." Assuming that CashEdge has accurately quoted the prosecution history -- its cite is incorrect -- the requirement that a user's appliance have access to the destination web page does not mean that the appliance must actually connect to the web page. CashEdge's second argument relies on
the specification, which states that the invention allows a user to "simply select a destination (a hyperlink) in the Password-All list, and the user's browser then invokes the URL for the selected destination." '073 patent, col. 7, lines 2-4. CashEdge argues that this passage requires that the browser actually connect to the destination. But just because the browser "invokes the URL for the selected destination" does not mean that the browser must actually connect to the destination. Rather, the browser may pass the URL to the portal software. In addition, this description of the preferred embodiment is not sufficient to limit the description in the claims. See Phillips, 415 F.3d at 1323.

The Court believes that the plain language of the claim is clear, and therefore declines to construe this phrase.

2. "upon detecting a predetermined drop in reflectance sufficient to indicate that said sample has reached said first surface" means a reflectance reading taken immediately following or very soon after detecting the point in time of a drop in reflectance, the magnitude of which is determined in advance, to be the point in time of the first breakthrough of sample to the testing surface. At that point in time, the reflectance drop must be mostly or entirely due to wetting of the testing surface and not color from chemical reaction.

The district court construed "upon detecting a predetermined drop in reflectance sufficient to indicate that sample reached said first surface" to mean:

[A] reflectance reading taken immediately following or very soon after detecting the point in time of a drop in reflectance, the magnitude of which is determined in advance, to be the point in time of the first breakthrough of sample to the testing surface. At that point in time, the reflectance drop must be mostly or entirely due to wetting of the testing surface and not color from chemical reaction.

Claim Construction Order, 2002 U.S. Dist. LEXIS 27575 at *10 (emphasis added). In sum, the district court strictly limited the claim term to the "first breakthrough of sample to the testing surface." Because the district court restricted claim 4 of the '162 patent to predetermined timing methods, it limited the initiation of the measuring phase to "the first breakthrough." As discussed previously, this interpretation improperly limits claim 4 to a preferred embodiment and does not give the disputed claim terms their proper scope in this technology at the time of invention. Therefore, "upon detecting a predetermined drop in reflectance sufficient to indicate that sample reached said first surface" means "immediately following or very soon after detecting the point in time of a predetermined drop in reflectance, where the predetermined drop in reflectance is mostly or entirely due to wetting of the testing surface."

3. "upon detection of a suitably stable endpoint" means at the expiration of the predetermined time period.

In this case, this court must ascertain the meaning of the claim language "upon detection of a suitable stable endpoint." The claim language does not explicitly require a predetermined time for the reaction, but instead measures the endpoint by the stability of the reflectance. Thus, according to this language, the endpoint coincides with a suitable stability in the reflectance readings. At this stable endpoint, the method calculates the glucose concentration. The claim limitation emphasizes that the method does not require any determination of a starting point for application of the blood sample to the matrix. In sum, the claim language limits the endpoint by reference to suitable stability in the reflectance readings, not by reference to a predetermined time.
The specification contains further enlightenment on the accustomed usage of "upon detection of a suitably stable endpoint" among artisans of ordinary skill at the time of invention. In discussing the invention as a whole, the specification states that the concentration of an analyte in a sample: "may be determined by measuring the change . . . between two or more points in time." Id. at col. 7, ll. 57-59 (emphasis added). This language shows that a "suitably stable endpoint" varies between unspecified points in time. A predetermined timing method is simply one means of determining when a "suitably stable endpoint" has been reached. In discussing a single embodiment of the invention that used a predetermined reaction time, the '162 patent specifically states: "using the preferred embodiments described herein, the endpoint is not particularly stable and must be precisely timed." Id. at col. 14, ll. 42-44. Thus, the specification limits its discussion of predetermined timing methods to preferred embodiments. Nevertheless, the invention as claimed permits detection of the endpoint with reference to the stability of the reflectance readings.

To overcome the presumption biasing claim construction in favor of the accustomed usage of a term in the relevant community at the relevant time, HDI must show a clear disavowal of such scope in the specification, prosecution history, or both. The district court erred by placing too much emphasis on the specification's discussion of the preferred embodiments, rather than the meaning of the claims themselves. Because the specification discussed only predetermined timing methods, the district court concluded incorrectly that the applicant had disavowed other ways to reach an endpoint. The specification describes a preferred embodiment of the '162 patent that uses a predetermined twenty second time period for blood samples with glucose concentrations below 250 mg/dl and a predetermined thirty second time period for samples with glucose concentrations between 250 mg/dl and 450 mg/dl. '162 patent, col. 14, ll. 47-49. Because the specification described no other embodiments in detail, the district court apparently interpreted the specification's silence regarding alternative embodiments as a disavowal. However, the applicant's choice to describe only a single embodiment does not mean that the patent clearly and unambiguously disavowed other embodiments. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 907-08 (Fed. Cir. 2004).

As noted earlier, the specification's overall context shows that the endpoint "may be determined by measuring the change . . . between two or more points in time." Id. at col. 7, ll. 57-59 (emphasis added). The preferred embodiments that used the predetermined timing method simply do not limit the broader claim language. This court has previously stated that reference to a preferred embodiment does not alone undermine the customary meaning and scope of claim language. Teleflex, 299 F.3d at 1327. The meaning of the claim term "upon detection of a suitably stable endpoint" encompasses multiple methods for finding the proper endpoint. The patent's preferred embodiment is just that - one way of using the invention. That disclosure alone does not clearly and unambiguously disavow other ways of computing the endpoint within the scope of the claim language.

A patentee may claim an invention broadly and expect enforcement of the full scope of that language absent a clear disavowal or contrary definition in the specification. Id. at 1325. The history of the '162 patent illustrates that this applicant took this course. The '162 patent is part of a family of patents that includes U.S. Patent Nos. 5,049,487 (the '487 patent) and 5,843,692 (the '692 patent). These patents stem from the same initial application and contain the same or essentially the same specifications. In place of a "suitably stable endpoint," the '487 patent claims recite a "predetermined time period." '487 patent, col. 22, l. 36. Similarly, the '692 patent claims recite a "predetermined incubation period" rather than a "suitably stable endpoint." '692 patent, col. 23, l. 22. This progression, from "predetermined time period" to "predetermined incubation period" to "suitably stable endpoint," shows that LifeScan purposefully sought in the '162 patent claim scope broader than the predetermined timing method. Absent a clear disavowal or contrary definition in the specification or the prosecution history, the patentee is entitled to the full scope of its claim language.

The prior art identified by the '162 patent gives additional reasons that an artisan of ordinary skill would not limit "upon detection of a suitably stable endpoint" to predetermined timing methods. See Kumar v. Ovonic Battery Co., 351 F.3d 1364, 1368 (Fed. Cir. 2003); see also Arthur A. Collins, Inc. v. N. Telecom, Ltd., 216 F.3d 1042, 1045 (Fed. Cir. 2000) ("When prior art that sheds light on the meaning of a term is cited by the patentee, it can have particular value as a guide to the proper construction of the term, because it may indicate not only the meaning of the term to persons skilled in the art, but also that the patentee intended to adopt that meaning.").

Specifically, U.S. Patent Nos. 4,178,153 and 4,627,014 (the '153 patent and the '014 patent) show the usage of the claim terms at the time of invention. The '153 patent, entitled "Method and Apparatus for Chemical Spot Test Analysis" relates to chemical analysis of a sample with reagents on a fibrous or porous medium after a predetermined period of time. '153...
The '153 patent discloses both an endpoint-seeking methodology and a predetermined-timing methodology. In disclosing an endpoint-seeking methodology, the '153 patent states that a sample can be analyzed, "by monitoring the resultant constituent manifesting reaction." Id. at col. 3, ll. 26-27. Alternatively, the '153 patent discloses that the analysis can utilize, "a single point measurement, i.e., with a single measurement of reaction product." Id. at col. 4, ll. 27-28. The '153 patent demonstrates that as early as 1979, artisans of ordinary skill in the art knew that a chemical analysis of a sample with reagents could be accomplished by either monitoring the reaction itself or by using a single measurement of the reaction product.

The '014 patent, entitled "Method and Apparatus for Determination of an Analyte and Method of Calibrating such Apparatus," reinforces this point. This prior art reference states that the measurement of an analyte can utilize "any chemical analyzer constructed to perform rate or endpoint colorimetric assays." '014 patent, col. 7, ll. 50-52.

In light of the preceding analysis, this court determines that the customary meaning in this art field of "upon detection of a suitable stable endpoint" means "when the stated reaction is sufficiently complete that the glucose concentration of the sample can be calculated without an error of clinical significance." This determination is confirmed by using the contemporary understanding of a skilled artisan to guide an inquiry into dictionary meanings. Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1477 (Fed. Cir. 1998). LifeScan offers a dictionary definition of the term "stable" as "not subject to sudden change: subject to relatively limited fluctuations." Webster's Third New International Dictionary 2071 (3d ed. 1986). Alternatively, Webster's also defines "stable" as "firmly established." Id. The first definition conforms to the usage of "stable" by one of ordinary skill in the art as manifested by the pertinent prior art references identified by the '162 patent.

In contrast, the alternative dictionary definition would import an additional limitation into the claim, namely that the analyte's reaction product and the reagent must be firmly established.

Thus, an examination of dictionary sources guided by the prior art references enlightens the meaning of "stable" and confirms this court's determination that the customary meaning in this art field of "upon detection of a suitable stable endpoint" means "when the stated reaction is sufficiently complete that the glucose concentration of the sample can be calculated without an error of clinical significance."

The parties agree that the term to be construed should be "upon plugging" rather than "upon plug." The plaintiff argues that the plain meaning of "upon plug" is "after plugging." The plaintiff states that there is no time limitation associated with this term and that it should not be construed to include a causal limitation.

The defendant's position is that events occur in the claims only after the portable storage device is plugged into the USB or IEEE 1394 interface. Therefore, the subsequent events must be direct consequences of plugging in the device. The defendant argues against the plaintiff's construction by, inter alia, stating that construing "upon plug" to mean "after being plugged in" is no limitation at all. But the defendant fails to provide a tenable argument to the court for further limiting the claim term.

The specification makes it clear that various events occur when the external storage device is plugged in. The specification, however, does not support importing a causal limitation into this claim term. For example, consider the following passages from the specification:

When the external storage device is plugged into the data processing host, the firmware coordinates with the driver in the operating system to accomplish the initialization of the device.

Col. 4, ll. 32-35.

When the external storage device is plugged into the data processing host, the driver coordinates with the firmware to
accomplish the initialization of the device and notifies the operating system to assign and display a device symbol for the external storage device (steps S2, S2), then waits for the operation request.

Col. 4, ll. 47-52.

The defendant fail to support its argument that "upon plug" must require the limitation "as a direct consequence." The record does not support that limitation.

The court defines "upon plug" to mean "after being plugged in."

A. Claim Interpretation

The '804 patent claims a "Method and Apparatus for Scalable, High Bandwidth Storage Retrieval and Transportation of Multimedia Data on a Network." The '804 patent provides "a better means and method for providing multimedia data in a networked system," (Col. 2, ll. 15-16) by allowing a client flexible access to various multimedia sources over a network. Claim 1 of the '804 patent teaches:

1. A high bandwidth, scalable server for storing, retrieving, and transporting multimedia data to a client in a networked system, said server comprising:

   an upstream manager receiving messages from said client and routing said messages to an appropriate service on said server, said upstream manager being coupled to a first network; a downstream manager sending a stream of said multimedia data from said appropriate service on said server to said client, said downstream manager being coupled to a second network; and a connection service for maintaining information to connect said client, said upstream manager, said downstream manager, and said appropriate service on said server.

In the invention, as shown in Fig. 6 from the '804 patent below, the client communicates his desires to the system using a client device 110. The upstream manager 220 accepts a message, e.g., a request for a particular service, from the client device and routes them to the media server service 322, which will supply that service.

* All column and line references are to the '804 patent.

The client may request such services as interactive shopping, news, games, education, movies, etc. The downstream manager 210 sends the data, i.e., the requested service, to the client device 110. (Col. 16, ll. 11-18) The additional elements in the figure deal with managing the requested service data flows to the requesting client, including obtaining and associating the addresses of the client and the appropriate media server.

This court must interpret the terms governing operation of an "upstream manager" and use of addresses in the invention. As mentioned, the invention of the '804 patent allows the client to receive requested material from different types of networks. This function, in turn, requires the invention to accommodate the addressing schemes of each separate network, which may differ from one another. In order to accommodate the different types of addresses for each data link, the network protocol of the invention superimposes its own independent addresses on top of those of the nodes used in the diverse links of the various networks. (Col. 13, ll. 11-16.) Thus, the invention can route commands and data from the requesting client to the appropriate media server by using the system's own network protocol. As part of this scheme, the connection service described in the specification assigns a "logical" (i.e., ad hoc) address to the "physical" address (i.e., the real physical location) of a client, in the connection manager 230. (Col. 17, ll. 27-51). The relationship between the logical and related
physical addresses is stored in the connection service table 320.

The trial court construed the term "Upstream Manager" as follows:

**Upstream Manager:** a computer system component that (a) accepts messages from a client bound for services on a server, (b) routes messages from a client to services on a server; and (c) is distinct from the Downstream Manager.

The parties agree on this much of the construction, but SeaChange seeks further limitation. In particular, SeaChange contends that the upstream manager must (d) receive and route all messages from clients that are "bound for" services, and (e) must do so using only logical, not physical, addresses, of both sender and receiver of a message. SeaChange also reserves an argument of noninfringement even under the court's claim construction.

The district court's claim construction correctly does not require the upstream manager to receive and route all messages from a client bound for a server. The patent claims require that the upstream manager receive messages from the client and the downstream manager send data to the client, but do not make these the exclusive functions of the units. Figures 1, 2, and 6 of the specification show that the paths from the client to the upstream manager are unidirectionally upward, and from the downstream manager to the client unidirectionally downward, and the text of the specification reflects this asymmetry. (Col. 3, II. 21-22.) However, the specification describes only one embodiment of the invention, and encompasses divergence from that embodiment: "it may be the case that some server process, under the direction of an external network control node, actually establishes contact with the client." (Col. 17, II. 24-26). Thus, the district court correctly stated that the claims encompass this form of communication.

The trial court's construction of "upstream manager" also correctly reflects that this element may route messages using either logical or physical addresses. In the embodiment described in the specification "all routing is accomplished based on logical addresses, not physical addresses." (Col. 23, II. 1-4). Thus, "packets (and therefore messages) only contain logical addresses of the sender and receiver." Id. The logical address of a client is used to establish a unique "virtual circuit" for connection with that client. (Col. 17, II. 28-48). However, the upstream manager of claim 1 is broader than the upstream manager of this embodiment. The creation of a virtual circuit, or "virtual connection," appears only in dependent claim 2 as a "further" function of the connection service. The use of a client logical address first appears specifically only in claim 4. The embodiment described in the specification, in which the service request message includes the client's downstream logical address and a service destination logical address, is specifically described in unasserted claims 5 and 11. Claim 1 does not describe an upstream manager that requires routing only with logical addresses. To read a requirement for use of logical addresses into claim 1 would impermissibly read the "virtual connection" limitation of claim 2 into claim 1, making these claims redundant. See, e.g., LizardTech, Inc. v. Earth Res. Mapping, Inc., 424 F.3d 1336, 1344 (Fed. Cir. 2005). In this case, the claim term "upstream manager" is not "so amorphous that one of skill in the art can only reconcile the claim language with the inventor's disclosure by recourse to the specification." Comark Communs. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). It is clear that the upstream manager of claim 1 routes messages. This court need not interpret what the patentee meant by "upstream manager" in this claim by importing the limitation of claim 2 into this term. See E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988) (holding that it is improper to read a limitation "into a claim from the specification wholly apart from any need to interpret what the patentee meant by particular words or phrases in the claim."). The prosecution history does not contradict the district court's interpretation. During prosecution, the inventor differentiated the invention from the prior art of Mizuhara in several ways: not only by describing the uniqueness of its use of logical addresses, but also by demonstrating that Mizuhara did not teach a partitioned architecture, separating the functions of upstream and downstream managers, and connection service.

The step at issue is described in claim 4. Claim 4 outlines a method by which a server receives a request then decides whether to process the request itself or forward it to a different server for processing. This "determining step" balances incoming requests according to the existence -- or not -- of "a URI in the request." (Second Am. Compl., Ex. 1, '279 Patent 11:45-7). Because the parties hotly dispute the definition of URI, whether WebLogic executes this step remains in controversy. URI abbreviates Uniform Resource Identifier and relates to another technical term, URL, that stands for Uniform Resource Locator.
Plaintiff argues that the patent specification provides idiosyncratic, relative definitions of URI and URL as comprised of certain character strings that form a web address. In asserting that defendant acted as its own lexicographer in drafting the '279 patent, plaintiff relies upon the following language found in the description of the second embodiment:

"The ordinary and customary meaning of a claim term is the meaning that the term would have to a person of ordinary skill in the art at question at the time of the invention, i.e., as of the effective filing date of the patent application." Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005). A claim term should be interpreted not only in light of the claim itself, but also "in the context of the entire patent, including the specification. Id. When a term's meaning is not "immediately apparent ... and because patentees frequently use terms idiosyncratically," courts may consult additional resources and references, including prosecution history and extrinsic evidence, for guidance on appropriate interpretation. Id. at 1314. As between a patent specification and extrinsic evidence, the former is significantly more relevant to gaining an accurate understanding of the term than is the latter, especially given "the statutory requirement that the specification describe the claimed invention in full, clear, concise, and exact terms." Id. at 1315 (quoting 35 U.S.C. § 112, P 1). However, there is a "distinction between using the specification to interpret the meaning of a claim and importing limitations from the specification into the claim. . . ." Id. at 1323. "For instance, although the specification often describes very specific embodiments of the invention, [the Federal Circuit] has repeatedly warned against confining the claims to those embodiments." Id. An embodiment is neither necessarily limiting nor necessarily extraneous to understanding the claims, and its appropriate role should be divined from the context of the patent itself. Id. at 1323-24.

Plaintiff correctly argues that an understanding of the claim terms URI and URL should begin with review of the patent itself. The relative definitions of URI and URL cited by plaintiff come from the second embodiment in the specification for the '279 patent that characterizes URI as a discrete part of a web address, separate from URL. The embodiment also discusses "requests having no URL," an example that further undermines defendant's claim that the term URI includes a URL. (Second Am. Compl., Ex. 1, '279 Patent 8:9-11, 22-5; Def.'s Response to Pl.'s Mot. for Summ. J. 2). Plaintiff's argument that defendant acted as its own lexicographer and intended to provide a unique definition for URI would be more persuasive if the rest of the patent specification treated URI and URL as necessarily discrete character strings. The patent itself does not elevate this embodiment, however, and other parts of the specification that discuss URI do not clearly require that it be considered a separate part of the web address. For example, the patent summary maintains that "servers may be configured to recognize specific URIs which designate entry points for stateful transactions." (Second Am. Compl., Ex. 1, '279 Patent 4:22-4). Whether URI, as used in this sentence, refers to the entire web address or, as plaintiff argues, a discrete portion of the address following the URL, does not necessarily alter the meaning of this sentence. Additionally, plaintiff's assertion that the specification only defines URI in comparison to URL is not accurate. (See, e.g., id. at 4:1-3). In light of the Federal Circuit's warning against importing claim limitations from preferred embodiments, confining URI to the meaning implied by the second embodiment is inappropriate.

As the patent language does not adequately instruct a particular meaning of URI, and the parties have not offered prosecution history to advance their positions, extrinsic evidence may be considered in order to elucidate exactly what a person of ordinary skill in the art would understand the term URI to mean. According to plaintiff's expert, Anthony Joseph,
to a person of ordinary skill in the art, "URI refers to a particular resource or location." (Joseph Decl: Ex. A at 6). Mr. O'Neil, defendant's expert, offers a similar definition: "URLs enable a person using a computer on a network to find resources on other computers connected to the network." (O'Neil Decl. P 8). By its own terms, the '279 patent describes a network of servers that process incoming requests "based on a URI in the request," in other words, based on the network resource that a user seeks to access. (Second Am. Compl., Ex. 1, '279 Patent 11:45-7). The WebLogic session ID, on the other hand, enables a server that receives an incoming request to "pin" a user to a particular server for the duration of that user's transaction. (Def.'s Response to PL's Mot. for Summ. J. 5). In other words, the '279 patent contemplates that a particular server will field all of the requests for a particular resource (or URI), whereas under WebLogic, a particular server handles all of the requests from a particular user (or session ID). The session ID inserted by WebLogic does not point to a network resource but, instead, to a user and thus fundamentally differs from a URI.

4676

A

First and foremost, the analytical focus of claim construction must begin, and remain centered, on the language of the claims themselves. Tex. Digital Sys., Inc. v. Telegenhix, Inc., 308 F.3d 1193, 1201-02 (Fed. Cir. 2002) (quoting Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323, 1331 (Fed. Cir. 2001)). Because the claim language is chosen by the patentee to "particularly point[] out and distinctly claim[] the subject matter" of the invention, 35 U.S.C. § 112, P 2, the claim terms chosen by the patentee carry a presumption that "they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art." Tex. Digital, 308 F.3d at 1202. In the absence of an express intent to impart a novel meaning to the claim terms, the words are presumed to take on the ordinary and customary meanings attributed to them by those of ordinary skill in the art. See, e.g., Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002). The ordinary and customary meaning of a claim term may be determined by reviewing a variety of sources, including the claims themselves, see Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357 (Fed. Cir. 1999); dictionaries and treatises, Tex. Digital, 308 F.3d at 1202; and the written description, the drawings, and the prosecution history, see, e.g., DeMarini Sports, Inc. v. Worth, Inc., 239 F.3d 1314, 1324 (Fed. Cir. 2001). While certain terms may be at the center of the claim construction debate, the context of the surrounding words of the claim also must be considered in determining the ordinary and customary meaning of those terms. See Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1299 (Fed. Cir. 2003); Hockerson-Halberstadt, Inc. v. Converse Inc., 183 F.3d 1369, 1374 (Fed. Cir. 1999).

ACTV, in arguing that the ordinary and customary meaning of the term URL encompasses both relative and absolute URLs, provides a document entitled Request for Comments 1808 ("RFC 1808"), from the World Wide Web Consortium ("W3C"), an industry working group, as authoritative support for this position. RFC 1808 discusses both absolute and relative URLs, noting that a relative URL "is a shortened form of that for [an] absolute [URL]" and that a relative URL is "a compact representation of the location of a resource." In response, Disney offers an earlier document entitled Request for Comments 1738 ("RFC 1738"), from the same organization, in support of its argument that URL encompasses only absolute URLs. Specifically, RFC 1738 indicates that a URL has a typical syntax requiring both a protocol type and a resource locator. RFC 1738 also distinguishes between "relative links," in which the expression of a related resource is described "in the same place as this one except with the following relative path," and general URL syntax, which provides "an abstract identification of the resource location."

As this court has previously noted,

    dictionaries, encyclopedias and treatises, publicly available at the time the patent is issued, are objective resources that serve as reliable sources of information on the established meanings that would have been attributed to the terms of the claims by those of skill in the art. Such references are unbiased reflections of common understanding not influenced by expert testimony or events subsequent to the fixing of the intrinsic record by the grant of the patent, not colored by the motives of the parties, and not inspired by litigation. Indeed, these materials may be the most meaningful sources of information to aid judges in better understanding both the technology and the terminology used by those skilled in the art to describe the technology.

Tex. Digital, 308 F.3d at 1202-03.
As a preliminary matter, we consider whether the RFCs presented by the parties rise to the level of unbiased, contemporaneous reflection of the common understanding of the technical terms in question as to be considered a reliable source of information on the meaning attributed to those terms by those skilled in the art. The purpose of the W3C organization is "to lead the World Wide Web to its full potential by developing common protocols that promote its evolution and ensure its interoperability." About the World Wide Web Consortium (W3C), at http://www.w3c.org/Consortium/ (last visited Aug. 7, 2003) ("W3C Website"). To this end, members of W3C (including various industry groups, manufacturers, and others, each with their own conceivable interests in the agenda) are involved in developing standards to describe the various building blocks of the Internet. Id. Both RFC 1738 and RFC 1808 are working papers generated during standardization discussions by one subset, or working group, within W3C. See, e.g., Uniform Resource Locators (RFC 1738), at http://www.w3.org/Addressing/rfc1738.txt (T. Berners-Lee et al. eds. Dec. 1994) ("This document specifies an Internet standards track protocol . . ."). The purpose of the RFCs is thus to collect commentary and to select language to facilitate a common understanding, or to select a standard, from a variety of competing technologies and vocabularies and from a variety of potentially competing interests. Indeed, the acronym "RFC" suggests that end: "Request for Comments." This purpose is in sharp contrast to the role of dictionaries and treatises, which aim not to select or give meaning to a word or phrase, but to report the meaning already established and commonly understood by those skilled in the art. See, e.g., Samuel A. Thumma & Jeffrey L. Kirchmeier, The Lexicon Has Become a Fortress: The United States Supreme Court's Use of Dictionaries, 47 Buff. L. Rev. 227, 291 (1999) (stating that first resort to a dictionary may be appropriate in determining meaning because "dictionaries are designed to reflect usage." (emphasis added)).

Both parties offer these RFC documents as authoritative, unbiased sources relating to the meaning of the expression URL. Because the RFCs were not designed to reflect common usage, but rather to assign language to facilitate further conversation, and because of the seeming contradictions between RFC 1738 and RFC 1808, we conclude that both documents are extrinsic evidence, and in light of the discussion below, we decline to rely on them in our claim construction analysis. See Vitravionics Corp. v. Conceptronc, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) ("[I]f an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term . . . it is improper to rely on extrinsic evidence."). It should be understood, however, that there is no general prohibition on the use of publications from standards-setting organizations to aid in determining the ordinary and customary meaning of technical terms. Where such a document reflects common usage by those skilled in the relevant art, the document may indeed be an appropriate reference. Where, as in this case, the documents of the standards-setting organizations do not reflect common usage, but purport to select language to be used in the future, elevation of these Requests for Comments to the same authoritative, unbiased level as dictionaries is improper.

In the present case, the construction of URL is principally informed by the plain language and surrounding context of the claims themselves. See Brookhill-Wilk, 334 F.3d at 1299. The claims recite that a URL "specifies one or more Internet addresses of the information segments which relate specifically to the content of the video and audio signals of the programming." '81 patent, col. 59, ll. 8-12 (emphasis added). In construing the claim term URL, these additional terms contained in the claimed means-plus-function expressions provide context for the term URL and must themselves be construed. See, e.g., Hockerson-Halberstadt, 183 F.3d at 1374 ("Proper claim construction, however, demands interpretation of the entire claim in context, not a single element in isolation."). Thus, even though the district court's constructions of "Internet address" and "information segments" were not explicitly appealed, we must also construe those terms to properly construe the appealed term URL.

The district court's construction of "information segments" as "simply referring to parts into which information on the Internet is commonly divided" is supported by the claim language and the specification. See Markman Memorandum, 204 F. Supp. 2d at 653; '81 patent, col. 3, l. 6, col. 6, l. 12; '664 patent, col. 3, l. 31, col. 8, l. 32; '768 patent, col. 3, l. 33, col. 8, l. 55. These parts are exemplified by, but not limited to, items such as web pages, audio clips, and images. See id. However, the district court's construction of the term "Internet address," as "a particular host on the Internet, specified by a uniform resource locator that is unique to that host," Markman Memorandum, 204 F. Supp. 2d at 654, is not supported by the claim language or specification, and relies on circular reasoning related back to URL. Rather, the context of the term "Internet address" informs that it is simply a reference to a location of the information segment on the Internet. There is no support for the district court's added requirements that the "Internet address" be a particular host or that it be unique. A URL, then, as defined by the language and context of the claims, is something that identifies the location of relevant information segments. This can include web pages, audio clips, images, and the like. It can be an absolute URL or a relative URL, as long as it specifies one or more Internet addresses of information segments relating to Internet content.
Digital Reg contends this term does not require construction or alternatively should be construed as "information which a content producer or supplier wishes to consider in regulating access to the digital content." Defendants contend the term means "data used to control, for example, circulation materials such as industry and trade publications, which require the recipient to provide employment data in order to have a 'no charge' edition of the publication."

To support its proposed construction, Digital Reg cites to the specification, which states "Alternatively or in addition to payment information, use information may be required, such as employment-related data, educational information, family information, or any other information which a content producer or supplier wishes to consider in regulating access to the object." See col. 4:22-26. Digital Reg contends Defendants' construction improperly relies on examples in the specification that describe a preferred embodiment.

Defendants contend that the passage from the specification that Digital Reg relies on is not intended to define "use information" but merely describes the type of use information that may be required. See col. 4:22-26. Defendants argue that the specification explicitly defines "use information": "Use information is data used to control, for example, circulation materials such as industry and trade publications, which require the recipient to provide employment data in order to have a 'no charge' edition of the publication." See col. 9:32-36.

Thus, both parties contend the specification expressly defines the term, but they disagree on which portion of the specification is defining and which is exemplary. Column 4, lines 22-26 give a generic description of "use information," which serves a definition. Column 9, lines 32-36 is a subset of what is set forth in column 4. Accordingly, the Court construes "use information" as "information which a content producer or supplier wishes to consider in regulating access to the digital content."

As an initial matter, the Court concludes that the terms "use mode" and "fully enabled mode/full version run" mean the same thing. At the Markman hearing, Microsoft readily agreed that these terms are synonymous. Uniloc, however, was hesitant to agree to synonymous treatment on the spot. But importantly, when pressed by the Court, Uniloc was once again unable to offer an example of a situation when "fully enabled mode" would mean anything other than "use mode." So, although Uniloc has not explicitly agreed that these terms are synonymous, Uniloc has been unable to make an argument, compelling or otherwise, that the terms deserve different treatment. Moreover, the Court observes that Uniloc's proposed constructions for these terms do not vary materially. While Uniloc has included the word "unrestricted" in its construction of the term "fully enabled mode," there is nothing to indicate that "use mode" is restricted in any way other than the scope of the license. Indeed, Uniloc's own expert, David Klausner, stated that use mode is an unrestricted mode:

One of ordinary skill in the art recognizes the patent relates to the use of software or digital data in a restricted or unrestricted mode (use mode/non-use mode). The terms "fully-enabled mode" and "full version run" are used similar to "use mode" to mean allowing unrestricted use in accordance with the license.

Klausner Decl. at P 18. Moreover, the specification discusses these terms in a similar context by explaining that they are the converse of the term "partly enabled or demonstration mode." Compare '216 Patent, col. 2, ll. 44-48 ("The use mode is to be distinguished from what might generally be termed unlicensed modes of operation (which is not to say unauthorized modes of operation) as typified by the demonstration modes later described in this specification"), with id. at col. 15, ll. 1-5 (explaining that the mode switching means switches software between a fully enabled mode on the one hand, and a partly enabled or demonstration mode on the other).

Turning then to the parties' proposed constructions, the main point of disagreement is whether the difference between the
full and demonstration modes involves only functional limitations (such as limitations on the ability to save or print a
document), or whether the claim terms should be construed broadly enough to encompass temporal limitations as well (such
as only being able to use the software for two days). In support of its argument that the demonstration mode only involves
functions being disabled, Microsoft cites portions of embodiments 1 and 5. See id. at col. 6, ll. 47-48 (explaining that "a
demonstration of the software (which typically has features such as save and/or print disabled)"); id. at col. 11, ll. 14-17
(stating that the "[t]he registration code portion 38 can include a preview or demonstration related to a subset of the balance
of the digital data on the CD 54 which can be executed by the platform without license"). But while these embodiments
discuss characteristics which a demonstration mode can have, or typically has, the Court declines to read these examples
from two embodiments to mandate that in all instances, the demonstration mode only can involve functional limitations. See
generally Phillips, 415 F.3d at 1323 (the general rule is that "persons of ordinary skill in the art rarely would confine their
definitions of terms to the exact representations depicted in the embodiments."). For these reasons, the words "functionality"
and "functions are disabled" will not be part of the Court's construction of these terms.

Instead, the Court determines that the use and fully enabled modes are best described as allowing "full use" of software "in
accordance with the license." This language is consistent with the specification's explanation of the term "use mode," see
'216 Patent, col. 2, ll. 40-48 (explaining that use mode refers to use of the digital data or software so as to fulfill the
licensor's obligations), as well as the specification's general guidance that once the registration routine is complete, "full
access to the software is allowed." Id. at col. 8, l. 28.

Accordingly, the terms "use mode" and "fully enabled mode/full version run" shall be construed as: A mode that allows full
use of the digital data or software in accordance with the license.

n12 Although Microsoft agreed that the terms "use mode" and "fully enabled mode/full version run" should be treated the
same, it did not specify which of its proposed constructions was preferable in that event. Nonetheless, to the extent
Microsoft may have intended to press its proposed construction of "use mode," this writer notes that the Court's construction
incorporates the limitation expressed therein: that use mode means using the data in accordance with the obligations
imposed by the license.

11. "said first responsive information is used for one or more of" ('702 patent)

<table>
<thead>
<tr>
<th>Beneficial's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>No construction is necessary.</td>
<td>&quot;the first responsive information is capable of performing all of, and actually performs at least one or more of.&quot;</td>
</tr>
<tr>
<td>Alternatively, &quot;one or more of&quot; means &quot;at least one or more of.&quot;</td>
<td></td>
</tr>
</tbody>
</table>

The primary dispute regarding this term is whether the first responsive information "is capable of performing all of, and
actually performs at least one of" as Beneficial proposes. The Court finds that there is a difference between being "used for" and being "capable of performing." The Defendants' construction attempts to rewrite the claim language from "...is used for one or more of" to "...is capable of performing all of, and actually performs at least one of." Defendants' argument relies primarily upon an example in the specification that is capable of performing all of the recited elements. The Court is not inclined to adopt Defendants' construction. The Court finds that the language "used for one or more of" does not necessitate that "said responsive information" be capable of performing all of the elements rather than capable of performing at least one of the elements. Thus, the Court construes the phrase "said first responsive information is used for one or more of" to mean "the first responsive information is used for at least one or more of."
a. The "User" Limitation

The district court construed the term "user" to mean "a person, a person using a computer, a computer, or computers." Supplemental Claim Construction Opinion at 3. Microsoft had attempted to limit "users" to "persons," thereby excluding a computer or computers, while z4 advocated for the broad interpretation adopted by the district court. Id. at 1. Under its definition, Microsoft argues that the asserted claims require the authorization of a "particular user, regardless of what particular computer they are using," while the accused products authorize "a particular computer, regardless of who is using it." Microsoft thus asserts that there can be no infringement because its products do not recognize "unauthorized users," but rather unAuthorized computers. In its reply brief, however, Microsoft concedes a construction of "user" as including both "a person" and "a person using a computer." Reply Br. at 4 ("Properly construed, a 'user' is a person or a person using a computer. . . . It is only the district court's elimination of the person altogether, in allowing a computer by itself to be a 'user,' that we ask this Court to overrule as an error of law.").

In construing a disputed claim term, we begin with the language of the claims. Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc). Claims of the '825 patent include the limitations "enabling the software on a computer for use by a user," and "comparing previously stored registration information . . . to at least one of the software, the user, and the computer." In these recitations, the "user" and the "computer" are distinct entities. To construe the term "user" to mean a "computer" would result in the claim being interpreted to recite, for example, "enabling the software on a computer for use by a [computer]." The written description makes clear that the terms "users" and "computers" are distinct and used to describe different things. E.g., '471 patent col.1 ll.48-51 (discussing "users who may have a legitimate need to . . . transfer a copy to a new computer"); id. col.7 ll.7-9 ("[T]he user installs . . . the software in his computer or computer network."). Because a construction that would equate a "user" with a "computer or computers" conflicts with "both the plain language of the claims and the teachings of the specification," NeoMagic Corp. v. Trident Microsystems, Inc., 287 F.3d 1062, 1070 (Fed. Cir. 2002), the district court's inclusion of "computer or computers" in its claim construction cannot be sustained. Because we agree with Microsoft that the district court erred in construing "user" to include a computer or computers apart from a person, we modify the district court's claim construction and hold that a "user" is properly construed as "a person or a person using a computer." This construction applies to all of the asserted claims. See Omega Eng'g, Inc., v. Raytek Corp., 334 F.3d 1314, 1334 (Fed. Cir. 2003) ("[W]e presume, unless otherwise compelled, that the same claim term in the same patent or related patents carries the same construed meaning.").

-------------------------------------------------------------------

2 In so holding, we rely in part on Microsoft's concession that "user" includes both "a person" and "a person using a computer." See Reply Br. at 4. Accordingly, we express no opinion as to whether "a person" and "a person using a computer" differ meaningfully.

-------------------------------------------------------------------

Notwithstanding our modification of the district court's claim construction, however, we find Microsoft's contention that the asserted claims require the authorization of a "particular user, regardless of what particular computer they are using" to be artificial and inconsequential. Although the claims recite "software including instructions to reduce use of the software by unauthorized users," '471 patent claim 32, and "determin[ing] if the user is an authorized or an unauthorized user," '825 patent claims 44, 131, both the claims and specification describe methods of making this determination based on computer-specific information, among other things. This conclusion is based on relevant language that appears in the claims and not on any particular construction of the term "user." Specifically, the claims recite that the software representative may identify authorized users based on a comparison of "registration information provided by the user," with "previously stored registration information related to at least one of the software, the user, and the computer." Id. Because the "[u]se of the phrase 'at least one' means that there could be only one or more than one" of the listed types of previously stored registration information, Rhine v. Casio, Inc., 183 F.3d 1342, 1345 (Fed. Cir. 1999), the identification called for by the claims may be accomplished by comparing the registration information with previously-stored information related: (a) to the software installed by a person on the computer; (b) to the person using the computer; or (c) to the computer hardware. Microsoft's argument that the asserted claims require the authorization of a "particular user, regardless of what particular computer they
are using" ignores the language of the claims which, as noted above, permits the identification of authorized users based on, inter alia, "previously stored registration information related [only] to . . . the computer." Our construction of the term "user" to mean "a person or a person using a computer" does not foreclose or in any way affect such a conclusion nor does it preclude a determination that the accused Microsoft products infringe. Thus, Microsoft's argument, while correct as to the construction of the claim term "user," is not determinative of the question of infringement.

With respect to infringement, substantial evidence supports the jury verdict, even under our modified construction. Because the claims explicitly contemplate tracking authorized users through, inter alia, the identity of the computers on which they install the software as discussed, supra, and because Microsoft admits that it makes Product Activation determinations based on registration information related to user's computers, see Reply Br. at 2, a reasonable juror could find that Microsoft infringed the asserted claims notwithstanding our modification of the district court's construction of the term user. See Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1328 (Fed. Cir. 2002) (noting that when we determine that the district court "has misinterpreted a patent claim, we independently construe the claim to determine its correct meaning," and that "[w]e may affirm the jury's findings on infringement . . . if substantial evidence appears in the record supporting the jury's verdict and if correction of the errors in a jury instruction on claim construction would not have changed the result, given the evidence presented").

Defendants contend "user" should be construed to mean: "The person using the computer to customize the proposal. The user is not the customer for whom the proposal is customized." Thus, Defendants again assert that a "customer" and a "user" cannot be the same person. For the reasons given above, the Court rejects this argument. The patent uses this term according to its plain lay meaning. This term does not require construction.

Hyundai contends "user" should be construed to mean "one who deals with customers." In the Staples case, the Court rejected the distinction between user and customer and found the term did not require construction because the patent uses this term according to its plain lay meaning. Accordingly, the Court rejects Hyundai's proposed construction and construes the term according to its ordinary meaning.

3) "user" (claims 1, 15, 16)

STV Asia asserts that the word "user" should be given the plain meaning of the term, that is, "an individual who utilizes the network management system." Defendants, on the other hand, argue that the inventor gave the term a special meaning in the specification and therefore, that the term "user" in the '069 patent means "a person located in the distribution center who has access to the product movement information from the receiving sites." The Court agrees with Defendants.

In the Summary of Invention, the inventors state that "[t]he user, located in the distribution center, has access to the product movement information." '069 patent, 2: 49-50. This statement is made in a paragraph that begins, "The present invention is . . ." Where the inventor has made such a clear statement about the nature of his invention and in particular, the meaning of the word "user" as it is used in the '069 patent, it would be improper for the Court to adopt a broader definition, even if a "user" might well mean "an individual who uses" when that word is used in a more general context. See Scimed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001) (holding that "[w]here the specification makes clear that an invention does not include a particular feature, that feature is deemed to be outside the reach of the
claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question.

STV Asia's reliance on Bell Atlantic Network Servs., Inc. v. Covad Commc'n's Group, Inc., in support of its position that the term "user" is not "clearly redefine[d]" is misplaced. 262 F.3d 1258, 1268 (Fed. Cir. 2001) (emphasis added). In Bell Atlantic, the court explained that while "the specification must exhibit an 'express intent to impart a novel meaning' to claim terms . . . a claim term may be clearly redefined without an explicit statement of redefinition." Id. (citation omitted). Rather, "the specification may define claim terms by implication such that the meaning may be found in or ascertained by a reading of the patent documents." Id. (citation omitted). Indeed, in that case, the court upheld a claim construction based on the conclusion that a term had been implicitly defined in the specification, even though it was not expressly stated in the specification that the claim term was being given a special definition. Id. Similarly, the statement in the Summary of Invention quoted above defines the term "user" by implication.

This conclusion finds further support elsewhere in the specification, which makes clear that one of the main innovations of the invention is its ability to monitor product movements in order to "more efficiently tailor its commercial messages to particular chains, stores, times of day and geographic regions." '069 patent, col. 3, ll. 35-37. If users -- who create the advertising programs -- did not have access to product movement information, they would not be able to accomplish this objective. Nor is there any suggestion in the specification that the preferred embodiments that are described would allow for users without access to product information.

The Court rejects STV Asia's argument that "user" should be construed more broadly based on the statement in the specification that "each user has a security level which allows that user access to certain programs." '069 patent, col. 12, ll. 2-5. The specification explains that the security level of the user determines whether the user will be allowed to create playlists or merely edit them. Id. There is no reason to conclude on the basis of this distinction, however, that "users" were intended to include individuals who do not have access to product movement information.

Finally, the Court rejects STV Asia's reliance on the doctrine of claim differentiation in support of its position. STV Asia points out that in claim 1, the user is expressly identified as "having access to the product movement information from the tracking system" whereas, in claims 15 and 16, no such limitation is included, arguing that this means that the term "user," by itself, does not mean an individual who has access to product information. Under the doctrine of claim differentiation, different claims are presumed to be of different scope. Inpro II Licensing, S.A.R.L. v. T-Mobile U.S.A., Inc., 450 F.3d 1350, 1354 (Fed. Cir. 2006) (citing Tandon Corp. v. U.S. International Trade Com., 831 F.2d 1017, 1023-24 (Fed. Cir. 1987)). However, "describing claim elements or limitations in different words does not invariably change the scope of the claim." Id. Rather, the scope of the claims must be determined in light of the "description in the specification, as well as the prior art and the prosecution history." Id. (citing Phillips). Thus, for example, in Inpro, the Federal Circuit held that the district court correctly construed the term "host interface" in the disputed patent to require "a direct parallel bus interface" even though some of the claims expressly referred to such a limitation while others did not. Id. at 1357. The court reasoned that a host interface with a direct parallel bus interface was the only type of interface described in the specification and pointed to the inventor's statements emphasizing the importance of the parallel bus interface. Id. at 1355. Similarly, in this case, the specification describes only a user with access to product movement information, and such access is an important feature of the invention to the extent it allows for effective customization of programs for the individual receiving sites. The Court concludes that even though the claims, when read in isolation, might be read to support the broader construction of the term "user" proposed by STV Asia, when the claims are read in the context of the specification, it is clear that a more limited construction is appropriate.

The Court construes this claim term as follows: "a person located in the distribution center who has access to the product movement information from the receiving sites."

A. Claims 6 And 26 Of The '622 Patent

Claim I of the '622 patent states:
1. System for remotely determining the position of a selected category of items of interest in selected geographic vicinity from a database, the system comprising:

(A) a database for storing information about a plurality of items of interest, the information including, for each of the items of interest, a geographical position and at least one associated category,

(B) a communications link for communicating between a user of the system and the database,

(C) an information controller for transmitting a portion of the information in the database to the user via the link upon receipt of a request signal representative of a selected category and geographic vicinity, the transmitted portion of the information including identification of geographic position for at least one of the items of interest within the selected category and geographic vicinity, and

(D) a port for remotely accessing the portion of information via the link, the port generating the request signal in response to inputs by the user which are representative of the selected category and geographic vicinity, the port having a user interface for accepting the inputs and for indicating to the user the position at least one of the items of interest in the selected category and geographic vicinity.

(DSUF P 6.) Claims 6 and 26 depend from Claim 1 and therefore include each of the limitations of Claim 1. 35 U.S.C. § 112, P 4 (“A claim in dependent form shall be construed to incorporate by reference all the limitations of the claim to which it refers”). Expedia first argues that it does not infringe Claims 6 and 26 because it does not use the claimed port or communications link. The Court has construed the term "port" to mean a "terminal, e.g., a personal computer with a modem, from which a user of the invention can access the database storing the information about the items of interest." The Court has also ruled that "user" refers to a "human being." In opposing summary judgment, Civix argues that Expedia does use the claimed system by controlling its customers' use of the ports. 11

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

11 Civix also argues that Expedia is a co-infringer along with its customers and suppliers and is therefore jointly liable for infringement. Civix argues that Expedia induces the infringement of claims 6 and 26. Because the Court finds that genuine issues of fact exist whether Expedia, itself, uses the claimed system, the Court does not reach Civix's other arguments.

14. Users

Certain language in the preamble of claim 37 limits the claim because the preamble language provides antecedent basis. In particular, the language "plurality of programs of different users" provides antecedent basis for the term "said programs" recited in the body of claim 37. At issue is the definition of "user" in the phrase "programs of different users."

Biax contends that "user" includes both persons and programs. Intel and ADI contend that "user" must be limited to persons. Neither construction is proper. It is true that the cited portions of the specification relied on by the defendants support the view that "user" is different from "program." See '755 patent, col. 15, 11. 3-7 (“The TOLL software of the present invention can be used in connection with a number of simultaneously executing programs, each program being used by the same or different users.”)(emphasis added). Nothing in the specification, however, expressly limits the term "user" to a human being using a program to the exclusion of a machine. As a result, the court holds that the term "user" includes "a person or a computer."

GO BACK

4686

- 4909 -
"User"

"User" appears in each disputed patent claim (536 Patent: 1,6; 709 Patent: 1,17). The defendants contend that the phrase "user" means "a human who issues commands to the computer on which a digital data file was created or copied" (Doc. 62 at 14). The plaintiff argues that "user" means "an entity that issues requests to a system on which digital data exists" (Doc. 60 at 20). The plaintiff's urged construction avowedly encompasses a computer program or application as a "user" (Doc. 60 at 19-20). However, an examination of the intrinsic evidence reveals no "entity" other than a human being as performing the tasks of a "user."

In support of the construction of "user" as any human or non-human "entity" (including a computer program), the plaintiff argues that the specifications distinguish a "user" from an "end user," which "end user" the plaintiff concedes is a human (Doc. 60 at 19). Yet, in the paragraph on which the plaintiff relies, "user" and "end user" are employed interchangeably:

This removes the burden of the request process from the end user of the certificate. Certificates in this model can be issued in a centrally managed bulk process on behalf of the user, and any keys that will be used to encrypt data can be securely backed up in case the issued key gets lost.

(536 Patent at 33:22-27). Obviously, "end user" in the first sentence and "user" in the second sentence denote the identical user.

Throughout the patents and their specifications, the patentee repeatedly attributes human attributes to a "user." For example, "User B wants to send User A an offer to purchase a piece of property that User A owns and an authorization to his bank to transfer money if a user accepts the offer" (536 Patent at 10:1-3; 709 Patent at 9:60-62). Similarly, "Verification means 580 may comprise any biometric device (e.g., iris scan, retina scan, hand geometry, voice verification, and dynamic signature verification devices, etc.) that may be used in order to further verify the identity of a user" (709 Patent at 42:50-55). Finally, "This operation may take 0.5 to 2.0 seconds, which could be annoying to a user" (536 Patent at 25:7-8). A non-human "entity" (1) has no desire to sell property, (2) lacks eyes, fingers, hands, or a voice susceptible to "biometric" verification, and (3) is incapable of "annoyance."

Further, the specifications repeatedly depict a "user" as a human manipulating the computer toward some end. For example, "Hypothetically, a user at a computing means 400 signs a document and wants it time stamped" (536 patent at 11:42-43; 709 Patent at 11:30-32). Also, "Indeed, it is quite trivial for a user to reset the [local time clock] to any desirable date and time" (536 Patent at 6:24-25; 709 Patent at 6:24-25). Similarly, "[a] trusted date and time is programmed within real time clock 1000, such that it cannot be changed by a user of the PC system 700" (709 Patent at 28:6-8). Nothing in these statements permits a non-human "user."

In sum, the patentee's consistent use of "user" in the claims and specifications favors the construction urged by the defendants. The intrinsic evidence reveals that a "user" is a human who creates, time-stamps, and publicly verifies the moment of a file's creation. A "user" possesses an array of attributes unavailable to a computer program or other inanimate "entity." Accordingly, "user" means "a human who issues a command to the computer on which a digital data file was created or copied."

GO BACK

6. "user"

Claim 19 claims a method for a transmission system and a receiving system to distribute information in response to requests from a "user." The parties dispute the construction of the word "user."

The specification contains numerous references to the "user" and to a related word "subscriber:"
A system of distributing video and/or audio information employs digital signal processing to achieve high rates of data compression. The compressed and encoded audio and/or video information is sent over standard telephone, cable or satellite broadcast channels to a receiver specified by a subscriber of the service, ...

The Summary of the Invention provides:

Additionally, the present invention comprises a receiving system responsive to a user input identifying a choice of an item stored in a source material library to be played back to the subscriber ...

('992 Patent, Col. 2:62-65.)

The Description of Preferred Embodiments provides:

The user then enters a customer ID code by which the system accesses the user's account, and indicates to the system that the user is a subscriber of the system (step 3030). In response to the user entering his ID code in step 3030 the system confirms whether the user is in good standing (step 3040). If the user is in good standing, the system queues the user to input his request (step 3050).

The user request may preferably be made from a catalog sent to each of the subscribers of the system. The user will preferably identify his choice and enter the corresponding identification code of the item (step 3060). The system then preferably confirms the selection that the user has made and informs the user of the price of the selection (step 3070).

('992 Patent, Col. 14:14-28.) From the specification, one of skill in the art would understand that the method described in Claim 19, is one in which, a person, called a "user" requests information from the system. Some embodiments disclose a process by which only authorized users, i.e., "subscribers" are able to receive the information.

The specification of the '992 Patent also uses the word "operator" in describing the transmission and reception systems and methods. However, the word "operator" is used in the specification to signify someone who acts as part of the transmission system and is not used by the patentee to describe a "user." Two types of operators are described in the invention, both of which can act as part of the "transmission system."

The first operator function is the "system operator's function" and is described as:

The unique address code is an address assigned to the item by the system operator during storage encoding,

* * *

The storage encoding process may be run by the system operator.

('992 Patent, Col. 10:58-59; Col. 11:13-14.)

The second operator function is that of a "telephone operator," for the purpose of taking requests from a user and manually entering such requests into the transmission system:

Access by the users via operator assisted service includes telephone operators who answer calls from the users. The operators can sign up new customers, take orders, and help with any billing problems. The operators will preferably have computer terminals which give them access to account information and available program information. Operators can also assist a user who does not know a title by looking up information stored in files which may contain the program notes, as described above. Once the chosen program is identified, the operator informs the user of the price. After the user confirms the order, the user indicates the desired delivery time and destination. The operator then enters the user request into the system. The request is placed in the transmission queue.

('992 Patent, Col. 14:49-63.)

The Court finds that the construction of the word "user" should make clear that a "user" is not an "operator" as those terms
are used in the specification.

The Court construes "user" as follows:

In a distribution method as disclosed in Claim 19 of the '992 Patent, in which a transmission system sends information to receiving systems at remote locations in response to a user's request, the word "user" means "a person who requests information from items in the transmission system." Any person acting as part of the transmission system, such as an operator, is not a user or a subscriber.

D. "user account"

The term "user account" appears in several claims, e.g., "a user account corresponding to at least one user" ('704 patent, claim 7); "providing a user with a user account . . . associating the licensed plurality of media assets with the user account . . . authorizing over a network a plurality of media player devices with the user account." ('414 patent, claim 10). "User account" is described in the specification as follows: "Initially, a user becomes a member or subscriber to a portal . . . Once a membership exists, a virtual private media asset database is created and associated with the user's login account and password in the portal." ('704 patent, 10:25-27) (emphasis added). According to the plaintiff, this term means "a record stored in system memory indicating that the user has the right to access a system for managing media assets, and one or more media player devices that may access referenced media assets." Apple argues that the definition should be "a user's membership record in a portal/server that specifies the plurality of media player devices that may access the referenced media assets." The parties' proposed constructions differ in two ways: (1) whether the account must exist in the portal/server or in system memory; and (2) whether the account must specify the media player devices.

Apple argues that the patent neither describes nor enables a user account anywhere but the portal or server. The Summary of the Invention states, "The portal executes a media library database server application that manages access to a master library of media assets that can be accessed by users . . . ." ('704 patent, 1:36-38). Thus, the portal provides the access control functionality, and that access control is based upon the rights assigned to user accounts. ('704 patent, 3:25-28 ("The portal 300 also serves as a central repository within which media assets are 'tagged' with identity and access privileges of those users . . . ."). In response, Zapmedia argues that the location of the user account is unimportant, and the term should not be limited to a disclosed preferred embodiment--user account on the portal. Claim 10 of the '414 patent describes "providing a user with a user account," but nowhere in the claim is a server or portal disclosed; thus, user accounts are not always tied to a portal or server. Additionally, some of the claims specify that the account resides on the portal or server, so adding a location requirement in the construction would be superfluous. As such, the user account is not required to be on the portal or server.

Next, according to Apple, the user account must specify all of the media player devices, not merely some or permitted to access that account's media assets. In support of its proposal, the defendant cites the '704 patent's prosecution history, which states, "The user account specifies the plurality of media player devices that may access the media assets." (Dkt. No. 84, Ex. L, at 11). Zapmedia responds that Apple's proposed construction precludes user accounts that have only one media player device. Zapmedia also contends that the specification describes accounts with one or more associated devices. ('704 patent, 10:15-16 ("[E]ach account on the portal has one or more media player devices associated with it . . . ."). The claim language, however, refers to a "plurality of media player devices." As such, the "one or more" versus "plurality" argument does not have to be resolved in the context of the "user account." In all, the court construes the term to mean "a record indicating that the user has the right to access the media assets, and indicating which media player devices may access referenced media assets."
The parties agree that the term indicates a mode "in which graphics are displayed to attract users to the jukebox," but disagree as to when the jukebox is in this mode. Touchtunes proposes that this mode is "triggered by a determination that no song selection is playing on the jukebox," whereas Arachnid proposes that the jukebox is in user attract mode "when the jukebox is not in selection mode."

Touchtunes' proposed construction seeks to introduce a "triggering" element into the claim, although the term "trigger" does not appear in any Arachnid patent. To support its proposed construction, Touchtunes relies on a preferred embodiment which states that, "if no song selection is playing, the processing circuit 121 operates in a user attract mode" and "[i]f, however, a song selection is being played when the block 161 is encountered, the attract mode sequencing does not occur." '575 Patent at 6:39-59. However, the description of the preferred embodiment is the converse of Touchtunes' characterization. Rather than being "triggered," the user attract mode automatically occurs unless a song selection is being played.

Touchtunes' proposed construction is also incorrect because, by incorporating the concept that user attract mode is triggered by a determination that no song is playing, it renders superfluous the phrase "when no song is playing on the jukebox," as recited in claim 4 of the '189 Patent and claim 6 of the '575 Patent. A claim construction that renders claim language superfluous is almost always incorrect. See Stumbo v. Eastman Outdoors, Inc., 508 F.3d 1358, 1362 (Fed. Cir. 2007).

Arachnid's proposed construction is consistent with the plain meaning of the term: it is a mode to attract users to the jukebox that is exited when the user "uses" the jukebox by making a song selection.

The term "user attract mode" is therefore construed to mean "a mode, when the jukebox is not in selection mode, in which graphics are displayed to attract users to the jukebox."

2. "user authorization information" (claims 1 & 15)

Plaintiff proposes that this "user authorization information" should be construed to mean "a password or user ID used to authenticate a user." Defendant argues that the term should mean "any user information upon which access is determined."

Plaintiff's proposed claim construction is not supported by the record. Plaintiff asks the court to limit "user authorization information" to a password or a user ID used to authenticate the user, but does not provide any support for substantially limiting this term. Unlike the '538 patent in which password protection was a limitation expressed in the claims themselves, claims 1 and 15 of the '940 patent do not include any such limitation. For example, claim 1 includes the limitation of "determining whether a user is authorized to add said record from said user authorization information." See claim 1 of the '940 patent. Similarly, claim 15 includes the following language "means for receiving user authorization information. . . . means for determining whether a user is authorized to add said record from said user authorization information. . . ." See claim 15 of the '940 patent. Neither claim 1 nor claim 15 limits the user authorization information to a password or user ID.

The court declines to adopt Plaintiff's proposed construction. "User authorization information" means "user information upon which access is granted."

4. "user commands"

Manheim contends that the term "user commands" is a well-known term that one of reasonable skill in the art would understand to mean "instructions by a user, such as key presses or mouse clicks, that cause a computer to carry out an action." Thus, according to Manheim, the term "user commands" should be construed to mean "user actions such as key presses or mouse clicks." AMS and Bidsoft, on the other hand, argue that "user commands" means "instructions, issued by a user remotely connected to the host computer network, causing selected portions of the auction data stored on the host..."
computer network to be located, organized, and transmitted over the communication network to the user's workstation."

The Court agrees with AMS and Bidsoft that Manheim's construction must be rejected. As they correctly point out, claim 1 recites

a set of user application modules which cause the computer workstations and host computer network to generate on the video monitors a series of command options selectable by the user to generate the user commands, whereby the selected portions of the auction data stored on the host computer network are located, organized, and transmitted over the communications network to a workstation in response to one or more particular user commands and are displayed on the video monitors.

(873 patent col. 11, ll. 12-22.) Manheim's expert stated that a user would select a "command option" through user actions such as mouse clicks or key strokes. (Bailey Dep. [377-8] at 196.) Thus, Manheim's proposed construction would mean, in essence, command options selectable by the user by pressing a key or clicking a mouse to generate key presses or mouse clicks. As this is nonsensical, the Court rejects Manheim's proposed construction. See ASM America, Inc. v. Genus, Inc., 401 F.3d 1340, 1346-47 (Fed. Cir. 2005) (rejecting proposed claim construction where it would result in nonsensical construction of the claim as a whole).

In contrast, the Court finds AMS and Bidsoft's construction to be consistent with the claim language and specification of '873 patent. For example, claim 1(a) recites a "database server that electronically stores and organizes auction data and that retrieves and transmits selected portions of the auction data in response to user commands." (873 patent col. 10, l. 66-col. 11, l. 3.) Similarly, claim 1(d) recites "a set of user application modules . . . to generate user commands, whereby the selected portions of the auction data stored on the host computer network are located, organized, and transmitted over the communications network to a workstation in response to one or more particular user commands. . . ." (Id., col. 11, ll. 6-7).

Thus, as AMS and Bidsoft correctly explain, "user commands" must be operable to cause selected portions of the auction data to be located, organized and transmitted to the user workstation. Moreover, the construction proposed by AMS and Bidsoft is in consonance with both the remainder of the claim language and the expert testimony. (See id. at col. 11, l. 3. (claiming "means to send user commands to the host computer network"); Bailey Dec. [379-8] at P 24 (explaining that "User commands" are also well-known in the art and would commonly be understood by one of ordinary skill in the art to be instructions, issued by the user, that cause an action to be carried out.)).

Accordingly, the Court concludes that the term "user commands" in claim 1 shall mean "instructions issued by a remote computer, causing selected portions of the auction data stored on the host computer network to be located, organized, and transmitted over the communications network to the user's workstation."
user computers such as mainframes, the specification excludes those mainframes from the definition of user computers.

It is true that the specification suggests that, as the number of users using a mainframe increases, the amount of processing power necessary to run all the user applications increases, and consequently the cost of a mainframe capable of handling all the requisite processing increases. '989 patent, col. 1, ll. 26-41. The specification continues by describing why one potential solution--using several processors in communication with one another to perform the role of a single processor--is inadequate. In that system, the specification explains, the overhead necessary for communication between multiple processors would consume substantial computing resources. Id., col. 1, l. 42 to col. 2, l. 3.

The Background of the Invention thus highlights the problems inherent in performing all the processing necessary to run multiple user applications at a central computer, whether that computer includes only one very expensive processor or several less expensive processors consuming valuable computing resources talking to one another. The specification does not, however, disclaim the networking of mainframes to a central computer that is devoted to database access. To the contrary, the Background of the Invention appears to allow a configuration in which multiple user applications are run separately on several mainframe computers, which communicate with a database computer that is dedicated to the functions of storing and retrieving data. In such a case, several less expensive mainframe computers could be used to manage the processing of an increasing number of user applications while the overhead associated with communication among processors would be limited to communications related to the storage and retrieval of data.

American Academy argues that the specification describes the user stations in a way that distinguishes a "user computer" from a multi-user computer. In particular, American Academy points to a portion of the specification that provides as follows:

the system of the present invention includes a plurality of user stations each dedicated to servicing a user (which could be a person, another device, or machine) and each functioning as a stand-alone computer, having its own central processing unit, typically a microprocessor, and equipment by which the user can communicate with the central processing unit, typically a video display and keyboard terminal. The user stations may have other peripheral equipment as well, such as disk drives, printers, card readers, or the like. The user stations service the users by executing application programs supplied by the users.

'989 patent, col. 2, ll. 35-47 (emphasis added). American Academy notes that the term "user station," which appears to be synonymous with "user computer" as used in the '989 patent, is referred to as "dedicated to servicing a user." That reference, according to American Academy, indicates that a "user station" or "user computer" must be a computer that is dedicated to a single user.

As the Director of the PTO points out in his brief, however, the specification states that a "user" can be "a person, another device, or machine," which suggests that the "user computer" could be a mainframe or minicomputer. The Director also points to a portion of the specification that provides as follows:

Although specific equipments are shown for the user station 4 and data center 8 of FIG. 2, it should be understood that a variety of configurations could be utilized to enable the user station 4 to operate as an interface with users and to process application programs 116, and to enable the data center 8 to serve as a storage and retrieval center for data of common interest to the user stations.

'989 patent, col. 6, ll. 7-14. The specification then proceeds to differentiate the user computers from the data center computer in terms of function, explaining that a "user station . . . would be utilized to interact with the operator, generate payroll information, produce accounting reports, process accounts payable and accounts receivable, sort, compile, process hotel or airline reservation requests, and in general process data pursuant to a variety of conventional application programs" while "the data centers . . . illustratively would serve to store data relating to the personnel of a company, payroll information regarding such personnel, accounts payable and accounts receivable data, information regarding occupancies and vacancies in a hotel chain or airline system, and generally any type of data which may be of interest to more than one user station . . . ." Id., col. 6, ll. 14-27. According to the Director, the specification thus makes clear that the term "user computer" is used to refer to the function of the computer in running a user application, not to the identification of the user computer as a personal computer as opposed to a mainframe.

- 4915 -
American Academy argues that to read "user computer" to encompass mainframes and minicomputers would vitiate the word "user." The Board, however, recognized that the addition of the word "user" would "disqualify those computers that are designed as special purpose computers for some use and are not intended to be reprogrammed by users for their own benefits."

American Academy also points to the specification's reference to the Zilog Z-80 as a type of computer that could be used in a system embodying the invention. The Zilog Z-80, American Academy argues, was never intended to serve as a multi-user computer, and thus, according to American Academy, the reference to the Zilog Z-80 indicates that multi-user computers were not intended to be within the scope of "user computers" as that term was used in the '989 patent. The specification, however, describes the Zilog Z-80 as part of an "illustrative embodiment" of a "conventional microprocessor," not as an essential element of the invention. '989 patent, col. 5, ll. 27-32. Moreover, the examiner, citing a contemporaneous reference on microprocessors, determined that the Zilog Z-80 had the capability to function as a multi-user computer.

We agree with the Board that the description in the specification would not preclude a mainframe or a minicomputer from serving as the "user computer" of the invention. In general, the specification distinguishes a user computer from a data center computer in terms of function. Although some of the language of the specification, when viewed in isolation, might lead a reader to conclude that the term "user computer" is meant to refer to a computer that serves only a single user, the specification as a whole suggests a construction that is not so narrow. Instead, the specification indicates that the invention is intended to reach "a variety of configurations" including those in which the "user" is not a person, but is another device or machine. Thus, in light of the description in the specification, a construction of "user computer" that includes multi-user computers, such as mainframes or minicomputers, is not unreasonably broad.

American Academy contends that the declarations of Dr. Maryanski, submitted at various points in the course of the reexamination proceedings, establish that one of ordinary skill in the art would understand the term "user computer" to mean a computer dedicated to a single user, and not a mainframe or minicomputer. See Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002) ("The ordinary meaning must be determined from the standpoint of a person of ordinary skill in the relevant art."); In re Cortright, 165 F.3d 1353, 1358 (Fed. Cir. 1999) ("Although the PTO must give claims their broadest reasonable interpretation, this interpretation must be consistent with the one that those skilled in the art would reach."). The Board upheld the examiner's determination that the declarations consisted only of Dr. Maryanski's personal opinions and did not constitute persuasive evidence in support of his conclusions.

The Board has broad discretion as to the weight to give to declarations offered in the course of prosecution. See Velander v. Garner, 348 F.3d 1359, 1371 (Fed. Cir. 2003) ("Accord[ing] little weight to broad conclusory statements [in expert testimony before the Board] that it determined were unsupported by corroborating references [was] within the discretion of the trier of fact to give each item of evidence such weight as it feels appropriate."); cf. Ashland Oil, Inc. v. Delta Resins & Refractories, Inc., 776 F.2d 281, 294 (Fed. Cir. 1985) ("Opinion testimony rendered by experts must be given consideration, and while not controlling, generally is entitled to some weight. Lack of factual support for expert opinion going to factual determinations, however, may render the testimony of little probative value in a validity determination." (citations omitted)). Although there is "no reason why opinion evidence relating to a fact issue should not be considered by an examiner," In re Alton, 76 F.3d 1168, 1175 n.10 (Fed. Cir. 1996), the Board is entitled to weigh the declarations and conclude that the lack of factual corroboration warrants discounting the opinions expressed in the declarations, see Velander, 348 F.3d at 1371; Ashland Oil, 776 F.2d at 294.

American Academy also asserts that the prosecution history of the original application that matured into the '989 patent supports its construction of the term "user computer." During prosecution, the PTO rejected the claims of the application based on a prior art patent to Anderson. The applicant characterized Anderson as including remote transaction terminals and a host data processing system, in which the host, and not the remote terminals, processed the transactions. American Academy argues that the failure of the applicant and the examiner to characterize the host computer as a "user computer" is evidence that a user computer is intended to service a single user. However, the applicant distinguished the Anderson reference on the ground that the application programs were run on the host computer, rather than on remote transaction terminals. In effect, the applicant analogized the system of Anderson to the mainframe and dumb terminal configuration described in the Background of the Invention section of the '989 patent, with the remote transaction terminals of Anderson likened to dumb terminals. Thus, it would not have made sense for the applicant to compare the host computer of Anderson with the user computers of the application, since the user computers of the application were intended to replace devices analogous to the remote transaction terminals of Anderson. Accordingly, the discussion of the Anderson reference in the
prosecution history of the original application for the '989 patent does not support American Academy's position.

Finally, American Academy points to an inconsistency between the Board's construction of the term "user computer" and that of the district court in American Academy's litigation against Novell.

In the district court litigation, the court construed "user computer" to refer to a computer that serves one user at a time. However, the Board is required to use a different standard for construing claims than that used by district courts. We have held that it is error for the Board to "apply the mode of claim interpretation that is used by courts in litigation, when interpreting the claims of issued patents in connection with determinations of infringement and validity." In re Zletz, 893 F.2d 319, 321 (Fed. Cir. 1989); accord In re Morris, 127 F.3d 1048, 1054 (Fed. Cir. 1997) ("It would be inconsistent with the role assigned to the PTO in issuing a patent to require it to interpret claims in the same manner as judges who, post-issuance, operate under the assumption the patent is valid."). Instead, as we explained above, the PTO is obligated to give claims their broadest reasonable interpretation during examination. Under that standard, it was proper for the Board to construe "user computer" to encompass the mainframes and minicomputers of the cited prior art.

4693

42. The term "user configuration information" - as used in the '498 Patent - means "information associated with the user such as the user's account information, email information, screen formats, or screen colors."

43. The term "user identification information" - as used in the '498 Patent - means "a user's given name or a system user name specially coined by the user that is used to identify the user in each transaction."

4694

13. The user context file for said one program

Claim 37 of the '755 patent requires adding information "identifying at least the user context file for said one program." The parties dispute what is meant by the term "user context file." Biax contends that the term "context file" means "a set of registers" and the term "user context file" means "a set of registers for a user." Intel and ADI contend that the term "user context file" means "a physical register file, assigned to the user of one program, which contains the data used by and specific to that one program."

Although the description of the preferred embodiment supports the defendants' construction, the court disagrees that the limitations should be read into the claim language. The specific language in the specification does not require that the invention be limited to a system having a different context file for each user. See '755 patent, col. 17, 11. 60-63 ("In an MIMD system of the present invention as shown in FIG. 6, each context file would contain data from a different user executing a program.")(emphasis added). Moreover, the specification counsels against a limitation that the context file must be specific to only one program. "The diagram of FIG. 6 represents an MIMD system wherein each context file 660 corresponds to at least one user program." '755 patent, col. 15, 11. 34-36. (emphasis added). As a result, the court adopts a construction similar to the one proposed by Biax. A user context file is "a set of registers assigned to a user." See '755 patent, col. 15, 11.34-36.

4695

C. "User-defined reference to aggregated fact data"

This term appears in claim 1. Hyperion proposes that the term means a "link from a relational database language request to data in a multidimensional data store." Hyperion Br at 11. HyperRoll instead contends that the term means a "user-defined pointer to aggregated fact data." HyperRoll Br at 16.
Hyperion's proposed construction is problematic for many reasons. First, Hyperion seeks to incorporate implicitly its proposed construction for "query statement" ("relational database language request"), which is a construction the court has already rejected. Second, Hyperion's proposed construction improperly reads out the requirements that the reference be "user-defined" and that the fact data be "aggregated."

Moreover, Hyperion improperly limits the definition of this term based on a disclosed embodiment in the specification. Hyperion relies on the steps shown in the flow chart in FIGS 6C1 and 6C2 to contend that "[t]he '604 Patent itself describes the 'user-defined reference to aggregated fact data' as providing a link from a relational database language request to data in a multidimensional data store." Hyperion Br at 11. But even if this were true, it would be improper to limit the claim based solely on this disclosed embodiment, as the court has already explained.

Additionally, Hyperion's construction improperly limits the term "reference" to a "link." In describing an exemplary embodiment of a "reference," the patent notes:

This reference is preferably defined using the Create View SQL statement, which allows the user to: i) define a table name (TN) associated with the MDD database stored in the MDD Aggregation Module, and ii) define a link used to route SQL statements on the table TN to the MDD Aggregation Module.

Id at 12:39-44 (emphasis added). This description indicates that at least in some embodiments, a reference may be more than just a link and may also include a "table name" associated with the MDD database.

Hyperion correctly notes that during reexamination, HyperRoll distinguished this patent over a prior art reference by noting that the user-defined reference "allows a user of the RDBMS to query aggregated fact data stored in a multidimensional data store that is separate from the relational data store." Hyperion Br, Ex G at 27-28. But contrary to Hyperion's suggestion, it would be redundant to import any of these limitations into the definition of "user-defined reference to aggregated fact data" because claim 1 already includes these limitations. '604 patent at claim 1 (A "user-defined reference" is used "to retrieve portions of aggregated fact data" stored "in a non-relationa multi-dimensional data store" that is part of an "aggregation module" separate from a "relational data store.").

The court agrees with HyperRoll that the term "user-defined" and "aggregated fact data" do not need additional construction, as their plain meaning corresponds with their usage in claim 1. The court, however, declines to follow HyperRoll's proposed construction of a "reference" as a "pointer." A "pointer" is a specific and well-known term of art in computer science. See, e.g., Microsoft Computer Dictionary 348 (4th ed 1999) ("pointer * * * [i]n programming and information processing, a variable that contains the memory location (address) of some data rather than the data itself"). Although the court does not dispute that in some embodiments a "reference" might be a "pointer," the court does not read claim 1 as requiring a "reference" to be limited necessarily to just a pointer. Moreover, the meaning of "reference" is clear from its usage in claim 1 and no further construction is needed.

In sum, the court rejects both parties' proposed constructions and declines to construe this term.

4696

In the present case, the validity issue turns on proper construction of the "user-defined cabinet design standards" limitation. At the heart of the dispute is whether "user-defined standards" signify creating new standards independent of the options presented on the menus. The district court rejected that broad interpretation. Instead, the district court limited "user-defined standards" to "selection and modification from the pre-existing parameters in the database." Cabinet Vision IV, slip op. at 12 (emphasis added). Upon review, this court agrees with the district court.

This court reads the term "user-defined standards" to mean selection and modification of only pre-existing parameters. The language of the claim specifies "user-defined cabinet design standards that are fully defined by the user." Later, the claim stipulates that the user may "selectively create custom defined layout rules." This language, however, does not disclose a method for user definition or creation of design standards or layout rules. The claim language is unclear on whether the user defines the standards by supplying responses to the pre-programmed computer menu or by programming "new" standards beyond those supplied by the computer program.
The written description of the '207 patent illuminates the meaning of "user-defined standards." See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2d (BNA) 1573, 1576 (Fed. Cir. 1996). The specification explains that a user may select custom parts, styles, and custom accessories "from a catalog" or "under menu control." '207 patent, col. 7, ll. 18-42. Additionally, it clarifies that the "process of customized creation of particular features of the cabinets, from a vast array of possibilities in the database 16, is an example of a user created standard." Id., ll. 39-42 (emphasis added). Further, the patent notes that the "user created standards function permits modification of previously defined standards." Id., col. 10, ll. 20-22 (emphasis added). Significantly, Mr. Cornwell admitted at trial that "what the user does to create a standard is just select something from the database . . . [and] that the user really makes choices from amongst what is in the database." [JA862, 866]

The specification does not, as Cabinet Vision asserts, adequately disclose a method for a user to create "new" standards beyond those provided by the program menu. Although it makes several vague references to teaching user created standards, the written description is far from satisfying the enablement requirement for creating "new" standards independent of the menu options. Thus, this court construes "user-defined standards" as "selection and modification from the pre-existing parameters in the database." This narrower interpretation preserves the validity of the claims for purposes of 35 U.S.C. § 112. Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1557, 37 U.S.P.Q.2D (BNA) 1609, 1617 (Fed. Cir. 1996) ("When claims are amenable to more than one construction, they should when reasonably possible be interpreted so as to preserve their validity [under 35 U.S.C. § 112].").

The district court reached and applied the same claim construction. Therefore, the trial court correctly concluded that substantial evidence does not support the jury's finding of validity. On appeal, Cabinet Vision's validity argument rests solely on the district court's claim construction. In fact, Cabinet Vision does not dispute that the admitted prior art would invalidate claims 2-4 under the district court's claim construction. By sustaining the district court's claim construction, this court also sustains the district court's judgment that claims 2-4 are invalid.

---

4697

A. "user IDs"

Claim 1 contains the term "user IDs": "a database with entries correlating each of a plurality of user IDs with an individualized rule set," "wherein the dial-up network server communicates a first user ID for one of the users' computers . . . to the authentication accounting server," and "wherein the authentication accounting server . . . communicates the individualized rule set that correlates with the first user ID." The term appears throughout the specification, e.g., "when the user connects to the local network . . . the user's ID and password are sent to the authentication accounting server." (118 patent, 2:66-3:1) (emphasis added). According to Linksmart, the court does not need to construe "user IDs." Alternatively, if the court determines that a construction is necessary, Linksmart's proposed construction is "identification of the user." The defendants assert the following construction: "a unique identification code for a particular person."

The defendants contendthat the user ID must be a unique identification assigned to a particular person. In support of their argument, the defendants note that the purpose of the invention, according to the patent's Summary of Invention, is "to allow the redirection, blocking, or allowing, of specific data traffic for specific users." (118 patent, 2:62-64) (emphasis added). Also, U.S. Provisional Application No. 60/084,014 ("014 application") is fully incorporated by reference, states that "[e]ach redirection is handled individually such that every user can have a different designated site." (014 application, at 8). But nothing in the specification requires that each person must be assigned a unique user ID--a single user ID could be assigned to a group of persons. Therefore, the court construes the term to mean "identification of the user or users."

4698

1. User Interface

The first element of claim 10 provides:
providing a user interface for controlling one of a seek time of the data storage device and an acoustic noise level of the data storage device; (emphasis added)

There are two disputes over the term "user interface." The first dispute is whether a "user interface" is limited to being either a graphic user interface (GUI) or electromechanical switches, or whether a "user interface" more broadly encompasses any means to alter the drive performance parameters. The second dispute is whether the "user interface" can only be used by the human end-user of the system. Plaintiffs assert that a "user interface" can more generally be used by any person or other system which is capable of setting the parameters.

Within the relevant art 9, there are distinctions between a "user interface" and a "graphic user interface." The dictionary meaning of "User interface" is "the means of communication between a human user and a computer system, referring in particular to the use of input/output devices with supporting software. Examples include the graphical user interface (GUI) and command-line interface (CLI)." A Dictionary of Computing, Oxford University Press, 1996. Defendants assert that the specification indicates that "user interface" should be construed as "a graphic user interface (GUI) of a type common to windowing operating systems such as Microsoft Windows or electro-mechanical switches." ('473 patent Col. 6:44 -- 9:44). This fails to distinguish between a "user interface" and a "graphic user interface". Defendants claim the specification defines the term "user interface" to be synonymous with "graphical user interface":

As an alternative to the GUI, or to supplement the GUI, the disk drive may include one or more electro-mechanical manual switches for controlling all or part of the drive's operation in the manner set forth above.

('473 patent Col. 9:38 -- 42).

--- Footnotes ---

9 The '473 patent discloses an invention for improving the performance of computer disk drives. The relevant art here is the field of computer engineering.

--- End Footnotes ---

This language, however, clearly indicates the breadth of the term "user interface" to include both a GUI or electromechanical switches. This language indicates that a GUI is one type of "user interface," and an electro-mechanical switch is another, albeit simpler, type of "user interface." The "alternative to the GUI" and "supplement the GUI" language indicates that the electro-mechanical switch is not intended to limit the definition of "user interface," but rather demonstrates the range of user interfaces encompassed by the invention. See Johnson Worldwide Assocs. v. Zebco Corp., 175 F.3d 985, 991 (Fed. Cir., 1999) ("Varied use of a disputed term in the written description demonstrates the breadth of the term rather than providing a limited definition.") Defendants' construction would require that "user interface" ensnare both a complex and simple user interface, but not the spectrum of user interfaces in between. The inventor did not demonstrate a manifest intent to disclaim every type of user interface not disclosed in the specification.

Plaintiffs' construction of "user" as "a person or device that uses the user interface" is too broad. It fails to give meaning to the adjective "user," which distinguishes the interface from other types of interfaces used in the computing field, for example, an advanced programming interface (API) which allows one software program to "interface" with another. The plain meaning of "user interface" requires a user, and the term "interface" typically indicates a means by which anything can interact with a device. Plaintiffs maintain that the term "user" cannot be limited to "a person" because this would exclude the situation where a person indirectly uses the interface. They argue, in essence, that any device can be broken down into a series of simpler devices. A potential infringer could, therefore, circumvent the patent by placing an intermediary device between the user and the invention. For instance, when using a GUI, the user typically positions the cursor on the screen using a mouse. A potential infringer could claim that the user is interfacing with the mouse, and the mouse is interfacing with the computer, thereby avoiding infringement. To avoid such pedantic arguments by accused infringers, the term is constructed specifically to include circumstances where a person has, at some point, dictated what the parameters should be. A patent cannot be constructed to deprive a claim term of all meaning, and plaintiffs' construction of "user interface" would render "user" meaningless.
Defendants also contend that the user of the "user interface" must be the human end-user of the drive. They claim that the description of the GUI in the specification compels an interpretation imposing the end-user restriction. However, the user can be any person who wants to make use of the device; in this case, setting the drive parameters. The plain meaning of "user" does not require an individual who is the end-user of a product. Even the word "end-user" militates against the proposed construction: "end" modifies "user," so in its regular usage "user" must mean something other than end-user. To impose a definition more limited than the normal meaning, there must be a clear intent on the part of the author to use the more limited definition. Johnson Worldwide Assocs., 175 F.3d at 990 (stating that anything other than the "ordinary and accustomed meaning" inheres only "if the patentee has chosen to be his or her own lexicographer by clearly setting forth an explicit definition for a claim term" … [or]… "the term or terms chosen by the patentee so deprive the claim of clarity that there is no means by which the scope of the claim may be ascertained from the language used.”) (internal citations omitted). Defendants do not assert that the term end-user appears in the patent, nor does any language limiting the potential user of the product appear.

Claim terms are to be given their normal broad meaning absent an explicit disavowal of scope. See Novartis Pharm. Corp. v. Eon Labs Mfg., 363 F.3d 1306, 1314 (Fed. Cir. 2004). The "Windows-like operating system," one of the types of user interfaces defendants claim fits under their definition, is still a user interface when it is used by a technician configuring the computer before sale. There is no contemplation within the patent that only the end-user of the drive be able to use the interface, and defendants' examples also militate toward no limitation based on the type of user.

Defendants contend that plaintiffs' proposed construction could be read to include disk drives that have been irrevocably configured at the factory. This meaning is beyond the scope of a "user interface." A user interface enables the alteration of parameters of the system. Drives manufactured in such a way as to only be capable of a one-time setting, which is then fixed in the hardware, do not possess a capability to alter the parameters. They only have a capability to set the parameters once. This is beyond the ordinary meaning of "user interface" in the art.

Accordingly, the term "user interface," as used in independent claims 1, 10, 11, and dependent claims 4, 12, and 13, is interpreted to mean:

"hardware, firmware, or a combination thereof that allows a person, directly or indirectly, to alter parameters."

1 There is agreement amongst the parties that this term is not subject to paragraph 6 of 35 U.S.C. section 112.

Keyscan seeks the following construction: "Options presented to a user by the input device software, one of which a user must select in order for the input device software to determine what is to be done with the scanned image." Soque seeks the following construction: "Options presented to a user regarding a course of action to be taken with a scanned image, such as faxing, emailing, printing, storing or performing word processing on a scanned image." The parties' argument focuses on whether this claim term should be limited to require the input device software, as opposed to any mine-run software, to present options to the user.

"User-selectable options" appears in every asserted claim. Keyscan's basic argument, based on the specification, is that in response to placement of a document in the input device, the input device software presents the user with options that it determined are available on the host computer. In response to the user's selection, the input device software invokes the third-party software application that corresponds to the user's selection. In support of its argument, Keyscan focuses on the preferred embodiment outlined in the patent specification. Soque, on the other hand, argues that "user-selectable options" must be construed in accordance with the language in the claim limitations themselves, and should not be limited by the
specific embodiment identified in the patent specification. Soque is correct.

The summary of the invention states: "As the term is used herein, an 'paper input device' is a computer peripheral which senses the insertion of a document to be scanned, initiates a host computer process, i.e., controls the host process by insertion of the paper and symbols on the paper, scans the images and text on the paper, provides immediate user interface feedback while sending the scanned data to the host for further electronic processing such as display, transmission, storage or modification." '108 Patent at 2:40-48. Although the preferred embodiment focuses solely on the input device software, the summary eschews any such language. Instead, the paper input device "provides immediate user feedback while sending the scanned data to the host for further electronic processing." Id. This demonstrates that the scope of the patent claims could be broader than the preferred embodiment.

As discussed above, the specification discloses an invention wherein an input device automatically senses the insertion of a document into the device, which device then scans the document and interrupts the computer. In the preferred embodiment, the input device software then presents a list of options to the user, and upon selection of an option, the input device software executes the appropriate software. '108 Patent at 10:34-11:8, 15:7-16:9, 18:34-19:10, Figure 13B, Figure 21B. Nowhere in the specification does the patentee evidence an intent to exclude an interpretation whereby options are presented to the user by software other than the input device software. A specific embodiment may not be read into the claim unless the patentee "intend[ed] for the claims and the embodiments in the specification to be strictly coextensive." Phillips, 415 F.3d at 1323. Here, the preferred embodiment plainly does not "reveal an intentional disclaimer, or disavowal, of claim scope." Id. at 1316.

The patent's plain language supports Soque's construction, that the user-selectable options need not necessarily be presented by the input device software. Id. at 1323 ("although the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments"). Thus, Soque's construction is adopted: "user-selectable options for processing said image data" is construed as "options presented to a user regarding a course of action to be taken with a scanned image, such as faxing, emailing, printing, storing or performing word processing on a scanned image."

To the extent input device software is employed to display the user-selectable options, as in the preferred embodiment, the patent specification allows the input device software to present options that are features or functions present completely within third-party software applications such as Microsoft Word. The patent specification contemplates that the input device software "generates the menu options by checking the bulk storage memory device (typically a hard disk) and the random access memory to determine what software packages are resident and then generates a menu option for each capability of the host as represented by these software packages." '108 Patent at 15:36-42; id. at 18:45-51 ("The options displayed in the pop-up window depend upon the software packages and circuit cards of the host computer. The available options are determined by the input device software resident on the host at installation, and may be updated as new capabilities are added to the host computer."). The preferred embodiment uses a pop-up window or equivalent. Id. at Fig. 21B, Box 296.

The specification, however, does not limit the "menu option" associated with a software package to the simple invocation of the third-party software application. For instance, the menu option need not simply state "Open Microsoft Word," but can provide the user with the option to "Print via Microsoft Word" or "Save using Microsoft Word." Moreover, there appears no limitation upon the input device software's invocation of third-party software in order to determine the capabilities of the third-party software. Consequently, in the preferred embodiment, user-selectable options may be presented to the user by the input device software subsequent to the launch of third-party software. 3

--- Footnotes ---

2 The image associated with the scan may or may not be displayed alongside the "user-selectable options." '108 Patent at 18:51-57 ("In the preferred embodiment, the incoming data is also displayed in a pop-up window, but in other embodiments, the incoming data may be shunted directly to whatever software package is to process it or directly into a file in random access memory or on an internal or external bulk storage device without display in a pop-up window.").

3 The court expresses no opinion on whether the mere invocation of third-party software in response to a scan constitutes the display of user-selectable options by the input device software, and leaves that question for the infringement phase of this action.
Keyscan, which argues essentially that this claim term be limited to the preferred embodiment, must demonstrate that the patentee intended to deviate from this phrase's ordinary and accustomed meaning. Keyscan first argues that the prosecution history demonstrates that the patentee limited the claims only to options presented by the input device software. During prosecution of the '108 patent, the patent examiner found that it was well known in the art to "automatically do something with [a scanned] image," but the prior art did not disclose "the specific means for displaying a plurality of user-selectable options for processing said image data, in response to the placement of a document to initiate the drawing of the document into scanning relationship with the scanner"

Docket No. 39-1 (Godinez Dec.), Exh. D (Patent Reexamination) at KeyScan422. This finding, however, does nothing to limit the scope of user-selectable options to be only those options presented by the input device software itself. In January 1995, the patentee introduced the term "user-selectable options" to require the display of user-selectable options in response to placement of a document in the scanner. Specifically, independent claim 88, which eventually issued as claim 1 of the '108 patent, was amended to include "means for displaying a plurality of user-selectable options for processing said image data in response to placement of the document by the user."

Id., Exh. B (Patent Application) at Soque273; id. at Soque345 (adding "in response to said placement"). These amendments also do not limit the scope of user-selectable options to be only those options presented by the input device software itself.

Keyscan next argues that the patent specification only discloses a "document-driven system" wherein the input device and its software control the operations of a host computer to, among other things, determine and present to a user options regarding what is to be done with scanned data. In support of this argument, Keyscan cites solely to the preferred embodiment outlined in the patent specification. See, e.g., '108 Patent at 18:34-19:9 (describing sequence of events the input device software follows in the preferred embodiment); id. at 10:52-55 (discussing alternatives the input device software may present to the user in the preferred embodiment); id. at 15:36-42 (discussing how the input device software determines the universe of options to present to the user in the preferred embodiment). None of these disclosures limit the patent to require use of the input device software to display the user-selectable options. Keyscan is correct that the summary of the invention states that "[s]pecial software in the input device . . . automatically carries out the desired processing either by receiving a command from the user by manual pointing to menu selections presented to the user by the software . . . ." Id. at 2:55-60. However, the immediately preceding sentence states: "In the preferred embodiment, the input device using scanning technology includes a scanning mechanism." Id. at 2:54-55. Keyscan's attempt to limit this claim term in accordance with the preferred embodiment is unavailing.

Keyscan's reliance upon Toro Co. v. White Consol. Indus., 199 F.3d 1295, 1300-01 (Fed. Cir. 1999), is unpersuasive. There, the Federal Circuit found that the patent encompassed only the "unitary structure" described in the preferred embodiment because "the specification describes the advantages of the unitary structure as important to the invention" and because the structure was "not simply the preferred embodiment; it [was] the only embodiment." Neither situation applies here: nowhere does the specification speak to the advantages associated with employing the input device software, nor is presentation of options to the user through the input device software the only embodiment--the patent specifically discloses symbol recognition as a method through which the user may signal her desires regarding post-scan processing. Keyscan also argues that "[a]lthough precedent offers assorted quotations in support of differing conclusions concerning the scope of the specification, these cases must be viewed in the factual context in which they arose. Whether an invention is fairly claimed more broadly than the 'preferred embodiment' in the specification is a question specific to the content of the specification, the context in which the embodiment is described, the prosecution history, and if appropriate the prior art . . . ." Wang Lab., Inc. v. Am. Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999). Wang is inapposite. Unlike Wang, the prosecution history here does not demonstrate that the inventors intended to limit the patent to the preferred embodiment. Id. at 1383-84. 4

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 Keyscan cites the parent application of the '108 patent in support of its construction; however, it provides no authority that the parent application is part of the intrinsic record upon which the court may rely. Moreover, Keyscan does not cite any authority that prohibits a patentee from later seeking to expand upon claims specified in the parent application.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

At bottom, Keyscan is arguing that Soque's construction provides a meaning broader than the meaning derived from the intrinsic evidence. See Netcraft Corp. v. eBay, Inc., 549 F.3d 1394, 1397 (Fed. Cir. 2008) (limiting invention based in part
on use of the phrase "the present invention"). However, at no point here did the patentee explicitly or implicitly limit the claims through use of limiting language. Although the patentee explicitly described the preferred embodiment, the patentee declined to limit the invention to the preferred embodiment. See '108 Patent at 23:21-23 ("those skilled in the art will appreciate numerous modifications and enhancements which can be made without departing from the true spirit of the invention."). Consequently, Keyscan's arguments are rejected and Soque's proposed construction is adopted.

d. "Said User Selection Criteria" (Claims 18 and 66)

The disputed limitation of claims 18 and 66 of the '121 patent is:

supplying user program selection criteria to the data processor, said user program selection criteria comprising a plurality of independent user chosen program selection criteria and at least one program choice, the data processor combining said user selection criteria, selecting those programs meeting the combined user selection criteria for viewing . . . .

Re'121 patent, claims 18, 66 (emphasis added).

(1) Theme, Channel, and Prime Time

The ITC initially found that "user selection criteria" was limited by the written description and reexamination prosecution history to the "theme," "channel," and "prime time" criteria. FID Opinion 2002 ITC LEXIS 812 at *78. It relied on a passage in the written description that stated: "At the bottom of the screen is a two line status display, showing the actual time and date, and whether any of the search restrictions (prime, theme, and channel) are activated." Id. (citing '121 patent, col. 11, ll. 34-37). The ITC cited other examples in the written description indicating the system only performed searches based on theme, channel, and prime time. 2002 ITC LEXIS 812 at *89. The ITC also cited instances during reexamination where Gemstar reiterated theme, channel, and prime time as individual selection criteria. 2002 ITC LEXIS 812 at *89.

Gemstar argues that the ordinary meaning of "user selection criteria" includes any search criteria selected by the user, and that the written description discloses many other types of "user selection criteria" besides theme, channel, and prime time. Gemstar contends that during reexamination, it provided theme, channel, and prime time as examples of "user selection criteria," not as an exhaustive list limiting claim scope. Scientific-Atlanta responds that the written description and reexamination prosecution history identify only theme, channel, and prime time as "user selection criteria," and fail to identify a single search criterion other than these three parameters.

The ITC correctly looked to dictionary definitions, including a definition of "criterion," the singular form of "criteria," from Webster's Third New International Dictionary 538 (1993): "a standard on which a decision or judgment may be based." From this definition, the ordinary meaning of "user selection criteria" is simply any parameter chosen by the user in selecting a program.

The next step is to consider the written description and prosecution history to see if the applicant disclaimed or otherwise narrowed the scope of this claim limitation. From our examination, the passages from the written description and reexamination proceedings cited by the ITC and Scientific-Atlanta fail to establish that "user selection criteria" was limited to theme, channel, and prime time. Although Gemstar routinely referred to theme, channel, and prime time as examples of user selection criteria in the written description and during reexamination, these passages lack "words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope" required to limit user selection criteria to these three parameters. ACTV, 346 F.3d at 1091. As an example, Gemstar stated during reexamination:

The user selection criteria may be entered and activated independently under different categories (theme, channel, prime time) and are maintained by the data processor whether currently activated or not. This is disclosed, for example from column 12 line 12 to column 15 line 17 (wherein it is stated that buttons can be pressed to independently activate the THEME, PRIME-TIME, and CHANNEL selection criteria) and from column 18 line 11 to column 20 line 38. Furthermore, the selection criteria can be combined as alternatives (in a logical OR fashion), such as a list of acceptable channels or a list of acceptable themes.
Supplemental Amendment After Final, Feb. 25, 1993, at 23-24. Because Gemstar did not expressly limit "user selection criteria" to the theme, channel, and prime time parameters, but simply cited them as examples during reexamination, "user selection criteria" are not limited to theme, channel, and prime time.

(2) Program Choice

The ITC and the parties agreed that the expression "said user selection criteria" in claims 18 and 66 does not have an exact antecedent--the preceding claim language reciting "user program selection criteria" and "independent user chosen program selection criteria." Re'121 patent, col. 5, ll. 17-23 (emphases added); see FID Opinion 2002 ITC LEXIS 812 at *82. The ITC found that the plain language of the claim indicated that "said user selection criteria" referred back to "independent user chosen program selection criteria" and was exclusive of program choice. FID Opinion 2002 ITC LEXIS 812 at *81.

Gemstar argues it was error for the ITC to construe "said user selection criteria" to refer back to "independent user chosen program selection criteria" instead of "user program selection criteria," thereby excluding program choice from the user selection criteria. Scientific-Atlanta responds that including program choice in "said user selection criteria" would be superfluous since the invention requires the user to make a program choice only after the data processor has combined the user selection criteria and produced a list of programs satisfying the combined criteria. Further, Scientific-Atlanta argues that Gemstar consistently described the operation of its invention in this manner during the reexamination.

From an examination of the disputed claim language, we conclude that the ITC correctly held that "user selection criteria" did not include program choice. Although it may appear on first glance that "said user selection criteria" actually refers back to "said user program selection criteria" and thus includes "a plurality of independent user chosen program selection criteria and at least one program choice," see Re'121 patent, col. 5, ll. 17-23, our prior claim construction of "combining" makes clear that such a conclusion is incorrect. The operative claim language is "combining said user selection criteria." Re'121 patent, claims 18, 66 (emphasis added). We previously construed this claim language to require that the combination of "user selection criteria" occur prior to any search. Statements made during the reexamination proceeding make clear that "user selection criteria" are first selected, then combined, following which the system produces search results from the program listing satisfying the "user selection criteria." A statement by the examiner during reexamination clarified that from the search results, a user makes a program choice:

Applicant also agreed to add further limitations to the claims so as to set forth the user's ability to control the processor to select programs from the schedule information which was selected from incoming information based on the "combined" user selection criteria.

Examiner's Statement in Reexamination Advisory Action, Feb. 16, 1993, at 2. Gemstar agreed with this understanding:

Combining User Selection Criteria and Selecting Programs

Several of the present claims recite a process in which the user enters user program selection criteria, and the data processor combines the program selection criteria, searches through the stored schedule information, and creates and stores a display list of program listings that meet the combined criteria. This is disclosed, for example, at col. 17 lines 33 et seq. The user may then make program selection choices (which the Examiner has characterized as further program selection criteria) from this display. The data processor then stores information for these program selections, including information identifying program titles, in a reminder calendar list.

Supplemental Amendment After Final, Feb. 25, 1993, at 22-23 (emphases added). Gemstar and the examiner agreed during reexamination that a program choice was made after the "user selection criteria" were combined. From this it is clear that a contrary construction was disclaimed. "Said user selection criteria" must refer to what the language of the claim describes as "independent user chosen program selection criteria," excluding program choice.

In conclusion, the limitation "said user selection criteria" refers to any parameters chosen by the user to search for a program. Such parameters are not limited to theme, channel, and prime time. Further, "said user selection criteria" does not include a specific program choice.
1. Claims 1 & 5 -- "User Station"

The term "user station" appears throughout the '170 patent and is a term crucial to the invention. Defendants argue that "user station" is a fixed, public structure and not a non-fixed, non-public structure, such as a personal computer. CIVIX, on the other hand, contends that "user station" should not be so narrowly defined and instead is any computer or other electronic device, available to a user for interrogating a database.

CIVIX bases its interpretation of "user station" on the view that "work station," a common computer term, is defined as "a computer terminal or microcomputer connected to a mainframe, minicomputer, or data-processing network." Random House Webster's Unabridged Dictionary, Second Edition 1997. Additionally, CIVIX stresses that the '170 patent itself explains that the "user station" is designed to interrogate a database containing a map and subscriber electronic information. ('170 Patent, Col. 1 lines 46-55). Furthermore, CIVIX looks to the prosecution history where the applicants added the phrase "user station, such as" before the word "kiosks" to emphasize the fact that a kiosk is merely a type of user station. ('170 Patent, Col. 1 line 31) ('170 Prosecution History File, CIV000015, CIV 000058). Finally, CIVIX argues that the terms "kiosk" and/or "fixed" never appear in the claims themselves and, therefore, I should not read this limitation into them. Instead, a fixed kiosks is merely one embodiment of a user station.

I first address Defendants' means-plus-function argument surrounding the term "user station." Defendants urge that the term "user station" appears as part of a functional term and is thus limited to the kiosk specification. Claim 1 of the '170 patent teaches, "a user station within said predetermined region for interrogating said apparatus." Defendants argue that this phrase denotes only a place for interrogating the apparatus, recites no structure and, accordingly, must be construed as limited to the corresponding structure disclosed in the patent specification. 35 U.S.C. § 112 P 6. I disagree that this phrase implies a means-plus-function limitation.

Paragraph 6 of 35 U.S.C. § 112 provides that limitations "expressed as a means . . . for performing a specified function without the recital of structure . . . in support thereof, . . . shall be construed to cover the corresponding structure . . . described in the specification and equivalents thereof." Paragraph 6 "operates to cut back on the type of means which could literally satisfy the claim language." Johnston v. IVAC Corp., 885 F.2d 1574, 1580 (Fed. Cir. 1989). More specifically, "where a claim sets forth a means for performing a specific function, without reciting any specific structure for performing that function, the structure disclosed in the specification must be considered, and the patent claim construed to cover both the disclosed structure and equivalents thereof." Data Line Corp. v. Micro Technologies, Inc., 813 F.2d 1196, 1201 (Fed. Cir. 1987).

The phrase at issue here does not use the word "means," and although a claim element might still meet the requirements of 35 U.S.C. § 112, P 6, this does not. In Personalized Media Communications, LLC v. International Trade Com'n, 161 F.3d 696, 703 (Fed. Cir. 1998), the Federal Circuit stated:

We also made clear that use of the term "means" is central to the analysis: "the use of the term 'means' has come to be so closely associated with 'means-plus-function' claiming that it is fair to say that the use of the term 'means' . . . generally invokes [35 U.S.C. § 112, P 6] and that the use of a different formulation generally does not." . . . Failure to use the word "means" creates a presumption that 35 U.S.C. § 112, P 6 does not apply. . . . In deciding whether either presumption has been rebutted, the focus remains on whether the claim as properly construed recites sufficiently definite structure to avoid the ambit of 35 U.S.C. § 112, P 6.

Id. at 703-704 (internal citations omitted); see also Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996) ("To invoke [35 U.S.C. § 112 P 6], the alleged means-plus-function claim element must not recite a definite structure which performs the described function.").

In Cole, the claim recited a "perforation means . . . for tearing." The court held that the statute did not apply because the claim "describes the structure supporting the tearing function (i.e., perforations)." Id. In addition, the claim "describes not only the structure that supports the tearing function, but also its location (extending from the leg band to the waist band) and extent (extending through the outer impermeable layer)." Id. The court concluded that "an element with such a detailed
recitation of its structure, as opposed to its function, cannot meet the requirements of the statute." Id.

The same rationale applies here. The phrase at issue provides for a "a user station within said predetermined region for interrogating said apparatus." (525 patent, Claim 1). Although the latter part of the quoted phrase describes a function, the claim includes a specific recitation of the structure to support that function -- a "user station." In addition, as in Cole, this phrase includes a limitation on the user station -- it must be "within said predetermined region." Furthermore, the phrase "user station" is expressed throughout Claims 1 & 5 as a specific structural element, such as a kiosk. Accordingly, the phrase at issue does not meet the requirements of 35 U.S.C. § 112 P 6, and I will not analyze it as a means-plus-function element. Although I do not find that 35 U.S.C. § 112 P 6 limits the scope of the term "user station," the overwhelming weight of relevant evidence supports a more limited construction than that proposed by CIVIX.

This invention was intended to provide travelers a convenient substitute for visitor's centers and Chambers of Commerce. ('170 Patent, Col. 1 lines 25-27). For example, the '170 patent states that a kiosk is to be "placed on the sidewalk of the downtown area of a city. Preferably, user station, such as kiosks are placed on the sidewalks at a plurality of locations throughout the city." ('170 Patent, Col. 1 lines 29-32). The preferred embodiment in figure 1 shows a "base station 2 in the form of a kiosk. The kiosk is preferably placed on a sidewalk, and receives power from cables (not shown) buried beneath the sidewalk." ('170 Patent, Col. 2 lines 40-43). The patent explains that a user station "may be located on a sidewalk at a street intersection for easy access by pedestrians." ('170 Patent, Col. 2 lines 53-54). Further, the patent proudly states that, It will be appreciated that a unique method and apparatus has been described wherein anyone in the city may obtain a map of the area immediately surrounding where they are, the map having information regarding the locations of businesses, historical sites, or the like by simply activating an input key on a kiosk.

('170 Patent, Col. 3 lines 62-67) (emphasis added). The patent specification does not detail or teach any mobile, private, or non-fixed user station. In fact, the patent's stated purpose to provide travelers with information about local businesses could not be furthered without an accessible public structure.

I look to the ordinary meaning of these terms because there is no specialized meaning asserted. See, e.g., Karlin Technology, Inc. v. Surgical Dynamics, Inc., 177 F.3d 968 (Fed. Cir. 1999). A "station" merely denotes "a place established to provide a public service," such as a fire station, police station, or gas station. Webster's Third New Int'l Dictionary 2229 (3d ed. 1986). The modifying word "user," in this context, not surprisingly, means that the station is one for users. I conclude that in early 1990, the time of the filing of the '170 patent application, one of ordinary skill in the art would not have understood the term "user station" to mean a personal computer or "work station," see Markman, 52 F.3d at 986 ("the focus is on the objective test of what one of ordinary skill in the art at the time of the invention would have understood the term to mean.").

Finally, if any ambiguity remains in the meaning of the term "user station," the '525 patent is illuminating. The '525 patent notes the insufficiencies of the '170 patent: "such a system is inflexible. . . . A user of the system must also know the exact location of the kiosk in order to use the system. Tourists and business travelers to the city are unlikely to know of the kiosk; and thus the kiosk system is of little use to such users. Further, a user must be physically present at the kiosk in order to access the information about the businesses and/or sites in the surrounding area." (525 Patent, Col. 1 lines 29-37) (emphasis added). This characterization by the '525 patentees are also those of Mr. Bouve, a named inventor on both the '170 and '525 patents. Therefore, these comments are relevant to the construction of the terms and corroborate my interpretation. Although I do not limit the term "user station" to include only "kiosks," I conclude that "user station," as used in the '170 patent, is limited to a fixed public structure.

GO BACK

C. "User Store" ('783 and '245 Patents)

"User store" appears in independent claim 20 of the '783 patent and independent claim 9 of the '245 patent. The term was construed by the Block court to mean "a storage component accessible by a processor containing information identifying
information providers that house personal information for a given end user." Yodlee Exh. V at 10-11. Yodlee advances this construction in the instant dispute. CashEdge asserts that this definition impermissibly limits the user store as containing only information identifying information providers, since the patent indicates that the user store also contains "configuration and verification information concerning particular end users." '783 patent col. 5, lines 3-5. CashEdge construes "user store" to mean "the storage component that contains the end user data." The Court agrees with CashEdge that any construction of "user store" must encompass verification information for the end user, as the specification indicates that such data is contained in the user store both in general and in the preferred embodiment. See '783 patent, col. 5, lines 3-8 ("A user store is also necessary to maintain configuration and verification information concerning particular end users."); '783 patent, col. 5, line 57 -- col. 6, line 12. The claim language also refers to the "user store" as "storing end user data associated with each end user," including information identifying the information providers "securely storing" the user's personal information. '783 patent, col. 18 lines 33-37. The use of the word "securely" clearly means that verification data is required to access the user's personal information. Accordingly, the Court construes "user store" to mean "a storage component accessible by a processor containing verification data and information identifying information providers that house personal information for a given end user."

**4703**

Step 1

The final disputed phrase is "automatically generating at least one user target profile interest summary for a user at a user terminal, each of said user target profile interest summary being indicative of ones of said target objects and sets of target object characteristics accessed by said user." Amazon narrowly construes this phrase as meaning, "creating with essentially no human input a numerical measurement constituting a summary of digital profiles of target objects that a user likes and/or dislikes representing multiple areas of interest for a user at a user terminal being indicative of both target objects and sets of target object characteristics accessed by the user." In contrast, Pinpoint's proposed construction is broader: "automatically generating a concise statement of the data that describes the significant characteristics of target objects that a user likes and/or dislikes pointing out or showing indirectly the target objects and/or sets of target object characteristics accessed by the user." As an initial matter, Amazon's proposed construction must fail to the extent it includes its proposed construction of "target objects and sets of target object characteristics." The court has rejected this construction.

The remaining disputed phrase is "target profile interest summary." The parties' dispute centers on whether the phrase "target profile interest summary" is properly construed as requiring a "numerical measurement," as Amazon contends. This term was expressly defined by the inventors; it means "a summary of digital profiles of target objects that a user likes and/or dislikes." Def. Mem., Ex. 3 at Col. 4. Pinpoint's proposed construction adopts the inventors' definition, substituting only the dictionary definitions of "summary" and "profile," that is "a concise statement" and "data that describes the significant characteristics of a user, a group of users, or one or more computer resources." Pl. Opp. Mem. at 7-8 (quoting Merriam-Webster Dictionary at 725 and IBM Dictionary of Computing 534 (1994)). In contrast, Amazon restricts the inventors' definition by adding the additional limitation that the summary be a "numerical measurement." Amazon errs. Neither the plain language nor the express definition of the specification defines the "target profile interest summary" as a "numerical measurement." Teleflex, Inc. v. Ficosa North America Corp., 299 F.3d 1313 (Fed. Cir. 2002) ("an inventor may choose to be his own lexicographer"). Amazon's reliance on the specification's reference to "the user's interest" as a "numerical measurement" cannot alter this express definition. Def. Mem. at 38 (citing Ex. 3, at Col. 9). Pinpoint's proposed construction, which defines the phrase "target profile interest summary" in accordance with the inventors' own explicit definition, is adopted. Teleflex, 299 F.3d at 1313. The court construes the disputed phrase as "automatically generating a concise statement of the data that describes the significant characteristics of target objects that a user likes and/or dislikes pointing out or showing indirectly the target objects and/or sets of target object characteristics accessed by the user."
assigned network address." According to Linksmart, no construction of this term is necessary. Alternatively, Linksmart proposes the following construction: "elements or conditions about the user's session." The defendants (except BWI) contend that "user's rule set" means "filtering and redirection rules for a particular user which apply during an authorized session." Finally, BWI's proposed construction is "filtering and redirection rules unique to a particular user which apply during an authorized session."

The defendants assert that "user's rule set" requires "filtering and redirection rules" and "an authorized session." For the reasons discussed above in "individualized rule set," the court declines to adopt these limitations.

BWI argues that the rules must be "unique to a particular user." BWI notes that claim 15 refers to "user" in the singular form: "a user's rule set" and "the user." But when used with an open-ended transition, the indefinite article "a" means "one or more" except in rare circumstances where the patentee clearly intended to limit the term to a single item. Baldwin Graphic Sys., Inc. v. Siebert, Inc., 512 F.3d 1338, 1342 (Fed. Cir. 2008). The subsequent use of "the user" does not change the presumption of plurality. Id. To support its argument, BWI notes that the specification explains, "Rule sets . . . are unique for each user ID, or a group of user IDs." ('118 patent, 4:40-41). BWI argues that the language quoted above presents two distinct options--the rules are unique for a single user ID or unique for a group of user IDs--and the claim language shows that the patentees chose the first option.

The court is not persuaded that the patentees clearly intended to limit "user's rule set" to a single user. The claim language does not disclaim the "group of user ID's" embodiment in the specification. Thus court construes "user's rule set" to mean "elements or conditions that apply during a user's or users' session."

Uses

Hyundai argues "uses" should be construed as "environments." In the Staples Markman, the Court rejected the Staples Defendants' similar proposed construction based on the specification. In Staples, the Court determined that "uses" is used according to its ordinary meaning and no other construction was necessary. Hyundai makes the same specification-based arguments here, and they are equally unpersuasive.

Hyundai also argues the applicant acted as his own lexicographer during prosecution and used "uses" to mean "environments." Specifically, Hyundai cites to an amendment in the prosecution history where the applicant replaced "environments of product use" and "distinctive environments in which the product may be used" with "uses." Hyundai argues these changes were not meant to change the meaning of the claims because the applicant made no statement that he intended to change the meaning of the claims and because the applicant characterized the amendments as corrections of "minor technical matters." See January 24, 1999 Amendment and Interview Summary, Application No. 07/878,602.

However, the applicant did not amend all of the claims in this manner. The applicant amended then claim 2 in other ways, but did not change "environments" to "uses": ". . . related to distinctive environments in which the [product] vehicle may be used . . . ." Id. at 1. As issued, claim 2 also uses the phrase "distinctive environments in which the products may be used." Thus, it is far from clear that the applicant acted as his own lexicographer to exclusively define "use" as synonymous with "environments." Accordingly, the Court rejects Hyundai's proposed construction.

4706

(d) Using a computer

Step (b) of Claim 1 adds the limitation of "using a computer." The Plaintiff proposes to define the term "to mean that the sub-steps recited in elements (b)(1), (b)(2), and (b)(3) are carried out on or with the aid of a computer." (Pl. Br. at 24; DE 34.) The Defendant suggests that "using a computer" as used in the '815 Patent means employing a computerized data processing method to calculate benefit payments based upon preexisting formulas and, further, to determine the annuity
account value." (Df. Br. at 26; DE 39-2.) The Defendant believes this to be the case because insurance is a formula driven business. In addition, the Defendant submits that the Plaintiff's use of formulas within the '815 Patent are consistent with that interpretation.

The Defendant's interpretation is too narrow. The claim does not contain any formulas, and there is no otherwise clear implication in the specification that the use of the computer must be based upon pre-existing formulas. Likewise, the fact that many of the dependent claims contain specific formulas to calculate benefit payments and account value (e.g., 4, 8, 14-16, 23, 27, and 32) creates a presumption that Claim 1 is not so limited. See Phillips, 415 F.3d at 1323 ("[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim.") Accordingly, the Court construes the phrase "using a computer" as meaning the use of a computer to aid in performing the sub-steps in (b)(1)-(b)(3).

Next, the parties seek construction of "using a telecommunications line" and "using a telecommunications network line," as those terms appear in the preamble to Claims 1 and 6 of the 456 Patent. The standard dictionary definition of "telecommunications" is "the electronic systems used in transmitting messages, as by telegraph, cable, telephone, radio, or television." THE AMERICAN HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE at 1845 (3d ed. 1992). A "network" is "a complex, interconnected group or system." Id. at 1214. A "line" is "a wire or system of wires connecting telephone or telegraph systems." Id. at 1045. Combining the ordinary meanings of those terms, "using a telecommunications line" means "using a system of wires and other components to transmit messages between users by various devices such as telegraph, cable, telephone, radio, or television." Likewise, the ordinary meaning of "using a telecommunications network line" is "using a system of wires and other components to transmit messages among a group of users by various devices such as telegraph, cable, telephone, radio, or television."

Paymentech argues for a limitation that would restrict the definition of both terms to "a caller using a telephone connected to a telecommunications line." (Def. Op. Br. at 7). The court rejects this proposed construction. Nothing in the plain language of the claims themselves requires the use of a standard telephone. Although the specifications contain an example of a consumer accessing the Telepay system by using a telephone, it makes clear that "the present invention can take many forms and embodiments. The embodiments shown herein are intended to illustrate rather than to limit the invention[.]") (Compare Plf. App., Exh. 3 at 38 with id., Exh. 3 at 42). Consequently, the requirement of using a telephone to access a "telecommunications line" or "telecommunications network line" should not be read into Claims 1 and 6 of the 456 Patent. See, e.g., In re American Academy of Science Tech Center, 367 F.3d 1359, 1366 (Fed. Cir. 2004) (rejecting proposed construction limiting claim to use of particular type of device based on reference to that device contained in specification).

This phrase appears in claim 1. See Tang Decl., Ex. A at 12:34-49, Ex. D at 2 (amended Claim 1). Trimble contends that it should be construed to mean "using the computed terrestrial locations obtained during the deviation to define the direction of path or travel actually taken by the vehicle." Defendants, by contrast, contend that the phrase should be construed to mean "using the new positions computed while deviating from the previously computed second path across the area to recompute the second path across the area to be treated."

The phrase "define an updated form line" has already been discussed, and has been construed to mean "recompute a previously computed path across the area to be treated." Since this is the case, the only issue is what the sub-phrase "using the computed positions" means.

The meaning of this sub-phrase is illuminated by looking at the context surrounding the sub-phrase in claim 1. See Tang
Decl., Ex. A at 12:34-49, Ex. D at 2 (amended Claim 1). Prior to introduction of the term "computed positions," the language in claim 1 discusses the process of defining an updated second form line. See id. at Ex. D at 2. As the claim language describes it, a second from line is updated when the operator makes one or more deviations from the second form line while following the second form line, new GPS data is collected during this process, and the data is used to "comput[e] one or more positions therefrom…". See id. Only after positions are computed based on the GPS data collected through the deviation process, according to the claim language, are these "computed positions" then used to define the updated second form line.

From this description, therefore, it is apparent that the sub-phrase "computed positions" refers back to, and is based upon, the collection of new GPS data that occurred while the operator followed the second form line, and deviated from it. "Using computed positions," therefore, should be construed as using those positions that were computed while following and deviating from the original second form line. See also '383 patent specification, Tang Decl., Ex. A at 2:4-12 ("New GPS data is collected during these steps of following and deviating from the second form line (as computed) and new positions are computed from the new GPS data").

As such, and in view of the fact that "form line" has already been construed to mean a "path across the area to be treated," it is therefore clear that, with respect to the disputed term at issue here, defendants are correct. The court therefore construes the term "using the computed positions to define the updated second form line" as: "using the new positions computed while deviating from the previously computed second path across the area to recompute the second path across the area to be treated."

**N. "Using the Network Code to Route the User Communication Through the Packet Communication System to the Network Element"**

Claim 1 of the '561 patent recites the phrase "using the network code to route the user communication through the packet communication system to the network element." Sprint contends that, in accordance with the above constructions of "network code" and "route," this phrase does not require construction and should be afforded its plain and ordinary meaning. Vonage contends that this phrase should be construed to mean using the logical address identifying the network element to deliver the user communication through the packet communication system to the egress network element.

Vonage contends that this claim construction is warranted, first, given the proper constructions for "network code" and "route." For reasons described previously, the court will construe these claim terms to have the same meaning and scope as set forth above. Additionally, Vonage contends that the phrase "the network element" plainly refers to an antecedent network element, which is the element that provides egress from the packet communication set forth in the second limitation of claim 1. The court agrees. Claim 1 recites a method of operating a processing system which comprises, among other things, a second limitation of "processing the signaling message to select a network code that identifies a network element to provide egress from the packet communication system" (emphasis added) and a fifth limitation of "using the network code to route the user communication through the packet communication system to the network element" (emphasis added). Plainly, this claim language envisions that "the network element" recited in the fifth limitation is the network element initially recited in the second limitation. As such, it is indeed the egress network element. Accordingly, the court construes the phrase to mean using the logical address identifying a network element (which network element provides an exit from the packet communication system) to direct the user communication through the packet communication system by a selected route or in a specified direction to the network element that provides an exit from the packet communication system.

**C. Indefiniteness of Claims 6, 9, 10, and 13 of the ‘432 Patent**

MicroStrategy also appeals the district court's grant of summary judgment that claims 6, 9, 10, and 13 of the ‘432 patent
were indefinite and, therefore, invalid under 35 U.S.C. § 112, P 2. According to the district court, the claims were indefinite since the word "using" in the phrase "the client system using and transmitting the retrieved information to the at least one web server" lacked an object, and there was more than one plausible way to correct the error (i.e., by adding an object or deleting the phrase "using and"). MicroStrategy contends this was error, and that the district court should have instead construed "the retrieved information" to be the object of both "using" and "transmitting."

In determining that the claims were indefinite, the district court relied on Novo Industries, L.P. v. Micro Molds Corp., 350 F.3d 1348, 1354 (Fed. Cir. 2003), in which we held that a court can only correct an error in a patent if "(1) the correction is not subject to reasonable debate based on the consideration of the claim language and the specification and (2) the prosecution history does not suggest a different interpretation of the claims."

MicroStrategy does not dispute that the inclusion of the phrase "using and" in the claims was erroneous, nor does MicroStrategy dispute that there is more than one plausible way to correct this error. MicroStrategy does, however, dispute that this renders the claims indefinite. According to MicroStrategy, even with the error uncorrected, the claims are not "insolubly ambiguous" and are, therefore, subject to construction and not indefinite.

In making this argument, MicroStrategy relies on Bancorp Services, L.L.C. v. Hartford Life Insurance Co. in which we stated:

[I]f [a] claim is subject to construction, i.e., it is not insolubly ambiguous, it is not invalid for indefiniteness. That is, if the meaning of the claim is discernible, "even though . . . the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds." . . . [C]lose questions of indefiniteness in litigation involving issued patents are properly resolved in favor of the patentee."

359 F.3d 1367, 1371 (Fed. Cir. 2005) (citations omitted). However, the argument MicroStrategy advances, i.e., construing "the retrieved information" to be the object of "using," is the same as one of the corrections considered and correctly rejected by the district court. MicroStrategy's argument does no more than identify a second way to cope with an otherwise indefinite claim term. To credit MicroStrategy's argument would eviscerate our holding in Novo Industries. We decline to do so. Simply put, MicroStrategy cannot make an end run around Novo Industries.

Moreover, even if we were to adopt MicroStrategy's proposed construction and construe "the retrieved information" as the object of "using," the claims would still be indefinite. Although MicroStrategy asserts that "using" and "transmitting" mean the same thing, our case law instructs that different claim terms are presumed to have different meanings. CAE Screenplates Inc. v. Heinrich Fiedler GmbH & Co. KG, 224 F.3d 1308, 1317 (Fed. Cir. 2000) ("In the absence of any evidence to the contrary, we must presume that the use of these different terms in the claims connotes different meanings."); Applied Med. Res. Corp. v. U.S. Surgical Corp., 448 F.3d 1324, 1333 n.3 (Fed. Cir. 2006) ("[T]he use of two terms in a claim requires that they connote different meanings . . ."). Here, there is no evidence that the terms have the same meaning. Therefore, "using the retrieved information" must be presumed to mean something other than "transmitting the retrieved information."

However, without some information in the patent or its prosecution history about the way in which the retrieved information is being used, or for what purpose it is being used, we are unable to discern what that meaning is. Accordingly, even if we were to construe "the retrieved information" to be the object of "using," claims 6, 9, 10, and 13 of the '432 patent would still be indefinite. As such, the district court's grant of summary judgment of invalidity of these claims was not in error.

B. The '863 Patent - Claim 17

Claim 17 provides:

A method of distributing audio/video information comprising:

  formatting items of audio/video information as compressed digitized data at a central processing location;

  transmitting compressed, digitized data representing a complete copy of at least one item of audio/video information from
the central processing location;

    receiving the transmitted compressed, digitized data representing a complete copy of at least one item of audio/video
information, at a local distribution system;

    storing the received compressed, digitized data representing the complete copy of at least one item at a local distribution
system; and

    using the stored compressed, digitized data to transmit a representation of at least one item to at a plurality of subscriber
receiving stations coupled to the local distribution system;

wherein the formatting step comprises:

    inputting an item having information into the transmission system; assigning a unique identification code to the item
having information; formatting the item having information as a sequence of addressable data blocks; and

    compressing the formatted and sequenced data blocks.

For Claim 17, the parties only dispute the proper construction of the phrase "using the stored compressed, digitized data to
transmit a representation."

First, the Court applies its constructions of Claim 14 of the '863 Patent and Claim 19 of the '992 Patent to the corresponding
terms of Claim 17. Second, even though the phrase "using the stored compressed, digitized data to transmit a
representation" is grammatically awkward, the Court construes it as follows:

The phrase "using the stored compressed, digitized data to transmit a representation" means "transmitting a copy of the
stored compressed digitized data.

P. "the usual driver for the input/output [storage] device"

Claim Fourteen of the '399 Patent and Claim Eighteen of the '449 Patent both use the phrase "the usual driver for the
input/output [storage] device" as follows:

    regardless of the type of the data transmit/receive device attached to the second connecting device of the interface device,
responding to the inquiry from the host device by the interface device in such a way that it is an input/output device
customary in a host device, whereupon the host device communicates with the interface device by means of the usual driver
for the input/output device . . . .

'399 Patent, col. 14:51-57 (emphasis added); '449 Patent, col. 14:22-28 (same, but referring to a storage device and not an
input/output device). The Camera Manufacturers assert that the phrase is indefinite because it has no antecedent basis, but to
the extent that the phrase can be construed, it should be construed to mean the driver normally present in most commercially
available computers at the time of the invention. Papst contends that "usual" modifies "input/output device" or "storage
device" and not the term "driver." Thus, Papst seeks to construe the phrase as "a software driver that is normally used by the
computer to communicate with the customary hardware device." Papst's proposal fails to follow the English language. The
analysis is the same as the analysis of the phrase "the driver for the input/output [storage] device customary in a host
device" discussed above. In Claim Fourteen of the '399 Patent, the phrase "the usual driver for the input/output device"
means "the customary driver(s) in a host device used to communicate with customary internal and external input/output
device(s), which driver(s) were normally present within the chassis of most commercially available computers at the time of
the invention." In Claim Eighteen of the '449 Patent, the phrase "the usual driver for the storage device" means "the
customary driver(s) in a host device used to communicate with customary internal and external storage device(s), which
driver(s) were normally present within the chassis of most commercially available computers at the time of the invention."
D. "Utilized By Said Browser To Identify and Locate"

What is the browser supposed to do once it knows of some type information associated with the object? The claim says the type information is "utilized by said browser to identify and locate an executable application external to the first distributed hypertext media document." '906 Patent, col. 18, ll. 20-23. Microsoft asks that I clarify the meaning of this phrase to ensure that it is the browser, not the operating system, that does the "heavy lifting" of utilizing, identifying and locating.

1. The Claim

The claim certainly says that it is the browser, and not any other code, that utilizes the type information to identify and locate the executable application. I read the claim language to mean that the browser identifies and locates the executable application and that it is able to perform these functions because it is armed with the knowledge of type information. Professor Felten agreed that the browser must do the identifying and locating. Felten Cross-Examination, October 25, 2000, Tr. at 149. The question is whether the browser can delegate this function to an outside resource. In other words, can the browser ask the operating system, or perhaps some shared utility, to help it identify and locate an executable application?

Persons skilled in the art define code by its function. Professor Dunsmore, for example, testified that he thinks of browsers and operating systems as defined by functionality. Dunsmore Cross Examination, October 26, 2000, Tr. at 256. Sometimes it is easy to draw a line between browsers and other pieces of code. Functions that are unique to a web browser (e.g., understanding HTML) are considered a part of the browser. Id. However, componentization allows for shared functionality -- the lines begin to blur. When asked to identify when a shared function could be considered part of the browser, Professor Dunsmore said it was a tough question. He hypothesized three possibilities: 1) code is part of the browser; 2) the browser invokes some component; or 3) the operating system is asked to perform the function for the browser. Id. at 257. Professor Felten also acknowledged the difficulty in articulating the minimum amount the browser must do for it to be characterized as performing the functions of identifying and locating. Felten Cross-Examination, October 25, 2000, Tr. at 149. However, I believe that experts are able to make such a judgment when presented with specific code.

The claim language assigns the functions of identifying and locating the executable application to the browser. Whether the browser is performing these functions in any given permutation is a question of fact.

2. The Specification

In a preferred embodiment in the specification, the browser, not the operating system, identifies and locates the executable application. However, the browser does not work alone. The specification makes clear that the inventors contemplated the browser's use of some outside resources. Microsoft agrees that operating systems are always involved on some level, and Microsoft also agrees that the specification discloses the use of outside resources. Microsoft does not propose a claim construction that would entirely preclude the browser from using the operating system or some external resource. In the specification, the browser, armed with the type information, consults a user-defined list of application type/application pairs, such as the MIME (Multipurpose Internet Mail Extensions) database. '906 Patent, col. 15, ll. 13-18. The parties agree that the MIME database is external to the browser. Microsoft's position is that this embodiment is consistent with its construction because it is the browser that consults the MIME database, and it is the browser that uses the MIME database to learn the application type. This example is also consistent with Eolas's broad definition of "utilize" -- to put to use. The browser puts the type information to use by taking it to some outside resource and then using the resource to identify and locate the executable application. This is exactly what the claim language says is supposed to happen.

The parties' dispute over this term appears to be more properly viewed as an infringement question than a claim construction issue. One infringement question will be whether Microsoft's browser, Internet Explorer, identifies and locates executable applications. This is not a question I can answer, yet. All I can decide is that the claim language means what it says, the functions must be performed by the browser.

3. The File History
By arguing that both Khoyi and Koppolu-OLE were different because they were operating system-dependent, the inventors highlighted the difference between having the browser link an object type to an application and using OLE's CLASSID to perform that function. In Khoyi, according to the inventors, "the object managers for different data types are coordinated by the operating system so that each type of displayed data is rendered by its associated object manager, the actual linking operations are coordinated by the operating system." File History, Paper # 14, p. 14. In attempting to overcome the Koppolu-based rejection, the inventors said the same thing: "the actual linking mechanism between the container document and the containee server application is coordinated by the operating system's registry database." File History, Paper # 19, p. 9. I read the inventors' argument as saying not just that the operating system maintains a registry that a browser can use, but that in OLE, it is the operating system itself that performs the linking function. This is different than the invention.

The claim language, the specification and the File History all suggest that the functions of using type information to identify and locate the executable application must be performed by the browser. No one suggests that the browser must do it alone, and I do not construe the claim to require that. However, I accept Microsoft's construction that, as a factual matter, one must be able to characterize the browser as doing the heavy lifting, which is what it does in the specification. Neither the claim nor the specification give adequate guidance as to what heavy lifting may be because neither had a need to address the issue. This is not surprising. "Utilize" is a common English word, and there is no evidence of a particular meaning it may have to those skilled in the art.

This does not mean the question is unanswerable, it merely means the answer lies in specific factual contexts. This is evidenced by both experts' inability to articulate a definition in the abstract. A careful examination of code would be necessary to decide what the browser is utilizing and how it is utilizing it. Framing this as a claim construction question, Eolas took the view that "by said browser" did not exclude some use of the operating system, probably because it viewed Microsoft as contending that the browser must do it all by itself. Microsoft did not take this position. It conceded that the operating system was necessarily a part of the browser's arsenal. Microsoft stood on the proposition that the browser had to do the heavy lifting in contrast to OLE, where the operating system performs the enumerated functions. Beyond this, both sides left the specifics undeveloped. Therefore I am left to simply construe the claim language to mean what it says, the functions of utilizing the type information to identify and locate the executable application must be performed by the browser, not the operating system as in Koppolu's OLE.

III. Conclusion

A. An "executable application," as used in the '906 Patent, is any computer program code, that is not the operating system or a utility, that is launched to enable an end-user to directly interact with data.

B. "Type Information" may include the name of an application associated with the object.

C. "Utilized by said browser to identify and locate" means that the enumerated functions are performed by the browser. This is a fact-intensive inquiry.

4. "utilizing an output from the rules engine to determine if intervention is warranted"

Plaintiff proposes "using information generated by the rules engine to determine if intervention is warranted to manage the care of an individual patient." Defendants propose "using information generated by the rules engine at the remote command center to determine if intervention is warranted." Each side adds one phrase to its proposed meaning that the other side disputes. Plaintiff proposes "to manage the care of an individual patient" and defendants suggest "at the remote command center." The Court disagrees with both proposed constructions.

First, plaintiff's additional language is unnecessary and redundant. As will be set forth below, at plaintiff's urging, the Court will construe the claim term "intervention" to include the phrase "manage the care of an individual patient." (See, infra, § III.B.6.) Thus, there is no need to repeat the same language a second time here.

We also decline to accept defendants' suggestion to add language about the remote command center. The claim terms refer
to the remote command center in reference to where patient data is sent (i.e., "communicating over a network the monitored patient data elements to a remote command center.") The remote command center is also referenced in the "wherein" clause where monitoring determines if intervention is warranted. The claim terms at issue here, which deal with a rules engine and determining if intervention is needed, do not reflect that the "utilizing" step should occur at the remote command center. We, again, decline defendants' suggestion that sections of the "wherein" clause be cut and pasted to other unrelated claims in order to narrow the claim language. "Utilizing an output from the rules engine to determine if intervention is warranted" is construed as: "using information generated by the rules engine to determine if intervention is warranted."

4715

Utilizing metadata from the metadata database

JuxtaComm contends this term does not require construction or should be construed as "using metadata from a metadata database." JuxtaComm contends its construction is supported by the plain and ordinary meaning. In their briefing, Defendants contended the term should be construed to mean "accessing the logical import and export data interfaces and data transformation rule sets from the metadata database during execution of a script." At the hearing, Defendants offered the following modified construction: "accessing the logical import and export data interfaces and data transformation rule sets and scripts from the metadata database during execution of the script processor." Defendants contend their construction is required by the prosecution history.

According to Defendants, the applicants argued that accessing metadata while a script is being executed allows the source and target data structures to be modified without having to regenerate the entire script. This allows the claimed invention to be more flexible than Morgenstern. Also, according to Defendants, the applicants argued that in Morgenstern the transformation was performed without accessing the metadata, whereas the '662 patent uses instructions in the script to identify and access metadata items when the script is executed.

The Court disagrees with Defendants' characterization of the prosecution history. The entire phrase indicates that nothing more than a script is being accessed during run-time. The primary distinction being made by the applicants in their remarks was that Morgenstern does not disclose a script processor that accesses metadata (i.e., a script) from the database when data transformation is to occur. That is, the script processor executes a script stored in the metadata database to convert data. Instead, Morgenstern uses a pre-built transformer engine 66 that is activated when data transformation is to occur. In other words, there is no "intermediate" program structure that converts the script commands to executable code. There being no such structure in Morgenstern, there necessarily is no metadata database to access to load a script when data transformation is to occur.

The specification describes that: "Scripts 55 must be defined to control data movement into and out of the system, and to control data transformation within the system." Col. 5:65-67. Thus, scripts are identified as the metadata being "utilized." The requirement that the script processor access the database for data transformation is inherent in the claim language itself ("utilizing metadata . . . to control data transformation within said systems interface . . ."). Thus, when data transformation is to occur, a script from the database is accessed for use. Col. 7:19-20 ("Finally, in step 80, the user initiates the script processor 37 to execute the script."). The prosecution history does not support Defendants' version of the limitations imposed by the applicants' remarks. Rather than indicating that the phrase means that the metadata items are accessed by the script processor during execution of a script, the remarks only point out that Morgenstern does not use a script of commands that is pulled from a database and converted by a script processor program to a form for execution by a computer processor.

Defendants' construction also is inconsistent with the specification. Defendants' construction has the script processor accessing the data transformation rule sets, whereas the specification and claim 9 indicate that the rule set processor accesses the database to obtain the data transformation rule sets. See col. 4:32-37; 4:45-48; 7:16-18.

Finally, Defendants' proposed construction is inconsistent with the claim language. The claim indicates nothing more than that the script processor utilizes script metadata obtained from the database during data transformation. Defendants' construction, however, indicates that other metadata (data interfaces and data transformation rule sets) are accessed.

Accordingly, the Court construes the term as "using metadata from a metadata database."
B. VGA (VIDEO GRAPHICS ARRAY)

The '788 patent treats the term "VGA" as an abbreviation for "Video Graphics Array":

The present invention relates generally to a USB (Universal Serial Bus) to VGA (Video Graphics Array) converter, and in particular to a USB-to-VGA converter connectable between a USB port of a computer and a VGA display device.

'788 patent at 1:6-9. The parties propose the following constructions:

<table>
<thead>
<tr>
<th>Term</th>
<th>Display Link's proposed construction</th>
<th>MCT's proposed construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>VGA</td>
<td>Video Graphics Array, the technology described in IBM Corporation, Personal System/2 Hardware Interface Technical Reference (1988 and as updated in 1991) and in IBM Personal System/2 and Personal Computer BIOS Interface Technical Reference (1991).</td>
<td>VGA has an ordinary and customary meaning to a person of ordinary skill in the art. VGA generically refers to all video display standards compatible with any 15-pin VGA port/plug.</td>
</tr>
</tbody>
</table>

Thus, the parties dispute whether the term "VGA" as used in the patent is a generic term that covers many forms of video display standards compatible with a distinctive port/plug or is a term that is defined by the VGA standard set forth by IBM.

VGA technology was developed by IBM in the late 1980s. Min decl. at P25. This technology allowed computer displays to offer better resolution, an increased color palette, and the ability to simultaneously display more colors than previous adaptors. Jones decl. at P11. Notably, the VGA standard has a resolution of 640-by-480. The details of the VGA graphics architecture are described in a series of Technical Reference Manuals published by IBM in 1988 and updated in 1991. Jones decl. at P10.

After the VGA standard was introduced by IBM in 1989, clone makers introduced into the market a video graphics array specification called super video graphics array or SVGA. In 1990, IBM introduced the eXtended graphics array or "XGA" video graphics array. Today there are many variations of video graphics array specifications on the market, including SXGA, UXGA, and QXGA. All of these video graphics array specifications utilize the 15 prong port/plug and the signals assigned to each of the pins in the connectors are the same as in the original VGA. Min decl. at P 25. However, they differ in the speed of data transmission. According to Dr. Min, certain video graphics array standards are preferred to others. For example, SVGA is a popular graphics array standard. Tr. at 35:22-36:5; 54:4-9.

MCT asserts that because at the time of patenting, other video graphics array specifications existed, including SVG and VGA, the patentee could not have meant for the term VGA to be limited to only VGA technology as described by the 1991 IBM specification. Rather, MCT asserts that VGA is a term that is used generically by persons of ordinary skill in the art to refer to any video graphic array standard that is compatible with the distinctive 15 prong plug/port. MCT asserts that the specific IBM VGA specification was considered sunset technology at the time of patenting and thus the term VGA must encompass more than the IBM VGA specification itself.

MCT asserts that the '788 patent specification supports its proposed construction. Specifically MCT points to the language in the specification that states: "The present invention relates generally to a USB (Universal Serial Bus) to VGA (Video Graphics Array) converter, and in particular a USB-to-VGA converter." '788 patent at.1:6-9 (emphasis added). MCT asserts the term "VGA" is being used in the patent as a general term, meaning that the term is used generically, and not in relation to the specific VGA standard itself. However, "generally" as used in the patent is not modifying VGA but rather the
converter. There is nothing in the specification or claims of the '788 patent that indicates or suggests that the term "VGA" is used generically. The specification and prosecution history do not mention the term "VGA" being compatible with other video graphics array standards, even though these standards were known by a person of ordinary skill in the art at the time the patent was filed.

MCT next asserts that the statement in the patent that the invention can work with any operating system is evidence that "VGA" is a term used generically to cover all video graphics arrays. Specifically, the '788 patent states: "[t]he operation process discussed herein is based on the WINDOWS operation system released by Microsoft Company, comprising the following steps . . . ." Id. at col.3:54-56. At the hearing, Dr. Min testified that as of December 2002, the filing date of the patent, the most current version of Windows available was Windows XP. Tr. at 40:16-19. Dr. Min further testified that Windows XP would not display the 640-by-480 resolution set forth in the IBM VGA standard. Thus, MCT asserts that the patent could not have contemplated limiting the term "VGA" to the standard using only the letters "VGA" as opposed to other standards such as SGV A. However, at the time the patent was filed, other Windows operating systems were known and in use including Windows 95, Windows 98, and Windows 2000. These operating systems would display VGA. Tr. at 88:6-12. The patent language quoted by MCT does not state which Windows operating system is being referenced.

The construction proposed by MCT is circular and, therefore, it is difficult to understand how it would practically be applied. It construes VGA to refer generically to "all video display standards compatible with any 15-pin VGA port/plug." (Emphasis added). In other words, MCT uses "VGA" to define "VGA."

DisplayLink asserts that MCT is trying to grossly expand the scope of its patent. DisplayLink asserts that a person of ordinary skill in the art would understand the term "VGA" to mean the 640-by-480 resolution as set forth in the IBM specifications for VGA. In response to MCT's argument that such a construction would limit the patent to sunset technology, DisplayLink asserts that this argument is irrelevant and that the patent discloses and claims what it claims, not what MCT wishes it to claim. Further, at the hearing, Dr. Min admitted that at the time the patent was filed in 2001, VGA was supported by virtually all personal computers. Tr. at 50:22-51:1. Additionally, DisplayLink notes that at the time the patent was filed, a person of ordinary skill in the art would have known about the SVGA and XGA standards and that these standards would not work on a VGA monitor. Tr. 51:24-52:5; 52:11-19; 53:22-25. Yet, notes DisplayLink, these standards were not even mentioned in the patent or prosecution history of the '788 patent.

DisplayLink notes that in the claims, VGA modifies "signals," "controller," and "plug." See '788 patent at 4:65- 5:15. Thus, asserts DisplayLink, "VGA" must mean something more than a 15 prong plug/port. DisplayLink further notes that MCT's definition of "VGA controller" is a "device that communicates with a display device according to the VGA standard . . . ." Therefore, DisplayLink argues that MCT itself recognizes that the term "VGA" references a standard. Also, DisplayLink notes that Figure 6 in the specification shows an alternate embodiment of the invention. This embodiment does not contain a 15 prong port/plug. Thus, DisplayLink points out, MCT's proposed construction would not cover one of the embodiments of the patent.

DisplayLink notes that Figure 4 provides an illustration of how a host computer issues USB based display signals to a USB controller. Id. at 2:2-10. The patent describes the steps of how the host computer system transmits the USB display signal. Id. at 3:52-65. None of the steps detailed in the patent specification discuss compression. Tr. at 57:21-25. Further, the patent talks about transmitting USB signals directly from the host computer to the display device. '788 patent at 1:41-45. At the hearing, Dr. Min agreed that USB 2.0 could not support a XGA signal without compression and that the '788 patent does not mention any compression. Min depo., vol. 2 at 211:11-212:12, 225:5-7; see also Tr. 55:12-59:22. Specifically, Dr. Min testified:

Q. Now sir, a person of ordinary skill in the art at the time the '788 patent was filed would understand that USB 2.0 did not have the bandwidth sufficient to directly transmit the XGA signals without compression, correct?

A. That's right.

Q. And the patent is entitled USB to VGA converter, correct?

A. That is correct as well.
Q. And this patent does not teach how to transmit an XGA signal to a monitor; correct?

A. That is correct. I mean it doesn't really talk about XGA signal being specifically part of this transmission.

Tr. 58:7-20. Dr. Min further acknowledged that the patent does not teach or reference compression which would be necessary to transmit any of the signals other than VGA. Tr. 59:2-22. He explained that the bit rate demands for Super XGA, Ultra XGA, and Quad XGA are much higher than the bit rate demands of XGA. Tr. at 59:9-12. Like XGA, Dr. Min agreed that those video graphics array standards could not be transmitted without compression. Tr. at 13-19. Thus, asserts DisplayLink, the '788 patent does not teach how to transmit any video graphics array signals except VGA.

The court on balance is persuaded that DisplayLink's construction should be adopted. It is undisputed that at the time the patent was filed XGA and SVGA were in existence. Several Windows operating systems available when the patent was filed supported VGA. The patent does not teach, give an example of or even mention a compression limitation which would be necessary in order to transmit signals for display other than VGA. The court, therefore, believes that a person of ordinary skill in the art reading the '788 patent at the time it was filed would have understood the term VGA to refer to the specification set forth in the IBM VGA technical references. This does not mean that products using other standards are not essentially identical or equivalent. But that seems more properly a question of infringement as opposed to one of claim construction.

The court does recognize that a review of the intrinsic evidence and a consideration of Dr. Min's testimony about the state of the art at the time leaves unanswered the troubling question as to why the patent would claim an invention that only covered "sunset technology." However, even if the court found (which it does not) that the intrinsic evidence rendered the claim equally susceptible to a broader and narrower interpretation, the narrower interpretation should be adopted. See Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335,1344 (Fed.Cir. 1998) (pointing out that the applicant has the burden to particularly point out and distinctly claim the subject matter of the invention).

Accordingly, the court construes the term "VGA" as follows:

The VGA controller of the '788 patent refers to a device positioned between the bridge and the display device. '788 patent Fig.1. The parties propose the following constructions:

<table>
<thead>
<tr>
<th>Term</th>
<th>DisplayLink's proposed construction</th>
<th>MCT's proposed construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>VGA Controller</td>
<td>Component(s) that controls the routing of VGA signals pursuant to the VGA standard and communicates with the bridge in the signal form understood by the bridge.</td>
<td>Device that communicates with a display device according to the VGA standard</td>
</tr>
</tbody>
</table>

MCT asserts that its proposed construction is consistent with the intrinsic evidence and that DisplayLink's proposed construction improperly includes the term "routing," which MCT argues is not supported by the intrinsic evidence. Like "USB Controller" discussed above, DisplayLink asserts that the VGA controller does more than merely communicate with the bridge and the display device; it controls the routing of VGA signals to the display device.
Claim 1 of the ’788 patent claims "a VGA controller disposed external to the computer and adapted to connect to the display
device for conveying VGA signals to the display device." Id. at 4:65-67. Claim 1 further provides that the VGA controller
receives signals from the bridge and "in turn applies the VGA signals to the display device." Id. at 5:10-11. The
specification of the ’788 patent states that the "[t]he VGA controller is connectable to a display device 300 whereby the
USB-to-VGA converter 100 provides a signal conversion and connection between the host computer 200 and the display
device 300." Id. at 2:29-32. The specification additionally states that "[t]he VGA controller [after receiving VGA signals]
forwards the VGA signals to the display device 300 for display by the display device." Id. at 2:38-40. Thus, the claim
language and the specification support DisplayLink's proposed construction that the "VGA controller" controls the routing
of VGA signals to the display device. Accordingly, the court construes the term "VGA controller" as follows:

A "VGA controller" is a component or components that control the routing of VGA signals pursuant to the VGA standard.

23 The ’164 patent, claims 3 and 16.

24 "In steps 41 (End of File) and 42, the process of the computer programmed in accordance with the present invention is
completed and the program exited from. At this point the user 3 has either confirmed that the code(s) for which payment is
requested are valid or have been modified to become valid or have been pending so that more information may be obtained
by the user 3 from the physician or his or her billing entity to aid in processing the claims." (’164 patent, col. 10, ll. 8-16) It
is axiomatic that the same claim term must be construed consistently throughout a patent's claims. Phillips, 415 F.3d at
1314. The parties agree that this construction applies to the claim limitation in other claims. The court finds no reason to
deviate from this construction in this claim.

9 The Specification of the ’347 Patent states, in relevant part, that "[a] utility operating on the service processors will give
the user a report of all the non-valid (out of sync) tracks." ’347 Patent, Col. 8, ll. 38-40.
Indeed, in order to provide for efficient error recovery, which is one purpose of the subject invention, each indicator must provide a fairly certain suggestion of whether each data element stored on each respective data storage system has been correctly stored. Such an indication does not simply mean that the data is consistent between the two storage systems. For example, if an indicator on the first data storage system indicates that the data stored there is valid that indication, alone, is not a sign that the data is consistent between the first and second data storage systems. Rather, it indicates that the data has been correctly stored to the first data storage system. It is only if the second indicator provides an indication that the data is valid that the term "valid" become synonymous with consistent.

Similarly, where the first data storage system is write disabled such that the data must be copied, in the first instance, to the second data storage system, the second data storage system may indicate that a particular data element is invalid on the first system but valid on its own system. The latter indication does not signify consistency between the two systems, because, as previously described, the first data storage system is write disabled. These examples illustrate that the term "valid" is not simply a synonym of "consistent" but must be construed in accordance with its broad plain meaning, i.e. correctly stored in a particular data storage system.

F. "validating," "verifying," and the "variations thereof" as they appear in the patent in the context of the verification process

The magistrate judge recommended that the terms "validating," "verifying," and the "variations thereof" in the context of the verification process be construed as "the process used for comparing the UTID generated by an originator and the amount of the transaction to confirm the identity of the originator and the transaction related thereto." First Report at 6, 12. The magistrate judge reasoned that the UTID must be generated by an "originator" based on arguments made by VLMachine to distinguish prior art during prosecution. See id. at 5-6. The magistrate judge quoted extensively from the Petition Statement to support his proposed claim construction:

[None of the prior art patents] provid[ed] a validated electronic commerce transaction wherein a [UTID] is generated by an originator and ultimately, the electronic commerce transaction and its associated identifier are returned to the originator to provide for validation of the electronic commerce transaction prior to completion of the transaction. Neither [do prior patents disclose] a process for returning the identifier to the originator by a [TA] validating the identity of the originator and determining where to return the electronic transaction and identifier based on the validation.

First Report at 5 (emphasis added). Both parties have filed objections to the magistrate judge's proposed claim construction of "validating," "verifying," and the "variations thereof" in the context of the verification process. As the parties' objections at times overlap, the court will consider the objections in tandem.

Plaintiffs object that the magistrate judge's proposed definition of "verifying," "validating" and "variations thereof" is "unduly restrictive" in that it: (1) "requires generation of the UTID by the originator rather than allowing for the UTID to be optionally generated by the TA, as specifically taught by the specification," and (2) "specifically requires the 'amount of the transaction' rather than a more generic reference to 'transaction content.'" Pl. Obj. to First Report at 9. In light of these objections, Plaintiffs propose two changes to the magistrate judge's proposed definition: (1) the deletion of the requirement that the UTID be "generated by an originator" and (2) the addition of "or" between the UTID and transaction data followed by replacing "amount of the transaction" with "transaction content." Id. at 9-13. Plaintiffs' proposed definition of "verifying," "validating" and "variations thereof" in the context of the verification process is: "The process used for comparing the UTID and/or the transaction content to confirm the identity of the originator and the transaction related thereto." Id. at 9.

Visa similarly objects to the magistrate judge's inclusion of the term "amount of the transaction" in his recommended construction of the terms "validating," "verifying," and "variations thereof." Visa asks the court to define the terms "validating" and "verifying" in keeping with the specification and file history as: "The process used for comparing (a) the UTID that is generated by an originator and associated with a transaction with (b) the record of UTIDs for transactions
generated by the originator, to confirm the identity of the originator and the transaction related thereto." Def. Obj. to First Report at 8.

1. "generated by an originator"

a. Plaintiffs' Objections

In support of their contention that "generated by the originator" should be deleted from the magistrate judge's proposed claim construction of "validating," "verifying," and "variations thereof," Plaintiffs make several arguments. First, Plaintiffs point to the alternative embodiment in the specification in which the UTID is generated by the transaction administrator. Id. at 10 (citing '878 patent, col. 6 lines 61-62) (“In the alternative embodiment parties other than the originator may create the UTID, for example the TA[.]”); id. (citing '878 patent, col. 7 lines 15-16) (noting that the UTIDs in the system shown and described in Figures 7 and 8 are "created by the processor" which is part of the TA's computer system). Plaintiffs further contend that the magistrate judge erred in relying on the prosecution history because the examiner did not similarly read the specification to require that the UTID be generated by the originator in claim 50. Instead, Plaintiffs argue, the examiner failed to specify how the UTID was generated in connection with claim 50, and thus the examiner intended that claim 50 encompass the alternative embodiments from the specification where someone other than the originator generates the UTID. Id. at 11 (“If the Court adopts the Recommendations' requirement that the originator must always generate the UTID, the embodiment described in the specification and set forth in claim 50 will be erased.”). Additionally, Plaintiffs argue that the Petition Statement relied upon by the magistrate judge does not declare "that only the originator can generate the UTID or that generation by the originator is necessary to distinguish the invention over the prior art." Pl. Obj. to Second Report at 12 (original emphasis). Therefore, Plaintiffs argue, the Petition Statement "does not amount to 'words or expressions of a manifest exclusion or restriction.'" Id. at 12. Finally, Plaintiffs argue that the magistrate judge erroneously "read into the claims a limitation that is simply not there." Id. at 10-11.

b. Visa's Response to Plaintiffs' Objections

In response to Plaintiffs' objections, Visa contends that the magistrate judge properly concluded that the UTID must be generated by an originator based on the applicants' own Petition Statement, wherein VI Machine described various prior art references and explained why their invention was allowable over those references. See Def. Resp. to Pl. Obj. to Second Report at 11. According to Visa, “[b]y identifying a UTID 'generated by an originator' as one of the features that distinguished their invention over the prior art, the applicants gave up other embodiments in which the UTID was generated by an entity other than the originator.” Id. 9 Visa also points to the "Summary of Invention" which described the electronic transaction as including "a unique transaction identifier that has been generated by the originator[.]" Id. at 6.

9 In further support of the magistrate judge's proposed claim construction requiring that the UTID be generated by an originator, Visa contends that "[t]he disclaimer is even more apparent when one looks at the prior art the applicants were distinguishing. Two prior art patents discussed by the applicants in the Petition -- Brachtl and Tamada -- disclosed other methods of generating the UTID . . . By arguing that the UTID, in the context of the '878 patent, is generated by an originator, the Petition Statement expressly distinguished the UTID from the 'first authentication code' in Brachtl and the 'confirmation data' of Tamada." Id. at 11-12 n.5.

As to Plaintiffs' argument that an alternative embodiment in the specification allows for the TA to generate the UTID, Visa argues that an alternative "embodiment described in the specification can be disclaimed during prosecution." Id. at 12 (citing Springs Window Fashions LP v. Novo Industries LP, 323 F.3d 989, 996 (Fed. Cir. 2003) ("[W]e have adopted claim constructions excluding an embodiment when the prosecution history requires the claim construction because of disclaimer.")). With regard to Plaintiffs' contention that the Petition Statement "does not amount to 'words or expressions of a manifest exclusion or restriction'" (see Pl. Obj. to Second Report at 12), Visa argues that the doctrine of prosecution disclaimer does not require an express statement that a particular embodiment is the "only" or "necessary" embodiment. "Rather, the prosecution statement need only be 'clear and unmistakable' in stating the point of distinction between the claimed invention and the prior art." Def. Resp. to Pl. Obj. to Second Report at 13 (citing Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1325-26 (Fed. Cir. 2003)). Visa also asks the court to reject Plaintiffs' argument that the magistrate
judge erroneously "read into the claims a limitation that is simply not there." See Pl. Obj. to First Report at 10-11. Visa states that the recommended constructions relate to the terms "verifying" and "validating," which literally appear in relevant phrases of the claims. These words appearing in the claims provide the "textual reference in the actual language of the claim with which to associate [the recommended] claim construction." Def. Reply. to Pl. Obj. to First Report at 17 (quoting Johnson Worldwide Assocs. v. Zebo Corp., 175 F.3d 985, 990 (Fed. Cir. 1999)). According to Defendants, Plaintiffs "put the public on notice during prosecution that '[t]he pending claims' and 'claimed invention' recited 'a method for providing a validated electronic commerce transaction wherein a unique transaction identifier is generated by the originator.'" Id. (quoting Petition Statement). Based on the doctrine of prosecution disclaimer, "when statements in the prosecution history require a particular construction of a claim term, the term must be construed to exclude the disclaimed subject matter, even when the specific words describing the exclusion do not appear in the claim language." Id. at 17-18.

c. Discussion

Federal Circuit precedent establishes that when statements in the prosecution history require a particular construction of a claim term, the term must be construed to exclude the disclaimed subject matter. See generally N. Am. Container v. Plastipak Packaging, Inc., 415 F.3d 1335, 1345 (Fed. Cir. 2005) (to overcome an obviousness rejection, applicant distinguished his invention based on prior art disclosing "slightly concave" inner walls; the "inescapable consequence of such an argument in that the scope of applicant's claims cannot cover inner walls that are "slightly concave"); Seachange Inf't, Inc. v. C-Cor Inc., 413 F.3d 1361, 1373 (Fed. Cir. 2005) ("Where an applicant argues that a claim possesses a feature in order to overcome a prior art rejection, the argument may serve to narrow the scope of otherwise broad claim language."); Innova/Pure Water, 381 F.3d at 1117 ("Because the inquiry into the meaning of claim terms is an objective one, a patentee who notifies the public that claim terms are to be limited beyond their ordinary meaning to one of skill in the art will be bound by the notification, even where it may have been unintended."); Omega Eng'g, 334 F.3d at 1323-24 ("[W]here the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender."); Rheox, Inc. v. Entact, Inc., 276 F.3d 1319, 1325 (Fed. Cir. 2002) ("Explicit arguments made during prosecution to overcome prior art can lead to narrow claim interpretations because the public has a right to rely on such definitive statements made during prosecution.") (internal quotations and citation omitted). In Phillips, although recognizing that the prosecution history "often lacks the clarity of the specification and thus is less useful for claim construction purposes[,]" the court went on to state: "Nonetheless, the prosecution history can often inform the meaning of the claim language by demonstrating how the inventor understood the invention and whether the inventor limited the invention in the course of prosecution, making the claim scope narrower than it would otherwise be." Id. (citing Vitronics, 90 F.3d at 1582-83).

The magistrate judge, after considering the Petition Statement and the doctrine of prosecution disclaimer, as well as the specification, correctly determined that by identifying a UTID "generated by an originator" as one of the key features that distinguished their invention over prior art, Plaintiffs surrendered other embodiments in which the UTID was generated by another entity. The Petition Statement unequivocally states that "the pending claims" and "the claimed invention" are distinguished their invention based on prior art disclosing "slightly concave" inner walls; the "inescapable consequence of such an argument in that the scope of applicant's claims cannot cover inner walls that are "slightly concave"); Seachange Inf't, Inc. v. C-Cor Inc., 413 F.3d 1361, 1373 (Fed. Cir. 2005) ("Where an applicant argues that a claim possesses a feature in order to overcome a prior art rejection, the argument may serve to narrow the scope of otherwise broad claim language."); Innova/Pure Water, 381 F.3d at 1117 ("Because the inquiry into the meaning of claim terms is an objective one, a patentee who notifies the public that claim terms are to be limited beyond their ordinary meaning to one of skill in the art will be bound by the notification, even where it may have been unintended."); Omega Eng'g, 334 F.3d at 1323-24 ("[W]here the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender."); Rheox, Inc. v. Entact, Inc., 276 F.3d 1319, 1325 (Fed. Cir. 2002) ("Explicit arguments made during prosecution to overcome prior art can lead to narrow claim interpretations because the public has a right to rely on such definitive statements made during prosecution.") (internal quotations and citation omitted). In Phillips, although recognizing that the prosecution history "often lacks the clarity of the specification and thus is less useful for claim construction purposes[,]" the court went on to state: "Nonetheless, the prosecution history can often inform the meaning of the claim language by demonstrating how the inventor understood the invention and whether the inventor limited the invention in the course of prosecution, making the claim scope narrower than it would otherwise be." Id. (citing Vitronics, 90 F.3d at 1582-83).

Further, the court rejects Plaintiffs' argument that the patent claims should be construed by reference to the patent examiner's statement and subjective intent. It is irrelevand for purposes of examining the prosecution history in this context that the examiner did not specify how the UTID was generated in connection with claim 50, and thus might have intended that claim 50 encompass the alternative embodiments from the specification where someone other than the originator generates the UTID. See Innova/Pure Water, 381 F.3d at 1124 ("It is well settled . . . that it is the applicant, not the examiner, who must give up or disclaim subject matter that would otherwise fall within the scope of the claims."); Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1350 (Fed. Cir. 2004) ("We have stated on numerous occasions that a patentee's statements during prosecution, whether relied on by the examiner or not, are relevant to claim interpretation."); Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456, 1462 (Fed. Cir. 1998) ("The fact that an examiner placed no reliance on an applicant's statement distinguishing prior art does not mean that the statement is inconsequential for purposes of claim construction.").

The court also rejects Plaintiffs' argument that the magistrate judge erroneously "read into the claims a limitation that is simply not there." Pl. Obj. to First Report at 10-11. The Federal Circuit has "warned against importing limitations from the
specification into the claims absent a clear disclaimer of claim scope." Andersen, 474 F.3d 1361, 1373 (citation omitted); see also Phillips, 415 F.3d at 1323 ("[T]he distinction between using the specification to interpret the meaning of a claim and importing limitations from the specification into the claim can be a difficult one to apply in practice."). In this case, the court is faced with intrinsic evidence of limitation derived from both the specification and the prosecution history. In light of the Summary of Invention and the Abstract, the court is certain that requiring that the UTID be generated by the originator is using the specification to interpret the meaning of the claim terms, rather than importing limitations into the claims. Even if this were a close call, the prosecution history described above "definitively resolves the question." Andersen, 474 F.3d at 1373 (rejecting patentee's claim that district court imported limitations from specification into the claims based on intrinsic evidence of restriction from specification and prosecutorial disclaimer evident from prosecution history). Based on the foregoing analysis of Plaintiffs' objections, the court overrules Plaintiffs' objection to the magistrate judge's recommendation that the UTID be "generated by the originator." 11

10 The "Summary of Invention" describes the invention as using a UTID that has been generated by the originator. The "Abstract" on the first page of the '878 patent also states that "verification" of a transaction occurs through use of a UTID generated by a purchaser (originator). 11 Visa contends that Plaintiffs, for the first time at the November 5, 2005 claim construction hearing, argued that the magistrate judge's construction of "validating" and "verifying" must be in error because it was inconsistent with the use of the phrases "verifying the identifier for the originator" in claim 15 and "verify the originator identifier" in claim 27. See Def. Resp. to Pl. Obj. to Second Report at 16-17. As Visa correctly notes, the magistrate judge's recommended constructions of "validating" and "verifying" specifically concern "the process of verifying or validation a transaction," which is thereafter referred to as "the validating, verification process." Id. at 16 (quoting First Report at 5-6). The First Report did not construe "validating" and "verifying" as they appear in phrases that concern only verifying the originator identifier, that is, simply verifying that the account exists, without also verifying that the person trying to use the account is truly the account owner. See id. Thus, the court rejects any arguments made by Plaintiffs predicated on inconsistencies between the magistrate judge's recommended constructions of "validating" and "verifying" (which concerned verifying the transaction) the phrases "verifying the identifier for the originator" in claim 15 and "verify the originator identifier" in claim 27. Although the court agrees with Visa that Plaintiffs' arguments should be rejected, the court declines Visa's further request that it define all phrases containing "verify," "validate" and "variations thereof," in the context of the verification of transactions. Id. at 17. The magistrate judge's proposed construction of "verifying" and "validating" and "variants thereof" pertaining to the process of verifying or validating a transaction is clear as it stands. Adopting Visa's suggestion would only create redundancy.

2. "the process used for comparing the UTID generated by an originator and the amount of the transaction to confirm the identity of the originator and the transaction related thereto." (First Report at 6, 12)

a. Parties' Objections

In its next objection to the magistrate judge's proposed construction of "validating," "verifying," and the "variations thereof," Plaintiffs propose the addition of "/or" between the UTID and transaction data and replacing "amount of the transaction" with "transaction content," resulting in "validating," "verifying," and the "variations thereof" being construed as: "The process used for comparing the UTID and/or the transaction content to confirm the identity of the originator and the transaction related thereto." Pl. Obj. to First Report at 9.

In support of the insertion of "/or" between the UTID and transaction content, Plaintiffs refer to certain instances in the '878 patent discussing validation or verification using the UTID "and/or" the "transaction content." Pl. Obj. to First Report at12. Plaintiffs cite to the '878 patent at Figure 4, and note that in box 90 the "TA sends the electronic transaction with UTID and/or transaction content to Originator for validation." Plaintiffs also refer to the '878 patent, column 3 lines 4-6, which defines a "validated transaction" as one in which the "TA validates the entities, facilitates the transaction and/or validates the contents of the transaction by the originator." Based on these instances, Plaintiffs argue that ":[b]y specifying only that the validation is of the UTID 'and' the 'transaction amount,' the Recommendation contradicts the teaching of the specification." Id. (original emphasis). Plaintiffs further argue that the doctrine of claim differentiation supports their suggested changes:

[C]laim 50 only references validation by reference to the UTID -- there is no reference in claim 50 to the "amount of the
transaction" or to "transaction content." Claim 52, which depends from 50, adds the limitation of also validating the "transaction data." If "validation" always includes use of the transaction amount as suggested by the Recommendation, there is no "claim differentiation" between claims 50 and 52. Therefore, the Court should add "/or" and change the "amount of the transaction" to the more generic phrase used in the specification, "transaction content." These two changes make the construction consistent with the specification and claims and ensure that there is differentiation among the asserted claims.

Id. at 12-13.

With regard to the term "amount of the transaction" used by the magistrate judge, Plaintiffs argue that the more generic phrase "transaction content" is appropriate, since the transaction amount is only a specific part of the information related to the internet transaction. "Transaction content" would "implicate not only 'transaction amount,' but also the date of the transaction, description of the goods and services, the merchant at which the order was placed, and the like." Pl. Reply to Def. Obj. to Second Report at 5.

Visa contends that the court should reject Plaintiffs' request to add "/or" and to replace "amount of transaction" with "transaction content" based on the prosecution history and the '878 patent specification. Visa argues that adopting Plaintiffs' requested changes "would have the effect of eliminating the requirement that the UTID be used in the validating/verifying process. Rather, under Plaintiffs' proposed revision, the claim could be satisfied by a process of comparing the 'transaction content,' without using the UTID at all." Def. Reply to Pl. Obj. to First Report at 18. Visa argues that "[t]his result would be contrary to the result required by the specification and by the doctrine of prosecution disclaimer." Id. Visa also points to the specification which provides that "verifying" and "validating" a transaction requires the use of a UTID. The specification states that: "[t]he identifier [UTID] is compared to a listing of generated transaction identifiers at the client [originator]." '878 patent, col. 3 lines 36-39. Visa also contends that Plaintiffs' reference to the '878 patent at Figure 4, box 90 is misleading. Although the box representing claim 90 in Figure 4 does provide that the: "TA sends the electronic transaction with UTID and/or transaction content to Originator for validation," the text in the specification that explains step 90 reads:

If the OID [originator identifier] is valid, the transaction administrator 60 determined the originator associated with the OID, transmits the transaction request and associated data to the originator 50 and requests that the originator validate the transaction request containing the UTID at step 90. The transaction administrator 60 may also validate amounts and credit limits at this time or upon receiving a response for the originator.

Id. (quoting patent '878, col. 5 lines 5-14) (Visa's emphasis). According to Visa, "step 90 in Figure 4 actually supports the Magistrate Judge's conclusion that the use of the UTID is required, and is not an optional choice alongside use of the 'transaction content' for validation purposes." Id. at 19.

While Visa opposes Plaintiffs' proposal to replace the phrase "amount of the transaction" with "transaction content," Visa does agree with Plaintiffs that the magistrate judge's use of the phrase "amount of the transaction" is incorrect, as it appears to require that the UTID for a transaction be compared with the amount of the transaction, which is unsupported by the patent specification. Id. at 19 n.11; see also Def. Obj. to First Report at 8. Visa asks the court to define the terms "validating" and "verifying" as: "The process used for comparing (a) the UTID that is generated by an originator and associated with a transaction with (b) the record of UTIDs for transactions generated by the originator, to confirm the identity of the originator and the transaction related thereto." Def. Obj. to First Report at 8. According to Visa, the magistrate judge's recommended claim construction "does not correctly capture the meaning that he appeared to intend based on his discussion of the issue." Id. Visa's proposed definition removes any reference to "transaction amount" or "transaction content" in the validation and verification process.

b. Discussion

The court first addresses Plaintiffs' objections to the magistrate judge's recommended claim construction insofar as Plaintiffs propose the insertion of "/or" between the UTID and transaction content. To reiterate, Plaintiffs point to certain instances in the '878 patent discussion of "/or" between the UTID and transaction content. To reiterate, Plaintiffs point to certain instances in the '878 patent discussing validation or verification using the UTID "and/or" the "transaction content." Pl. Obj. to First Report at 12. The court rejects Plaintiffs' argument and agrees with Visa that by inserting the "/or," the claim could be satisfied by a process of comparing the "transaction content," without using the UTID at all. Such a construction would be contrary to the specification and the prosecution history. See First Report at 5 (quoting Petition Statement):
[None of the prior art patents] provided a validated electronic commerce transaction wherein a [UTID] is generated by an originator and ultimately, the electronic commerce transaction and its associated identifier are returned to the originator to provide for validation of the electronic commerce transaction prior to completion of the transaction. Neither [do prior patents disclose] a process for returning the identifier to the originator by a [TA] validating the identity of the originator and determining where to return the electronic transaction and identifier based on the validation.

In the Petition Statement, VMachine "clearly and unmistakably" stated the point of distinction between the claimed invention and prior art, namely, a UTID generated by an originator and ultimately a UTID returned to the originator to provide for validation of the transaction.

In further support of inserting "/or," Plaintiffs argue that failure to insert the 'or" would violate the doctrine of claim differentiation, since claim 50 only references validation by reference to the UTID without a reference to the "amount of the transaction" or to "transaction content," whereas claim 52, which depends from claim 50, adds the limitation of also validating the "transaction data." The doctrine of claim differentiation is based on "the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope." Andersen, 474 F.3d at 1369 (citation omitted). "To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between the claims is significant." Id. (citation omitted). The written description and prosecution history, however, may "overcome any presumption arising from the doctrine of claim differentiation." Id. (quoting with approval Kraft Foods, Inc. v. Int'l trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000)). Further, "the doctrine of claim differentiation cannot broaden claims beyond their correct scope, determined in light of the specification and the prosecution history and any relevant extrinsic evidence. . . . [C]laims that are written in different words may ultimately cover the same subject matter." Id. (quoting with approval MultiForm Desiccants, Inc. v. Medzam Ltd., 133 F.3d 1473, 1480 (Fed. Cir. 1998)); see also Seachange International, 413 F.3d at 1369 (doctrine of claim differentiation is "not a hard and fast rule and will be overcome by a contrary construction dictated by the written description or prosecution history."). The court determines that the written description and prosecution history overcome any presumption arising from the doctrine of claim differentiation. Based on the foregoing analysis, the court overrules Plaintiffs' objection to the magistrate judge's proposed definition insofar as Plaintiffs propose the addition of "/or" between the UTID and transaction data.

Further, and also based on the prosecution history set forth above, the court overrules Plaintiffs' proposal to replace "amount of the transaction" with "transaction content." In support of this proposed change, Plaintiffs rely on the same references as where the specification describes the use of the UTID "and/or transaction content" as part of the verification and validation process. Again, by choosing to limit the scope of the claimed invention in the Petition Statement, Plaintiffs cannot now seek an expansive interpretation which would effectively allow a claim to be satisfied by a process of comparing the "transaction content," without using the UTID at all.

The court sustains Visa's objection to the magistrate judge's definition of "verifying," "validating," and "variations thereof," as the magistrate judge's insertion of the phrase "the amount of the transaction" is at odds with his analysis. See First Report at 5-6. Visa's proposed claim construction is consistent with the magistrate judge's discussion regarding the prosecution history, and his express recognition that in the Petition Statement, the applicants distinguished their verifying process from that of prior patents. Thus, the court will replace the magistrate judge's proposed claim construction of "verifying," "validating," and "variations thereof," with that proposed by Visa, namely: "The process used for comparing (a) the UTID that is generated by an originator and associated with a transaction with (b) the record of UTIDs for transactions generated by the originator, to confirm the identity of the originator and the transaction related thereto." See Def. Obj. to First Report at 8. 12

12 In response to Defendants' proposed construction, Plaintiffs argue that removal of any references to "transaction content" is "completely inconsistent with the specification and claims. Multiple times the specification describes the UTID and/or transaction content" as part of the verification/validation process." Pl. Reply to Def. Obj. to Second Report at 7. The court rejects Plaintiffs' argument based on prosecutorial disclaimer in the Petition Statement. See supra.

### A. Claim Construction

On February 16, 2006, the Court held a claims-construction hearing in this matter. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The Court considered the '136 Patent and prosecution history, the parties’ Markman briefs, the applicable law regarding, inter alia, claim construction, indefiniteness, and means-plus-function claims, and the argument of counsel. On May 25, 2006, this Court rendered a claims-construction order (Doc. # 292), which construed the terms as following:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Construed Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Debit Card&quot;</td>
<td>&quot;a prepaid card for exchange of value&quot;</td>
</tr>
<tr>
<td>&quot;ID information [stored on the debit card]&quot;</td>
<td>&quot;encrypted data, excluding the card number, stored on the debit card in the form of merchant ID, store ID, or terminal ID&quot;</td>
</tr>
<tr>
<td>&quot;Terminal&quot;</td>
<td>&quot;a point-of-sale apparatus, which includes a central processing unit, a card reader, a keypad, and a communications interface&quot;</td>
</tr>
<tr>
<td>&quot;ID information [stored on the terminal]&quot;</td>
<td>&quot;data stored on the terminal in the form of merchant ID, store ID, or terminal ID&quot;</td>
</tr>
<tr>
<td>&quot;Stored thereon prior to the transaction&quot;</td>
<td>&quot;stored on the terminal prior to the consumer presenting the debit card to the merchant&quot;</td>
</tr>
<tr>
<td>&quot;Relates . . . in a predetermined manner&quot;</td>
<td>&quot;prior to a transaction, ID information stored on the debit card and ID information stored on the terminal are capable of being matched&quot;</td>
</tr>
<tr>
<td>&quot;Matching&quot; and &quot;Matched&quot;</td>
<td>&quot;determining whether ID information stored on the debit card and corresponding ID information stored on the terminal are equal or identical&quot;</td>
</tr>
<tr>
<td>&quot;Retrieving via the terminal&quot;</td>
<td>&quot;locating and returning, by means of the terminal, ID information and a card number stored on the debit card&quot;</td>
</tr>
<tr>
<td>&quot;Computer&quot; and &quot;Computer means&quot;</td>
<td>&quot;a data processing device&quot;</td>
</tr>
<tr>
<td>&quot;Transmitting to a computer&quot;</td>
<td>&quot;sending by means of a signal path to a computer&quot;</td>
</tr>
<tr>
<td>&quot;Validation&quot; and &quot;Valid&quot;</td>
<td>&quot;indication of whether the ID information stored on the debit card matches the&quot;</td>
</tr>
</tbody>
</table>

- 4947 -
"Computer means disposed remotely"  "a computer that is located apart from a terminal and connected to the terminal by a signal path"

"Card reader means"  "a device, included as part of a terminal, used for retrieving ID information from a debit card"

"Communication means function"  "transmitting the ID information stored on the debit card and the ID information stored on the terminal to the computer means"

"Communication means structure"  "a modem or a signal path"

"Selected from a group of ID information (Claim 2)  "chosen from one of the following ID information"

n2 "ID," as used throughout this opinion, in whatever context, is shorthand for "identification."

The district court interpreted the "value" of a bid, as used in the patent, to mean the monetary "amount" of the bid, i.e., the...
price offered by the bidder. Bid for Position contends that the term "value" includes equivalents of the monetary amount of the bid. Bid for Position further argues that the Quality Score in the AdWords system is obtained simply through a mechanical conversion of the bid amount (i.e., the Maximum CPC), akin to a currency exchange conversion. Therefore, according to Bid for Position, the "value" of the bid, as that term is used in the '151 patent, includes the Ad Rank that results from adjusting the bid by the Quality Score.

The flaw in Bid for Position's argument is that the order of the bidders' bid amounts, arranged according to Maximum CPC, can be entirely different from the order of the bidders' Ad Ranks. If the conversion of bids to Ad Ranks were simply substitutions of equivalent values, the same order of positions would obtain after the conversions. Instead, the application of the Quality Score creates rankings that have no consistent mapping to the original bids.

Bid for Position is also incorrect in arguing for a construction of "value" that is distinct from the amount or price of the bid. The claim language uses the terms "bid" and "value of the bid" interchangeably, such that the two cannot be read to have separate meanings. Claim 1 recites, in a single subparagraph, the step of "checking for whether a first bid from the first bidder exceeds a second bid from the second bidder," wherein the bidders' relative position of priority "is dependent on whether the value of the first bid exceeds the value of the second bid." '151 patent, col. 14, ll. 15-16, 20-22 (emphases added). Under that formulation, it is clear that checking for whether the first bid exceeds the second bid has the function of determining whether the value of the first bid exceeds the value of the second bid, and thus that there is no distinction between the comparison of "bids" and the comparison of "bid values."

The next step in claim 1 recites "incrementing the first bid to a value exceeding the second bid if the first bid does not exceed the second bid." That step would make no sense if the "value" of the bid for purposes of the patent were different from the amount of the bid submitted by the bidder. It would be meaningless to refer to the "value" of the first bid "exceeding the second bid" if the value of a bid meant something different from the amount of the bid.

The specification supplies further evidence that the terms "bid" and "value of the bid" mean the same thing in the '151 patent. In the detailed description of the first preferred embodiment, for example, the patent provides that a bidder may enter maximum bids into the system and that the system will increase the bidder's lower bids "until they reach desired bidding positions entered by the bidders as long as the bids do not exceed maximum values entered by the respective bidders." The system will ensure relative priority for the bidder "as long as the maximum bid is not exceeded." '151 patent, col. 3, ll. 40-52. As applied to AdWords, the "maximum values entered by the respective bidders" cannot refer to the Ad Ranks, since the bidders do not know what Quality Score the system might assign to their advertisements. Instead, "value," as used in that passage, can only refer to the bid amount, a quantity that the bidders do control.

The same theme is repeated in several of the other embodiments. In the embodiment relating to an auction for a priority position for a website, the specification states that the system "checks for whether the bidder's bid exceeds all other bids in the auction for determining continuing priority for listing the bidder's web page." '151 patent, col. 4, ll. 52-55. Thus, it is the comparison of the bids (i.e., the bid amounts submitted by the bidders) that determines the position of priority, not the comparison of a separately determined "value" of the bids, as calculated by the system. The specification likewise equates the bidders' bids with the "value" of those bids when it describes an auction for golf tee times as determining priority "based on the relative value of related bids" and checking "for whether the golfer's bid exceeds all other bids in the auction." Id., col. 6, ll. 37-38, 48-49. The same formulation is employed in the description of each of the other embodiments. See id., col. 8, ll. 37-38, 48-50 (in an auction for frequent flyer airline seats, "wherein priority is based on the relative value of related bids," the system "checks for whether the frequent flyer's bid exceeds all other bids in the auction for determining priority for preferred seating"); id., col. 10, ll. 43-44, 55-57 (in an auction for priority position for online vendors, "wherein sales are based on the relative value of related bids," the system "checks for whether the vendor's bid is lower than all other bids in the auction"). In each instance, the "value" of the bid is equated with the bid itself, i.e., the amount of the bid as offered by the bidder.

The consistent use of the term "value" throughout the patent thus confirms that the '151 patent does not read on AdWords with Position Preference, which bases the award of priority on something other than a comparison of the bid amounts. The district court therefore correctly entered summary judgment of no literal infringement with respect to AdWords with Position Preference.
2. "Ion output current reference value"

ITW defines this term as "a value corresponding to a desired ion current output by at least one electrode, the value is used as a reference value." Pl. Revised Proposed Order Regarding Claim Construction at 2. Ion contends it is "a binary number corresponding to an ion current output by at least one electrode; the value is used as a reference value." Def.’s Proposed Order re Claim Construction for the ’756 patent at 3.

The only word is really in dispute is "value." The construction for "value" shall ultimately reflect limitations required by language from the specification. Before incorporating these limitations, however, I will begin by discussing the dictionary definition and the claim language. This process will ensure that the construction does not improperly import limitations from the specification. See Tulip Computers, 236 F. Supp. 2d at 373.

The primary definition for "value" in the New IEEE Standard Dictionary of Electrical and Electronics Terms is "the quantitative measure of a signal or variable." New IEEE Standard Dictionary of Electrical and Electronics Terms (5th ed. 1993). This definition from a technical dictionary resembles the mathematical entry for the word in an ordinary dictionary: "an assigned or calculated numerical quantity." American Heritage Dictionary of the English Language (4th 2000). In light of Texas Digital, these definitions can be construed to suggest the ordinary meaning of the word "value" as understood by one of ordinary skill in the art.

Neither of these two dictionary definitions restricts the numerical representation in question to a binary format. Under existing case law, the claim construction analysis should therefore begin with the presumption that "value" could be binary, but need not be. The practical consequence of such a presumption is that "value" could be binary, meaning digital or software-based, analog, meaning hardware-based, or both binary and analog. It remains only to be determined whether such a definition conflicts with either the claim language or the specification. See Interactive Gift, 256 F.3d at 1331.

Ion makes two sets of arguments for why the ’756 patent's intrinsic evidence conflicts in such a way as to require that "value" always be digital. The first set involves the claim language and the second set concerns the specification.

Ion argues that the claim language requires a narrower construction of the word "value." It points to the word "storing" in the language of claim 17 as evidence that the value must be digitally preserved. The claim language clearly states that the ion output current reference value is stored in "a software-adjustable memory." ITW agrees that the "reference value" is digitally stored. See Markman Hr’g Tr. at 15. Nonetheless, it does not concede that "value," for purposes of the ’756 patent, is necessarily digital. Pl.’s Reply Claim Construction Br. at 10. Rather, ITW argues that the fact that a value is stored digitally does not mean the value itself must originally be digital. Id. at 8-10. ITW argues that nothing in the claim language supports Ion's universal construction of "value" as a digital numerical representation, for no mention is ever made of either a specifically binary or digital value and the fact that a value is stored digitally does not require that the value be digital at the outset. Ion has failed to rebut this argument.

Ion makes two arguments for limitations based on language found within the specification. First, Ion points to language from the specification that both introduces the patent and comments on its preferred embodiment. Ion argues that this language necessarily narrows the dictionary definition of "value" because the specification disavows certain forms that a value can take. If language within the specification disclaims a usage or distinguishes its patent application from prior art on the basis of a different type of use, the claim construction should reflect these self-imposed limitations. See CCS Fitness, 288 F.3d at 1367; SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1340-1341 (Fed. Cir. 2001) (holding that, when the specification clearly disavows a feature, that feature is outside the reach of the claim language even if the language might otherwise be broad enough to encompass the feature in question). It must therefore be determined whether ITW has in fact disclaimed a form or type of value that would otherwise be consistent with the word's ordinary and accustomed meaning.

There are two passages within the ’756 patent that potentially conflict with a definition of value that encompasses both digital and analog numerical representations. The first passage states "instead of using analog-type trim potentiometers, the emitter module uses a digital or electronic potentiometer or a D/A converter. The balance and ion current values are stored
in a memory location in the emitter module and are adjusted via software control." '756 patent, col. 6:17-22. This language comes shortly after an introduction of the '756 system's "improved capabilities over conventional systems" and is listed as part of the first example of "some of the improved capabilities." '756 patent, col. 6:10-12. These improved capabilities are informed by an earlier section of the patent specification, wherein the drafters distinguished their product from prior art:

Most feedback systems are entirely or primarily hardware-based. Many of these feedback systems cannot provide very fine balance control, since feedback control signals are fixed based upon hardware component values. Furthermore, the overall range of balance control of such hardware-based feedback systems may be limited based upon the hardware component values.

'756 patent, col. 1:54-60. In light of both the prior art and the "improvements" made by the '756 patent, plaintiff cannot now claim that "value" should encompass hardware component values or any value connected to use of an analog-type trim potentiometer. Such a reading would conflict with the plaintiff's own patent specification.

Second, Ion notes that, in the patent's preferred embodiment, the ion output current values are stored digitally. 8 The structures and methods recited in a preferred embodiment, however, do not restrict the range of physical entities covered by a patent to those described in the embodiment. Renishaw, 158 F.3d at 1248. The fact that the preferred embodiment discloses a digital value therefore cannot, by itself, limit a claim's construction.

--- Footnotes ---
8 "The 'preferred embodiment' is a practical, workable example of the invention described by the claims of the patent." Slater Elec., Inc. v. Thyssen-Bornemisza Inc., 650 F. Supp. 444, 450 (S.D. N.Y. 1986). The preferred embodiment is contained within the specification.

--- End Footnotes ---

For these reasons, "value" shall be defined as "any numerical quantity or measure that is not generated by an analog-type trim potentiometer or described as 'hardware component.'" 9 The word "value", for purposes of construing this claim, is to be modified by the ordinary meanings of the words "ion," "output," "current," and "reference." Because "the same term or phrase should be interpreted consistently where it appears in claims of common ancestry," Epcon Gas Sys., Inc v. Bauer Compressors, Inc., 279 F.3d 1022, 1030 (Fed. Cir. 2002) (citing Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 980 (Fed. Cir. 1999)), I will not repeatedly redefine the word "value." See also CAE Screenplates v. Heinrich Fiedler GmbH, 224 F.3d 1308, 1317 (Fed. Cir. 2000) (noting that, ordinarily, the same word in a patent has the same meaning); Georgia Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1331 (Fed. Cir. 2000) (same). Rather, the word "value," for purposes of the '756 patent, retains the same definition throughout.

--- Footnotes ---
9 It may in fact be that any value that is consistent with these limitations is digital. The parties' presentations to the court suggest that a value is either digital or analog. Rather than making an unjustified conclusion on the basis of those introductory materials submitted to the court, I have restricted the claim construction to only those meanings that the specification clearly supports.

--- End Footnotes ---
2. "an associated value representing a desired quality of result" (claims 9 and 23)

Omax proposes that this phrase "means a value that itself represents desired quality of result, and that can be specified by selecting any numeric, verbal, pictorial or other symbol representing such desired quality, (and which value is stored in computer memory, and is a value that a computer mathematically combines, with one or more other parameters which affect(s) the quality of result, to determine motion control commands provided to the machine tool to adjust velocity or acceleration to achieve the desired quality of result)." Omax continues by noting that an "associated value representing a desired quality of result can be expressed as a so-called 'percentage of speed' if it meets the criteria stated above. It cannot, however, be an actual speed stated in distance/time if such speed specification causes the machine tool to move strictly at the specified speed, without adjustment of the speed to achieve the desired quality of result." Flow's proposed construction is as follows: "A single number that directly represents finished surface quality itself; but cannot be a variable that affects the finished surface quality such as a number related to velocity (e.g. normalized speed or percentage speed scale) or material thickness."

The parties' central dispute is how the value that is inputted by the user "represents" the quality of result that is desired by the user. Flow alleges that this claim was plainly defined during the claim prosecution, when Omax differentiated from prior art by declaring:

However, neither Cutler, nor any other cited art, suggests that the number which should be stored should represent finished surface quality itself rather than any one of many factors which contributes to surface quality. In the claimed invention, a single value is stored which value represents directly the quality of result.

FLO 2268-69. Therefore, Flow argues, the absence of the word "directly" in Omax's proposed construction, and their effort to include "normalized speed" in their definition, is an effort to retrieve ground lost during claim prosecution. Schriber-Schroth Co. v. Cleveland Trust Co., 311 U.S. 211, 220-21, 61 S. Ct. 235, 85 L. Ed. 132, 1941 Dec. Comm'r Pat. 802 (1940) ("It is a rule of patent construction consistently observed that a claim in a patent as allowed must be read and interpreted with reference to claims that have been cancelled or rejected, and the claims allowed cannot by construction be read to cover what was thus eliminated from the patent.").

Omax, of course, disputes this characterization of its statement during the prosecution. The context of the disclaimer was the Cutler prior art, which required an operator to enter velocities of the cutter in surface feet per minute and inches of feed per spindle revolution. These velocity values were typically derived in reliance on a chart that proposed different speeds based on desired quality. Omax was attempting to distinguish the previous system by explaining that the value was not a velocity, but rather the quality level itself. It used the word "directly" to emphasize this difference, and not to distinguish its claim from any claim where the input "inferred" quality. There is no unequivocal disavowal of a variable inputted into an equation which infers quality, so long as it is not an actual velocity. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1325-26 ("Consequently, for prosecution disclaimer to attach, our precedent requires that the alleged disavowing actions or statements made during prosecution be both clear and unmistakable."). Thus, Omax's patent prosecution statement must be construed in the proper context--distinguishing the new method from the Cutler prior art.

The Court is persuaded by Omax's expert's representation that "representing" has no specialized meaning in the art that would require the explicit exclusion of Flow's method. Hutchins's '596 Expert Report at 15 ("[I]t is my opinion that in this context the term 'represents' would reasonably be understood by a person of ordinary skill as meaning 'symbolizes' or 'stands for.'"). In its ordinary and customary meaning, and as used in the claim specification, the "value representing quality of result" is a variable that relates to or infers the ultimate quality of the piece that is cut. It is one of a number of factors included in a formula that ultimately dictates how the cutting head behaves.

Pursuant to the rules of claim construction, the Court will not determine infringement through its claim construction; instead, the Court will adopt a construction of this claim term without reference to Flow's "percentage" or "normalized" speed. Whether Flow's formula and input method infringe on Omax's patent will be a jury question. The claim will be construed as follows: "One value from a range of values representing the quality of a cut. This value is inputted into an equation containing other values that reflect characteristics of the task that will impact the quality of the cut, such as material type."
4727 e. "variable"

This is not a technical term that requires construction and may be understood according to its plain and ordinary meaning. The Court declines to construe this term.

4728 A. "Variable Authentication Number (VAN)"

Defendants argue that the VAN must be limited to a number created by applying a symmetric key algorithm. Neither the claims, specification, nor prosecution history impose such a limitation. While nearly all of the embodiments apply symmetric key algorithms to create the VAN, the patent does contemplate creating the VAN using asymmetric algorithms. ('148 patent, col. 5, ll. 34-44) In addition, the patent provides examples of VAN's created using asymmetric algorithms, such as the RVAN. ('148 patent, col. 7, ll. 33-38) Thus, "variable authentication number (VAN)" shall be construed to mean "a variable number that can be used in verifying the identity of a party or the integrity of information or both."

4729 B. "variable authentication number (VAN)"

This term appears in the '302 patent, claim 41 and the '148 patent, claims 28, 34, and 35. The parties dispute whether Plaintiff is collaterally estopped from arguing a different construction than what it previously proposed and that a Delaware
Plaintiff argues that the Delaware court's construction is of little value because, even though the patentee acted as his own lexicographer, the court's construction "was based entirely on dictionary definitions of the words 'variable,' 'authentication,' and 'number.'" Plaintiff's Brief at 11. After Phillips, according the Plaintiff, Courts are to defer to the patentee when he defines the terms that appear in the claims.

Plaintiff argues that the patentee acted as his own lexicographer when he wrote in the summary of the invention:

In accordance with an embodiment of the present invention, when a transaction, document or thing needs to be authenticated, information associated with at least one of the parties involved (e.g., an originator and/or a recipient) is coded to produce a joint code. This joint code is then utilized to code information relevant to the transaction, document or record, in order to produce a variable authentication number (VAN) or code at the initiation of the transaction.

'302 patent, 2:9-17. Plaintiff argues that VAN is further defined in one of the embodiments: "Note that the VAN is alternatively generated directly from INFO and information associated with at least one of the parties, without the intermediate step of generating the JK." '302 patent, 5:9-25. According to Plaintiff, because "every description and embodiment from the specification" shows the VAN "created by coding information associated with or related to a transaction or credential with either a joint key or 'information associated with at least one of the parties, without the intermediate step of generating the [joint key]."' Plaintiffs Brief at 13 (quoting '302 patent, 5:24-25).

Defendants argue that Plaintiff is collaterally estopped from arguing a different definition in this case and that Philips is not intervening law. To prevail on the theory of collateral estoppel, a party must show the following: "(1) the issue is identical to one decided in the first action; (2) the issue was actually litigated in the first action; (3) resolution of the issue was essential to a final judgment in the first action; and (4) plaintiff had a full and fair opportunity to litigate the issue in the first action." In re Freeman, 30 F.3d 1459, 1465 (Fed. Cir. 1994); see also U.S. v. Shanbaum, 10 F.3d 305, 311 (5th Cir. 1994) (setting forth a similar test). Defendant argues that only the third element is disputed and that the third element is satisfied because the jury in the Delaware court returned a verdict of non-infringement. Defendants also argue that Phillips does not represent a change in law but, rather, is a clarification of then-existing law. Defendant's Brief at 14.

Should the Court reject Defendant's collateral estoppel argument, the Defendants alternately argue that defining a VAN by the manner in which is generated is unnecessarily importing a limitation from the preferred embodiment. Defendants point out that "each of the claims in which VAN appears specifically includes a limitation dictating precisely how the VAN in that particular claim must be generated." Def. Brief at 15. Both parties agree that the manner in which a VAN is used is necessary to the definition and is consistent in all of the claims, Defendants argue, however, that the VAN is not created the same way in each of claims and to include it in the definition would be superfluous in many of the claims.

Plaintiff's argument that Claim 41, for example, does not tell a person of ordinary skill in the art that the VAN is generated from information relevant to a transaction is not persuasive. The very text of Claim 41 recites, "generating a variable authentication number (VAN) using at least a portion of the received funds transfer information." Funds transfer information, likewise, is described within Claim 41 as "including at least information for identifying the second account of the second party, and a transfer amount." Furthermore, the Court does not agree that the patentee acted as his own lexicographer in the passages that Plaintiff cites.

Absent a showing that a previous construction is incorrect, the Court will not alter a prior court's claim construction. Moreover, where, as here, the Plaintiff obtains the constructions that he advanced previously, the Court is not easily persuaded to depart from those prior constructions. Central to the invention, however, is that the VAN represents an unalterable truth—thereby thwarting fraud. In order to prevent the manipulation or alteration of the VAN, it is encoded and only decodable by selected, trusted parties. The Delaware court's construction does not reflect that the VAN has been encoded. The Court slightly modifies the Delaware construction to read, "an encoded variable number that can be used in verifying the identity of a party or the integrity of information or both."
A key aspect of the Hill invention is the notion of distributing the data needed to obtain complete information about a product on two different computers, the main computer, which contains all of the product information data for the electronic catalog, and the remote computer which holds a subset of that data. This is the essence of the distributed data design technique employed by the inventor to accomplish his design objectives. Two of the three stated objectives of the invention are met by using this system. First, the objective of providing the customer "with an instantaneous distribution of the latest catalog data available" is met because the main computer is responsible for keeping all of the most current data and transmitting the requested data along with any changes to constant data each time a customer seeks information. This feature meets the "latest catalog data available" element. The "instantaneous distribution" element is met because a subset of the catalog data is kept on the remote computer, which reduces the amount of data that must be transmitted when a customer requests product information.

Second, the objective of minimizing "computer on-line time" is met by the distributed data design for the same reason the instantaneous distribution element is met. Keeping a subset of catalog data on the remote computer, which can be easily updated by the main computer transmitting updated portions of data automatically, allows for less time on-line receiving data. The patent teaches that the data classified as constant and kept on the remote computer may include the type of data files, such as graphics, that take a long time to transmit. See '490 Patent, Col. 1, ll. 20-25 (describing disadvantage of prior art "dial-up" electronic catalog system); see also Plf's Ex. 93, Tab 4 at 4; Tab 6 at 3-4; Tab 9 at 5-6.

The parties disagree about the construction of the claim terms "constant" and "variable" data, with Compuserve proposing a definition that contains many elements and Hill proposing a much simpler one. Compuserve's proposed definition of "variable data" is:

"Variable data" is product data: (a) that has been classified by the vendor, before operation of the system, as being more likely to change than constant data; (b) is in a file that relates to only one product; (c) that is transmitted to a remote computer after transmission of all constant data; and (d) for which the main revision status level is not incremented when a new variable data file is changed or updated.

Def's Brf. at 13. According to Compuserve, the four attributes of this definition are required by the Hill patent specification.

The Court finds that "variable data" is adequately defined in the specification itself, and declines Compuserve's invitation to add the four proposed limitations to that definition. In the summary of the invention, variable data is defined as "data that can change at any time." This definition corresponds with ordinary dictionary meanings for the word "variable." For example, one dictionary defines "variable" as "liable or likely to change or vary; subject to variation; changeable; inconstant." American Heritage Dictionary (1976). Another provides a similar definition: "able or apt to vary or change; characterized by variation or by varying." Webster's Third New International Dictionary. Moreover, each time the term "variable data" is used in the patent, this definition could be substituted with no change in the meaning of the sentence. For instance, in Claim 1 the method recites the step of "transmitting variable data [data that can change at any time] related to the at least one product from the main computer to the remote computer." '490 Patent, Col. 22, ll. 9-11. Similarly, the summary of the invention states "a combination of constant data residing on the customer's computer and variable data [data that can change at any time] downloaded from the vendor's computer is integrated and merged to create a completely updated data sheet . . . ." Id., Col. 2, ll. 22-25.

It is the patent's use of the claim term "constant data" that conveys a slightly different meaning than the ordinary dictionary meaning. One dictionary definition is: "unchanging in nature, value or extent; invariable." American Heritage Dictionary. A second definition is: "something that does not vary or change in its relationship with other things; fixed and invariable; remaining unchanged." Webser's Third New World International Dictionary. In the context of the Hill patent, however, "constant data" does not mean data that does not change. That is clear from the fact that the main computer stores and maintains a "main revision status," which is described as "indicating the revision level of the constant data stored in the main computer." '490 Patent, Col. 21, ll. 58-61. Another step describes a similar revision status that indicates the revision level of the constant data stored in the remote computer. Id., ll. 65-67. Finally, the updating step specifically establishes that
"constant data maintained" on the main computer could be different from the constant data stored on the remote computer. The prosecution history also supports a finding that "constant data" is expected to change. See Plf's Ex. 93, Tab 4 at 4; Tab 6 at 3-4; Tab 9 at 5-6. By clear implication, the "constant data" to which the patent refers must undergo changes.

Hill's suggested definition for "constant data" is: "product information likely to change less often than variable data." Hill's Brf at 27. Compuserve, on the other hand, proposes a definition for constant data as follows:

"Constant data" is product data: (a) that has been classified by the vendor before the operation of the system, as being less likely to change than variable data; (b) that can be related to more than one product; (c) that is transmitted to a remote computer before the transmission of any variable data; and (d) for which a main revision status level is incremented when a new constant data file is changed or updated.

Def's Brf at 13. Both parties agree that constant data is "less likely to change than variable data." They disagree, however, about whether the definitions for constant and variable data must include a statement regarding who classifies product information into the two subsets of data. They also dispute defining variable data as relating to only one product and constant data to more than one product, as well as including the order in which the data is transmitted and whether a main revision level is incremented when the data is changed in the definition.

According to Compuserve, these attributes must be included in the definitions for constant and variable data so that the Court will be able to apply the definitions later in the case to determine whether infringement has occurred. Def's Brf at 19. To make that determination, Compuserve asserts, the Court would be required to classify data as either constant or variable. Id. The apparent premise for this conclusion is that the Court will be presented with a list of data files and asked to determine which are constant and which variable. However, the patent does not include any step that describes classifying data. Instead, the invention assumes data is already classified and then describes the operations performed on or with that data. If the Court were to add elements to the definitions of constant or variable data that limit who classifies it, how it is to be classified, and when, the Court would be doing more than construing claim terms, it would be adding claims. The proposed additional limitations exceed the scope of the claimed invention.

Compuserve points to illustration figure 1B, showing the distribution of data and software programs on the vendor's computer, as supporting the disputed elements. That figure depicts constant and variable data being stored separately in the memory of the main computer. While this may be true, that fact alone does not require the Court to define constant or variable data in terms of who classifies it or when. Compuserve cites portions of the prosecution history in further support of adding this element to the definition. Specifically, Compuserve points to Hill's original specification and states that "Hill told the Patent Office that constant data and variable data are already classified as depicted in Fig. 1B" on page 12, lines 15-17. Def's Brf at 14 (citing the Original Specification, Apr. 10, 1992, see Plf's Ex. 93). The only communication the Court can discern from that citation is a description of Figure 1B as "a block diagram illustrating the software and data stored in the memory of the vendor's computer." Plf's Ex. 93, Tab 1 at 12, ll. 15-17. The same statement is included in the specification of the '490 Patent. See '490 Patent, Col. 7, ll. 1-2. Both of these statements refer to a preferred embodiment of the invention, and neither conveys anything other than that the invention assumes, without limiting, classification of the data to be stored, maintained and used as claimed in the patent.

Similarly, Compuserve cites Hill's March 9, 1994, response to an office action, which Compuserve describes as Hill's admission "that the constant data is identified even before being loaded or transferred to the customer's computer from a main computer," in support of the proposed limitation. See Plf's Ex. 93, Tab 6 at 4. It provides no such support. In his response to the examiner, Hill described examples of the types of data that might be stored as constant or variable data. Id. That general description does not constitute an admission of anything about who classifies the data or when. Consequently, the Court finds that a limitation in the claim terms "constant and variable data" requiring the vendor to classify the data before operation of the system is not warranted by the intrinsic evidence in the patent.

The second attribute proposed by Compuserve concerns whether constant and variable data must be defined in terms of whether it relates to one, or more than one, product. In support of this limitation Compuserve offers an excerpt from the specification in which constant data is described as including "logo, graphics data for outlines and boxes, format data which labels the units of the product specifications . . . and graphics data illustrating the configuration of various products." '490 Patent, Col. 9, ll. 41-45. This description is found in the portion of the specification that is a detailed description of a preferred embodiment. Compuserve offers no reason to the Court for importing this limitation from a preferred embodiment
into the claim term of "constant data." Nor can the Court discern one.

Further support for this limitation, according to Compuserve, is found in a reference in the prosecution history which shows that "constant data can relate to multiple products." Def's Brf. at 15. In the reference, the patentee described an amendment to Claims 1, 15, 30 and 35, made in response to the patent examiner's earlier rejection of those claims. See Plf's Ex. 93, Tab 9 at 5. The amendment was intended to clarify the nature of constant data as "a subset of the product information data." Id. In their final form, the claims referred to "a subset of product information data related to the at least one product," or "a subset of product information data related to the plurality of products." '490 Patent, Col. 21, ll. 64-66, Col. 23, ll. 37-39. Given the fact that in Claim 1 the constant data is described as a subset relating to "the at least one product," it does not follow that constant data itself must be defined as capable of being related to more than one product. Apparently, the patent contemplates constant data that can relate to only one product. For this reason, it would be improper to limit the definition of constant data to data that can be related to multiple products.

A similar problem prevents the importation of a limitation that variable data must relate only to one product, from Compuserve's designation of a passage from the summary of the invention. That passage describes the transmission of variable data "related to the specific product selected by the customer." '490 Patent, Col. 2, ll. 17-18. The fact that the invention contemplates the transmission of variable data related to a specific product in order to create a product information sheet does not mean that each piece of variable data only relates to one file. For example, a variable data file may include information about the horsepower of an engine, and the specific product selected may have that size of an engine. This does not mean that there are no other products with that size of an engine. Compuserve's argument that variable data files must only relate to a single product is not required or even suggested by the intrinsic evidence of the patent. The Court will not import this limitation into the definition of constant and variable data.

The next limitation suggested by Compuserve relates to the sequence of transmission of the constant and variable data. Before this limitation could be an element of the definition of these two claim terms, the Court must find that the sequence of steps in the method claims is mandated. Assuming, without deciding, that it is, there is no evidence that supports including this characteristic in a definition of the claim terms "constant and variable data." The ordinary meanings for those terms, as modified to reflect that constant data is data that will be changed, suffices for purposes of understanding the method claims in which the terms appear. Compuserve has pointed to details from the specification that describe differences in how the constant or variable data is treated, but has provided no reason for the Court to find that a "special and particular definition [was] created by the patent applicant." See Renishaw, 158 F.3d at 1249. Nor has Compuserve demonstrated that the common dictionary meanings for these terms, as modified, would be "nonsensical in light of the patent disclosure." See id. at 1250. Consequently, the Court will not import this limitation into the definitions for constant or variable data.

The last element Compuserve seeks to add to the definition of these claim terms is whether the main revision level is incremented when changes occur to the data. This limitation is described as "another way for the Court to distinguish constant data from variable data." Def's Brf. at 17. However, Compuserve has not provided the Court with any reason why the differences already noted between constant and variable data will not suffice to make clear the meaning of each term. While it may be true that both Hill and his expert witness have indicated that it would be difficult to classify data into such categories simply by looking at the data on the computer, that fact does not mean that constant and variable data must be defined in a way that allows such a visual classification. See Hill Dep. at 190-91; Tr. Vol. I at 127. There are various ways of determining which data is constant and which is variable other than just looking at the data files. One example, suggested by Hill during his deposition but also supported in the claims, is to look at how the data is handled by the electronic catalog system. See Hill Dep. at 191; '490 Patent, Col. 21, ll. 56-61 (noting that main revision status indicates revision level of constant data stored in main computer). Another would be to observe the relative number of changes the data has undergone over time, to determine its rate of change in comparison to other data. Hill's expert testified that a person skilled in the art would know how to divide the data into constant and variable data. Tr., Vol. I at 127. Moreover, contrary to Compuserve's claim construction theory, the definitions of these claim terms need not be limited by the differences in how they are treated in order for those differences to provide clues about which data is constant or variable.

The key here is that Hill's patent is not about the proper classification of data for an electronic catalog system. It is about distributing that data between two different computers, a main and a remote, establishing a system for updating the data left on the remote computer, and transmitting the updated variable data to the remote to create the most current product information available. It presumes some sort of classification of the data, but does not limit how that is accomplished. Thus, the Court finds that the definition for "variable data" that is most true to the claim language and in alignment with the
patent's description of the invention, see Renishaw, 158 F.3d at 1250, is "product information classified as capable of changing at any time." The definition that best conveys the meaning of "constant data" is "product information classified as likely to change less often than variable data."

Variable parameters and Measurable parameters

ConnecTel contends "variable parameters" and "measurable parameters" should be construed to mean "those parameters whose values can vary over relatively short periods of time." Cisco argues "variable parameters" and "measurable parameters" "refer to parameters of the paths that can vary and are measured." The parties' disagreement on this term is whether the variation in value must occur over short periods of time. ConnecTel argues that the variable parameters discussed in the preferred embodiment—$presentstate$, $avgsate$, $latency$, $time$, and $availbandwidth$—vary over a short period of time. ConnecTel's limitation of "short periods of time" is vague and unsupported by the specification. Although the variable parameters described in the specification are likely to vary over short periods of time, there is no requirement in the claims or specification that they must vary over short, as opposed to long, periods of time. Accordingly, the Court rejects this limitation.

The Court adopts Cisco's construction and construes "variable parameters" and "measurable parameters" to mean "parameters of the paths that can vary and are measured." This comports with the common meaning of the terms.

GO BACK

4732

e. "variable speed"

The next term is "variable speed." The plaintiffs' proposed construction is "capable of operating at speeds that can change." The defendants argue that the term means "a speed (frequency) that is not tightly controlled and varies more than minimally."

The plaintiffs contend that the specification discloses a ring oscillator that is capable of operating at various speeds based on variations in operating conditions. '336 patent, 16:59-63. The plaintiffs also argue that the defendants' proposed construction is too restrictive. The defendants, on the other hand, point to the prosecution where the applicant describes fixed-frequency as a speed that is "tightly controlled" and "var[ies] minimally." Amendment, July 7, 1997, at 3-4. According to the defendants, "variable speed" is the opposite of fixed-frequency.

Notwithstanding the defendants' arguments, one of ordinary skill in the art would understand "variable speed" to describe a component capable of operating at different speeds. Accordingly, the Court construes the term to mean "capable of operating at different speeds."

GO BACK

4733

1. "Variable speed wind turbine controller"

Plaintiff suggests that this term be interpreted to mean "the hardware and software that is used to control the wind turbine"; defendant contends that it should be defined as "the hardware and software that provides torque command signals to the frequency converter." If defendant's reading is appropriate, it is preferable, because it is more precise and therefore gives greater guidance to persons wishing to avoid infringement. In re Warmerdam, 33 F.3d 1354, 1359 (Fed. Cir. 1994) ("Claims should be evaluated by their limitations, not by what they incidentally cover."). The claim discloses a turbine controller that "provid[es] a generator torque command signal"; a set of hardware and software that does not provide a torque command signal would not satisfy this limitation. Plaintiff's proposed construction is unacceptable because it could encompass sets of hardware and software that do not provide torque command signals and therefore, would not constitute a variable speed wind turbine controller. Correct claim construction "stays true to the claim language and [] naturally aligns with the patent's description of the invention." Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998).
Plaintiff finds defendant's proposal too narrow because it would exclude the high pass filter and summing junction that generate an "augmented torque command signal," as disclosed in dependent claim 2. In fact, defendant's proposed construction does not exclude "augmented" torque command signals. Defendant's construction (hardware and software providing torque command signals) would encompass the high pass filter and summing junction because they generate torque command signals, albeit augmented signals.

However, plaintiff has a second challenge to defendant's construction: it would not reflect the fact that claim 7 of the '736 patent discloses a wind turbine controller with means for providing a turbine rotor speed reference signal in addition to providing torque command signals. Plaintiff overlooks the nature of claim 7, which is a dependent claim. Although courts are to interpret dependent and independent claims of a patent consistently when it is reasonable to do so, Rambus, Inc. v. Infineon Technologies Ag, 318 F.3d 1081, 1093 (Fed. Cir. 2003) (interpretations of independent claims that render terms in dependent claim meaningless are disfavored), plaintiff's challenge does not implicate this rule.

Defendant's construction is not inconsistent with dependent claim 7 simply because the construction does not describe an additional limitation described in that claim. To the contrary, the general rule is that courts are not to read limitations stated in dependent claims into independent claims. Innova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 381 F.3d 1111, 1123 (Fed. Cir. 2004). A construction incorporating a dependent claim limitation would be improper. To the extent that there might be some confusion whether defendant's proposal implies a limitation on the functions performed by the turbine controller, I will add the phrase "among other things" to make it clear that the variable speed controller performs functions other than generating a torque command signal.

Last, plaintiff contends that defendant's proposed construction is confusing because it includes two claim terms that are not defined: "torque command signal" and "frequency converter." However, as plaintiff goes on to note, the meaning of these terms is not disputed. A frequency converter is a device that converts variable frequency AC to fixed frequency AC while a torque command signal dictates the amount of rotational force (torque) used inside the generator, regulating the speed at which the rotor spins. I see no basis for plaintiff's suggestion that these terms render defendant's construction too confusing.

I will make two minor modifications to defendant's proposal. The first is to eliminate the clause "to the frequency converter" because no such restriction exists in the fifth paragraph of claim 1. Although the sixth paragraph discloses a frequency converter that is "responsive to the generator torque command signal," defendant's proposal suggests a need for direct transmittal that is not mandated by the claim language. The second modification simply makes it clear that a controller is an integrated set of hardware and software. I conclude, therefore, that the phrase "variable speed wind turbine controller" means "an integrated set of hardware and software that provides torque command signals, among other things."

The Parties' Proposed Constructions

AMO proposes that I construe "variably controlling" to mean "the ability of the control unit to alter the amount of power being provided by the ultrasonic power source in some fashion other than merely enabling the power (turning power on) or disabling the power (turning off)." (D.I. 164 at 10.) AMO further proposes that I construe "in response to a sensed vacuum level in the handpiece corresponding to the occluded condition of the handpiece" to mean "to alter or change, including automatically or manually, the ultrasonic power." 3 (Id.)

3 During the Markman hearing, Alcon included in their slide presentation to the court a demonstrative exhibit in which Alcon asserts that the applicant for the '240 patent acquiesced in the examiner's interpretation that the term "varying"
includes turning on and off. (See slide '240-50, Alcon's submitted copy of slides presented during the Markman hearing, Dec. 20, 2004). Alcon, however, made no reference to such assertion in its extensive briefing on the construction of the term "varying" as used in the claims of the '240 patent, despite the disparity between the parties' proposed constructions. (See D.I. 171 at 31-33, 35; D.I. 187 at 16-18.) Thus, AMO has not had a fair opportunity to respond. Even considering Alcon's assertion, in the context of the claim language, see my discussion, infra Part IV.A.1.g.ii., it is clear that the term "variably controlling" in step (f) of claim 1, was intended to refer to the ability to change the ultrasonic power level from one real level of power to another.

--- End Footnotes ---

ii. The Court's Construction

There are two main disputes between the parties with regard to this claim term. The first, is whether this step, step (f), can be performed manually as well as automatically, and the second is whether the "variably controlling" term includes turning the power on or off, as opposed to only adjusting the power level once on. For the same reasons described supra Part IV.A.1.f.ii., I construe this term to be limited to automatic means. Additionally, for the reasons that follow, I construe this term to exclude merely turning the power on or off.

I begin with the language of the claim term itself. The parties agree that the term "variably" is the adverb form of "variable" which means "changeable." (D.I. 171 at 31; D.I. 192 at 34.) The claim term states "variably controlling … the ultrasonic power being provided to the handpiece." (‘240 patent, col. 7, ll. 56-57 (emphasis added).) Because the term describes varying the power that is being provided, this necessarily implies that power is already being provided, i.e. turned on. Thus, this term would not include turning the power on. A sense of symmetry in construction and of logical extension indicates that this term would not include turning the power off. Therefore, consistent with the "corresponding to" term agreed to by the parties, see supra Part IV.A.1.f.i., I construe "variably controlling, in response to a sensed vacuum level in the handpiece corresponding to the occluded condition of the handpiece, the ultrasonic power being provided to the handpiece" to mean "the ability of the control unit to automatically change the amount of ultrasonic power, other than merely turning it on or off, being provided to the handpiece in response to a signal from the vacuum sensor indicating that a sensed rise in the vacuum of the aspiration line has reached a particular numeric value which is equal to the vacuum that exists in the aspiration line when the doctor believes he is going to have an occlusion issue."

The next term is "varying together." The plaintiffs contend that the term means "both increase or both decrease." The defendants' proposed construction is "increasing and decreasing by the same amount." The dispute is whether this term is limited to "the same amount."

The defendants claim that the only way for the invention to work is to match the clock speed to the CPU's processing speed capability. According to the defendants, if the frequency capability increased from 50 MHz to 100 MHz but the clock rate only increased from 25 MHz to 150 MHZ, then the CPU would not be operable. In addition, the defendants argue that there are numerous statements in the prosecution history stating that the processing frequency should "track" or "vary correspondingly with" the clock rate. See Response to Office Action, April 11, 1996, at 6, 8; Response to Office Action, January 8, 1997, at 4.

There is no limitation in the intrinsic evidence requiring the variation between the frequency capability and the clock to
match exactly. The Court construes the term to mean "increasing and decreasing proportionally."

4736

B. "Vcc current bus" (claim 1, asserted claim 5)

The parties agree that the Vcc bus is the main power supply for an integrated circuit and that in the '830 patent, the Vcc bus is internal to the integrated circuit. They also agree that the Vcc bus supplies current 9 to the circuit. The only dispute is whether the construction of this term should specify that the Vcc bus supplies current to the transistors and capacitors. AMD's proposed construction is: "An internal bus (main conduit) for an integrated circuit that supplies charge for the transistors and capacitors" (emphasis added). Samsung proposes construing Vcc current bus as "The main power supply bus on an integrated circuit for receiving external current and providing that current to the integrated circuit." Although AMD's construction specifies that the Vcc bus supplies current to transistors and capacitors, AMD does not dispute that the Vcc bus is the current supply for the entire integrated circuit. The Court finds that AMD's construction could give the incorrect impression that the Vcc bus supplies current for the transistors and capacitors only. For this reason, Samsung's construction will be clearer to a jury.

9 AMD proposes the word "charge," but agrees that current is "merely charge over time." Supp. Friedman Decl. P 9.

AMD objects that Samsung's reference to "external" current could give jurors the incorrect impression that the Vcc bus is not part of the integrated circuit. The Court agrees that the word external could be confusing. Accordingly, the Court adopts a modified version of Samsung's construction: "The main power supply bus on an integrated circuit for receiving external current and providing that current to the integrated circuit. The Vcc bus is internal to the integrated circuit."

4737

1. "V[dd]"

The central dispute surrounding the claim term "V[dd]" concerns whether it is limited to an externally supplied voltage applied to a pin of the DRAM, or whether it can also include an internally supplied, or "on-chip," voltage. This distinction is significant because a DRAM chip may use the externally applied voltage in one of two ways. First, a DRAM chip may use an externally applied voltage, e.g., 5 volts, in some circuits on the chip without any manipulation. Second, a DRAM chip may reduce, referred to as "stepping down" or "down converting," the externally applied voltage to a lesser voltage and use that lesser voltage in some circuits on the chip. For example, an externally applied voltage of 5 volts may be stepped down to 3.3 volts, which is then used in certain circuits on the chip. Defendants contend that "V[dd]" does not include any stepped down voltages that may be used on the chip. MOSAID contends that "V[dd]" should not be limited to an external voltage, but may also include stepped down voltages.

Claim construction analysis begins by determining whether the claim term has an ordinary meaning. To that end, one first looks to the language of the claims. The claims of the '602 patent do not explicitly limit "V[dd]" to an externally applied voltage. For example, claim 1 of the '602 patent states:

1. A dynamic random access memory (DRAM) comprising bit lines and word lines, memory cells connected to the bit lines and word lines, each memory cell being comprised of an access field effect transistor (FET) having its source-drain circuit connected between a bit line and a high logic level voltage V[dd], bit charge storage capacitor, the field effect transistor having a gate connected to a corresponding word line;

a high V[pp] supply voltage source which is in excess of high logic level voltage V[dd] plus one transistor threshold
voltage; means for selecting the word line and means having an input driven by the selecting means for applying the V/pp supply voltage level directly to the word line through the source-drain circuit of an FET. '602 patent, claim 1 (emphasis added).

Claim 1, like the other ‘602 claims, says nothing about "V[dd]" being an externally applied voltage. Instead, the claim speaks of "V[dd]" as a voltage level that the memory cell capacitor can store. Thus, looking solely at the claim language, "V[dd]" is not limited to an external voltage.

Footnotes 1

13 The parties agreed that all of the disputed claim terms have the same meaning regardless of what patent they appear in. Consequently, as a matter of convenience when dealing with the 9 patents in suit, for each disputed claim term, the Court began by looking at the term in the context of the first patent that issued from the Patent Office. To the extent that the parties felt it was necessary, they were encouraged to direct the Court to other locations in other patents where the context of the claim term may shed light on its meaning. Accordingly, although certain claim terms may only be addressed in the context of one patent, they were considered in the context of all of the patents in suit.

End Footnotes

The Defendants do not dispute the plain language of the ‘602 claims. Instead, they point to claims 1 and 2 of the ‘703 patent to support their construction that "V[dd]" should be limited to an externally applied voltage. Claims 1 and 2 of the ‘703 patent are:

1. A method of selecting a word line in a dynamic random access memory to store a V[dd] logic level in a memory cell comprising:
   - applying a controlled supply voltage V[pp] greater than V[dd] to a level shifter circuit;
   - applying only V[dd] logic level signals to the level shifter circuit to produce a logic signal having a state at the V[pp] voltage; and
   - applying the logic signal having the state at the V[pp] voltage to the word line.
2. A method of selecting a word line in a dynamic random access memory to store a logic level in a memory cell comprising:
   - applying a controlled supply voltage V[pp], greater than the voltage stored in the memory cell, to a level shifter circuit;
   - applying only logic signals having a level less than V[pp] to the level shifter circuit to produce a logic signal having a state at the V[pp] voltage; and
   - applying the logic signal having the state at the V[pp] voltage to the word line. ‘703 patent, claims 1 and 2 (emphasis added).

The Defendants assert that claims 1 and 2 are identical except that claim 1 speaks of "a V[dd] logic level in a memory cell," whereas claim 2 simply speaks of "a logic level stored in the memory cell." According to Defendants, since claims 1 and 2 are independent claims, under the doctrine of claim differentiation, this difference must be significant and must mean that "V[dd]" means something other than a logic level stored in the memory cell, such as an externally applied voltage.

The Defendants' conclusion, however, is mistaken. The doctrine of claim differentiation does not require that two claims differ in scope. O.I. Corp. v. Tekmar Co. Inc., 115 F.3d 1576, 1582 (Fed. Cir. 1997) ("Although the doctrine of claim differentiation may at times be controlling, construction of claims is not based solely upon the language of other claims; the doctrine cannot alter a definition that is otherwise clear from the claim language, description, and prosecution history.") But even if it did, in this case, assuming that the two claims are of different scope does nothing to support Defendants' argument that "V[dd]" should be limited to an externally applied voltage. Significantly, '703 claim 2 does not require that the "logic level" stored in the memory cell be the only internal voltage on the chip. Accordingly, the '703 claims, like the '602 claims,
do not limit "V[dd]" to an externally applied voltage.

Dictionaries and treatises may also be informative of a claim term's ordinary meaning. Only one dictionary definition for "V[dd]" was submitted in this case. The Radio Shack dictionary states in pertinent part:

V[DD], V[SS], V[CC], V[EE] - In a MOS circuit, the designation of the power-supply terminal serving the drain, source, collector, or emitter. The double subscript refers to the power-supply terminal, while a single subscript references the parameter at the element of a device... In CMOS, the term V[DD] has been adopted as a convention referring to the positive power-supply terminal, although it is actually applied to the source of a p-channel transistor. Radio Shack Modern Dict. of Elecs. 794 (5th ed. 1978).

MOSAID submits this definition as evidence that the ordinary meaning of "V[dd]" includes internal voltages. Defendants contend that the Radio Shack definition supports its narrow construction. Defendants maintain that the definition, by using the word "terminal," indicates to one of skill in the art that V[dd] is supplied through an external connection. In support of this argument, Defendants submit a dictionary definition for "terminal," which is defined as "an externally available point of connection to one or more electrodes or elements within a device." IEEE Standard Dict. of Electrical and Electronics Terms 997 (4th ed. 1988). Defendants point to the word "externally" in that definition as evidence of the correctness of their proposed construction.

The dictionary definitions support a broader construction of "V[dd]." The Radio Shack definition of "V[dd]" does not limit "V[dd]" to an externally applied voltage. In fact, it suggests that "V[dd]" can be an internal voltage since it states that V[dd] can be "applied to the source of a p-channel transistor," and nothing requires that the source of a p-channel transistor be connected to the external pin of a DRAM chip. Likewise, nothing in the definition of terminal requires that V[dd] be externally applied to the DRAM chip. Although it does contain the word "externally," it does so in the context of external to "elements within a device," i.e., elements within the DRAM chip. Consequently, the ordinary meaning of "V[dd]" is "the substantially constant positive source-drain supply voltage in a MOS circuit."

The '602 specification does not alter the ordinary meaning of "V[dd]." The '602 specification includes statements about "V[dd]" such as: the "V[dd] level on the bit line 2A, 2B etc. is fully transferred to the associated capacitor," '620 col. 2, ll. 28-29; and the "signals at the voltage level V[dd] are applied to the inputs of NAND gate 5." '620 col. 3, ll. 15-16. Looking at Figure 1, it is clear that the bit lines and NAND gate 5 are internal circuitry of the chip. Therefore, the voltage being applied to these devices is an internal voltage that is not necessarily limited to an externally applied voltage.

Accordingly, "V[dd]" shall be construed as "the substantially constant positive source-drain supply voltage in a MOS circuit."

AMS and BidSoft contend that the term "vehicle condition grade" is incapable of being construed, although they offer no argument on this point. Manheim contends that the term should mean "a rating based on the condition of the vehicle."

"A claim is indefinite if its legal scope is not clear enough that a person of ordinary skill in the art could determine whether a particular composition infringes or not." Geneva Pharms., Inc. v. GlaxoSmithKline PLC, 349 F.3d 1373, 1384 (Fed. Cir. 2003). That is to say, a claim is indefinite if it "'is insolubly ambiguous, and no narrowing construction can properly be adopted.'" Invitrogen Corp. v. Biocrest Mfg., L.P., 424 F.3d 1374, 1383 (Fed. Cir. 2005) (quoting Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001)); see also Bancorp Servs., L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367, 1371 (Fed. Cir. 2004) ("We have held that a claim is not indefinite merely because it poses a difficult issue of claim construction; if the claim is subject to construction, i.e., it is not insolubly ambiguous, it is not invalid for indefiniteness.").

While the parties have not directed the Court to anything in the intrinsic record which would shed light on the proper meaning for this term, Manheim's proposed definition derives from the testimony of its expert, Dr. Bailey, who stated that
"one of ordinary skill in the art would understand [this term] to mean a rating based on the condition of the vehicle." (Bailey Decl. P 69.) In view of this testimony as to the understanding of one reasonably skilled in the art, and being presented with nothing to the contrary from AMS and BidSoft, the Court concludes that this term is not so "insolubly ambiguous" as to be rendered indefinite. As such, the term "vehicle condition grade" in claim 6 shall mean "a rating of the condition of the vehicle."

11. "vehicle sale type"

The parties dispute the meaning of the term "vehicle sale type" as that term appears in claim 1. AMS and Bidsoft contend that the term should mean "categories of auction events including regular sale, manufacturer sale, and heavy duty/truck sale." In support of their construction, they argue that the patentee served as its own lexicographer by clearly defining "vehicle sale type" in the specification and prosecution history, and as such, the inventors' definition should be applied. Manheim argues that one skilled in the art would understand this term to mean "a type of vehicle sale," and that AMS and Bidsoft's construction improperly imports a limitation from the specification and prosecution history.

It is well-settled that "a patentee is free to be his own lexicographer," Markman, 52 F.3d at 979, and thus may define claim terms in ways that differ from the common understanding of those skilled in the art. E.g., Renishaw PLC, 158 F.3d at 1249. However, in order for a patentee's definition of a claim term to be applied over the plain and ordinary meaning to one skilled in the art, the patentee must clearly set forth an explicit definition of the claim term which could differ in scope from that which would be afforded by its ordinary meaning. See Markman, 52 F.3d at 979 (explaining that the "caveat" to the rule affording the patentee the ability to specially define claim terms is that "any special definition given to a word must be clearly defined in the specification"); Mycogen Plant Sci. v. Monsanto Co., 243 F.3d 1316, 1327 (Fed. Cir. 2001) ("[A] patentee is free to be his own lexicographer, so long as the special definition of a term is made explicit in the patent specification or file history."). When the patentee chooses to act has his or her own lexicographer "by providing an explicit definition in the specification for a claim term . . . the definition selected by the patent applicant controls." Renishaw PLC, 158 F.3d at 1249.

The PTO initially rejected previously submitted claim 2 which included the term "sale calendar means" under 35 U.S.C. § 112, P 2, stating: "It appears from the specification that the sales calendar application allows the user to search the database for desired vehicles based on user criteria." (873 patent file history, May 9, 1997 Office Action [377-6] P 2.) In response, the applicants cancelled claim 2, but amended claim 1 to incorporate the limitations of claim 2, and explained that the term "vehicle sale type" referred to the type of sale, rather than the type of vehicle. (873 patent file history, Oct. 17, 1997 Response and Amendment [377-7] at 5.) Specifically, the applicants stated:

```
This module does not perform the function of searching by vehicle type; that is carried out in the Stock Locator module. The sale type refers to whether the auction is a "regular" sale (see Fig. 2-B), a "manufacturer" sale (see Fig. 2-C), or a "heavy duty/truck" sale (see Fig. 2-D)].
```

(Id.)

In the Court's view, this statement does not clearly and unambiguously offer a special definition for this claim term and explain how it would differ from its ordinary meaning. Rather, the statement, viewed as a whole, merely clarifies that the term "vehicle sale type" refers to the type of sale, and does not encompass a search for particular vehicles—a function performed by the stock locator module. While the applicants did refer to examples of certain sale types described in the specification, the Court views this statement merely as a clarifying reference, and not an explicit definition of the claim term. Therefore, the Court concludes that this statement is not sufficient to overcome the "heavy presumption" in favor of applying the ordinary meaning to a claim term. Apple Computer, Inc. v. Articulate Systems, Inc., 234 F.3d 14, 21 n.5 (Fed. Cir. 2000) ("[A] patentee must deliberately and clearly point out how these terms differ from the conventional understanding."). Accordingly, the term "vehicle sale type" in claim 1 shall mean "a type of vehicle sale which may include regular sale, manufacturer sale, and heavy duty/truck sale."
Claims in reexamination must "be given their broadest reasonable interpretation consistent with the specification, and limitations appearing in the specification are not to be read into the claims." In re Yamamoto, 740 F.2d 1569, 1571, 222 U.S.P.Q. (BNA) 934, 936 (Fed. Cir. 1984). In this case, the Bose Patent specification nowhere expressly defines "sound reproducing apparatus." Although the claims refer to "vehicle sound reproducing system" and "vehicle sound system," and the specification's "Background of the Invention" section states that "high fidelity sound systems for vehicles have met with wide acceptance," the background section does not purport to define Bose's "sound system" as limited to a "high fidelity sound system," and the claims do not require a "high fidelity" sound system. In any event, the definition of "high fidelity" given in the specification is simply: "faithfully transmitting sound signals." Thus, the Board's construction of the Bose claims as encompassing a vehicle sound reproducing apparatus generally and not as limited to a high fidelity audio "stereophonic" system for a car as Bose contends, is not in error.

Moreover, we do not view the Board's determination that a fiber-optic phone system is a system for faithfully transmitting sound signals as clearly erroneous. Nor do we find persuasive Bose's arguments that the "vehicle" limitation in the preamble precludes the Board's decision. Bose's specification does not limit a vehicle to a car, as Bose suggests, and his preamble refers to "vehicle" without further limitation. Thus, Reibaud suggests use of the claimed system in a "vehicle," as that term is used in Bose's claims. Moreover, the Board's finding that one skilled in the art would have had the motivation to utilize the technology disclosed in Electronics, or Cutler, in a vehicle is not clearly erroneous since the Electronics reference does not limit utilization of its technology to a particular environment and, indeed, invites utilization in various environments.

In anticipation of the potential finding that "vending machine" is more than simply a name for the invention, the parties dispute the meaning of this term. They agree that the general dictionary definition of vending machine is a coin-operated machine for vending merchandise. (See Pls.' Mem. On Claim Construction 10; Aly Decl. Ex. 9). This definition may inform the claim construction of vending machine, "so long as [it] does not contradict any definition found in or ascertained by a reading of the patent documents." Phillips, 415 F.3d at 1322-23. For example, the specification clearly contemplates payment other than by coins, so an appropriate construction will not limit "vending machine" to coin operation. (See '400 Patent 2:50-61). Similarly, payment is clearly required "to initiate a vending transaction," and both the Patents' specifications and the preamble to claim 1 describe the vending of telecommunications channel access, not merchandise. (See '400 Patent 2:43-45, 16:2-6, 12-17).

Although the dictionary definition describes "vending machine" as a single unit, plaintiffs still argue that vending machine should be construed as a system and method for vending services to multiple users contemporaneously, not as a traditional "single, stand-alone device" in a fixed location. (Pls.' Mem. On Claim Construction 11-12). If the Patents' specifications "reveal a special definition given to [vending machine] by the patentee that differs from the meaning it would otherwise possess," such lexicography must control the claim construction of that term. Phillips, 415 F.3d at 1316. According to plaintiffs, the inventors intended vending machine to include "various components . . . distributed in diverse locations, rather than located in a single device." (Id. at 12). Defendant criticizes this construction as not representing the view of a person of ordinary skill in the art and offers, instead, its expert's opinion that equates "vending machine" with "essentially a payphone for computers," as the patent specification diagrams "each show a vending machine that is a unitary, self-contained structure," and "[n]o figures in the . . . patents show it otherwise." (Cooley Aff. PP 15 and 26). In opposition, plaintiffs characterize Figure 4 as describing "not a single, stand-alone device, but . . . a block diagram. . . . including blocks representing the various components and functions that have to be present to provide telecommunications channel access," with "no requirement that the equipment providing those functions be combined into one single device." (Pls.' Mem. On Claim Construction 11). Plaintiffs' characterization disregards the fact that Figure 4, in fact, illustrates a single device labeled as item 300 in the diagram and described in the specification as the single machine to which users would connect. (See '400 Patent 11:41-43 and Fig. 4).
At the Markman hearing, plaintiffs cited the following specification language as supporting the contemporaneous use of one vending machine by multiple customers:

[I]t might be more cost effective to have one control unit operating multiple vending machines. These multiple vending machines may be arranged in the form of a kiosk to allow multiple customers access to the vending machine at the same time. Similarly, almost any combination of functional components of the vending machine could be moved to a location remote from the machine. This could be accomplished, for example, by networking a cluster of machines to a server either on site or at a remote location.

(‘400 Patent 4:28-37). This language describes multiple customers being served by multiple vending machines, not a single machine. That multiple vending machines may share a single control unit does not logically transform the multiple units into a single machine that serves multiple users. Plaintiffs’ argument that the sharing of a single control unit by multiple vending machines somehow converts the multiple machines into a single one effectively elevates the control unit to being the essence of a vending machine. Plaintiffs argue further that removing "any combination of functional components . . . to a location remote from the machine" leads to the same result, i.e., a single vending machine with multiple extensions. This position distills the essence of a vending machine into an undefined collection of whatever functional components are removed from the machine. Such construction is neither sensible nor supported by the specification or the claims, particularly claim 1 which clearly identifies several elements of a vending machine that must be present in order to embody the invention. Plaintiffs have not demonstrated that the Patents defined "vending machine" other than as a traditional stand-alone machine that serves a single customer at a time.

In light of the applicable legal standard, the parties' written submissions, and the argument of counsel, I construe the disputed claim language as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Court's construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vending machine</td>
<td>A device for vending telecommunications channel access to a single customer at a time when the customer provides sufficient payment</td>
</tr>
</tbody>
</table>

The disputed term "vending transaction" appears multiple times in claim 1, including in the context of "... at least one external telecommunications channel for enabling access ... at the beginning of a vending transaction and disabling access at the end of the vending transaction." (‘400 Patent 16:11-16). It is also included in the claim 1 phrase, "when the vending transaction is completed." Id. at 16:10-11. The parties agree that "when the vending transaction is completed" means "when the customer's connection to the vending machine has been terminated or the customer's payment has been exhausted." (Pls.' Mem. on Claim Construction 15; Def.'s Rebuttal Claim Construction Br. App. A). They disagree, however, about whether completing a transaction upon exhaustion of the customer's payment means that a customer may pre-pay for multiple access sessions and treat these as a single vending transaction. To that end, plaintiffs define "vending transaction" as "the transaction by which telecommunications channel access is provided to the customer in exchange for payment by or on account of the customer," while defendant proposes "a single open-ended session delineated by a turning on and off of access to the telecommunications channel ('pay-as-you-go') and does not include multiple session ('prepaid subscription')." (Pls.' Mem. on Claim Construction 15; Def.'s Rebuttal Claim Construction Br. 22).

The specification states that a "transaction ends when the customer disconnects from all of the connectors or otherwise indicates that the customer is finished." (‘400 Patent 2:67-3:1-2). According to the first preferred embodiment, a "transaction ends when the customer disconnects from the power connector and the telecommunications channel access connector or wireless connector . . . ." Id. at 6:27-29. Another embodiment provides that "[w]hen the customer is finished, they merely disconnect from the connectors and leave. The central control unit automatically senses this event [and] records the end of the transaction . . . ." Id. at 9:18-21. Later embodiments include "push-buttons that would allow the customer to select the language for the display, the connectors to be activated and, optionally, when to terminate the transaction. In the later case, the customer could push a button that would terminate the transaction and the connection, even though he had not disconnected from the connectors." Id. at 9:36-43. Yet another embodiment posits that "[w]hen the customer has stopped using both power and the telecommunications channel for six seconds, the program terminates the transaction by recording the stop time and turning off the switchable power circuit (when present), the switchable telecommunications channel (when
Neither these nor any other preferred embodiment describes a vending transaction as including more than one session. Moreover, in portraying the use of buttons or other means for terminating a session, the embodiments clarify the prior specification language that defines the end of a transaction as occurring either when the customer disconnects or "otherwise indicates" that the customer is finished. While the Federal Circuit "ha[s] repeatedly warned against confining the claims to [very specific] embodiments" and "strictly limiting the scope of the claims to the embodiments disclosed in the specification," it has also discouraged "divorcing the claim language from the specification." Phillips, 415 F.3d at 1323-24. Appropriate interpretation will consider the full context of the patent. See id.

For these reasons, I construe the disputed claim language as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Court's construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Vending transaction</td>
<td>A single open-ended session -- not multiple sessions -- initiated by payment by the customer and delineated by a turning on and off of access to the telecommunications channel</td>
</tr>
</tbody>
</table>

XIII. "Ventilation opening"

The term "ventilation opening" appears in claims 9 and 10 of the '925 patent.

A. The Parties' Proposed Constructions

Black & Decker construes the term "ventilation opening" as "a permeable opening [may include air or moisture permeable material]." Bosch counters that the term means "an opening in the enclosure so constructed as to provide for the circulation of external air through the enclosure to remove heat, fumes, or vapor."

B. The Construction Of "ventilation opening"

Bosch argues that Black & Decker's construction of "ventilation opening" is too broad because it would include any opening in the exterior surface of the radio allowing air or water to pass through. As an example, Bosch explained that the mere fact that a radio would fill with water if dropped into a lake would indicate that it had a ventilation opening under Black & Decker's proposed construction. Indeed, Black & Decker's construction is broader than the meaning of "ventilation opening" to a person of ordinary skill in the art at the time of the invention, based on the intrinsic record.

On the other hand, Bosch seeks to incorporate into the term "ventilation opening" the requirement that the opening provide for the circulation of external air through the enclosure to remove heat, fumes, or vapor. Bosch, however, does not point to any portion of the intrinsic record that specifically requires the circulation of external air. Both sides reference Figure 2 in the specification, showing a louver 25 that has a layer of hydrophobic air permeable material. While this embodiment shows that the ventilation opening allows air to pass through it, it does not expressly require from where the air comes, or how the air is used. Both sides also reference the prosecution history of the '059 patent, where the examiner states that "the use of such ventilation is well known [to] reduce the build up of heat within the radio enclosure." (R. 53-1; FH059072.) This statement reflects the understanding of the examiner as to the meaning of "ventilation opening" and closely tracks the last portion of Bosch's proposed construction, "to remove heat, fumes, or vapor." The Court adopts the construction as set forth in the prosecution history, modified slightly to track Bosch's proposed construction. The Court does not include any requirement that the opening provide for the circulation of external air, because the intrinsic record does not support that specific requirement. Also, the Court rejects Black & Decker's attempt to broaden the term "ventilation opening" to specifically allow for an opening that allows water to pass through it. Black & Decker does not point to any portion of the intrinsic record that supports such a construction. Conversely, the specification of the '925 patent emphasizes the importance of the radio enclosure being "moisture resistant" (col. 2, ll.25-27), "waterproof" (col. 2, ll.28-31), and "preventing moisture buildup" (col. 2, ll.32-34).
Accordingly, the Court construes the term "ventilation opening" as "an opening in the enclosure to provide for reducing the buildup of heat, fumes, or vapor, within the radio enclosure."

"Verifiable"

The second disputed claim term is the word "verifiable," as used in the phrase "verifiable digital cryptographic signature" contained in paragraph (c) of claim 1. Plaintiffs assert that "verifiable" should be construed in accordance with its plain and ordinary meaning as "possible to prove the truth of with evidence or testimony." In the context of the '954 patent, a "verifiable digital cryptographic signature" would then mean the provision of significant evidence of the identity of the agency that applied the digital signature. Defendant, on the other hand, offers a more restrictive interpretation of "verifiable" as meaning "indelibly incorporated into the digital data comprising the receipt in such a way as to make any change apparent and to deter the incorporation of a false time statement."

Under the rule in Vitronics, when interpreting a claim, terms are to be given their ordinary and accustomed meaning unless it appears that the inventor has clearly stated an alternative definition in the patent specification or the file wrapper. See Vitronics, 90 F.3d at 1582. There is no indication in the patent that the inventors intended a special meaning for this term. The term "verifiable" is used in the patent in a way that is consistent with its plain and ordinary meaning, and hence no alternative definition is necessary. Specifically, the '954 patent describes the word "verifiable" as providing "any member of the unlimited universe with significant evidence of the identity of the transmitter of the message." 14 Thus, a "verifiable digital cryptographic signature" shows that a particular time-stamp receipt was prepared by the outside agency applying the signature. And, contrary to defendant's assertion that "verifiable" includes deterring the application of a false time-stamp, the specification cites the well-known RSA verifiable signature scheme, which has nothing to do with the application of a time-stamp, as an example of a "verifiable digital cryptographic signature." 15

----------------- Footnotes -----------------

14 U.S. Pat. No. 34, 954, col. 2, ll. 15-18. The patent further states:

The TSA uses a verifiable signature scheme, of a type such as the public key method earlier noted, to certify the time-stamp prior to its transmittal to the author. Confirmation of the signature at a later time, such as by decryption with the TSA's public key, proves to the author and to the universe at large that the certificate originated with the TSA. Proof of the veracity of the time-stamp itself, however, relies upon a following different aspect of the invention[ i.e., the receipt-linking embodiment].

U.S. Pat. No. 34, 954, col. 3, line 66 to col. 4, line 7 (emphasis added).

15 See U.S. Pat. No. 34, 954, col. 6, ll. 29-39.

----------------- End Footnotes -----------------

Support for the conclusion that "verifiable" as used in claim 1 should not be construed to include deterring the application of a false time-stamp can be found in the receipt-linking time-stamping method, which does have a means of verifying the accuracy of the time-stamp. 16 In this method, the time-stamp prepared by the outside agency incorporates the time-stamp of the preceding and succeeding documents, which allows one to locate the position of a particular time-stamp in the chain
of time-stamps issued by that particular time-stamping agency, thereby providing some certainty as to the time of receipt of
the document by the agency. Claim 14 recites the limitations of the receipt-linking embodiment. Any attempt to read a
requirement of the proof of veracity of the time of receipt from claim 14 into claim 1 is forbidden by the Federal Circuit's
d Doctrine of claim differentiation. See Environmental Designs v. Union Oil Co., 713 F.2d 693, 699 (Fed. Cir. 1983). Thus,
defendant's proffered interpretation of "verifiable" cannot be adopted.

16 See U.S. Pat. No. 34, 954, col. 4, ll. 5-7.

II. Verify the Applicant's Identity
A. Construction of Claim Term

Each claim of the '007 Patent which is at issue in this action requires that the system "verify the applicant's identity." The
court construed this limitation as follows:

To "verify the applicant's identity" means to confirm or substantiate the applicant's identity. This is not limited to
checking biometric information and does not exclude verification using information such as name, address, and social
security number plus some additional information less likely to have been improperly obtained (e.g., mother's maiden name,
years at current address, years at job, etc).

Dkt No. 111 at 3-4 (emphasis in original).

In so construing the '007 Patent, this court declined to accept various limitations proposed by Federated (and aligned parties
in the related actions). For instance, the court declined to impose any requirement for a "biometric" form of verification
such as a electronic signature match.

Nonetheless, the construction adopted by the court recognizes that identity "verification" requires a check of information
which is qualitatively different from the specifically listed items of "name, address, and social security number." That
qualitative difference must be such as to make the information "less likely to have been improperly obtained" than the three
specifically listed items. Of the three listed items, the social security number would be the only one not generally available.
Nonetheless, as DCI correctly notes, the court's use of "such as" preceding the list of examples indicates that the list itself is
not exclusive.

AOL: "During receipt of real-time information confirming that the user's computer is functioning properly based on test
signals unrelated to the real-time information."

TWM: "Determine whether the computer is functioning."

The parties agree that this term should be constructed in alignment with the next term's construction. Therefore, for reasons
described in the Court's analysis of disputed claim 15, the Court adopts TWM's proposed construction.
The '311 patent is entitled "Method and Device for Simplifying the Use of a Plurality of Credit Cards, or the Like." It is directed to providing a method and device for storing information from various sources, such as credit cards, on one multifunction card. According to the specification, the invention "provid[es] the advantage of considerable simplification for the individual user and enormous advantages as regards safety against forgery and, generally, abusive use." '311 patent, col. 2, ll. 38-41. Claim 1 of the patent reads as follows:

A method for enabling a user of an electronic multi-function card to select data from a plurality of data sources such as credit cards, check cards, customer cards, identity cards, documents, keys, access information and master keys comprising the steps of:

transferring a data set from each of the plurality of data sources to the multi-function card;

storing said transferred data set from each of the plurality of data sources in the multi-function card;

assigning a secret code to activate the multi-function card;

entering said secret code into the multi-function card to activate the same;

selecting with said activated multi-function card a select one of said data sets; and

displaying on the multi-function card in at least one predetermined display area the data of said selected data set.

Claim 19, the only claim now asserted, is dependent on claim 1 and further requires the step of "storing a personal signature of the user on a central computer of the party issuing the data source and comparing the personal signature produced by the user with said stored personal signature to verify use of said card."

E-Pass asserts infringement of claim 19 by certain Personal Digital Assistants ("PDAs") sold by Hewlett-Packard as well as the Microsoft software that allegedly enables the PDA to perform the method of claim 19. Specifically, E-Pass asserts that claim 19 is infringed when a PDA is used to access data in an account on a central server that verifies a personal signature for entry into the user's account. E-Pass alleges that the PDA satisfies the "card" limitation in the claims. E-Pass has made the same assertion in other cases that have come before this court. E-Pass Techs. v. 3Com, 473 F.3d 1213 (Fed. Cir. 2007); E-Pass Techs. v. 3Com, 343 F.3d 1364 (Fed. Cir. 2003).

The district court granted summary judgment of noninfringement to Hewlett-Packard and Microsoft based on its construction of one of the claim limitations. Claim 19 requires a comparison of the personal signature of the user with a remotely stored signature to "verify use of said card." E-Pass asserts infringement of claim 19 when a PDA is used to access data in an account on a central server that verifies a personal signature for entry into the user's account. E-Pass alleges that the PDA satisfies the "card" limitation in the claims. E-Pass has made the same assertion in other cases that have come before this court. E-Pass Techs. v. 3Com, 473 F.3d 1213 (Fed. Cir. 2007); E-Pass Techs. v. 3Com, 343 F.3d 1364 (Fed. Cir. 2003).

II

On appeal, E-Pass argues that the district court misconstrued the requirements of claim 19 when it found that the claim required the entity that compares signatures to verify the use of the card. Instead, according to E-Pass, the signature comparison is meant to verify the identity of the user, and the "verify use of said card" limitation of claim 19 should be treated as completely independent of whether the card is being used.

The plain language of the claim supports the district court's construction, not E-Pass's. The phrase "verify use of said card" indicates that the signature comparison is performed so as to verify that the card is being used. Sometimes claim
construction "involves little more than the application of the widely accepted meaning of commonly understood words." Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005). This is such a case.

E-Pass argues that the signature comparison is meant to verify "the user's use of the [card]." and not the use of the card itself. In other words, E-Pass argues that it is the use to which the card is being put that is verified in claim 19, and that since the function of the card is to display the user's data at the request of the user, verification of that use involves verification of the user's identity. The problem with that argument is that to "verify use of said card" does not mean the same thing as to verify the identity of the user. To hold otherwise would be to rewrite the claim.

E-Pass also argues that verification through signatures personal to the user indicates that it is the identity of the user that is verified in the method step of claim 19. While it is true that verification of personal signatures effectively verifies the user's identity, that does not mean the claim does not require the use of the card to be verified as well. Indeed, both the patent claims and the specification indicate that claim 19 includes the card verification requirement.

The other claims of the patent indicate that verifying "use of the card" means something other than simply verifying signatures, which is all claim 19 would require under E-Pass's construction. Claims 2, 3, 7, 8, and 9 discuss "verifying the personal signature[s]" or "verifying said stored signature" by comparing a live signature with a stored signature. In contrast, claim 10 refers to "verifying proper use of said card" by comparing signatures while claim 19 refers to "verify[ing] use of said card." The difference in text between claims 2, 3, 7, 8, and 9 on the one hand, and claims 10 and 19 on the other, suggests that claims 10 and 19 should be construed to require verification that the card is being used. The only difference between those two groups of claims appears to be that the first group of claims requires the stored signature to be stored on the card. Accordingly, verifying the signatures in those claims necessarily verifies the use of the card and the identity of the user simultaneously; without the card there would be no stored signature against which the live signature could be compared. Claims 10 and 19, on the other hand, do not require the signature to be stored on the card. Verification of signatures alone would not necessarily verify the use and presence of the card, as required by those claims, although it would still verify the user's identity. n1

Accordingly, a terminology change would be required if and only if the patentee wanted to ensure that the use of the card was verified. Claims 10 and 19 contain such a terminology change, confirming the district court's construction of claim 19.

n1 Claim 10 reads as follows: "The method of claim 1, including the further step of verifying proper use of said card by comparing the personal signature of the user with a stored signature." Claim 10 is indifferent regarding where the signature is stored; it therefore appears to include the embodiment recited in claim 19, in which the signature is stored with a third party.

The specification provides further evidence that the language of claim 19 requires verification that the card itself is used, and not just verification of the identity of the user. As the district court noted, every embodiment in the specification requires that the card be used to complete the desired transaction. The patent describes three embodiments related to signatures: one in which the signature is stored on the card and verified by hand; one in which the signature is stored on a remote server and electronically or mechanically verified; and one in which the signature is stored on the card and electronically or mechanically verified. '311 patent, col. 5, ll. 11-14; col. 9, ll. 26-31; col. 9, ll. 48-50. In the first and third embodiments, the card must be present at the time of use to enable the signature comparison, and verification of the signatures necessarily verifies both the user and the use of the card. The description of the second embodiment, the embodiment captured by claim 19, also requires the card to be present before the signatures can be verified. As described in the specification, the card itself, in conjunction with a customized point-of-sale terminal, is used to "call up" the central database and retrieve the signature. Since the card is needed to retrieve the signature, comparing the signatures will verify both the use of the card and the identity of the user.

Additionally, in the description of the second embodiment—the only embodiment in which it might be possible to verify signatures without verifying the use of the card—the patent specifically indicates that the described process "verify[s] the inserted card." '311 patent, col. 9, ll. 30-31. Again, the card is verified in that case because the only way to retrieve the
signature stored by the third party is by using the card in the customized point-of-sale terminal. That singular description bolsters the pattern evidenced by the differences between those claims that "verify the card" and those that "verify the signatures." Throughout the patent, whenever the signature is not necessarily stored on the card the patent specifically indicates that the claimed method verifies the use of the card.

A requirement that the presence of the card be verified also makes sense in the context of the specification's description of the invention. One of the objects of the invention is "safety against forgery and, generally, abusive use." '311 patent, col. 2, ll. 38-41. Ensuring that the card is physically present and being used to access the user's data provides an extra measure of fraud prevention.

Since both the claims and the specification would lead a person of skill in the art to conclude that the language of claim 19 requires the party comparing the signatures to verify the use of the card itself, and not just the identity of the user, we hold that the district court correctly construed the disputed claim term. We therefore affirm the court's judgment.

J. Independent Claim 15 "verifying if the originator generated the payment transaction"

The magistrate judge recommended that the phrase "verifying if the originator generated the payment transaction" should be construed as:

"The originator must determine that the originator generated the payment transaction by comparing (a) the unique transaction identifier that has been returned to the originator with (b) a particular transaction with a record of unique transaction identifiers maintained by the originator."

First Report at 13. Both parties have filed objections.

1. Plaintiffs' Objections

Plaintiffs' objections to the magistrate judge's proposed claim construction of "verifying if the originator generated the payment transaction" in independent claim 15 are similar to those Plaintiffs raised in their objections to the magistrate judge's recommended claim construction of "validating," "verifying," and "variations thereof." Plaintiffs again object to the magistrate judge's use of the term "UTID" in his proposed claim construction, and ask the court to replace "UTID" with "transaction content." Plaintiffs contend that the recommendations of the magistrate judge improperly suggest importing the UTID limitation into Claim 15, violating both the general rule that limitation from the specification are not imported into the claims and eliminating claim differentiation between claim 15 and claim 18. See Pl. Obj. to First Report at 13. Plaintiffs propose substituting the term "transaction content" for "UTID." Plaintiffs proposed claim construction of "verifying if the originator generated the payment transaction" is: "The originator must determine that the originator generated the payment transaction by comparing the transaction content that has been returned to the originator with a record of unique transaction identifiers maintained by the originator." Pl. Obj. to Second Report at 13 (emphasis added).

In support of the insertion of "transaction content" for "UTID," Plaintiffs contend the magistrate judge's recommended claim construction of "verifying if the originator generated the payment transaction" in independent claim 15 improperly imports the UTID limitation from the specification into claim 15 and violates the principles of claim differentiation by eliminating the differences between claim 15 and claim 18. Plaintiffs once again recite those instances in the specification where validation may be achieved by referencing the UTID "and/or the transaction content." See supra at 31 (summarizing Plaintiffs' arguments in support of inserting an "or" into magistrate judge's proposed claim construction of "validating," "verifying" and "variants thereof."). Based on these instances, Plaintiffs contend that the magistrate judge's recommended claim construction, which does not include "transaction content," improperly imports the UTID requirement from the specification into the claims. Plaintiffs also argue that claim 15 does not explicitly embody a requirement that a UTID be used. Therefore, the magistrate judge should not read a UTID requirement into the claim. Pl. Obj. to First Report at 14 (and cases cited therein). With regard to Plaintiffs' contention that the magistrate judge's recommended claim construction is contrary to the doctrine of claim differentiation, Plaintiffs argue that claim 18 adds a limitation not present in claim 15 regarding a "unique identifier." "If a 'unique identifier' is equivalent to a 'unique transaction identifier,' then the Recommendation's construction eliminates the claim differentiation between independent
claim 15 and dependent claim 18." Id. Finally, Plaintiffs recognize that a patentee may demonstrate its intention to limit the claim scope using "words or expressions of a manifest exclusion or restriction." Id. at 14-15 (citation omitted). Plaintiffs contend that such phrases would include claims that the invention "always" uses a UTID or "cannot be performed without" a UTID. See id. Plaintiffs argue that no such disclaimer occurred here, and that the language in the Petition Statement upon which the magistrate judge relied "merely expresses a preference for an embodiment using a UTID." Id.

In response, Defendants contend that the court should reject Plaintiffs' objections since the proposed modification (replacing "UTID" with "transaction content") "has no support in the specification and attempts to re-claim material that the applicants disclaimed in the prosecution history." Def. Resp. to Pl. Obj. to Second Report at 17. The court agrees.

As already set forth in detail above, in the Petition Statement, VMachine distinguished the "pending claims" and the "claimed invention" over prior art based on the invention's use of a UTID. VMachine applied the limitation globally, not just to "some claims." The magistrate judge, recognizing the importance of the intrinsic record, concluded that the Petition Statement "makes clear that the presence of a unique transaction identifier is a necessary element to the applicants' claims which distinguish them from prior art. Therefore, the materials before the court support a construction of claim 15 which requires the utilization of a unique transaction identifier." First Report at 9. The magistrate judge not only relied on the prosecution history, but also on the specification since "in the summary of the invention, the utilization of a unique transaction identifier was prominently noted as a method for minimizing the potential for fraud." Id. at 9 n.3 (citing col. 3 lines 23-31). As the court stated previously in overruling similar objections, it is confident based on the specification and the prosecution history, that it is not importing limitations from the specification into the claim. 13 See generally Phillips, 415 F.3d at 1323 ("[T]he distinction between using the specification to interpret the meaning of a claim and importing limitations from the specification into the claim can be a difficult one to apply in practice."). Moreover, any doubt is overcome by the prosecution history. See supra. Regarding the doctrine of claim differentiation, the court first notes that claim 18 contains a limitation beyond claim 15, namely, with regard to the first and second verification requests, claim 18 recites "attaching" the identifier with "the transaction order." As claim 18 is narrower on its face than claim 15, the doctrine of claim differentiation is not triggered. Moreover, as already stated above, the prosecution history in this case overcomes the presumption of claim differentiation. See Seachange International, 413 F.3d at 1369 (doctrine of claim differentiation is "not a hard and fast rule and will be overcome by a contrary construction dictated by the written description or prosecution history.").

--- Footnotes ---
13 The "Summary of Invention" describes the invention as using a UTID that has been generated by the originator. The "Abstract" on the first page of the '878 patent also states that "verification" of a transaction occurs through use of a UTID generated by a purchaser (originator).
--- End Footnotes ---

Based on the foregoing analysis, the court overrules Plaintiffs' objections to the magistrate judge's recommended claim construction of "verifying if the originator generated the payment transaction" in independent claim 15.

2. Visa's Objections

In its objections, Visa contends that the magistrate judge's recommended construction contains a typographical error as to the placement of the "(b)." According to Visa, the "b" in the magistrate judge's proposed definition should be moved to after the phrase "a particular transaction," rather than before it. Visa's proposed claim construction thus reads as follows: "The originator must determine that the originator generated the payment transaction by comparing (a) the unique transaction identifier that has been returned to the originator with a particular transaction with (b) a record of unique transaction identifiers maintained by the originator." Visa argues that the magistrate judge's discussion and the prosecution history make clear that the UTID and transaction are returned together to the originator; thus both the UTID and transaction should be included under heading "(a)." The originator then compares the UTID for that transaction with the record or listing of UTIDs maintained by the originator for the transactions performed by that originator; thus the record of the UTIDs should be under heading "(b)." The court agrees that the comparison is between "(a) the UTID for a particular transaction that has been returned to the originator" and "(b) the record of UTIDs for transactions performed by that originator." See Def. Obj. to First Report at 7. Accordingly, the court sustains Visa's objection to the placement of "b" in the magistrate judge's proposed construction of "verifying if the originator generated the payment transaction" in independent claim 15. The court construes "verifying if the originator generated the payment transaction" in independent claim 15 as: "The originator must determine
that the originator generated the payment transaction by comparing (a) the unique transaction identifier that has been returned to the originator with a particular transaction with (b) a record of unique transaction identifiers maintained by the originator."

3. "Verifying" and Authenticity

Again, Claim 1 of the '581 patent recites the following: "a switchyard for directing accelerated beam from the accelerator to a selected one of the treatment rooms . . . comprising the steps of: (a) receiving a beam request signal from one . . . treatment rooms; (b) verifying the authenticity of one of the beam request signals from one of the treatment rooms."

(Rosenberg Decl. Ex. 2, the '581 Patent at 9:9-10.) Plaintiff argues the terms "'verifying' and 'authenticity' have well understood ordinary meanings." (Optivus P.&A. at p.15.) Relying on common dictionary definitions and intrinsic evidence, Plaintiff Optivus offers the following definition for the term at issue, Claim 1 step (b): "to confirm that one of the beam request signals from one of the treatment rooms is a valid request for the beam." (Optivus P.&A. at 15-16.)

Defendant, on the other hand, contends the term "verifying" is indefinite. (Ion Beam P.&A. at 12:16-19; see also Lennox Decl. at P 37.) Defendant Ion Beam's argument is conclusory and relies exclusively on the summary opinion stated by Dr. Lennox. (See id.) Moreover, Defendant Ion Beam suggests elsewhere that a similar term, namely "confirming," is perfectly clear. (See id. at 14:23-25.) Indeed, Ion Beam proffers the following definition of the disputed claim term: "confirming by comparison that at least the beam request signal is in agreement with another signal or value indicating the origin of the requesting treatment room." (Id.) Comparing the alternate definitions offered by Plaintiff Optivus and Defendant Ion Beam, it appears that both parties have simply replaced the claim term "verifying" with the word(s) "to confirm" or "confirming." (Compare id.; and Optivus P.&A. at 15-16.) Accordingly, the parties seem to agree that "verifying" means "confirming." 19

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

19 Defendant Ion Beam insists that "verifying" means "confirming by comparison." (Ion Beam P.&A. at 14-15.) However, the notion of "comparison" nowhere appears in the actual claim terms. Ion Beam asks the court to import the limitation of "comparison" from the patent specification. But that would probably be reversible error. See, e.g., Texas Digital Sys., 308 F.3d at 1204. The term is not ambiguous. Accordingly, there is no reason to resort to the patent specification in order to clarify the meaning of the term. Schering v. Amgen Inc., 18 F. Supp. 2d 372, 380 (D. Del. 1998), aff'd, 222 F.3d 1347 (Fed. Cir. 2000). Moreover, there is nothing in the patent specification suggesting the court must import the limitation "by comparison" to qualify the term "verifying." The '581 patent sets out, in the summary of the patent, the following language: "The verification and authorization steps may comprise comparing the beam request signals with a beam path. . . ." (Rosenberg Decl. Ex. 2, the '581 Patent at 1:39-41, emphasis added; see also the '581 Patent at 5:44-6:50.) If the patentees wanted to introduce such a limitation, they would have used more definite language, as they did in Claim 2 of the '581 patent: "The method of claim 1 wherein steps (b) and (c) comprise comparing the beam request signal with a beam path configuration signal." (Id. at 9:13-15.)

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

This construction is otherwise confirmed by common dictionary definitions. Webster's Third, for example, defines "verify" as "to confirm or establish the authenticity or existence of by examination, investigation, or competent evidence." (Airhart Decl. Ex. N at 232.) The following definition is found in the American Heritage Dictionary of the English Language (4th ed. 2000): "To determine or test the truth or accuracy of, as by comparison, investigation, or reference: . . . See Synonyms at confirm." Available at http://dictionary.reference.com/search?q=verifying. Moreover the Oxford English Dictionary includes the following definition: "In general use: To testify to, to assert, to affirm or confirm, as true or certain." OXFORD ENGLISH DICTIONARY (2d. ed. 1989). Accordingly, the court finds the meaning of the term "verifying" is abundantly clear and it means "to confirm or establish the authenticity, truth or accuracy." In the context of Claim 1 step (b), the court hereby adopts the following construction: "to confirm or establish the authenticity of one of the beam request signals from one of the treatment rooms."
4. "Authenticity"

Defendant Ion Beam refers the court to the following dictionary definitions of the term "Authenticity": "the condition or quality of being authentic, trustworthy, or genuine" and "having an undisputed origin; genuine." (Ion Beam P.&A. at 16:3-11.) Plaintiff Optivus does not disagree with this definition. (Optivus Opp'n at 13-14.) Accordingly, the entire phrase of Claim 1 step (b) is hereby constructed as "to confirm or establish the genuine or trustworthy nature of one of the beam request signals from one of the treatment rooms."

15. "VERIFYING THE OPERATIONAL STATUS OF THE USER'S ACCESS TO THE COMMUNICATIONS NETWORK DURING DELIVERY OF THE REAL-TIME INFORMATION"

AOL: "During receipt of real-time information, confirming the user's connection to the network is functioning properly, based on test signals unrelated to the real-time information."

TWM: "Determining whether the user's connection to the communications network is functioning while real-time information is being transmitted."

AOL argues that the "operational status" means "properly functioning." (D.E. 68, pgs. 16-17). TWM counters that operation status means "functioning," and that including "properly" would be superfluous. (D.E. 69, pg. 22). The question, then, is whether the word "properly" to modify "functioning" is necessary. AOL buttresses its argument by pointing to specification language describing "operational status" as "working and active." TWM points to specification language describing "operational language" as "up and running." Both arguments have merit. Describing a system as "working and active" does intimate that the system is properly functioning. And describing "up and running" does suggest that the system is merely functioning, whether or not in the proper manner. Whether to add "properly" to modify "functioning" would be a close call.

However, this term has not one, but two, disputes at issue. Specifically, the second dispute is whether the verification PING signals is based on "real-time" connections. AOL argues that the specification requires sending Pings over a separate network connection unrelated to the delivery of real-time information, e.g., the song being streamed. An inspection of the specification reveals, in contrast, that the preferred embodiment uses the TCP/IP and Ping methods for communications between the media server and the user. The preferred embodiment continues that when the media server receives a valid "play" command, it initiates real-time audio delivery to the user. The user in turn sends notification to the media server that information has been received through the TCP network, which remains open during the audio play operation, or through the UDP port. Therefore, the pings might be sent via the UDP port or the TCP network. Because the pings could travel on either, and the TCP network provides real-time information, AOL's suggestion that the specification requires verification "unrelated to the real-time information" is incorrect. The Court adopts TWM's proposal.

Whether Chemical Mechanical Polishing is Vertical Anisotropic Etching.

In the claims construction, the Court ruled that etching is defined as removing material. Boning's position is that the process used by Tower and UMC is chemical-mechanical polishing. He explains that this is a method for removing elevated portions of the exposed surface of a wafer. It is used primarily for the purposes of planarizing the wafer surface of defining structures. The mechanization process operates to chemically soften (often through oxidation) a shallow layer of the exposed surfaces of the wafer and then remove the softened layer by making sub-microscopic scratches across the oxidized surface using the abrasive particles of the slurry. The chemical agent in the slurry modifies only the exposed surfaces of the wafer surface. Only after the abrasive particles have removed the top exposed layer can the oxidizing agent modify the newly exposed wafer material, and the next layer can then be "scratched" away. In essence, he defines this process as a horizontal process rather than a vertical process.
2. Very long instruction words.

Intergraph invokes fundamental rules of claim construction and asserts that the phrase "very long instruction word" is specifically defined in the claims of the '028 patent as "having a predetermined number N of instructions and including at least one group of M individual instructions to be executed in parallel, where M is less than or equal to N." Intel contends that "VLIW," when employed in the context of a "wide-word" processing architecture, carries with it a definition standard
among those skilled in the art at the time the '028 patent was filed. Accordingly, Intel proposes a construction drawing upon the traditional definition of VLIW discussed in the patent's specification, but augmented by specific limitations it derives from Figs. 7, 10, & 11 of the '028 patent. In sum, Intel proposes the term "very long instruction word" as used in the claims should mean a fixed width frame containing at least 2 tightly packed groups of instructions, each instruction within each frame having a group identifier and a pipeline identifier contained therein.

1 Whether the term "very long instruction word" used in the claim was meant to embrace the same concept as the acronym "VLIW" used in the context of "wide-word" processing architecture is a matter for the Court. The patents only use VLIW in describing the prior art and purpose of the proposed invention. In the claims, however, the patentee repeatedly uses the phrase "very long instruction word," not "VLIW." Accordingly, the Court construes the term "very long instruction word."

The Court construes "very long instruction word" as a fixed-width instruction that encodes multiple operations. '028 patent at 1:64-66; 5:23-25. A "very long instruction word" may contain one or more groups of individual instructions. Id. at 5:25-28.

2. "Via the Modular Connector"

Although the parties purport to disagree over the construction of these combined terms, in essence the real dispute is over the implication of this language on the construction of the remaining terms of the claims, specifically "electrically couple." Defendants ask that I construe "via modular connector" as "by way of an electrical connector constructed with standardized units or dimensions," which in turn requires adopting the construction of "electrical couple" as a direct wire-to-wire connection with equal voltage. Plaintiffs agree with the definition of "modular connector" but not of "via." Plaintiffs construe these combined terms simply to mean "through an electrical connector constructed with standardized units or dimensions," and not requiring a direct wire-to-wire connection with equal voltage. I agree with plaintiffs.

a. Intrinsic Evidence

"Via the modular connector" does not appear in the remainder of the specification, so once again both parties argue its context in the claim language supports their construction. Defendants argue the phrases "electrically couple" and "via the modular connector" must be read together, and because coupling occurs "by way of the modular connector" it is clear that the coupling is direct and wire-to-wire. Plaintiffs argue defendants' construction is not consistent with the remainder of the claim language and that "electrically couple" and "via the modular connector" need not be interpreted together as requiring direct contact, for "via the modular connector" only appears once in claim 1 and claim 8 respectively, and the term
"electrically couple" is used a number of times in other claims without the term "via the modular connector." Similarly, the term "modular connector" is previously identified in the claim, independent from "electrically couple."

As set forth in claim 1, "the first cable assembly is configured to be electrically coupled to each of the plurality of cable assemblies via the modular connector." Once again, the structure of the invention as set forth in the language of the claims and specification weighs in favor of plaintiffs' construction. For one, the modular connector is identified as a separate part of the invention, therefore the text could be read as "electrically coupling" two separate parts of the invention, via a third distinct part. Accordingly, the electrical connection among the cable assemblies is not direct, but through a third part - the modular connector. Furthermore, although the first cable assembly is electrically coupled to the second cable assembly through the modular connector, i.e. electricity travels from the first cable assembly through the modular connector and into the second cable assembly, there is no requirement that the modular connector on the first cable assembly be directly connected to the second cable assembly. Electrical power can travel from the first cable assembly through the modular connector, through the mounting member, and to the second cable assembly. An electrical connection would still exist among these parts, via the modular connector, despite their failure to have a direct, wire-to-wire connection. This is consistent with the adopted construction for "electrically couple" as well.

Defendants also point to the remainder of the specification for an example consistent with their proffered definition. In the example, the modular connector is common to all the cable assemblies at the junction of the first cable issuing from the reel and the camera cable. (See '994 Patent, Figs. 1, 2.) Defendants also invoke U.S. Patent No. 5,094,396 ("the '396 patent"), which is referred to in the specification of the '994 patent when describing a cord reel. However, "particular embodiments appearing in the written description will not be used to limit claim language that has broader effect." Innova/Pure Water, 381 F.3d at 1117 (citations omitted). The examples in the specification, including the referenced '396 patent, simply do not dictate the claim terms be construed to require a direct, wire-to-wire coupling among all parts identified as "electrically coupled." See Ventana Medical Systems, Inc. v. Biogenex Laboratories, Inc., 473 F.3d 1173, 1180 (Fed. Cir. 2006) ("district court improperly imported limitations from the specification.") This would be inconsistent with the claim language.

Defendants also resort to the prosecution history of the '994 patent. The term "modular connector" was added to claim 1 in order to distinguish plaintiffs' invention from the art of record. As already discussed, however, the plaintiffs do not dispute defendants' construction of "modular connector," but of "via." Neither party points to any part of the prosecution history which elaborates on this term. Defendants do argue, without any citation to the record, that "the '994 patent application points out the structure of such a modular connector at the distal end of the first cable assembly mates with the proximal end of the second cable assembly." (Def. Markman Br. at 23.) Even assuming the record supports this assertion, defendants fail to explain why this makes the proper construction of "via" "by means of" instead of "through" and why this requires "electrical coupling" occur only through direct wire connections.

The intrinsic evidence does not contain language limiting the term to require direct wire-to-wire coupling or equal voltage. Neither the claim language nor specification restrict the claims to require a direct wire-to-wire connections among all the parts that are identified as "electrically coupled." The fact that the claim states that the modular connector serves to "electrically couple" certain parts is not enough to read in the limitations included in defendants' construction.

b. Extrinsic Evidence

The dictionary definition provided by defendants for "via" is "by way of" or "by means of." This is not inconsistent with plaintiffs' construction, nor is it of much significance in determining whether "via" requires a direct wire connection with equal voltage.

Overall, in light of all of the intrinsic and extrinsic evidence, I adopt plaintiffs' construction for "electrically couple" as "electrically connected" without requiring a direct, wire-to-wire connection. Similarly, I adopt plaintiffs' construction for "via the modular connector" as "through" the modular connector, but without requiring a direct wire-to-wire connection or equal voltage.

4756

video buffer image within said host computer
Claim 1 contains the term "video buffer image within said host computer." Accolade contends that "video buffer image within said host computer" means "information stored within the host computer which can be used to display an image." Citrix contends that the term means "a bit mapped (or pixel mapped) version of the image currently displayed on the screen of the host computer that is stored in memory of the host computer." Alternatively, Citrix argues that the term means "a bit mapped (or pixel mapped) version of the image currently displayed on the screen of the host computer, if it has one, that is stored in memory of the host computer." The parties generally dispute the limitations found in their proposed constructions. The Court preliminarily construed the term as "the bit mapped (or pixel mapped) version of the image currently displayed on the screen of the host computer, if it has one, that is stored in memory of the host computer."

In light of further consideration, the Court modifies its earlier preliminary construction of "video buffer image within said host computer" and construes this term as "video image data that is stored in memory within the host computer and is currently available for display." The Court does not adopt Citrix's proposal that includes "bitmapped (or pixel mapped)." Citrix's supporting excerpt from the specification states, "The actual image is taken from the video buffer of the host computer within the range specified by the rectangle. Preferably, the bit mapped (or pixel mapped) image taken from the video buffer is compressed . . . before transmission over the internet." U.S. Patent No. 7,100,069 Patent ("the '069 patent") (incorporated by reference into the '888 patent, col. 1:13-19), col. 13:7-13 (emphasis added). 6 While this excerpt makes reference to an image being "bit mapped (or pixel mapped)," the language used does not reach the level of creating a limitation. See Arlington Indus., Inc. v. Bridgeport Fittings, Inc., 345 F.3d 1318 (Fed. Cir. 2003) (declining to limit the claims from language in the specification where there was no indication in the written description that the patentee acted as her own lexicographer and there was no express disclaimer). The '069 patent reference does not provide any evidence of disclaimer or that the patentee acted as his own lexicographer. Thus, the Court does not adopt "bit mapped (or pixel mapped)" in its construction.

The Court also modifies Citrix's proposed language "currently displayed," and instead uses "currently available for display." The prosecution history states, "The present invention also teaches transmitting image information from the host computer to the client computer whereby the image information includes a portion of the video buffer image of the host computer. In this manner, the client program of the client computer may simulate the monitor of the host computer." Defs.' Br., Ex. 9 (11-13-00 Amendment B), 6. This language indicates that the invention includes an ability to display on the client computer the image currently being output for display on a monitor connected to the host computer, and thereby simulate the monitor of the host computer. Also, the fact that video image data in the video buffer is inherently available for current display confirms this interpretation of the prosecution history. Because the host computer may or may not include a monitor, the Court does not adopt "currently displayed" and instead uses "currently available for display."

Additionally, the Court's construction stating that image information "is stored in memory" is supported by the plain and ordinary meaning of buffer. The parties agree that video buffer is commonly understood to connote memory. See Defs.' Br. 39; see Accolade's Mot. to Recons. Prelim. Claim Constructions 4-5. Thus, the plain and ordinary meaning of buffer is used to construe the claim term. Accordingly, the Court construes "video buffer image within said host computer" as "video image data that is stored in memory within the host computer and is currently available for display." 7

6 The '888 patent makes reference to U.S. Patent Application Ser. No. 08/798,703, which became the '069 patent. See Defs.' Br. 37 n.11. Both parties refer to the '069 patent. See id.; Pl.'s Reply Br. 14.

7 No dispute exists as to the remaining language used in the Court's construction, "within the host computer," or "video image," which are taken directly from the claim language.
C. "Video Camera"

"Video camera" is found in claims 1, 7, and 16. Geospan again argues that no construction is necessary because "video camera" is used in the claim in accordance with its plain and ordinary meaning and will be well understood by the jury. J. Claim Constr. Stmt. at 7. Pictometry proposes the following construction: "An apparatus that converts an optical image into an electronic image that can either be displayed on a monitor or recorded onto magnetic tape to be replayed later." Id. In layman's terms, Pictometry's proposed construction would limit the claim term to analog, as opposed to digital, video cameras.

Pictometry contends the claim term "video camera" would have been understood to a person of ordinary skill in the art at the time of the invention, 1994, to be an analog video camera. In addition, Pictometry claims that the specification consistently describes a "video camera" solely in terms of an analog device by its references to "video tape recorder," "video monitor," and "video tapes." '946 patent, cols. 3:56-57, 5:58-6:2.

Geospan responds that because the plain and ordinary meaning of "video camera" includes both analog and digital video cameras, it would be improper to read the limitation "analog" into the claim term "video camera." In support, Geospan cites SuperGuide Corp. v. DirecTV Enterprises., Inc., 358 F.3d 870 (Fed. Cir. 2004). There, the alleged infringer argued, and the district court agreed, that people skilled in the art at the time of the patent, 1985, would have understood the claim terms "regularly received television signal" and "radio frequency information" to mean analog television signals that were being broadcast in 1985. Id. at 878. Further, the alleged infringer argued that nothing in the specification or prosecution history suggested that the patentees gave a different meaning to the claim terms. Id. The Federal Circuit reversed, concluding that although the alleged infringer's argument appeared "persuasive at first blush," a "closer analysis of the intrinsic record" did not support the proposed instruction because the claim language did not limit the disputed terms to any particular type of technology or specify a particular type of signal format and neither the word "analog" nor "digital" appeared anywhere in the asserted claims. Id. The court held, therefore, that the district court erred by concluding that "after-arising technologies," namely, digital technology, could not fall within the literal scope of the claim terms. Id. The court stressed that there was "little doubt that those skilled in the art knew of the existence of digital video [technology]" at the time of the invention, 1985, and that the patentees were "at least aware" that digital signals could be broadcast in the future, even though the technology may have been in its "infancy." Id. at 879, n.6.

The Court agrees with Geospan that this case requires the same conclusion reached in SuperGuide. If it can be said that those skilled in the art of television broadcast transmissions were aware of digital video technology in 1985, surely there can be no doubt that those skilled in the art of photogrammetry also were aware of digital video technology nine years later in 1994. Had the inventors intended to limit "video camera" to analog technology, "they could have easily done so by explicitly modifying the disputed claim language with the term 'analog'". Id. at 880. Nothing in the language of the claims or in the specification's description of the invention precludes the invention from using digital, as opposed to analog, video cameras in capturing video images.

Pictometry next argues that during the prosecution history of the '946 patent, the inventors consistently described a "video camera" through terminology associated with an analog video camera. Specifically, the inventors stated, in attempting to distinguish prior art, that they had amended the claims to "further define the method of the present invention and now state that the video images are recorded on a video tape . . . ." Hobson Decl., Ex. 5 at 4-5. Similarily, the inventors stated:

In order for the data collected according to the present invention to be usable for short range terrestrial photogrammetry, which differs from traditional stereophotogrammetry . . . . it is critical that for each recorded image the position of the video camera from which the recorded video image was obtained, be precisely known. . . . In particular, for each frame of the video tape on which video images are recorded, the video equipment controller provides the control computer with SMPTE time code of the frame on which the video tape recorder is recording . . . .

Id. at 6-7.

As with the prosecution statements cited by Pictometry in connection with "moving platform," the prosecution statements
cited in support of Pictometry's construction of "video camera" fail to show a clear and unmistakable disavowal of scope. The inventors' efforts to distinguish prior art did not seek to do so on the basis that the prior art captured video images through a digital video camera and recorded associated spatial position data in a digital format, whereas the invention in the '946 patent was confined to analog video cameras to capture video images and the recording of associated spatial position data in an analog format. Instead, the efforts were aimed at distinguishing the prior art on other bases, in particular the prior art's reliance on stereovision and the detail with which the spatial position data of the cameras is recorded and associated with captured video images.

The Court concludes that an examination of the intrinsic evidence reveals that no construction of "video camera" is necessary because the term is used in the claim in accordance with its plain and ordinary meaning to one skilled in the art and is not limited to analog video cameras. Accordingly, the Court need not examine extrinsic evidence.

GO BACK

4758

Claim 1 of the 849 patent recites, inter alia, "(f) a video combiner connected to said symbol generator and to said display computer for processing said symbol producing signals and delivering them to a selected display device . . . ." The district court construed the term "selected" to require that the claimed invention have (1) the capability to be attached to multiple display devices, and (2) the capability to project different images on different displays.

The district court's interpretation of section (f) is consistent with the specification, which makes clear that the claimed invention is capable of delivering different images to different display devices. The specification discloses that one of the objects of the invention is "to provide in a data converter means whereby the resulting picture of the symbol may be distributed to different display devices," 849 patent, col. 1, ll. 49-52, and teaches that "the video combiner acts as a video distributor in that it routes the output of each symbol to an appropriate display device on which the given symbol is to be displayed," 849 patent, col. 3, ll. 26-29.

The district court's construction of section (f) is also consistent with a statement made to the PTO during the prosecution of the 849 patent. In responding to a rejection by the examiner, Mr. Okor distinguished his invention from the Wagner prior art reference by stating that "Wagner's system does not allow for the selective positioning of symbols on different display screens." Mr. Okor's statement distinguishing the Wagner reference indicates that the term "selected" in section (f) of claim 1 refers to the ability to display different images on different display devices.

Mr. Okor challenges the district court's claim construction by citing to the following disclosure in the specification:

If there is more than one display device, it is necessary to know on which display devices to display each symbol. The selector word (S) tells the video combiner 24 where each symbol is to be displayed. The length of the selector word (S) is equal to the number of display devices. If the bit at location i of selector word (S) of symbol j is one, then symbol j could be displayed on display device i.

849 patent, col. 5, ll. 53-59. Mr. Okor argues that this disclosure does not preclude a mode of operation in which all the bits of the selector words are set to one, so that all symbols appear on only one display. According to Mr. Okor, the patent does not require that the claimed invention have the capability of being attached to multiple display devices, but contemplates that it can permanently select a single display device. Although Mr. Okor's argument is correct, it does not advance his position with respect to summary judgment. Even though all the bits of the selector words can be set to a single display device, the claimed invention still has the capability of selecting more than one device. For a "selection" to take place, more than one option must exist. In sum, the claim language, the specification, and the prosecution history persuade us that the district court's construction of section (f) of claim 1 is correct.

B. "video data"; "video pixel data"; "data set"; "image data set"; "the video data"; "the video pixel data"; "said video pixel data"; "the data sets"; "said image data sets"
1. The Parties' Proposed Constructions

The parties' dispute respecting these terms centers on the meaning of the term "data" when it is used in the context of a video still store system. The parties also disagree about the relationship between the first reference to "data" in each claim and subsequent references to "said data" or "the data." Ampex asserts that "data" should be construed to mean "information, in any form, representing a video image." (D.I. 305 at 7-8.) Ampex then argues that "said/the data" means "data representing the same image as the antecedent data." (Id. at 9.) In other words, the later referenced "data" need not be exactly the same as the initial "data," as long as it represents the same image. (D.I. 300 at 20-21.) Ampex claims support for its proposed claim construction in the preferred embodiments of the invention and the specification of the '121 patent. (Id. at 21-22.) Ampex also relies on extrinsic evidence, including dictionary definitions, expert testimony, and the claim construction arguments made by Kodak during licensing discussions with other companies. (D.I. 307, Exs. 16, 17; D.I. 346 at 13-14.)

Defendants assert that "data" simply means "numerical information." (D.I. 305 at 7.) In line with this proposed construction, Defendants argue that "said/the data" can only mean "the data that is first referenced in the claims." (Id. at 9.) Thus, Defendants contend that any subsequent use of the term "data" in the form "said/the data" refers to the same numerical information as the initial use of the term. (D.I. 299 at 10, 13.) The basis for Defendants' asserted claim construction is the claim language, specification, and prosecution history of the '121 patent, as well as extrinsic evidence in the form of dictionaries and expert testimony. (Id. at 9-13.)

While the parties' arguments focus almost exclusively on the meaning of "data," none of the claims in the '121 patent use the term "data" by itself. Rather, claims 7, 8, 11, and 14 use the term "video pixel data" ('121 patent at 6:23-48, 6:49-7:20, 7:65-8:14, 8:65-10:7), claim 10 uses the term "video data" (id. at 7:31-64), claim 12 uses the term "image data sets" (id. at 8:15-47), and claims 13 and 15 use the term "data sets" (id. at 8:48-64, 10:8-33). Although these terms were not discussed at length in the briefs, both parties have submitted proposed constructions for them. Therefore, I will consider the arguments made regarding the term "data" when construing the terms that are actually present in the claims.

2. The Court's Construction

The ordinary meaning of "data," in the context of a digital system, is "numerical information." See The American Heritage Dictionary (New College ed. 1982) (defining "data" as "numerical information in a form suitable for processing by computer") (cited by Defendants at D.I. 301 at A-009). Ampex's expert, Dr. Ligler, agreed that "data" refers to numerical information. When asked about the meaning of "video pixel data" in claim 7, Dr. Ligler stated that "data is represented using 1s and 0s which is mathematical data." (D.I. 301 at A-632, 280:3-14.) Dr. Ligler went on to say that, when in stored form, "data" cannot be anything other than numbers. (Id. at A-633-634, 288:21-289:6.) Although Ampex submits dictionaries that define "data" broadly to mean "information" (D.I. 307, Exs. 16, 17), Ampex does not overcome the evidence, both intrinsic and from its own expert, showing that "data" is limited to numerical information when used in the context of a digital still store system.

The specification of the '121 patent further explains what is meant by "data, and more particularly the claim terms "video data," "video pixel data," "data set," and "image data set," in the context of the claimed still store system. In order for a video image to be stored in a digital still store system, such as the one claimed in the '121 patent, the image must be in digital format. ('121 patent at 3:16-19.) According to the specification, in "digital sampled data form ... each pixel of video data is represented by three eight bit data bytes defining respectively luminance, red chrominance, and blue chrominance components." (Id. at 3:19-24.) Thus, once converted to digital form, every pixel in an image has three components, each of which has a particular numeric value. (Id. at 3:29-34.) These component values are then represented as a series of binary bits, with each bit being a one or a zero, and the resulting data being stored in the still store system. (See id.) Therefore, the specification confirms that, in a digital system, "data" refers to numerical information and "video data" refers to the numerical information that represents the pixel components of a video image.

There is no indication in the specification or claims that the terms "video data," "video pixel data," "data set," and "image data set" were intended to have different meanings. On the contrary, they appear to be used synonymously. For example, even after the specification explains that a digital video image is composed of pixel components (id. at 3:19-24 ("each pixel of video data has three components), the specification continues to use the term "video data," and not "video pixel data," to refer to information representing a digital image (id. at 3:47-48 ("video data representing a frame of a video image").
Also, the claims appear to use the terms "video data" and "video pixel data" interchangeably. Claim 8 recites a "random access memory means ... for storing the video pixel data presented at the input port" and a "bulk storage memory ... for presenting selected groups of video data at said input port for storage by said random access memory means." (Id. at 653-55, 6:60-63 emphasis added.) Thus, claim 8 uses "video data" and "video pixel data" to refer to the same data. Finally, the claims also use the terms "data set" and "image data set" to refer to information representing an image in the digital still store system. (Id. at 8:15-18 ("full size image data sets representative of corresponding full size images"); id. at 8:48-51 ("A method of storing video pixel data for access and display comprising: providing data sets for a plurality of full size images").) Since images stored in digital format are composed of pixel components, the terms "data set" and "image data set" must be referring to the same numerical information as the terms "video data" and "video pixel data." Since these four "data" terms are used synonymously in the specification and claims, I will give them the same construction. I will construe "video data," "video pixel data," "data set," and "image data set" to mean "numerical information representing the luminance, red chrominance, and blue chrominance components of each pixel in a video image."

In each of the asserted claims, the term "said" or "the" is used in conjunction with a reference to "video data," "video pixel data," "data set," or "image data set." (Id. at cols. 6-10.) The parties appear to agree that the first use of one of these "data" terms in each claim provides an antecedent basis for later references in the form "said data" or "the data." (D.I. 299 at 11; D.I. 346 at 12.) Since each "data" term refers to the numerical information representing the components of each pixel in an image, "said/the data" logically refers to the set of numerical information necessary to recreate those pixels. Ampex actually appears to acknowledge that conclusion when it argues that "said/the data" means that the data must create the same image as that born of the antecedent data. (D.I. 300 at 20.) The specification clearly teaches that, in digital form, an image is represented by the values of the three components of each pixel. (121 patent at 3:19-24.) Therefore, in order for digital data to represent the same image, it must represent the same luminance, red chrominance, and blue chrominance values for each pixel of that image. To the extent that the data necessary to achieve the same luminance and chrominance values must be the same bits originally referenced, the claims require that sameness. To the extent any difference in bits can occur and still achieve the same pixel values, and to that extent only, a variation in the bits is contemplated by the claims.

Ampex argues that construing "said/the data" to require the same numerical information would read a preferred embodiment of the invention out of the claims. (D.I. 300 at 21-22.) According to Ampex, the specification sets forth an embodiment of the invention in which a significant amount of processing takes place between the video input and the image store. (Id. at 21.) Ampex contends that Defendants' claim construction is improper because, in this preferred embodiment, the image store cannot contain the same numerical information that was originally supplied by the video input. (Id.) Of the asserted apparatus claims, only claim 12 is relevant to this argument because it is the only one that provides for a video input. n4 Claim 12 recites "[a] video still store system comprising: an external source for supplying a plurality of full size image data sets representative of corresponding full size images; an image store for storing said full size image data sets ..." (121 patent at 8:15-24.) Therefore, the critical issue is whether the external source performs the processing before it supplies the data or some other circuitry performs the processing between the external source and the image store.

n4 The other apparatus claims asserted by Ampex do not recite a video input ('121 patent at cols. 6-10.), and therefore, they are irrelevant to Ampex's argument that significant processing takes place between the video input and the image store.

Ampex points to two types of processing that are discussed in the specification. First, the specification discloses that "the video input ... will include appropriate video signal decoding means to process video data received from sources that provide the data in an encoded form." (Id. at 3:8-11.) The only element of claim 12 that can be considered a video input circuit is the "external source." (Id. at 8:15-47.) Thus, according to the specification, it appears that the external source itself will perform the decoding process. Contrary to Ampex's assertion, this processing will not occur between the external source and the image store.

Second, the specification states that "[a]n input analog-to-digital (A-D) converter ... is coupled to receive an input video signal provided by the video input circuit ... which typically includes video signal processing circuitry that prepares the signal for conversion by the A-D converter ..." (Id. at 3:12-14.) Claim 12 states that the "external source" supplies "a plurality of full size image data sets." (Id. at 8:16-18.) As previously discussed, the term "image data set" means numerical
information representing the pixel components of a video image. However, the pixel components of a video image only exist after the image has been converted to digital format. (Id. at 3:19-24.) Therefore, in claim 12, the analog-to-digital conversion must be performed before the external source can supply "image data sets" to the digital still store system. As a result, this processing cannot occur between the external source and the image store.

Since neither form of processing described in the specification takes place between the video input and the image store, construing the term "said/the data" to mean the same numerical information encompassed by the first reference to "data" does not read a preferred embodiment out of the claims. Moreover, the focus is not on the exact order of the ones and zeros; it is on the sameness of the image created. As construed above, references to "said/the data" require numerical information representing the same component values for each pixel in the image. Thus, any processing that may occur within the digital still store system, to the extent that it changes binary bit values but still maintains the same pixel values, will not remove the system from the scope of the claims. Again, however, the claims will not cover a system that, in the course of processing the data, changes the values of the luminance and chrominance components.

Finally, Ampex contends that the construction of "said/the data" affects a preferred embodiment of the invention in which the permanent memory component is a magnetic disk store. (D.I. 300 at 22.) Specifically, Ampex relies on expert testimony that "the data actually recorded on the magnetic disk storage system would not be mathematically identical to the data for the video image as stored in the framestore, because ... [it] would be encoded using formats more appropriate for more permanent storage." (D.I. 309 at 8, P 37.) Specifically, the encoding methods used for magnetic disk drives "would significantly change the actual bits recorded on the magnetic disk drive from their original form." (Id. at 8-9, P 40.) Defendants admit that storage on a magnetic disk drive would change the ones and zeros, but they contend that the values of the pixel components would remain the same. (D.I. 348 at 10.) Accordingly, a magnetic disk drive that changes binary bit values without affecting pixel values will not fall outside the scope of the claims.

In sum, I construe "the video data," "the video pixel data," "said video pixel data," "the data sets," and "said image data sets" to mean "numerical information representing the same luminance, red chrominance, and blue chrominance components of each pixel in a video image."

In sum, I construe "the video data," "the video pixel data," "said video pixel data," "the data sets," and "said image data sets" to mean "numerical information representing the same luminance, red chrominance, and blue chrominance components of each pixel in a video image."

2. "Video Delay Circuit"

Comark argues that the term "video delay circuit" means "a circuit which provides to the complementary non-linear amplifier a video signal which is delayed in time." Harris argues that the term means "a circuit element with no other purpose or effect than to delay a 'video signal,' to compensate for the large, unintentional delay inherent in a transmitter's IF vision modulator stage."

Claim 1 of the '904 patent describes "a video delay circuit for receiving and delaying the video signal to provide a delayed video signal." (Ex. DMX-1 at col. 6, lines 27-28.) The specification of the patent describes the video delay circuit as follows:

Because the video signal 25 is delayed by the IF vision modulator 19, the video delay circuit 13 is included to provide[] a similar delay of the video signal 25 so that there is a coincidence of the modified IF aural signal 28 with a visual signal 26, outputted by the IF vision modulator, at the adder 21.

Id. at col. 3, lines 29-34. This description appears almost verbatim in Claim 2. Id. at col. 6, lines 45-48. The fact that the "coincidence" requirement is in Claim 2 demonstrates that the "video delay circuit" of Claim 1 is different because it does not have this feature or any other limitation. Therefore, the court concludes that the "video delay circuit" claimed in Claim 1 is broader than the "video delay circuit" claimed in Claim 2. Claim 1 describes a more general delay circuit with no specific elements, functions, or objectives.

Harris' proposed definition is too narrow because the court does not find that the video delay circuit claimed in the '904 patent has only one purpose or effect or that the delay inherent in a transmitter's IF vision modulation stage is large or unintentional. Rather, Comark's definition is appropriate because it accurately describes the function of the circuit in the
context of Claim 1: to provide to the complementary non-linear amplifier a video signal which is delayed in time.

3. "Delayed Video Signal"

Comark and Harris agree that the term "delayed video signal" refers to a "video signal" that has passed through a "video delay circuit." (Pl.'s Proposed Findings of Fact and Conclusions of Law P 9; Def.'s Pre-Hr'g Mem. at 12.) This definition incorporates the definitions of "delayed video signal" and "video signal."

* * *

The term "video delay circuit" in Claim 1 means a circuit that provides to the complementary non-linear amplifier a video signal that is delayed in time.

The term "delayed video signal" in Claim 1 means a "video signal" that has passed through a "video delay circuit."

GO BACK

4761

In this case, the term "video delay circuit" has a clear and well-defined meaning. This term is not so amorphous that one of skill in the art can only reconcile the claim language with the inventor's disclosure by recourse to the specification. See E.I. du Pont de Nemours, 849 F.2d at 1433 (stating that the specification can supply understanding of unclear terms, but should never trump the clear meaning of the claim terms). Rather than looking to the specification to ascertain the meaning of a claim term as it is used by the inventor in the context of the entirety of his invention, Harris instead asks us to look to the specification in order to limit the phrase "video delay circuit" to its functional purpose as disclosed in the preferred embodiment. Harris is indeed correct that the specification clearly discloses that the video delay circuit functions to compensate for delay introduced to the video signal being processed by the IF vision modulator by introducing a similar delay to the same video signal in the correction path. However, the language in the specification does not at all aid in our interpretation of the phrase "video delay circuit." It simply details how the video delay circuit is to be used in a single embodiment of the invention. It in no way sheds light on either the meaning of the term to the inventor, or the common meaning of the term to one of skill in the art.

Further, the language that Harris argues should limit claim 1 is clearly found in the '904 patent's description of the preferred embodiment. It is precisely against this type of claim construction that our prior case law counsels. "Appellant misinterprets the principle that claims are interpreted in the light of the specification. Although the specification may aid the court in interpreting the meaning of disputed claim language, particular embodiments and examples appearing in the specification will not generally be read into the claims." Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571, 7 U.S.P.Q.2D (BNA) 1057, 1064 (Fed. Cir. 1988) (internal citation omitted); see Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865, 9 U.S.P.Q.2D (BNA) 1289, 1299 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations.").

Finally, as the district court correctly pointed out, Harris's proposed construction of claim 1 would violate the doctrine of claim differentiation by rendering claim 2 superfluous. While we recognize that the doctrine of claim differentiation is not a hard and fast rule of construction, it does create a presumption that each claim in a patent has a different scope. "There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims. To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023, 4 U.S.P.Q.2D (BNA) 1283, 1288 (Fed. Cir. 1987). Claim 2 incorporates claim 1 by reference and further defines the "video delay circuit" element with the following additional limitation: "wherein the video delay circuit provides a delay so that there is coincidence of the modified aural signal with the IF modulated signal at the adder circuit." To interpret the term "video delay circuit" to mean a video delay circuit that compensates for the delay introduced by the IF vision modulator, as Harris suggests, would render claim 2 completely superfluous and redundant of claim 1. Harris has not shown any reason sufficient to rebut the presumption that claim 1 should not be so limited in order to preserve the distinction between claims 1 and 2. Consequently, we decline Harris's invitation to limit the term "video delay circuit" to the specific function disclosed in the preferred embodiment and affirm the claim construction of the district court.

GO BACK
II. Video Display Device and Display Means

Plaintiffs propose to construe the terms "video display device" (‘964 Patent, claim 1) and "display means" (‘964 Patent, claim 4) broadly as a device for providing an image which may be viewed by a viewer, where the device is capable of displaying a moving image. Defendants propose to limit the terms to mean a raster scan device. In the alternative, Defendants propose to define the terms to mean a camera, scanner, television, laser printer, fax machine, or the like that is coupled to the video fill circuit and displays the enhanced image. Where one claim in a patent does not contain a certain limitation, but another claim in the patent does contain the limitation, "that limitation cannot be read into the former claim in determining either validity or infringement." Amgen Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1325-26 (Fed. Cir. 2003)(stating that "[t]here is a rebuttable presumption that different claims are of different scope" and that "courts must take extreme care when ascertaining the proper scope of the claims, lest they simultaneously import into the claims limitations that were unintended by the patentee"). In the instant action, the words "raster" and "scan" are absent from claims 1 and 4, but are present elsewhere in such patents, such as in claim 5 of the '964 Patent, which depends from and further limits claim 4. Defendants have not provided sufficient justification to read into claims 1 or 4 as limitations the words "raster" and "scan." Thus, the limiting construction "raster scan" cannot be read into claim 1 or 4.

In regard to Defendants' alternative proposed construction, Defendants propose to graft the Sony construction of "display means" onto the entire term "video display device." Plaintiffs, on the other hand, seek to preserve the relationship between the construction and the terms "display means" and "display device," accounting separately for the modifier "video." The court in Sony indicated that a display device should be construed broadly to encompass matrix and hard copy display devices as well as raster type displays, which is what Plaintiffs propose. 2005 U.S. Dist. LEXIS 17962, 2005 WL 2035578, at *3-*4. Defendants have not provided sufficient justification to reach a different construction in regard to the claims before this court. Therefore, we construe the terms "video display device" (‘964 Patent, claim 1) and "display means" (‘964 Patent, claim 4) in a manner consistent with Plaintiffs' proposed construction.

2. Video Game Controller

Defendants contend that the term "video game controller" should mean only those which are joy sticks or are stabilized with one hand and operated by the other hand. The Court cannot agree.

The patent expressly states that "game controllers take a variety of forms, but usually [hence, not always] include at least a button and either a dial or a joystick." 754 Patent col. 1, lines 17-18. The term "video game controller" in the claim should not be read narrowly to include only one of the possible types to which the inventor refers in the specification.

Nor can the Court find in the term "video game controller" a limitation to a device that is stabilized with one hand and operated by the other. While the patent refers to controllers so stabilized when describing the benefits of the invention 2, there is no indication that the term video game controller should be read to exclude such devices that might not be stabilized with one hand and operated with another. Indeed the Patent states: "Virtually all [hence not all] controllers require the use of both hands, one to hold the controller and one to operate the controls." 754 Patent, Col. 1, Lines 19 - 21.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 "The invention generally relates to a unique holder for video game controllers which frees one hand and simplifies the operation of the game controller . . ." 754 Patent, Col. 1, Lines 37 - 39. (Emphasis added)

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Moreover, the words "stabilized" and "stable" are, in the context of the 754 Patent, relative terms referring to a continuum of
conditions between a theoretical state of complete instability to a theoretical state of perfect stability. Thus, a video game controller can be "stabilized" by being held in one hand if it is made more stable than it would be if not so held, for example by being placed on a table. References to the use of the invention to "stabilize" such a game controller refer to making the controller more stable than it would be if the invention were not used.

Defendants, on the other hand, assert that the term "video" should be construed, by itself, to mean "a series of related electronic images created for rapid display to allow the appearance of movement." (D.I. 305 at 1.) Accordingly, Defendants contend that there is no aspect of the patent that supports using "video" to refer to a still image. (Id.) For example, Defendants argue that "video" means an "electronic signal representation of visual information that is one of a series of related electronic images created for rapid display to allow the appearance of movement." (D.I. 305 at 3.) This proposed construction does not limit the term "video" to motion videos. (D.I. 348 at 4.) But, according to Defendants' construction, the term "video" does limit the source of a still image. (Id.) In other words, a still video image is a single frame captured from a stream of video. (Id. at 5.) Defendants base their construction on the language of the specification, as well as extrinsic evidence regarding the use of the term "video" during the 1980s, which is when the application for the '121 patent was filed. (D.I. 299 at 6-8.) Defendants also contend that Ampex's proposed claim construction would render "video" meaningless because it would allow any electronic image to be considered a "video image." (Id. at 8-9.)

2. The Court's Construction

The specification of the '121 patent intermingles its use of the terms "image" and "video image" (compare '121 patent at 1:15-17 with id. at 1:27-30), which may be the source of some confusion as to the meaning of these terms. However, when considered in its entirety, the specification does not use the term "video image" to mean only those still images that have been extracted from a stream of images. The specification states that "[t]he invention provides an electronic imaging system that records both motion and still video images." (343 patent at 2:3-4 (cited by Ampex at D.I. 347, Ex. 43).) With respect to the still video images, the specification of Kodak's patent further explains that, in still mode, "a high resolution still image is captured and recorded by the recording unit ... each time the record switch ... is depressed." (Id. at 3:27-31.) Thus, Kodak used the term "video image" for a still image that was captured firsthand by the electronic imaging system, and not by extraction from a related motion image. European
Patent No. 0051305, which is referenced by the '121 patent, also uses the term "video" to describe electronic images. ('121 patent, References Cited.) Specifically, this patent uses the term "video signal" to refer to 2-dimensional picture information that was acquired using a scanner. (European Patent No. 0051305 at 5:23-29 (cited by Ampex at D.I. 308, Ex. 3).) Similarly, U.S. Patent No. 4,205,780 discloses a system that "includes a video camera ... mounted on the document scanner and positioned to capture the video image of each document." (U.S. Patent No. 4,205,780 at 5:55-58 (cited by Ampex at D.I. 307, Ex. 10).) In both of these patents, "video" refers to an image that is obtained by scanning a document, and not from a motion image. This review of other patents, albeit brief, demonstrates that others of skill in the art likely understood "video image" to include any still image in electronic form.

--- Footnotes ---

n2 Kodak's '343 patent was applied for on February 28, 1994. ('343 patent (cited by Ampex at D.I. 347, Ex. 43).)

--- End Footnotes ---

Defendants' argument that Ampex's proposed construction essentially reads "video" out of the claims is not persuasive. The term "image," alone, is not limited to electronic representations of visual information. Rather, as Ampex contends, "image" is broader because it includes the depiction of visual information in other formats, such as transmission through a lens or reflection from a mirror (D.I. 346 at 10), or images captured in non-electronic form, such as a photograph or painting. n3 Thus, Ampex's proposed construction does not render "video" superfluous. Accordingly, I will construe the term "video image" to mean "an electronic signal representation of visual information displayable in visual form on a monitor or other display device." I will also construe "video still store" to mean "a system capable of storing still video images."

--- Footnotes ---

n3 This is not to say that a non-electronic image, like a photograph, cannot become a "video image." It would become a "video image" if it were digitized and electronically stored.

--- End Footnotes ---

**L. "Video Player"**

The term "video player" appears in dependent claim 14. Consistent with its construction of the term "media playing means," Apple argues that a video player is not capable of playing music as Apple defines the phrase. As discussed above, a video player may be media playing means. The term is construed as "an electronic device capable of playing a video as well as musical sound."

**14. Based on the intrinsic evidence, the Court construes the '158 patent claim limitation "video program" to mean "recorded movies, broadcast television programs, and cable television, regardless of the media on which they are recorded." See Hearing Tr. at 4:2-5 (June 1, 2009).**

**1. "Video Signal"**

Comark argues that the term "video signal" means "a signal containing television picture information which is not modulated on to any carrier." Harris argues that the term means "a signal containing video information that is input to a
transmitter's IF vision modulator (as opposed to a signal derived from the output of the IF vision modulator, which is referred to in claim 1 as a 'visual signal.')"

A "video signal" can be used to describe the video signal inputted into the IF vision modulator in the '904 patent. (Tr. 10/21/96 at 137.) In addition, an engineer of ordinary skill in the art would use the term "video signal" to describe a signal that had been derived from the output of an IF vision modulator. (Tr. 10/18/96 at 120.) Engineers of ordinary skill in the art use the term "video signal" to describe all sorts of signals that are derived from the output of an IF vision modulator. Id. at 132.

The patent, however, does not use the term "video signal" to mean both types of signals. Claim 1 describes an aural carrier correction system for a common amplification television transmitter that includes "at least an IF vision modulator for receiving a video signal and for outputting the visual signal." (Ex. DMX-1 at col. 6, lines 25-26.) The specification describes the term "video signal" as being "inputted to both the IF vision modulator 19 of the transmitter 12 and the video delay circuit 13 of the correction system 11." Id. at col. 3, lines 26-29. Figure 1 is consistent with these descriptions of the term.

The patent is clear that a "video signal" is television picture information that is inputted to the IF vision modulator and the video delay circuit. The term is used in no other context and has no other meaning in the patent. The court will adopt a modified version of Harris' proposed construction. 5

--- Footnotes ---

5 The parties agree that the phrases "television picture information" in the Comark definition and "video information" in the Harris definition are interchangeable. (Def.'s Pre-Hr'g Mem. at 8 n.4; Pl.'s Post-Hr'g Mem. at 7 n.5.) The court is persuaded by Comark's suggestion that "television picture information" is more appropriate.

In addition, Harris' definition defines "video signal" as a signal "that is input to a transmitter's IF vision modulator." Because the specification of the '904 patent also provides that the signal also is input to the video delay circuit of the correction system, the court believes that both inputs should be part of the term's definition. The court will modify the definition accordingly.

--- End Footnotes ---

The term "video signal" in Claim 1 means a signal containing television picture information that is input to the transmitter's IF vision modulator and the video delay circuit.

**4768**

I. "Video Signals"

The term "video signals" appears in claim 16 of the '253 patent. ABC contends that "video signals" are "a type of data signal[s] sent from the remote computer to the local computer/interface unit for the production of images on the video display." 245 WebEx asserts that "video signals" are "signals specifically designated for carrying video information as opposed to general data." 246

--- Footnotes ---

245 ABC's Brief, Docket Entry No. 154, at 22.

246 WebEx's Brief, Docket Entry No. 156, at 28.

--- End Footnotes ---
1. Meaning of "Video"

The parties' proposed definitions differ in the way they describe how the word "video" describes or limits the word "signals." ABC's definition provides that video signals are signals "for the production of images on the video display." Therefore, ABC's definition explains that the adjective "video" connotes an association with the production of images. WebEx's definition, on the other hand, is apparently intended solely to differentiate video signals from data signals, and does not elaborate on the meaning of "video." WebEx's definition circularly provides that video signals are "for carrying video information . . . ."

The court concludes that ABC's proposed definition is more helpful in this regard, and is consistent with the intrinsic and extrinsic evidence. The specification of the '253 patent describes one embodiment of the invention in which video signals and data signals received by the local portion from the remote computer unit are formatted into "audio television signals, video television signals, or audio and video television signals." 247 These television signals are then "transmitted to the television display unit so that the television signals are perceivable by the individual located adjacent the television display unit." 248 This description indicates that video signals provide information that can be expressed in a perceivable format by a television or other similar device that, among other things, displays images. Furthermore, the description differentiates audio and video television signals, which indicates that the video signals provide the visual or image portion of the information that is expressed by the television or other similar device, and not the sound. 249

247 '253 patent, col.8 ll.3-9. The specification describes "television signals" as "signals adapted to be displayed by a television set, or any other type of suitable video and/or audio signals." Id. col.5 ll.41-44.

248 Id. col.8 ll.9-12.

249 Presumably, the audio or sound information is provided by the "data signals."

2. A Type of Data Signals

ABC defines video signals as "a type of data signal[s] . . . ." WebEx responds that the claim language and the specification of the '253 patent specifically differentiates between data signals and video signals and, therefore, that video signals are not a type of data signals. 252 WebEx asserts that video signals carry video information, while data signals may carry any other "non-video information." 253 Accordingly, WebEx contends that the definition of video signals should explain that video
signals are "specifically designated" for communicating video information, "as opposed to general data."

Both parties point to the claim language in support of their respective positions. Claim 16 states that

data signals received from each individual's local portion [are] transmitted to each individual's remote computer unit . . ., the data signals being processable by the individual's remote computer unit . . . to generate output signals, the output signals including video signals and being transmittable from the individual's remote computer unit . . . to the individual's local portion.

As WebEx points out, the claim language does not indicate that video signals are a type or subcategory of data signals. The claim uses the term "data signals" only to describe signals that are transmitted from the local portion to the remote computer unit for processing. The claim describes the signals transmitted from the remote computer unit back to the local portion as "output signals," of which "video signals" are a constituent. The claim language, however, does not necessarily foreclose the possibility that video signals could be a type of data signals. For example, "output signals" could be a type of "data signals." Therefore, the claim language alone does not provide a definitive answer, and the court looks to the specification for further guidance. See Markman, 52 F.3d at 979 ("Claims must be read in view of the specification of which they are a part.").

In support of its position WebEx also directs the court to a sentence in the specification describing a particular embodiment of the invention. The sentence states that "the remote portion 22 . . . provides video signals to the local portion 12 . . . via the sequential communication links 27b and 20a, and data signals to the local portion 12 . . . via the sequential communication links 27a and 16a." WebEx argues that because the specification describes video signals being relayed from the remote portion to the local portion over one set of communication links (27b and 20a) and data signals being relayed over another set of communication links (27a and 16a), the two types of signals must be mutually exclusive.

ABC counters that WebEx is improperly reading a limitation from the specification into the claim. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 904 (Fed. Cir. 2004) ("[I]t is improper to read a limitation from the specification into the claims."). ABC also points out that the specification provides that "each of the communication links are shown and described separately herein for the sole purpose of clearly illustrating the information being communicated between the various components. The communication links may not be separate communication links but may be a single physical communication link."

ABC counters that WebEx is improperly reading a limitation from the specification into the claim. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 904 (Fed. Cir. 2004) ("[I]t is improper to read a limitation from the specification into the claims."). ABC also points out that the specification provides that "each of the communication links are shown and described separately herein for the sole purpose of clearly illustrating the information being communicated between the various components. The communication links may not be separate communication links but may be a single physical communication link."
The court is persuaded by WebEx's argument. The cited portion of the specification gives no indication that video signals are a type of data signals. For example, the specification does not say that video signals are transmitted over one communication link while "other" data signals are transmitted over another. Instead, this portion of the specification simply describes video signals and data signals as two different types of signals. Therefore, the fact that it is possible to distinguish video signals from data signals and transmit each type of signal over its own respective communication link strongly indicates that the two categories are mutually exclusive.

Moreover, ABC's argument that WebEx is improperly reading a limitation from the specification into the claim is unavailing. WebEx is not arguing that data signals and video signals must be transmitted over separate communications links, as they are in the embodiment described. In other words, WebEx is not suggesting that an accused device that transmits the two types of signals on a single communication link would not infringe the asserted claim. Instead, WebEx is merely pointing out that the specification indicates that it is possible to distinguish the two types of signals and transmit them separately. WebEx is properly analyzing how the two terms "video signals" and "data signals" are used in the context of the specification to ascertain their meanings.

Although WebEx has cited only one small excerpt from the specification, the balance of the specification consistently describes data signals and video signals as two distinct types of signals. For example, the specification explains that the remote computer unit processes incoming data signals "to generate output signals including video and data signals." 257 This sentence indicates that there are two distinct categories of output signals -- video signals and data signals -- and it gives no indication that video signals are a type or subcategory of data signals. This sentence also makes clear that the output signals described in claim 16 -- of which video signals are a constituent or type -- are not themselves a type or subcategory of data signals. Instead, it is the other way around -- data signals are a type or category of output signals. 259

257 '253 patent, col.8 ll.20-23.

258 See '253 patent, claim 16 (as amended) (describing the remote computer unit "generat[ing] output signals, the output signals including video signals").

259 The court does not mean to suggest that all data signals are output signals. The patent describes data signals that are clearly not output signals. For example, the claim language describes data signals that are transmitted from the local portion to the remote computer unit for processing. See '253 patent, claim 16 (as amended). The court intends only to explain that some output signals are data signals.

3. Sent from the Remote Computer Unit to the Local Computer Unit

ABC's proposed definition describes video signals as "sent from the remote computer to the local computer/interface unit . . . " ABC's proposed definition therefore suggests that all video signals are necessarily sent from the remote computer unit to the local computer unit. This aspect of ABC's definition is not supported by claim language or the specification.

In claim 16 video signals are mentioned only once, and are described as "being transmittable from the individual's remote computer unit . . . to the individual's local portion." 260 The claim language therefore indicates that video signals can be sent from the remote computer unit to the local portion, but does not suggest that video signals are confined exclusively to that context. Furthermore, the specification describes video signals that are transmitted by a "television station block" to the local portion. 261 Therefore, the court concludes that video signals are not necessarily sent from the remote computer unit to the local computer unit and will not include this limitation in its definition.
260 '253 patent, claim 16 (as amended).

261 See '253 patent, col.6 ll.14-37 (explaining that the local portion may receive television signals from both a "television station block" and the remote computer unit, and defining a "television station block" as "any television station which transmits audio and/or video signals which can be displayed or otherwise output by the television display unit" (emphasis added)).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

4. Conclusion

The court concludes that "video signals" are "signals specifically designated for the production of images on the video display." "Video signals" are not a type of "data signals."

GO BACK

4769

"viewpoint motion"

Claims 1, 28, 42, and 52 of the '785 Patent contain the term "viewpoint motion." IPI contends the term means "a sequence of images that are perceptible as views of a three-dimensional workspace from a moving or displaced viewpoint." Google contends the term means "a sequence of images that causes the viewpoint to appear to move from an initial position to other positions." The parties dispute whether the specification adequately defines the term and whether the term's construction requires inclusion of references to a three-dimensional workspace and viewpoint displacement.

IPI contends its proposed construction is taken directly from the specification, which states: "'Viewpoint motion' or 'viewpoint displacement' occurs when a sequence of images is presented that are perceptible as views of a three-dimensional workspace from a moving or displaced viewpoint." '785 Patent, col. 7:41-44. IPI contends that the inventors acted as their own lexicographers and thus, that definition should be adopted as the appropriate construction. Further, IPI points to other portions of the specification that support this proposition. IPI's Opening Brief, at 26-27. Google counters that IPI's proposed construction is unnecessarily complicated and confusing because other portions of the claim already require that the views be of a three-dimensional workspace. See e.g., '785 Patent, col. 20:39-42 ("presenting a first image on the display; the first image including a first surface that is perceptible as viewed from a first viewpoint within a three-dimensional workspace"). Google further contends that IPI's inclusion of the concept of a "displaced viewpoint" is unsupported because "displaced" is not co-extensive with "motion."

Both parties' proposed constructions set forth "when" and "how" "viewpoint motion" occurs, i.e., by a sequence of images. Although the specification describes the operation of "viewpoint motion," a description of the operation does not constitute a definition of the term as to what "viewpoint motion" is. The specification's description of Figures 2A and 2B of the '785 Patent is particularly useful in defining "viewpoint motion." The relevant portion of the specification provides:

'785 Patent, col. 9:11-23. In light of the claim language and the specification, the Court proposed the following construction for "viewpoint motion" to the parties at the hearing: "perceived movement of an image presentation on a display." IPI's only objection to this proposed construction was that it did not cover "displacement" of the viewpoint. Although "motion" may include "displacement," they are not the same. Further, there is no support in the claim language or the specification to include the concept of "displacement" in the construction of the term "viewpoint motion." Google's only request was that the proposed construction clarify that the "viewpoint" of the image is what is moved, not the image itself. Google's
requested clarification is consistent with the claim language and the specification. Accordingly, the Court construes the term "viewpoint motion" to mean "perceived movement of the viewpoint of an image presentation on a display."

---

### 4770

#### 3. "Virtual address"

The court now considers the term "virtual address." The parties' dispute over this term primarily involves the incorporation of the word "application" as used in the defendants' definition. According to the plaintiff, these patents disclose hardware inventions. The plaintiff's argument is that because the patents are hardware patents, use of a definition that includes "application" improperly incorporates a software limitation into the claims. The defendant, for its part, points to several dictionary definitions of the term "virtual address" which suggest that the term itself implies a software limitation. After considering the parties' positions, the court construes the term "virtual address" to mean "a memory address provided by the CPU in executing an application software program and that is translated into a real memory address by hardware." See '846 Patent, Col. 6 ll. 50-53.

---

### 4771

#### X. "virtual block address" -- '051 patent

The claim term "virtual block address" appears in claims 2, 3, and 18 of the '051 patent. The parties propose constructions of the disputed claim phrase as follows:

<table>
<thead>
<tr>
<th>Lexar's proposed construction:</th>
<th>Toshiba's proposed construction:</th>
<th>Pretec's proposed construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Value to indicate a block location</td>
<td>[NOTE: Toshiba actually construes ‘first virtual block address’]. An address of a physical block in the nonvolatile memory where original information of an information block is stored.</td>
<td>The address of a simulated block that holds the address of a physical block.</td>
</tr>
</tbody>
</table>

The Court finds that Lexar's proposed construction is the correct one for this term. Toshiba's construction is flawed in that the use of the word "address" does not clarify what an "address" in the disputed claim phrase is. The Court finds that Lexar's proposed language, "value to indicate," is more useful here. The Court also finds that much of Toshiba's proposed language, such as "in the nonvolatile memory," is surplusage that fails to clarify what a "virtual block address" is. Additionally, referencing "a physical block" provides an overly narrow construction of "virtual block address" because the VBA does more than indicate a physical block. As Lexar discussed at oral argument, the VBA puts the information block back together and to limit its function to a physical block "depriv[es] it of some part of its function." (Claim Construction Hearing Transcript at 96:17-18.)

The Court also rejects Pretec's proposed construction of "virtual block address." Again, using "address" to define "address" is not helpful. Additionally, Pretec's proposal to include "simulated" adds a limitation to the claim phrase that does not exist in the claims themselves. Therefore, the Court adopts Lexar's proposed construction of "virtual block address:" value to indicate a block location.
4. Constructing a virtual bounding box around each inset of the maps

This term appears in the 615 patent. The defendants contend that the phrase means "drawing an imaginary box around each and every inset of the maps." The plaintiff contends that the term needs no construction; however, the plaintiff would agree to a construction of "defining an imaginary box around each inset of the maps." The court adopts this latter approach and defines the term to mean "defining an imaginary box around each inset of the maps."

GO BACK

4. "virtual files"

Claim Seven of the '399 Patent provides, "An interface device according to claim 2, which further comprises a root directory and virtual files which are present on the signaled hard disk drive and which can be accessed from the host device." '399 Patent, col. 13:33-36. Papst defines "virtual files" based on the type of media on which such files are stored as meaning "files which appear to be present on an emulated disk drive, yet which are not actually on a rotating disk." Papst's App. at 5. The Camera Manufacturers offer instead that a "virtual file" is "a file that does not physically exist as a file in the interface device but appears to the host device to be an actual file, and references data to be transmitted between the data transmit/receive device and the host device." CMs' Markman Br. at 38.

Claim Seven depends from Claim Two; under Claim Two, the interface device signals to the host device/computer that the interface device is a hard disk. See '399 Patent, col. 13:33 & 13-17. The "signaled hard disk drive" in Claim Seven refers back to the signal first mentioned in Claim Two. That signaled hard disk drive, which does not exist in fact, "further comprises a root directory and virtual files," id., col. 13:34, which also do not exist in fact.

The 1993 New IEEE Dictionary defined the term similarly to the construction proposed by the Camera Manufacturers. In the context of a "virtual record," "virtual" was defined as: "a record that appears to be but is not physically stored; rather, it is constructed or derived from existing data when its contents are requested by an application program." New IEEE Dictionary at 1461 (attached to CMs' Markman Br. as Ex. G); see also Oxford English Dictionary at 674 (2d ed. 1989) (defining "virtual" in the context of computers to mean "not physically existing as such but made by software to appear to do so from the point of view of the program or the user") (attached to CMs' Markman Br. as Ex. P). The '399 Patent and the specification do not indicate that Mr. Tasler used the term "virtual file" in any unique way, such as that proposed by Papst, and the Court construes the term to have its ordinary meaning.

Papst argues that if one interprets "virtual file" to mean "a file that does not physically exist as such but is made by software to appear to do so from the point of view of the program or the user," Claim Seven would be inconsistent with Claims Eight, Nine, and Ten which, Papst asserts, cover "virtual files that are actually stored in the interface device." Papst's Reply at 35. Papst misreads these Claims. Each says, "wherein the virtual files comprise" a configuration file "stored in the memory means," '399 Patent, col. 13:38 (Claim Eight); batch files or executable files for the microprocessor "stored in the interface device," id., col. 13:43-44 (Claim Nine); and batch files or executable files for the host device "stored in the interface device." Id., col: 13:48-49 (Claim Ten).

The Court perceives no conflict among the Claims. Virtual files that are "stored in the memory means" or "stored in the interface device" are no less virtual for that reason. Under Claims Eight, Nine, and Ten, what is "stored" are software instructions in the interface device which instruct the interface device to present data as if in real files of the types described, but which files are, in actuality, non-existent. The Court adopts the definition from the New IEEE Dictionary as the most clear and pertinent: "virtual files" in Claim Seven of the '399 Patent means "files that appear to be but are not physically stored; rather, they are constructed or derived from existing data when their contents are requested by an application program so that they appear to exist as files from the point of view of the host device."
H. Virtual Interface with the Device

Claim 4 further describes the bytecode instructions in the module's software that "generate on the client machine a virtual interface with the device." Digi asserts that "virtual interface with the device" should be defined as a "graphical user display running on the client machine that provides control options for the device and that allows the client machine to generate device control signals to be transmitted to the device control circuitry via the module." Lantronix, on the other hand, contends that the Court should construe this term as an "on-screen virtual image generated by software from the module of a control interface specific to a device."

The patent specification describes a virtual display that allows the user to monitor or control the device from a client machine. The patent specification states that "the user interface or virtual control panel displayed on the browser may be an HTML page, or a Java applet. In either case, graphics, buttons, indicators, etc., may be used to simulate the equipment's control panel or actual appearance." ('192 Patent c. 5, 11: 35-39.) The specification also describes, in the Java-based control method, a "virtual control panel" Java applet that is "created to provide the user of the client to remotely monitor and/or control the remote equipment." (Id. at c. 8, 11: 66-67 - c. 9, 11: 1-2.) In addition, this method describes the "activation of buttons and controls on the panel" that are "translated into commands by the applet and transmitted to the network interface chip." (Id. at c. 9, 11: 13-16.)

The Court finds that the claim language and the specification do not limit the construction of "virtual interface with the device" in the manner that Digi proposes, nor does it broaden the language in the manner that Lantronix proposes. First, neither the claim language nor the specification limits the construction of the virtual interface to a "graphical" display. In fact, the specification lists "graphics" as one of several examples of the way the virtual control panel can simulate the device's control panel. (Id. at c. 5, 11: 35-39.) Digi's proposed construction is too narrow in this regard. In addition, although the specification does not specifically delineate "control options" or "control signals," the specification does provide that the virtual interface is a control panel that generates commands that are sent to the device. (Id. at c. 8, 11: 66-68 - c.9, 11: 1-2; c. 9, 11: 13-16.)

Consistent with the claim language and the specification, the Court construes "virtual interface with the device" to mean "a virtual display that allows the user of the client machine to send commands from the client machine to the device control circuitry via the module."

8. The term "virtual keyboard" in claim 36 is construed with reference to The IEEE Standard Dictionary of Electrical and Electronics Terms -- Sixth Edition (D.I. 66 Ex. Y) as "an input device displayed on a screen consisting of a systematic arrangement of keys, used to encode data."

"Virtual Path"

Alcatel's proposed construction for "virtual path" is "a logical connection transmitted over a physical path and through which one or more virtual circuits may be constructed." Cisco's proposed construction is "a logical path through which data belonging to a particular customer's virtual private network travels and which (1) is dedicated to a particular customer and cannot be shared by other customers, and (2) has a guaranteed bandwidth (e.g., committed information rate)." The principle differences between the parties' proposals is that Cisco seeks to include two additional limitations, namely, that the "virtual path" is dedicated to a particular customer, and that it has a guaranteed bandwidth.

Both parties agree that "virtual path" was not a term commonly known to one of ordinary skill in the art at the time of the
Seid invention. Therefore, the Court will look to the language in the patent for guidance. In the summary of invention, the patent introduces the term "virtual path" ("VP") as follows: "Segments of the VCs [virtual circuits] are carried by VPs, each VP being a logical connection established between two VP terminators which are located in either network elements or customer premises equipment … Each VP is allocated a positive guaranteed bandwidth …" Seid, at 2:66-3:4 (emphasis added). Elsewhere in the patent, VPs are described as having a guaranteed bandwidth. See, e.g., Seid, at 6:3-4 ("A guaranteed (positive) bandwidth (VP-CIR) is allocated to each VP"), 6:22-23 ("[T]he VP reserves a committed bandwidth …"), 14:45 ("Each VP is defined by its bandwidth …").

Alcatel argues that, because "virtual paths" are described as having positive guaranteed bandwidth in claim 9, but not in claim 1 when the term "virtual path" is first introduced in the claims, Cisco is improperly trying to read a limitation from claim 9 into claim 1. See Grain Processing Corp. v. American Maize-Products Co., 840 F.2d 902, 911 (Fed. Cir. 1988) ("It is improper to read the limitations of one claim into another."). However, construing "virtual path" to require a guaranteed bandwidth would not be reading a limitation from one claim into another. When the reference to guaranteed bandwidth is first made in claim 9, it is being made because the claim also contains a discussion of when congestion occurs on a physical path, which requires "only a virtual path using bandwidth greater than the respective positive guaranteed bandwidth … to reduce [its] submission rate of packets onto the network." Seid, at 21:39-42. Claim 1 contains no such discussion regarding congestion, and therefore there is no need to refer to a "virtual path" as having a guaranteed bandwidth. However, simply because claim 1 does not contain language regarding guaranteed bandwidth, that does not necessarily imply that such guaranteed bandwidth is not a component of a "virtual path." In fact, a more complete reading of the patent indicates that guaranteed bandwidth is a required facet of a "virtual path."

Furthermore, the specification also indicates that a "virtual path" is assigned to a particular "virtual private network." In particular, the specification states, "A VP can be specified analogous to an FRC [frame relay connection] with the addition of two parameters of operation: (1) the identity of a VPN [virtual private network] (or reserved subscriber) to which the VP belongs; and (2) the maximum number of VCs that may be multiplexed on this VP." Seid, at 14:8-13 (emphasis added). Elsewhere, the specification states that "[t]he set of VPs established for a customer constitutes the customer's virtual private network." Id. at 14:40-41. See also Seid, at 15:18-19 ("[T]he FR [frame relay] network manager must … provide the identity of a VPN to which the VP will belong …").

In response, Alcatel only argues that the patent allows for sharing of bandwidth when certain "virtual paths" are not using their guaranteed bandwidth. See id. at 3:44-49, 11:28-32. While this is certainly true, it does nothing to refute the statements in the patent that a "virtual path" is assigned to a particular "virtual private network." 53

--- Footnotes ---

53 Cisco seeks a construction that would limit "virtual paths" to being dedicated to a particular customer, not simply to a particular "virtual private network." However, the Court feels that this is too strict a reading of the patent. As discussed previously in the discussion of "virtual private networks," every independent claim addressing "virtual private networks" contains a limitation that the network is "carrying traffic associated with a particular customer of the packet-based network." See, e.g., Seid, at 19:66-20:1, 21:11-13, 24:18-20. Therefore, such limitation need not be read into the construction of "virtual path."

--- End Footnotes ---

Therefore, the Court construes the term "virtual path" as "a logical connection transmitted over a physical path, which is dedicated to a particular virtual private network and has a guaranteed bandwidth, through which one or more virtual circuits may be constructed."

**virtual presence**

The term "virtual presence" means a remote user's ability to send and receive voice and data communications to and from a corporate office with the full capabilities and user interfaces of the corporate office just as if the remote user were physically

- 4997 -
The term "virtual presence" is not commonly used in the relevant art. The Court looks to the intrinsic evidence, from the perspective of one of ordinary skill in the relevant art, to determine the meaning of "virtual presence." 118

The term "virtual presence" is used in the "summary of invention" section of the '639 patent:

The present invention enables the concept of virtual presence or "telepresence" whereby a user at a remote location has the full capabilities and user interfaces of the corporate office just as if the user were physically located at the corporate office. Thus the telephone of the remote user mirrors the telephone the user sees at the corporate office, including substantially the same button configurations at substantially the same locations performing substantially the same functions. 119

This language shows that "virtual presence" entails full functionality of the office telephone and LAN from the remote location.

The "summary of invention" states further:

According to the invention, the remote user makes outgoing telephone calls, sends faxes, transmits data, sends email and performs internet access as if the remote user were physically present in the corporate office. Likewise, incoming calls, faxes, data transmissions and email received at the corporate office are routed to the remote user as if the remote user were physically present in the corporate office. Therefore, a co-worker or external party who telephones the user at the corporate office is unaware that the user is actually not physically located at the corporate office, but rather is at a remote location. 120

The plain meaning of this language shows that "virtual presence" entails transparency from the outside, that is, a person calling the corporate office for the remote worker would be connected to the remote user without being able to perceive that the remote user is not in the corporate office.

The joint claim construction chart indicates that plaintiff originally proposed this interpretation of "virtual presence": "the remote user transparently operates as if, and appears to a coworker or other party to be, physically located in the remote user's corporate office." 121 Plaintiff further highlighted the central feature of transparency in its opening statement, when arguing that if the office door of the remote worker were closed, the remote worker's colleagues at the corporate office should not be able to tell that the remote worker was not in his office when a call was placed to the remote worker's office phone. 122 Two of the inventors, Dr. Barker and Mr. Witt, testified, in sum, that virtual presence allows a remote user to appear to those interacting with him or her to be in the office. 123 In the course of the preliminary injunction hearing, however, plaintiff contended that the claims do not require transparency or, as characterized by plaintiff, "true virtual presence." Plaintiff now argues that the '639 patent "describes preferred embodiments in which the virtual presence server
instructs the corporate PBX to automatically forward all calls to the remote user" but, in these embodiments, the caller with a display telephone would be aware that the PBX had forwarded the call. Therefore, plaintiff argues, if virtual presence requires transparency, a preferred embodiment in the specification would not fall within the scope of the claims -- an interpretation, plaintiff argues, is rarely, if ever, correct. 124 Instead, plaintiff argues that a "reasonable impression" of transparency is all that is required. 125

--- Footnotes ---
121 Docket no. 76. As authority for this interpretation, plaintiff referred to the specification, '639 patent, col.2, lines 50-63 and col. 5, line 66 through col. 6, line 34.

122 Tr. 16-17. The summary of the invention states: "Therefore, a co-worker or external party who telephones the user at the corporate office, or sends email or a fax to the user at the corporate office is unaware that the user is actually not physically located at the corporate office, but rather is at a remote location. In general, a secretary or receptionist located just outside the user's physical corporate office location is unable to discern, without opening the door, whether the user is located in his office at the corporate office or at the remote location" ('639 patent, col. 3, lines 4-12).

123 Tr. 313-14, 470.

124 Docket no. 104 at 12. 125 Docket no. 104 at 12.

--- End Footnotes---

The words of the patent clearly indicate that transparency was part of the claimed invention. 126 In addition, the specification repeatedly emphasizes the importance of transparency to the concept of virtual presence and defines "virtual presence" or "telepresence" to include transparency. This definition, if not dispositive, is highly relevant. 127

--- Footnotes ---
126 As noted by plaintiff in its opening argument, "particular embodiments appearing in the specification will not generally be read into the claims . . . What is patented is not restricted to the examples, but is defined by the words in the claims." Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988) (citations omitted).

127 Vitronics, Corp., 90 F.3d at 1582 ("the specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term"); Renishaw PLC, 158 F.3d at 1250.

--- End Footnotes--

Transparency is not at issue with respect to data communications. 128 Transparency is at issue with respect to voice communications. Plaintiff's expert, Mr. Bradner, a person with ordinary skill in the art, agreed at the preliminary injunction hearing that, under the words of the '639 patent, a person who calls the office number of the remote user and whose call is transferred to a remote location should not be able to perceive that the remote worker is not in the office; therefore, if the forwarding of the call is apparent, it would be "incomplete virtual presence, at best" and that "virtual presence" "probably" is not present as that term is used in the patent. 129 To practice the invention, the PBX must send calls to the remote worker in a way that insures transparency. 130

--- Footnotes ---
128 Although the '639 patent purports to offer the full capability of the office LAN to the remote user, Mr. Witt admitted that there are some data, such as files sent to a fixed IP address of an office computer by file transfer protocol, that cannot be accessed remotely (Tr. 542-46, 566-68).

129 The Court notes that Mr. Bradner's declaration in opposition to summary judgment asserts that "virtual presence" under the patent "only requires that the remote worker reasonably appear to be in the office" rather than transparency (docket no. 108, ex. 1 at 2). To the extent, that this expert's testimony refers to claim construction, it has been supplanted by the Court's
legal decision on the meaning of "virtual presence" which includes the extension of the full capabilities of the PBX and LAN to the remote worker.

130 Mr. Bradner testified that the '639 patent covers situations in which there is no call forwarding at all (Tr. 816-17). For example, Mr. Bradner agreed that if a remote worker never works in the office and, in fact, does not have an office telephone, the VPS does not use call forwarding or remote call forwarding to forward office calls to the remote worker, but, instead, the remote worker is assigned an extension on the PBX that is permanently attached to the VPS.

The term "virtual presence server" means a server located at the corporate office that executes software that enables the remote user to maintain a virtual presence at the corporate office by dialing the VPS and establishing a direct connection.

The "summary of the invention" section of the '639 patent states: "The [VPS] executes software that enables the remote user to maintain a virtual presence at the corporate office" by dialing the VPS and establishing a connection." 146 Access from the remote user to the VPS is through the PSTN and not the LAN. After the remote user connects to the VPS through the PSTN, then the remote user connects to the LAN through the VPS. Access from the remote user to the telephony server is not through the LAN or RAS (remote access server) but directly through the VPS.

Plaintiff proposes a definition of VPS as a node on the LAN. With respect to data communications, the VPS may be a node on the LAN even though figure two to the patent suggests that the VPS is not connected directly to a LAN but connected to a LAN through a RAS. With respect to voice communications, a remote worker receives a call at a remote location when the call is sent from the PBX through the VPS. The LAN is not involved at all in the delivery of the call to the remote worker and, so far as voice is concerned, the VPS is not even a node on the LAN. Accordingly, plaintiff's definition of VPS to mean an node on a LAN is not accepted.

Plaintiff also suggests that the VPS must be capable of supporting more than one user at the same time. The definition of "remote user" makes it clear that a system that covers only one user is covered by the '639 patent. The two testifying experts, Bradner and Weiss, people with ordinary skill in the relevant art, each agreed that a server can serve only one user and that the claimed invention could be practices by a system that supports only one remote user. 147

Plaintiff proposes a definition of VPS as a node on the LAN. With respect to data communications, the VPS may be a node on the LAN even though figure two to the patent suggests that the VPS is not connected directly to a LAN but connected to a LAN through a RAS. With respect to voice communications, a remote worker receives a call at a remote location when the call is sent from the PBX through the VPS. The LAN is not involved at all in the delivery of the call to the remote worker and, so far as voice is concerned, the VPS is not even a node on the LAN. Accordingly, plaintiff's definition of VPS to mean an node on a LAN is not accepted.

Plaintiff also suggests that the VPS must be capable of supporting more than one user at the same time. The definition of "remote user" makes it clear that a system that covers only one user is covered by the '639 patent. The two testifying experts, Bradner and Weiss, people with ordinary skill in the relevant art, each agreed that a server can serve only one user and that the claimed invention could be practices by a system that supports only one remote user. 147

Plaintiff proposes a definition of VPS as a node on the LAN. With respect to data communications, the VPS may be a node on the LAN even though figure two to the patent suggests that the VPS is not connected directly to a LAN but connected to a LAN through a RAS. With respect to voice communications, a remote worker receives a call at a remote location when the call is sent from the PBX through the VPS. The LAN is not involved at all in the delivery of the call to the remote worker and, so far as voice is concerned, the VPS is not even a node on the LAN. Accordingly, plaintiff's definition of VPS to mean an node on a LAN is not accepted.

Plaintiff also suggests that the VPS must be capable of supporting more than one user at the same time. The definition of "remote user" makes it clear that a system that covers only one user is covered by the '639 patent. The two testifying experts, Bradner and Weiss, people with ordinary skill in the relevant art, each agreed that a server can serve only one user and that the claimed invention could be practices by a system that supports only one remote user. 147
A virtual presence server communications device is a modem, ISDN adapter or similar device attached to the VPS that connects to the VPS through the transmission media to allow the remote user to dial up the VPS and establish a connection with the VPS through the connection media in order to transmit and receive communications.

"Virtual Private Network"

Alcatel's proposed construction for "virtual private network" is "a collection of packet-based network elements logically connected over one or more physical paths." Cisco's proposed construction is "collection of logical nodes and virtual paths dedicated to one network customer." The primary differences between the two constructions is that Cisco seeks to limit the "virtual private network" to being comprised of "virtual paths" 49 and being dedicated to only one customer, while Alcatel seeks a construction without such limitations.

In determining the proper construction for this term, the Court will first look to the claim language itself. See Kraft Foods, 203 F.3d at 1366. In this regard, when the term "virtual private network" 50 is used in the claim language, it is always specifically described to include "a collection of packet-based network resources including respective network elements, customer premises equipment, virtual paths, and corresponding virtual circuits." See, e.g., Seid Supp., col. 20, ll. 15-18; col. 21, ll. 27-30; col. 23, ll. 3-6 (hereinafter Seid, at 20:15-18, 21:27-30, 23:3-6). Thus, limiting "virtual private networks" to being comprised solely of logical nodes and virtual paths, or limiting it only to network elements, would be at odds with the claim language.

Next, the Court turns to the language in the specification. See Interactive Gift Express v. Compuserve, 256 F.3d at 1336 ("Despite the plain language of the claims, we turn to the specification to discern whether [the inventor] attributed a different meaning to the term . . ."). Here, the specification provides support for both parties' constructions. The specification describes virtual private networks as being "simply a collection of network resources taken from an underlying network." Seid, at 1:46-47. The "virtual private network" in this invention is also described as follows:

According to the present invention, in a packet switching (packet-based) network, such as a frame relay (FR) network,
which includes network resources made up of networked elements and customer premises equipment interconnected by one or more physical paths, a VPN [virtual private network] is built above the underlying network and includes selected portions of the network resources. The VPN is a collection of logical nodes and virtual paths (VPs) and includes one or more virtual circuits (VCs), each VC being a logical connection between CV terminators including network elements and customer premises equipment.

Seid, at 2:56-66 (emphasis added).

Elsewhere, the patent again describes a "virtual private network" as "a collection of logical nodes and virtual paths," although the patent history shows that Alcatel specifically described the "virtual private network" to include "a collection of network resources including network elements, customer premises equipment, virtual paths, and corresponding virtual circuits." Id. at 5:32-34, AL0001143.

Taken together, the claim language itself clearly does not restrict the "virtual private networks" to logical nodes and virtual paths, nor does it only consist of network elements. However, in their proposed constructions of this term, both parties appear to misconstrue the fundamentals of claim construction. When the term "virtual private network" is being used in the claims, it is not creating a new term, but is using a term previously available in the prior art, and then specifically describing in the claims the differences of the virtual private networks in this invention. Therefore, the Court will not construe a claim term to include the limitations that are separately included in the actual claim. The reason why the above-referenced limitations are separately disclosed in every independent claim that contains the term "virtual private network" is because such limitations are not implied in the term itself. 51

51 In similar fashion, Cisco argues that "virtual private networks" must be dedicated to one network customer. However, every claim using the term "virtual private network" contains the limitation that the virtual private network is "carrying traffic associated with a particular customer of the packet-based network." See, e.g., Seid, at 19:66-20:1, 21:11-13, 24:18-20. Therefore, the fact that the inventor included this limitation in every independent claim containing the term "virtual private network" is strong evidence that the limitation was not implicit in the term itself.

The specification and the claim language show that a "virtual private network," as the term is used in the claims, is comprised of selected portions of network resources from the physical network over which the virtual private network is built. 52 See id. at 2:60-62. Any further limitation is contained in the claims themselves. Therefore, the Court construes the term "virtual private network" to mean "collection of selected portions of network resources logically connected over one or more physical paths."

52 The extrinsic evidence provided by the parties does nothing to alter the meaning of term as described in the patent.
be used to construe "virtual private network," whether VirnetX's proposed construction is overly broad, whether "virtual private network" requires anonymity, and whether IP tunneling is a limitation on "virtual private network." In light of intrinsic and extrinsic evidence, the Court construes "virtual private network" as "a network of computers which privately communicate with each other by encrypting traffic on insecure communication paths between the computers."

The '135 patent does not provide an explicit definition for "virtual private network." However, the '135 patent uses "virtual private network" in ways that are consistent with a "virtual private network" being "a network of computers which privately communicate with each other by encrypting traffic on insecure communication paths between the computers." The specification discusses a VPN in the context of connecting and communicating between nodes. For instance, the specification states, "In a second mode referred to as 'promiscuous per VPN' mode, a small set of fixed hardware addresses are used, with a fixed source/destination hardware address used for all nodes communicating over a virtual private network." Col. 23:11-14. This excerpt shows that the '135 invention includes nodes (computers) communicating over a virtual private network.

Furthermore, the claims and specification discuss a VPN in the context of private communication on insecure communication paths. Claim 1 states "A method of transparently creating a virtual private network (VPN) between a client computer and a target computer" and then states the steps of accomplishing this method including "requesting access to a secure web site." Col. 47:20-22, 30-31. Thus, claim 1 associates a "virtual private network" with "security." Also, the specification states, "If the user is not authorized to access the secure site, then a 'host unknown' message is returned (step 2705). If the user has sufficient security privileges, then in step 2706 a secure VPN is established between the user's computer and the secure target site." Col. 39:21-25. This excerpt shows how a "virtual private network" establishes a secure connection between nodes where security may not otherwise exist. Thus, the claim language and the specification are consistent with construing a "virtual private network" as "a network of computers which privately communicate with each other by encrypting traffic on insecure communication paths between the computers."

Extrinsic evidence also supports this construction. The Wiley Electrical and Electronics Engineering Dictionary defines a "virtual private network" as

A network which has the appearance, functionality, and security of a private network, but which is configured within a public network, such as the Internet. The use of a public infrastructure while ensuring privacy using measures such as encryption and tunneling protocols, helps provide the security of a private network at a cost similar to that of a public network.

WILEY ELECTRICAL AND ELECTRONICS ENGINEERING DICTIONARY 842 (2004) (published by the IEEE Press). This dictionary definition describes a network that has attributes of a private network but runs on a public network. The dictionary definition further states that encryption may be used to achieve privacy. The Court's construction is in line with this definition. All pertinent aspects of the Court's construction are explicitly found in the dictionary definition except for "insecure communication paths," which simply corresponds to the dictionary definition's reference to "a public network." Thus, the Court's construction is in accord with the dictionary definition.

Also, the '135 patent refers to the "FreeS/WAN" project in the specification. The specification explains that the "FreeS/WAN" project is developing a conventional scheme that provides secure virtual private networks over the Internet. Col. 37:50-58. The "FreeS/WAN" project defines "virtual private network" as "a network which can safely be used as if it were private, even though some of its communication uses insecure connections. All traffic on those connections is encrypted." "FreeS/WAN" Glossary 24-25, Pl. Br. (Docket No. 194) Ex. 6. The Court's construction is consistent with this definition. 3

--- Footnotes ---

3 The Court's construction largely adopts VirnetX's proposal. However, this construction excludes VirnetX's proposed language regarding the ability of a virtual private network to expand. VirnetX proposes this language to account for the possibility of including additional computers and communication paths in a virtual private network. Pl.'s Br. 6. The Court's construction does not limit a "virtual private network" to any particular number of computers or communication paths. Thus, VirnetX's proposed language is superfluous. Accordingly, the Court's construction accounts for the possibility of additional computers or communication paths.
Microsoft contends that the "FreeS/WAN" glossary is not an explicit definition of "virtual private network" and thus is not persuasive. Microsoft argues that the '135 patent's reference to the "FreeS/WAN" project is made only to describe the prior art and not to define "virtual private network." However, the specification explains that the "FreeS/WAN" project has been developing an implementation of one conventional scheme that provides secure virtual private networks over the Internet. Col. 37:50-58. Also, the applicant disclosed the "FreeS/WAN" project as prior art. See Def.'s Br. (Docket No. 201) Exs. M-O. While these references to the "FreeS/WAN" project do not explicitly define "virtual private network," they at least point to extrinsic evidence that can be considered in construing "virtual private network." Thus, the Court may consider the "FreeS/WAN" project/glossary as extrinsic evidence for construing "virtual private network."

Microsoft also contends that even if the "FreeS/WAN" glossary offers an acceptable definition for "virtual private network," portions of the "FreeS/WAN" glossary definition show that VirnetX's proposed construction is overly broad. Microsoft cites the portion of the "FreeS/WAN" glossary definition for "virtual private networks" that states "IPSEC [Internet Protocol Security] is not the only technique available for building VPNs, but it is the only method defined by RFCs [Request for Comments, Internet documents--some of which are informative while others are standards] and supported by many vendors. VPNs [virtual private networks] are by no means the only thing you can do with IPSEC, but they may be the most important application for many users." Def.'s Br. (Docket No. 201) at 10; "FreeS/WAN" Glossary 25, Pl. Br. (Docket No. 194) Ex. 6. Microsoft points out that IPSEC is the only method defined by RFCs and supported by many vendors. Microsoft argues that this narrow language shows that the "FreeS/WAN" glossary does not identify Secure Sockets Layer ("SSL") or Transport Layer Security ("TLS") as methods for building "virtual private networks." Microsoft then argues that VirnetX's proposed construction is overly broad because it allows for a network using SSL and TLS. However, Microsoft's cited excerpt is an ancillary portion of the "virtual private network" definition and is set apart in a different paragraph from the primary portion of the definition. See "FreeS/WAN" Glossary 24-25, Pl. Br. (Docket No. 194) Ex. 6. Also, Microsoft selectively asserts that IPSEC is the only method defined by RFCs and supported by many vendors and ignores that its cited excerpt states that "IPSEC is not the only technique available for building VPNs." Thus, Microsoft's cited excerpt does not support that the "FreeS/WAN" glossary restricts "virtual private network" to IPSEC.

Microsoft also contends that VirnetX's proposed construction suggests that the "virtual private network" achieves only data security when it should include both data security and anonymity. Microsoft is correct that "private" in "virtual private networks" means both data security and anonymity. The specification supports this interpretation. The Background of the Invention section states "[a] tremendous variety of methods have been proposed and implemented to provide security and anonymity for communications over the Internet." Col. 1:15-17. This section further describes data security as being "immune to eavesdropping" and states "[d]ata security is usually tackled using some form of data encryption" and anonymity as "preventing[ing] an eavesdropper from discovering that terminal 100 is in communication with terminal 110." Col. 1:23-25, 38-39, 27-28. This language suggests that the claimed invention will achieve both data security and anonymity because it prefaces the Detailed Description of the Invention section, which describes a method of creating a virtual private network.

Indeed, the descriptions of the invention later indicate that "private" in "virtual private network" means data security and anonymity. The Detailed Description of the Invention, Further Extensions section describes a mode of the invention as being able to "reduce the amount of overhead involved in checking for valid frames" while allowing "IP addresses . . . [to] still be hopped as before for secure communication within the VPN." Col. 2:66-25 (emphasis added). The "anonymity" feature of a VPN can be handled by the Tunneled Agile Routing Protocol ("TARP"), which executes "address hopping." See Col. 2:66-3:17; see Col. 5:49-64. Thus, the language "still be hopped" indicates that the modifications of the invention retain the anonymity feature of the "virtual private network." Accordingly, the Court construes "virtual private network" as requiring both data security and anonymity.

--- Footnotes ---

4 While the specification states that this mode of the invention "[o]f course . . . compromises the anonymity of the VPNs," this only means that those outside the VPN can discover the VPN and does not mean that the anonymity of the users within the VPN is compromised. This is clear from the example that follows the "compromising anonymity of the VPN" statement: "(i.e., an outsider can easily tell what traffic belongs in which VPN, though he cannot correlate it to a specific
machine/person)." Col. 23:25-28 (emphasis added). Thus, the specification is consistent with construing a "virtual private network" as achieving both data security and anonymity.

Finally, Microsoft contends that "virtual private network" requires IP tunneling. Microsoft argues that the intrinsic evidence shows that TARP and IPSEC are two ways of obtaining anonymity in a virtual private network. Microsoft then argues that tunneling is required to achieve anonymity when TARP, IPSEC, or any other means is employed to achieve anonymity. The Court first and foremost considers the intrinsic evidence. The claims do not assert "tunneling" as a limitation nor has Microsoft pointed to any type of limitation in the specification. Microsoft's citations to the Background of the Invention section only state explanations of how TARP works and does not use any limiting language. See Col. 3:5-18, 19-20, 58-60. Furthermore, Microsoft's citation to the Detailed Description of the Invention, Further Extensions section only refers to a preferred implementation of the virtual private network, stating "The VPN is preferably implemented using the IP address hopping features of the basic invention described above, such that the true identity of the two nodes cannot be determined even if packets during the communication are intercepted." Col. 38:2-6. Again, this excerpt does not include any limiting language and in fact expressly uses the non-limiting language "preferably." Accordingly, "virtual private network" is not limited to IP tunneling, and the Court construes "virtual private network" as "a network of computers which privately communicate with each other by encrypting traffic on insecure communication paths between the computers."

4782

S. "virtual queue"

The Plaintiff proposes the following construction for "virtual queue": "an electronically-stored representation of a physical queue including reservation information for an attraction retained in solid-state memory such as RAM, magnetic storage such as a disk drive, or other electronic storage facility." The Defendants acknowledge that a "virtual queue" consists of a list of pending and confirmed reservations. (Defs.' Opening Claim Construction Br. at 44.) Nevertheless, the Defendants argue that "virtual queue" is part of a means-plus-function limitation in claims 5 and 17, and a step-plus-function limitation in claim 19. Step-plus-function limitations, like means-plus-function limitations, are permitted under § 112, P 6 for method claims. Similar to the use of "means," if a claim uses the term "steps for," it signals the patentee's intention to invoke § 112, P 6. Likewise, the absence of that language creates a contrary presumption. Cardiac Pacemakers, Inc. v. St. Jude Med., Inc., 381 F.3d 1371, 1382 (Fed. Cir. 2004); Masco Corp. v. United States, 303 F.3d 1316, 1326 (Fed. Cir. 2002). None of the claims at issue contain "means" or "steps for" language and, thus, it is presumed that § 112, P 6 is not applicable. The Defendants have not offered any evidence to rebut the presumption, and the Court sees no basis for construing "virtual queue" as a means-or step-plus-function limitation. Instead, the Court agrees with the Plaintiff that "virtual queue" is intrinsically defined in the specification. As noted above, the present invention is directed at a system and method for assigning and managing patron reservations in such a way that the patentee can avoid unnecessary time spent waiting in lines, or physical queues, for attractions or other activities. As explained in the Background section of the specification, "[i]t is desirable to allow a patron to effectively 'wait' in line while engaging in other activities in the park . . . so that the time spent waiting is otherwise productive, thus reducing the feeling of having wasted time when delays or malfunctions occur." (col. 2, ll. 37-43.) Therefore, rather than standing in a physical queue, the patron is able to maintain his position in absentia through a reservation electronically stored in the attraction computer. (See col. 10, ll. 61-63 ("Virtual queue 210 is preferably stored in RAM 123 and may be stored, or mirrored to magnetic storage such as disk drive. . . .").) More specifically, the reservations are recorded in the "virtual queue," as described in the specification.

Virtual queue 210 maintains a list of pending and confirmed reservations for the attraction. Virtual queue 210 holds a varying number of reservations, each reservation having data identifying or describing the patron holding the reservation, and either a time or position for the reservation.

(col. 10, ll. 12-16.) Therefore, consistent with the specification, the Court will adopt the Plaintiff's construction and construe "virtual queue" as "an electronically-stored representation of a physical queue including reservation information for an attraction retained in solid-state memory such as RAM, magnetic storage such as a disk drive, or other electronic storage facility."
"Virtual Router"

Cisco's proposed construction of "virtual router" is "logical router that is identified by addresses which can be shared by physical routers." 33 Alcatel's proposed construction is "a virtual entity defined by a group virtual MAC address and a group virtual network layer address that can be emulated by a physical router assuming the state of the active router."

Footnotes

33 In the Revised Joint Statement, on which the Court is relying in determining the parties proposed constructions, Cisco actually proposed the following construction: "Logical router that is identified by addresses which can be adopted by physical routers." Revised Joint Statement, Ex. B, at 13 (emphasis added). However, in its opening claim construction brief, Cisco once again alters its proposed definition, to Alcatel's disadvantage, since Alcatel's opening brief relied upon the proposed construction contained in the Revised Joint Statement. Nevertheless, because the Court finds both of Cisco's proposed constructions overly broad in light of the patent, the Court does not find it necessary to decide whether Cisco should be held to the proposed construction that they originally put forth, or their new proposed construction.

Footnotes

The patent specification contains the following definition of virtual router:

A virtual router in this invention is defined by virtual MAC layer and network layer (e.g., IP) addresses which are shared by a group of routers running the protocol of this invention. The router selected by the protocol to be the active router (R1, R2 or R3 in this case) adopts these virtual MAC and network layer addresses - possibly in addition to its own addresses - and thus receives and routes packets destined for the group's virtual router.

Li Supp., col. 6, 11. 46-53 (hereinafter Li, at 6:46-53).

This definition contemplates the "virtual router" being defined by virtual MAC layer and network layer addresses. Cisco argues that this definition was not meant to be a definition of "virtual router" since it was not contained in the "Definitions" section of the patent. The Court finds this language inconclusive, as the above language in the specification clearly states that it is defining "virtual router" as it is used "in this invention," and is not simply limiting the definition to a particular embodiment, but the language is found within the description of the preferred embodiment, and therefore it may simply be implied that it is describing only the invention identified in the preferred embodiment. 34

Footnotes

34 Regardless, even if the definition of "virtual router" was referring to the preferred embodiment, that would not preclude the Court from using that definition to construe the claim term "virtual router" if the term "virtual router" is used throughout the patent in a manner consistent with only that definition. See Bell Atlantic Network Svcs., Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1271 (Fed. Cir. 2001); see also Comark, 156 F.3d at 1186 ("We recognize that there is sometimes a fine line between reading a claim in light of the specification, and reading a limitation into the claim from the specification.").

Footnotes

Instead, Cisco attempts to define "virtual router" by using the term "logical router," which is not a term used anywhere in the patent, nor is it claimed to be a term of art, and therefore provides no guidance in defining "virtual router." Cisco offers nothing to support its argument other than the conclusory statement that claim 10 (the first claim to introduce the term "virtual router") "shows that the 'virtual router' is the logical router to which packets are addressed by a host." Cisco's Opening Claim Construction Brief Concerning U.S. Patent No. 5,473,599 (Li) ("Cisco's '599 Opening Brief"), at 7. However, claim 10 never refers to a "logical router," and thus does not support Cisco's proposed construction.

- 5006 -
Cisco also argues that a "virtual router" does not have to be comprised of both MAC layer and network layer addresses. In support of this argument, Cisco points to the definition of "virtual address." In that definition, the patent describes the virtual router as adopting "one or more virtual addresses." Li, at 4:36-37. Cisco claims that this demonstrates that a virtual router can be comprised of one or more addresses, and not simply a combination of MAC and network layer addresses. However, Cisco seemingly ignores the next sentence in the definition, which defines a virtual address as encompassing "both MAC layer and network layer addresses" in preferred embodiments. Thus, when the patent defines the virtual router as adopting "one or more virtual addresses," it is referring to adopting one or more combinations of MAC and network layer addresses. Nevertheless, the fact that the patent specifically identified the MAC layer and network layer address as the type of addresses used in preferred embodiments is an indication that the invention could be applicable to other types of addresses.

Finally, Cisco argues that the principles of claim differentiation do not allow the Court to construe "virtual router" as being defined by MAC and network layer addresses because claims 16 and 27 expressly add this address combination as a limitation to claims 10 and 21. However, while the principles of claim differentiation instruct that a claim term should not be construed so as to make a claim superfluous, Alcatel's proposed construction would not make claims 16 and 27 superfluous because they differ from claims 10 and 21 in ways other than the reference to MAC and network layer addresses. See Tate Access Floors, 222 F.3d at 967; Comark Communications, 156 F.3d at 1187. In particular, both claims 16 and 27 refer to an IP address rather than simply a network layer address, which, as Cisco's expert acknowledges, is significant since the invention could be used on IPX networks, which do not use IP addresses at all. See Lumish Decl., Ex. DD ("Halpern '599 Report"), at 9. Furthermore, claim 16 requires the virtual router of claim 10 to have an IP address and MAC address that is distinct from the IP and MAC addresses of the two or more other routers, thus providing an additional limitation. See Li, at 18:37-40.

Despite the flaws in Cisco's arguments, Alcatel's proposed construction is also not without error. Alcatel's argument is entirely based on the language defining "virtual router" in the preferred embodiment, as well as Alcatel's assertion that the specification discloses only MAC and network layer addresses. While the Court agrees that the patent discusses only MAC and network layer addresses, the claim language and the specification (other than the preferred embodiment) indicate that the claims are broader than simply MAC and network layer addresses.

In particular, claims 1 to 9 claim a router that is capable of adopting a group virtual address and becoming the active router, 35 without any limitation to any particular type of address that must be adopted, be it a MAC address, a network layer address, or both. See id. at 17:4-55. Furthermore, claim 10 - where the term "virtual router" is first used - also does not make any reference to MAC or network layer addresses. In fact, the first time the terms MAC address or IP address are used in the claims is not until claim 16. While the Court recognized above that claim differentiation does not necessarily indicate that claim 10 was intended to exclude those limitations, the fact that no reference was made in 15 prior claims to any specific type of addresses that must be used in this patent would apprise one of ordinary skill in the art that those claims were not limited to those specific types of addresses.

--- Footnotes ---

35 The parties agree that an "active router" is "a router emulating the virtual router." See Revised Joint Statement, Ex. B, at 14.

--- End Footnotes ---

When reading the claims in light of the specification, the Court finds that while a "virtual router" is a virtual entity that is defined by a group virtual MAC address and a group virtual network layer address in the preferred embodiment, there is no limitation to those specific types of addresses. A MAC address is "intended to apply to a specific physical device no matter where it is plugged into the network." Id. at 4:25-27. As the patent notes, "This should be distinguished from the case of a network layer address ... which changes depending upon where it is plugged into the network." Id. at 4:29-32. Hence, a "virtual router" requires an address capable of being emulated by a physical router (i.e. the active router) that identifies both a physical device and its location in the network. To the extent that another address or set of addresses other than the combination of a MAC address and a network layer address is capable of performing this function, then that type of address or set of addresses could be used to define the "virtual router."

In sum, while Alcatel's proposed construction generally complies with the language of the patent, it limits the claims beyond
what the claim language provides. Furthermore, Cisco's proposed construction is overly broad and does not provide a workable definition of a "virtual router." Therefore, the Court construes the term "virtual router" as used in claims 10 through 28 to be "a virtual entity defined by an address or set of addresses capable of identifying a device and its location in the network that can be emulated by a physical router."

Virtual terminal process

Again the Court rejects both parties' proposed constructions and construes "virtual terminal process" to mean "a process to simulate the operation of a selected real terminal with respect to the transmission and receipt of input and output streams, except that each virtual terminal merely prepares and stores a set of instructions (a display list) for creating a full screen display according to the data from the associated first process; and each virtual terminal process does not independently control a separate screen." This construction is taken from the inventor's description of "virtual terminal" process, a term he coined, and with his statements made during prosecution in discussing an implementation of the invention. See Col. 2:27-39; Prosecution history, Amendment, June, 1987, pg. 4 ("[e]ach virtual terminal emulates a real terminal with respect to sending and receiving the input and output data streams produced by the corresponding program").

VI. "Virtual Topology"

According to Claim 1, the intermediate nodes "define a virtual topology on top of a computer-based communications network." In plaintiff's view, a virtual topology is "a topological representation of overlay network connectivity." This definition is lifted from the patent's description of a preferred embodiment. See Col. 6:11-12. In defendant's view, a virtual topology is "a set of connections between nodes of an underlying network that are not part of the physical configuration of the network."

As their competing constructions indicate, the parties agree that the virtual topology is a map of connections among intermediate nodes, and neither party disputes that the nodes themselves are part of the physical network. They disagree, however, as to whether the internode connections that make up the virtual topology may themselves exist in physical space. While defendant argues that the virtual topology includes only connections between intermediate nodes that are not connected physically, plaintiff contends that the virtual topology includes all connections between intermediate nodes, whether or not the nodes are physically linked.

Once again, defendant points to nothing in the specification or prosecution history suggesting that the virtual topology consists only of the subset of inter-node connections that are not part of the network's physical configuration. Although in practice it may be true that most or even all of the intermediate nodes on a particular network are not physically connected, the claim language does not exclude the possibility that two intermediate nodes may have a physical connection between them. The intrinsic evidence supports a construction of "virtual topology" that includes all connections between intermediate nodes, whether or not those connections are physical.

Plaintiff's proposed construction, however, uses the word "topological" to define "topology." Such a construction will be of limited utility to the trier of fact. Accordingly, the Court will construe "virtual topology" to mean "a map of the connections between intermediate nodes."

2. Virtually Simultaneously and Concurrently

Claim 1 refers to information being "simultaneously and concurrently" entered by two persons sharing a common display at
their respective stations. This means that a person at one station can enter information for display at both stations at the precisely identical time that a person at another station is entering information for display of both stations (Tr. 40-43).

Claim 1 refers to information being "virtually" rather than precisely simultaneously and concurrently" transmitted because, necessarily, the transmission of data from one station to another cannot be absolutely instantaneous. In context, the term "virtually simultaneously and concurrently" means that the transmission is sufficiently swift that insofar as humans are able to perceive, the transmission is effectively, even though not precisely, instantaneous (Tr. 43).

J. "visible exterior surface"

The plaintiff proposes "a surface, at least a portion of which is visible from the exterior of the light bar." Defendants propose "outside surface in plain view."

The plaintiff argues that the prosecution history shows that the examiner characterized prior art as a light enclosed within a transparent cover and visible from the exterior. The plaintiff further argues that, based on this characterization, the patentee amended claims to distinguish the invention from the prior art. See, e.g., '269 patent, Prosecution History, July 18, 2001 Office Action; '269 patent, Prosecution History, Sept. 26, 2001 Response to Office Action. According to the plaintiff, Defendants' construction of "outside surface" would not encompass the embodiments of a light bar with a transparent cover. The plaintiff argues that the requirement of "outside surface" would render the "visible" limitation superfluous, which is contrary to case law. See Merck & Co., Inc., 395 F.3d 1364, at 1372. The plaintiff also argues that it added "a portion" to its proposed construction because something does not need to be completely in plain view in order to be "visible" (e.g., a man sitting behind a desk).

Defendants claim that their definition is appropriate based on the ordinary and plain meaning of the phrase. They also argue that the plaintiff's construction does not make a distinction between "light support" and "light bar." Claims of the '996 and '487 patent involve a "light support" with a "visible exterior surface" while the claims of the '269, '631, '217, and '578 patents involve a "light bar" with a "visible exterior surface." Defendants further argue that in order to distinguish prior art, the patentee stated that the prior involved LEDs within a cylindrical glass as opposed to the invention where the LEDs are mounted on the exterior surface. '189 application, Sept. 5, 2001 Amendment, at 10. Defendants also point to provisional applications which claim that the invention eliminates the need for filters, reflectors, and lenses.

The Court disagrees with the defendants and does not find any support to limit the construction to the "outside surface." The Court concludes that the phrase can be understood as written and no further construction is necessary.

C. "throughout the entire visible spectrum from about 380 to about 780 nanometers, comprising"

TLI contends that the term "throughout the entire visible spectrum from about 380 to about 780 nanometers" should be accorded its ordinary and customary meaning in the art. See TLI's Br. at 12. According to TLI, the term "visible spectrum" is known as the portion of the electromagnetic spectrum that is visible to and can be detected by the human eye. See id. Accordingly, one skilled in the art understands that there are no exact bounds to the visible spectrum, and that a typical human eye will respond to wavelengths from about 380 to 780 nanometers. See id.

Sylvania argues that the claim term "throughout the entire visible spectrum from about 380 to about 780 nanometers" modifies the claim element "substantially identical in uniformity to" which as explained above, is explicitly defined in the specification. See Sylvania's Br. at 9. Sylvania further asserts that the "visible spectrum" range outlined in this claim ("from about 380 to about 780 nanometers") is in conflict with the range set forth in the specification for the defined term "substantially identical," which states "between about 400 and 700 nanometers"). See id. Sylvania contends this conflict creates an inherent inconsistency as to what defines the "visible spectrum." Accordingly, Sylvania argues that due to this
inherent inconsistency, the claim element cannot be construed and is indefinite. Datamize v. Plumtree Software, Inc., 417 F.3d 1342, 1347 (Fed. Cir. 2005)(claims that are "insolubly ambiguous" are indefinite). See id.

I find, however, that TLI's proposed construction of the term "visible spectrum" is not inherently inconsistent with the term "substantially identical in uniformity to." The reference in the '017 Patent to the range from 400 to 700 nanometers does not refer to the visible light spectrum, but instead refers to artificial light emitted from a bulb that can (if within specified values) be considered substantially identical to natural daylight. As stated above, the patentee simply chose to define "substantially identical" light as that which falls within 30 percent of the D(l) value of a reference daylight within the 400 to 700 nanometer range, provided that the combined average of all wavelengths within the 400 to 700 range is within 10 percent of the D(l) value of the chosen reference daylight. That the patentee chose to focus only on a part of the visible light spectrum (400 to 700 nanometers) rather than the "entire" visible spectrum (380 to 780 nanometers) in determining whether or not artificial light from the disclosed bulb is "substantially identical" to natural daylight is a choice that the patentee was free to make, and does not suggest that the term "visible light spectrum" should be afforded any construction other than its known meaning within the art. Accordingly, I find that the term "visible light spectrum" refers to the light spectrum between 380 and 780 nanometers.

2. "Displaying" and "visual display" (claims 1, 3, 4, 21)

TriPath contends that the terms "displaying" and "visual display" should be construed broadly to mean "spreading before the view" and "a display made available to a human observer," respectively. Cytyc interprets the terms in a computer science context: "presenting information on a computer screen" and "the presentation of scanned images on a computer monitor." The disagreement here is not about the ordinary meaning of the word display, but the mechanism by which the objects are displayed. TriPath's proposed construction would not specify any particular mechanism, while Cytyc would restrict the claims to only one.

Although I have construed "image" to be a digital representation, it does not necessarily follow that "display" or "visual display" must be on a computer monitor. If, for example, the patent contemplated another vehicle for presenting objects to humans, including digital images, the definition of "displaying" and "visual display" would expand to incorporate it. However, the patent appears to leave no room for a display other than on a computer monitor.

The claims themselves do not specifically mention a computer monitor, but properly read, the intrinsic evidence suggests one alternative. Whenever the term "displaying" or "visual display" appears in the claims, it is in the context of a digital object or image. For example, claim 1(e) states "displaying at least part of such second image to produce a visual display of said at least one selected object." As discussed above, "image" refers to a digital representation. Claim 1(b) makes clear that an "object" is part of an "image" and therefore must also be digital.

Moving from the claims to the specification, the Summary of the Invention indicates only one possible mechanism for displaying digital images or objects: a monitor. The Summary describes the invention as an apparatus consisting of "a monitor for displaying at least part of the second image to produce a visual display of at least one of the objects." 182 patent at col. 2, 11. 52-54. Figure 1 is a diagram "of a cytopathological classification or screening device in accordance with the present invention." It shows a high resolution monitor as the mechanism for display. Figure 3, another diagram of the screening device, also shows a monitor for display.

The Detailed Description of the Invention repeatedly mentions displays on a "summary screen." See, e.g., id. at col. 4, 11, 40, 45, 46, 53, 60, 68 and col. 7, 11, 61, 62. Some of these references are, to be sure, with respect to a preferred embodiment. Keeping in mind that a court must not read a preferred embodiment as a limitation on the claim, Phillips, 415 F.3d at 1323, the written description still points towards a monitor as the only display mechanism. The preferred embodiments provide examples of ways to configure the display on the summary screen, to arrange the images, and to identify suspect cells, but only one way to view the displays: a screen. 182 patent at col. 4, 11., 40, 45, 46, 53, 60, 68 and col. 7, 11, 61, 62. The examples make clear that the patentee contemplated a variety of uses for the displays, but never doubted that the displays would be presented on a screen or monitor.
Claim 21 uses a different form than claim 1, but yields the same definition of "displaying" and "visual display". Claim 21 reads in pertinent part, a "means for displaying at least part of such second image to produce a visual display of said at least one selected object" (emphasis added). This is a "means plus function" claim that invokes 35 U.S.C. § 112, P 6:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

Accordingly, the definitions of "displaying" and "visual display" are limited to the structures or their equivalents actually described in the specification. As discussed above, the specification describes no display mechanism other than a monitor. Therefore, the terms "displaying" and "visual display" as used in claims 1, 3, 4, and 21 refer to displays on a computer monitor or screen.

Scientific-Atlanta further contends that Gemstar's proposed construction would improperly include conventional cursors, which were disclaimed in the written description when it discussed the conventional cursor's undesirable properties. Scientific-Atlanta responds that Gemstar's restriction requirement argument is both waived and incorrect.

We begin our claim construction analysis with the words of the claim. Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1201 (Fed. Cir. 2002). "Unless compelled otherwise, a court will give a claim term the full range of its ordinary meaning as understood by persons skilled in the relevant art." Id. at 1202. The ordinary and customary meaning of a claim term may be determined by reviewing a variety of sources, which may include the claims themselves; dictionaries and treatises; and the written description, the drawings, and the prosecution history. Ferguson Beauregard v. Mega Sys., LLC, 350 F.3d 1327, 1338 (Fed. Cir. 2003). The presumption of ordinary meaning will be "rebutted if the inventor has disavowed or disclaimed scope of coverage, by using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." ACTV, 346 F.3d at 1091.

The ITC failed to examine the ordinary meaning of the "visual identification" claim term. See FID Opinion 2002 ITC LEXIS 812 at *175. Instead, the ITC exclusively looked to the '204 patent written description, including the following passage:
Turning now to the drawings, more particularly to FIGS. 1-7, there are shown a series of menu screens 10, 12, 14, 16, 18, 20 and 22 used in operation of the system and carrying out the process of the invention. Screens 10, 12, 14, 16 and 20 each consists of an array 24 of irregular cells 26, which vary in length, corresponding to different television program lengths of one half hour to one-and-one half hours or more. The array is arranged as three columns 28 of one-half hour in duration, and twelve rows 30 of program listings. Some of the program listings overlap two or more of the columns 28 because of their length. Because of the widely varying length of the cells 26, if a conventional cursor used to select a cell location were to simply step from one cell to another, the result would be abrupt changes in the screens 10, 12, 14, 18 and 20 as the cursor moved from a cell 26 of several hours length to an adjacent cell in the same row. Such abrupt changes disorient a user of the system.

An effective way of taming the motion is to assume that behind every array 24 is an underlying array of regular cells. By restricting cursor movements to the regular cells, abrupt screen changes will be avoided. However, there is now a potential ambiguity between the underlying cell which governs cursor movement and a visible cell 26 which holds the program title.

Viz.: if the cursor moves in half hour steps, and the cell length is, say four hours, should the cursor be 1/2 hour long or four hours long? If the cursor only spans the interval of the underlying cell (1/2 hour), the cursor appears to be highlighting a segment of the cell, which is misleading. On the other hand, if the cursor spans the entire four hours of the TV listing, the cursor underlying position will be obscure. In this case, cursor right/left commands will appear inoperative while traversing a long cell. The absence of feedback following a cursor command is befuddling to users. Therefore, an innovative cursor 32 (FIG. 1) for the irregular array 24 is required which satisfies several conflicting requirements.

The statement in the written description that the "innovative cursor . . . is required" was made in the context of a discussion of the features of the preferred embodiment. The passage reproduced above beginning at column 4, line 35 is the initial discussion in the Detailed Description of the Invention section of the preferred embodiment in the '204 patent specification. See '204 patent, col. 4, l. 33 - col. 5, l. 5. The passage describes a series of menu screens from the preferred embodiment depicted in Figures 1-7 of the '204 patent. See id. at col. 4, ll. 35-38. In the discussion, the embodiment discusses some of the drawbacks of using a conventional cursor in navigating the menu screens of the preferred embodiment. See id. at col. 4, ll. 46-52. In the context of discussing the advantages of an alternate cursor approach, there is a statement in the written description that: "Therefore, an innovative cursor 32 (FIG. 1) for the irregular array 24 is required which satisfies several conflicting requirements." Id. at col. 5, ll. 3-5. From this language, it follows that the "innovative cursor 32" is a preferred cursor for navigating irregular array 24 in the menu depicted in Figure 1 of the '204 patent. See id.

Our precedent has emphasized that the disclosure in the written description of a single embodiment does not limit the claimed invention to the features described in the disclosed embodiment. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) ("This court has expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment."). "Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction." Id. (quoting Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002)).

In the context of the disclosure of the preferred embodiment of the '204 patent, the statement that "innovative cursor 32 . . . is required," is not the "use [of] words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Teleflex, 299 F.2d at 1327; see also ACTV, 346 F.3d at 1091. This statement did not limit the "visual identification" to the "innovative cursor 32" discussed in the written description. Properly read in this context, the statement merely conveys the advantages of "innovative cursor 32" over prior art conventional cursors in the preferred embodiment. It was not a disavowal or disclaimer indicating that the claims excluded all or part of the properties of prior art conventional cursors. Indeed, if the innovative cursor constituted the entirety of the invention, all of the particular formatting and movement characteristics specific to the innovative cursor must be attributed to the "visual identification." See '204 patent, col. 5, ll. 6-13 (describing aspects of the innovative cursor, including, "3-D highlighting," "offset shadows," and "segmented" and "solid" portions of the "underlying black bar" denoting the "current position" of the cursor). Instead, the ITC construed "visual identification" to include only select properties of the innovative cursor, namely "a cursor that (1)
highlights the entire cell, (2) identifies the current half-hour position within a cell that is longer than a half-hour, and (3) differentially identifies the remaining portions of the cell." FID Opinion 2002 ITC LEXIS 812 at *175. Because Gemstar did not disclaim cursors beyond the innovative cursor discussed in the embodiment disclosed in the '204 patent, "visual identification" is not limited to innovative cursors.

The parties agree that "visual identification" is not a term of art or explicitly used in the written description. Because the parties have presented no evidence that "visual identification" has a specialized technical meaning in the art, we consult non-technical dictionary definitions to determine its ordinary meaning. Inverness Med. Switz. GmbH v. Princeton Biomeditech Corp., 309 F.3d 1365, 1369 (Fed. Cir. 2002) ("The parties here do not argue that the term . . . has an established specialized meaning in technical dictionaries, encyclopedias, or treatises of the relevant field of art, and we agree . . . . Accordingly, standard dictionaries of the English language are the proper source of ordinary meaning of the phrase."); see also Vanderlande Indus. Nederland BV v. Int'l Trade Comm'n, 366 F.3d 1311, 1321 (Fed. Cir. 2004). "Visual" is defined as "capable of being seen: VISIBLE." Webster's Third New International Dictionary 2558 (1993). "Identification" is "an act or the action of identifying or the state of being identified," id. at 1123; "identify" is "to link in an inseparable fashion: make correlative with something," id. We examine the language of claim 31 in considering the ordinary meaning in the context of the claims:

providing a visual identification of a selected one of said irregular cells, moving said visual identification in the first dimension and in the second dimension between first and second ones of said irregular cells to select a desired one of said irregular cells corresponding to a desired program . . . .

'204 patent, col. 20, ll. 6-11. Thus, the "visual identification" within the meaning of claim 31 visibly correlates or links an irregular cell selected by the user with the selected irregular cell on the television screen.

Scientific-Atlanta argues that this construction of "visual identification" may include aspects of a conventional cursor, which it argues were disclaimed in the written description of the '204 patent. For the reasons previously discussed, the passage pertaining to conventional and innovative cursors in the '204 patent written description, see id. at col. 4, l. 39 - col. 5, l. 5, establishes neither a disavowal or disclaimer of prior art conventional cursors nor a limitation of the claim scope to the disclosed innovative cursor.

In light of our claim construction that "visual identification" is not limited to the innovative cursor described in the written description of the '204 patent, we need not reach Gemstar's additional claim construction arguments pertaining to the examiner's restriction requirements made during the prosecution of the '204 patent.

Based on the foregoing, the ITC's claim construction erroneously limited the "visual identification" limitation to the features of the innovative cursor. "Visual identification" within the meaning of the claim requires a visual correlation or linkage of a selected irregular cell with the selected irregular cell displayed on the television screen. This may include the properties of a conventional cursor.

4791

# 6

# 6 -- "visual representations" -- (appears in claims 14, 15, 17, 19, 29, 30, 32 and 34) Luma's Construction (Luma May 4, 2005, p. 3).

MASTER'S CONSTRUCTION

# 6 -- "visual representations" -- means visual representations and may include but are not required to include: text that is anti-aliased; graphical objects; possess the attribute of translucency; prompts for prompting a user; and images.

REASONS

INTRINSIC EVIDENCE
The Patent Specification gives some guidance to what may be included in the "visual representations" and they are included in the Master's Construction (Col. 2, Ls. 21-37).

EXTRINSIC EVIDENCE

Nothing was found in the Markman Hearing that helped the Master in this construction of the term.

LIMA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

Luma's position is set forth in (Luma May 4, 2005, p. 3). Luma proposes the construction as any entity capable of display on a visual medium. Luma's construction appears to be consistent with the Master's Construction. If it is found in any aspect to be inconsistent then the Master's Construction should prevail.

stryker's position and master's comments on that position

Stryker's position is set forth in (Stryker May 23, 2005 p. 9). Stryker argues that Luma does not distinguish between "visual representation" and "graphical objects". The Master's Construction provides that "visual representations" may include graphical objects. The phrase "comprising graphical objects" following "visual representations" is a limitation. For example, in claims 14 (Col. 48, Ls. 23-24), "graphical objects" modifies or limits "visual representations" to require "graphical objects". It is the phrase "comprising graphical objects" that limits "visual representation". The term "visual representations" is not to be constructed to be inherently limited to "graphical objects". Language in the claims subsequent to "visual representations" provides limitations to the term "visual representations". This limitation will be provided when the claim as a whole is construed. Stryker objects to "piecemeal" construction. The Master has addressed the issue in "# 2" above.

KSEA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

KSEA's position is set forth in (KSEA May 23, 2005, Sheet 7). KSEA does not object to Luma's Construction. The Master's Comments regarding Luma's Construction are applicable with respect to KSEA as well as with Luma on this term.

4792

3. "Visualization functionality": "Hardware and/or software that produces a designed effect, that is, to download via the image server a thumbnail visual image which is associated with a given hyperlink." This construction is consistent with claims 43 and 44, as well as the specification: col. 2, ll. 6-10; col. 3, ll. 49-53; col. 5, ll. 58-65; col. 6, ll. 24-31.

4793

C.1.e.1. Functional Limitations

The functional limitations associated with processing means are: 1) receiving customer number data entered by a caller, 2) storing the customer number data in a central memory, 3) coupling an incoming call to the operator terminal based on the occurrence of a condition, and 4) "visually displaying" the customer number data. It appears from the parties' briefs, that Verizon and Katz dispute the meaning of "visually displaying." In an apparent attempt to avoid additional structure, such as a display, from falling into corresponding structure, Katz asserts that "visually displaying" means presenting data to a terminal. Katz Brief at 80-81.

Here, "visually displaying" means "making something viewable on a display device." The Court's construction is consistent with the plain and ordinary meaning of the language. Katz's asserted interpretation, merely requiring the transmission of data signals to a terminal, appears to contravene the plain meaning of the terms. Webster's defines "display," in relevant part, as "to put or spread before the view." Webster's Ninth New Collegiate Dictionary at 365; see also American Heritage Dictionary at 521 ("display," in relevant part, means "to provide (information or graphics) on a screen."). The term
"visually" underscores this requirement. See Webster's Ninth New Collegiate Dictionary at 1318 ("visual" means "visible"); see also The American Heritage Dictionary at 1924 (visual means "seen or able to be seen by the eye; visible."). In addition, the specification does not suggest a contrary interpretation. See 551 patent, Col. 5:22-24 ("the CRT display serves to visually display data regarding select subsets as explained in detail below.").

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

12 Katz's contention does have some appeal in that, in the context of claim 21 of the 551 patent, the limitation "visually displaying the customer number data" appears upon a cursory review of the claim language to refer to visually displaying the customer number data on the operator terminal, rendering its asserted interpretation more plausible. However, the plain meaning of the claim language merely requires "visually displaying the customer number data" and is not specific to any display device. Furthermore, regardless of the presence of the operator terminal in claim 21, as discussed above, Katz's asserted interpretation, and the supporting extrinsic evidence it sights (e.g., "screen pops"), appear to be inconsistent with the plain meaning of the claim language.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

Katz's interpretation of visually displaying appears to contravene the ordered analysis contemplated by the Federal Circuit. Specifically, the Federal Circuit instructs that construction of the functional language in a means-plus-function element drives the determination of corresponding structure. Harley-Davidson, 250 F.3d at 1376. Here, it appears that Katz has conducted the analysis in reverse order. See Katz Brief at 81 ("It follows from Katz's identification of structure that the processing means "displays" data by presenting it to a terminal.").

3. Paragraph (2) of Claim 20 of the '998 Patent - "Visually Displaying The Waveform"

Macromedia contends that the phrase "visually displaying the waveform" should be construed to mean "providing a graphical pattern of pressure variation, both positive and negative, along time and amplitude axes on a programmable display or computer screen." (D.I. 243 at 10). Adobe contends that a sound waveform can be graphically depicted as either a positive and negative pressure variation or an absolute value representation (i.e. positive) of this variation. (D.I. 305 at 18-19). Because there is no indication in the '998 Patent that the display of the waveform requires positive and negative pressure variation, Adobe contends that the phrase "visually displaying the waveform" should be construed to mean "displaying a graphical representation of a sound waveform." (D.I. 305 at 19).

In construing the phrase "visually displaying the waveform," the Court has considered the specification and prosecution history of the '998 Patent. (See D.I. 248, Ex. B, '998 Patent, Col. 1, lines 9-64; D.I. 248, Ex. B, '998 Patent, Col. 119, Claim 20, lines 30-56; D.I. 248, Ex. C). Because neither the claims, specification, nor prosecution history of the '998 Patent limit the phrase "visually displaying the waveform" to a positive and negative graphical depiction of a sound waveform, the Court construes this phrase to mean "displaying a graphical representation of a sound waveform."

4795

E. Viterbi-like

Before briefing the disputed terms, the parties had an agreed upon construction for the term "Viterbi-like." The prior agreed construction was "Viterbi-like means similar to and including the Viterbi algorithm" where the disputed term was "Viterbi algorithm." (Docket No. 74-1 at 4). Following the initial claim construction briefing and discussion at the hearing, it became apparent that the parties disputed the scope of the term "Viterbi-like."

"When the parties raise an actual dispute regarding the proper scope of these claims, the court, not the jury must resolve that dispute." O2 Micro International Limited v. Benyon Innovation Technology Co., LTD., 521 F.3d 1351, 1360 (Fed. Cir.
2008)(citing Markman, 52 U.S. at 979). Marvell stated at the hearing that based on a construction of "Viterbi", along with the ordinary meaning of the word "like", the jury would be asked if the accused device(s) and/or method(s) contained an element that was "Viterbi-like." However, that the parties dispute, for instance, that the Fitzpatrick Patent is "Viterbi-like", makes clear there is a question of claim scope that cannot be put before the jury. "A determination that a claim term 'needs no construction' or has the 'plain and ordinary meaning' may be inadequate when the term has more than one 'ordinary' meaning or reliance on a term's 'ordinary' meaning does not resolve the parties' dispute." O2 Micro, 521 F.3d at 1361.

Furthermore, the question (of claim scope) as to when an algorithm is like the "Viterbi algorithm" is a question that must be answered by asking how the PHOSITA would read the claims, thus requiring the court to construe the claim term. 12 Only then, with that question answered, could a jury answer the question of whether the accused device(s) and/or method(s) contain elements that the PHOSITA would understand to be "Viterbi-like."

The term "Viterbi-like detector" can be found in Zeng, et al., Modified Viterbi Algorithm for Jitter-Dominated 1-D2 Channel, (Docket No. 82-10 at 3), thus indicating that the term has meaning for those in the art. However, the Zeng article does not use the term in a manner such that it is helpful to this Court's construction of the disputed term.

1. A method of determining branch metric values for branches of a trellis for a Viterbi-like [sic] detector, comprising:

   selecting a branch metric function for each of the branches at a certain time index; and
   applying each of said selected functions to a plurality of signal samples to determine the metric value corresponding to the branch for which the applied branch metric function was selected, wherein each sample corresponds to a different sampling time instant.

23. A system for recording information on a magnetic medium, comprising:

   a write signal processing circuit for processing a plurality of data from a data source; a write control circuit;
   a write head responsive to said write control circuit for receiving a plurality of signals from said write signal processing circuit, said write head for writing said signals to the recording medium;
   a read control circuit;
   a read head for reading said signals from the recording medium, said read head responsive to said read control circuit; and
   a detector circuit for detecting a plurality of data from said read signals, said detector comprising:
   a Viterbi-like detector circuit, said Viterbi-like detector circuit for producing a plurality of delayed decisions and a plurality of delayed signal samples from a plurality of signal samples;
   a noise statistics tracker circuit responsive to said Viterbi-like detector circuit for updating a plurality of noise covariance matrices in response to said delayed decisions and said delayed signal samples; and
   a correlation-sensitive metric computation update circuit responsive to said noise statistics tracker circuit for recalculating a plurality of correlation-sensitive branch metrics from said noise covariance matrices, said branch metrics output to said Viterbi-like detector circuit.

'839 Patent col. 13 ln. 61 - col.14 ln. 2; col. 16 ln. 22-51.

CMU's construction of "Viterbi algorithm" and "Viterbi-like" are as follows:

"Viterbi algorithm" means "an iterative algorithm that uses a trellis to determine the best sequence of hidden states (in this case, written symbols) based on observed events (in this case, observed readings that represent the written symbols), where the determined sequence is indicated by the best path through the trellis and is determined using branch metric values calculated for branches of the trellis."
"Viterbi-like [algorithm]" means "an algorithm that is or is similar to an iterative algorithm that uses a trellis to determine the best sequence of hidden states (in this case, written symbols) based on observed events (in this case, observed readings that represent the written symbols), where the determined sequence is indicated by the best path through the trellis and is determined using branch metric values calculated for branches of the trellis."

RDCTC at 13-14.

Marvell's constructions of "Viterbi algorithm" and "Viterbi-like" are as follows:

"Viterbi Algorithm" means "an algorithm that uses a trellis to perform sequence detection by calculating branch metrics for each branch of the trellis, comparing the accumulated branch metrics for extensions of retained paths leading to each node of the trellis at a given time, and for each node, retaining only the path having the best accumulated metric."

"Viterbi-like" means "similar to and including the 'Viterbi algorithm.'" The Viterbi algorithm includes the step of calculating branch metrics for each branch of the trellis. Therefore, a "Viterbi-like" algorithm must either calculate branch metrics for each branch of the trellis or it must perform a step similar to calculating branch metrics for each branch of the trellis (in addition to other steps similar to or identical to the other Viterbi algorithm steps) such that the overall sequence detection process is similar to the Viterbi algorithm. Under Defendant's construction, a process that only calculated branch metrics for a fraction of the branches in a trellis or only compares a few paths would not be Viterbi-like.

RDCTC at 13-14.

At the hearing, the parties presented two discreet disputes as to the scope of "Viterbi" and "Viterbi-like." Those issues were whether the "Viterbi algorithm" had to calculate a branch metric for every branch of the trellis and whether the "Viterbi-like" algorithm covered the use of a post-processor as used in U.S. Patent 5,689,532 ('532 Patent or "Fitzpatrick Patent"). In the post hearing briefing and reply, Marvell indicated that "Viterbi-like" "does not require calculating branch metrics for every branch of a trellis, and it does not require a specific add-compare-select process at every node of the trellis." (Docket No 138 at 6). Rather, its construction allows for "a step similar to calculating branch metrics for each branch of the trellis" to be used for "Viterbi-like." RDCTC at 13-14. Furthermore, Marvell does not dispute that the reduced state RAM-RSE algorithm referenced in the '839 Patent at col. 1 ln. 33, col. 7 ln. 9-10, is a "Viterbi-like" algorithm. Id. Marvell continues to dispute, however, that the postprocessor error correction circuitry in Fitzpatrick is encompassed by "Viterbi-like."

"Viterbi-like" appears throughout the specification and examples of "Viterbi-like" detectors are given in the background of the invention section.

Traditional peak detectors (PD), such as those described in Nakagawa et al., "A Study of Detection Methods of NRZ Recording", IEEE Trans. Magn., vol. 16, pp. 1041-110, Jan. 1980, have been replaced by Viterbi-like detectors in the form of partial response maximum likelihood (PRML) schemes or hybrids between tree/trellis detectors and decision feedback equalizers (DFE), such as FDTS/DF, MDFE and RAM-RSE.

'839 Patent col. 1 ln. 26-33. Furthermore, in the detailed description section, it is stated that "[i]n the derivations of the branch metrics (8), (10) and (13), no assumptions were made on the exact Viterbi-type architecture, that is, the metrics can be applied to any Viterbi-type algorithm such as PRML, FDTS/DF, RAM-RSE, or, MDFE." '839 Patent col. 7 ln. 5-9.

During the prosecution of the '839 Patent, the examiner issued a rejection finding that the Fitzpatrick patent anticipated claims of the '839 Patent application. (Docket No. 128-2 at 22-24). Pertinent to this discussion is that the examiner found that "Fitzpatrick discloses a method for determining branch metric values of [a] trellis for a Viterbi-like detector." (Docket No. 128-2 at 23). The patentee successfully traversed the examiner's rejection with the following statement:

Applicants have herein amended claims 1, 4, 27, and 28 to clarify that each of said selected functions is applied to a plurality of signal samples to determine the metric value corresponding to the branch for which the applied branch metric function was selected, wherein each sample corresponds to a different sampling time instant. Applicants submit that Fitzpatrick does not teach, among other steps, such a step. In particular, each of the branch metrics is not determined based on a plurality of signal samples.
Fitzpatrick does not specify the manner in which the branch metrics are computed. However, the Viterbi detector described in Fitzpatrick is described as an EPR4 Viterbi detector. Such a Viterbi detector computes a branch metric using:

\[ M_i (r_i, a_{i-3}, \ldots, a_i) = [r_i - y(a_{i-3}, \ldots, a_i)]^2 \]

where \( r_i \) is a single waveform, not a plurality of time variant signal samples.

(Docket No. 83-1 at 8).

Marvell argues that the only Viterbi detector found in Fitzpatrick is the PR4 Viterbi detector and that the post-processor that follows the PR4 Viterbi detector does not fall within the scope of the term "Viterbi-like." Additionally, Marvell points out that the branch metric the patentee cited in the prosecution history was not the error-event metric calculated by the postprocessor and that the patentee ignored all aspects of the post-processor in the prosecution history. Finally, Marvell points to Fig. 5 of the Fitzpatrick patent as indicating that only the PR4 detector is referred to as being a Viterbi detector and not the EPR4 detector or the post-processor 13

[SEE FIG. 5 IN ORIGINAL]

'532 Patent Fig. 5. (See Docket No. 138 at 10-13).

13 At the claim construction hearing, the Court entered into evidence Marvell Exhibit A, the 10/8/2001 email from Dr. Kavcic to Gregory Silvus. (Docket No. 106-1). The Court gives no weight to this email as it is of the type of extrinsic evidence that the PHOSITA could not be aware of since it is a personal email and it post-dates the filing and issuance of the '839 Patent. Furthermore, the email is contradicted by the intrinsic evidence, as discussed below, therefore even if the PHOSITA were aware of the contents of the email, it would be disregarded in favor of the conclusions that would be drawn from the intrinsic record.

The argument that the patentee presented to the examiner was that Fitzpatrick did not contain correlation-sensitive branch metrics because Fitzpatrick did not use a "plurality of time variant signal samples." The patentee specifically described Fitzpatrick as having an EPR4 Viterbi detector and stated that "such a Viterbi detector computes a branch metric using: Mi (r_i, a_{i-3}, \ldots, a_i) = [r_i - y(a_{i-3}, \ldots, a_i)]^2" (Docket No. 83-1 at 8). This is recognized as being the Euclidian branch metric from equation (8). '839 Patent col. 6 ln. 10-14. As a result, Fitzpatrick lacked the use of a "plurality of time variant signal samples."

The specification of the Fitzpatrick patent states the invention relates to a reduced complexity post-processor for a binary input extended partial response class 4 (EPR4) channel. '532 Patent col. 1 ln. 15-17. In discussing the prior art, it then states that "the main drawback to implementing [extending partial response class 4 with maximum-likelihood detection] within a magnetic recording system has heretofore been that the EPR4 Viterbi detector is much more complex that a PR4 Viterbi detector, and has been practically realized only at considerably greater expense." '532 Patent col. 2 ln. 8-12. The patent goes on to discuss the standard approach of implementing a Viterbi detector with a Viterbi algorithm. '532 Patent col. 2 ln. 32-55. The patent also discusses alternate approaches to implementing an EPR4 Viterbi detector and various methods leading up to the method displayed in Fig 5. '532 Patent col. 2 ln. 56 - col. 3 ln. 28. For the method using the post-processor, the patent states:

Another implementation approach is to use a PR4 Viterbi detector, followed by a post-processor for EPR4. A post-processor for an EPR4 channel that achieves nearly maximum-likelihood performance was described by Wood, "Turbo PRML: A Compromise EPRML Detector", IEEE Trans. on Magnetics, Vol. 29, No. 6, Nov. 1993, pp. 4018-4020. In the Turbo PRML post-processor technique, PR4 equalized samples are sent to a PR4 Viterbi detector that produces a preliminary estimate of the binary input sequence. Then, the preliminary estimate is sent to the post-processor to produce a final improved estimate of the binary input sequence.

'532 Patent col. 3 ln 29- 40.
In the detailed description section, the patent discusses the EPR4 Viterbi detector stating:

Typically, an EPR4 Viterbi detector is designed to find the path through the EPR4 trellis that minimizes the squared Euclidean distance between the received samples and the ideal EPR4 samples along the path. The output of the EPR4 Viterbi detector is a maximum likelihood sequence estimate for an EPR4 channel corrupted by independent and identically distributed Gaussian noise with zero mean.

'532 Patent col. 7 ln. 57-64. (emphasis added). In describing the post-processor in Fig. 5 the patent states:

The post-processor 40 uses the estimated binary input sequence at the PR4 Viterbi detector output to establish a PR4 path through the EPR4 trellis. The objective of an EPR4 post-processor is to find the path through the EPR4 trellis that minimizes the squared Euclidean distance between the EPR4 equalized samples and the noiseless EPR4 samples, given that this path is restricted to the set of paths that deviate from the PR4 path by a sequence of non-overlapping minimum distance error-events. If the post-processor achieves this objective, then the estimated input sequence at the output of the post-processor, denoted by \{x[0], x[1],..., x[j], ...\}, is equal to the output of an EPR4 Viterbi detector under the conditions that only minimum distance error-events occurred and that these error-events were sufficiently far apart. The post-processor 40 produces a sequence estimate (x 44 in FIG. 5) which is "nearly" a maximum likelihood sequence estimate for an EPR4 channel corrupted by independent and identically distributed Gaussian noise with zero mean.

'532 Patent col. 9 ln. 20-38. (emphasis added). Based on these quoted passages, the PHOSITA would conclude that the post-processor has the same objective as the EPR4 Viterbi detector and that the post-processor "nearly" produces the same result as the maximum likelihood sequence estimate for the EPR4.

Marvell cites to the following language to show that the post-processor computes too few calculations in order to be considered "Viterbi-like":

In the reduced-complexity post-processor described in the present invention, the post-processor calculates and compares two error-event metrics, independent of the modulation code. The post-processor uses the merge bits from the PR4 Viterbi detector to determine the "best type A" error event and the "best type B" error-event ending at a particular state. In this manner, the post-processor only considers the most-likely error-event of each type, as determined by the PR4 Viterbi detector.

'532 Patent col. 11 ln. 57-65. Although the post-processor in Fitzpatrick only calculates and compares two metrics that are first passed through a PR4 Viterbi detector, the post-processor does perform a metric calculation, comparison and selection of the most likely path through a trellis. These functions of the post-processor are what CMU pointed to in its construction of "Viterbi-like" and what the Fitzpatrick patent stated is considered to be the Viterbi algorithm. "The Viterbi algorithm is an iterative process of keeping track of the path with the smallest accumulated metric leading to each state in the trellis. The metrics of all of the paths leading into a particular state are calculated and compared. Then, the path with the smallest metric is selected as the survivor path." '532 Patent col. 7 ln. 64- col. 8 ln. 2.

After reading the specification of the Fitzpatrick Patent, the PHOSITA would conclude that an EPR4 post-processor would be understood to be "Viterbi-like" based on the examiner's rejection and the patentee's acquiescence, and Fitzpatrick's description of the post-processor. Yet, Marvell has stated that its construction would exclude the post-processor based on the limitation that "a process that only calculates branch metrics for a fraction of the branches in a trellis or only compares a few paths would not be Viterbi-like." ( Docket No. 138 at 9). CMU's construction of "Viterbi-like" reflects, however, that the critical elements are that the objective of the algorithm is to determine the best path through a trellis and that it is performed by calculating metric values. As a result, the Court will adopt CMU's construction for the term "Viterbi-like." 14 As discussed above, no construction will be needed for the term "Viterbi [algorithm]" as any definition may lead the jury to attempt to decide issues of claim construction.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

14 It is noted that '180 Patent contains language that discusses "beyond Viterbi-like detectors." '180 col. 14 In. 10. This language, however, was only cursorily addressed in the briefing and at the hearing and the Court finds that it does not bear
on whether "Viterbi-like" encompasses the post-processor found in Fitzpatrick. Furthermore, it is noted that the '180 Patent issued from a continuation-in-part application filed eleven months after the '839 Patent application and the "beyond Viterbi-like detector" language is found in the new matter added to the '180 Patent specification. Additionally, "Viterbi-like" is not found in the claims of the '180 Patent. As a result, it would be inappropriate to consider the new matter added to the specification of the '180 Patent as intrinsic evidence for construing the claims of the '839 Patent. See Goldenberg v. Cytogen, Inc., 373 F.3d 1158, 1167-68 (Fed. Cir. 2004)(District court erred in considering new-matter content of a related patent as part of the intrinsic record for the patent at issue).

As a result, it is concluded that the construction of the term "Viterbi-like" is as follows:

Viterbi-like means "an algorithm that is or is similar to an iterative algorithm that uses a trellis to determine the best sequence of hidden states (in this case, written symbols) based on observed events (in this case, observed readings that represent the written symbols), where the determined sequence is indicated by the best path through the trellis and is determined using branch metric values calculated for branches of the trellis."

1. "A plurality of voice circuits." Transmission lines capable of carrying voice communications.

15. Voice communication commands

After considering the submissions of counsel, the court concludes that "voice communication commands" does not require construction.

20. Voice communication link

With respect to the term "voice communication link," Foundry asserts that "voice communication" is understood by one of ordinary skill in the art. Foundry further submits that "link" is generally defined as "a connecting structure." Lucent, on the other hand, argues that "voice communication link" should be construed consistently with the definition of "voice-over-IP-link" contained in the specification of the '864 patent. The court does not agree with Lucent's position. As it appears from reading the claims and the specification, a "voice over-IP-link" is a type of "voice communication link." Thus, the term "voice communication link" is broader than the term "voice-over-IP-link." The court therefore construes "voice communication link" to mean "a connecting structure capable of supporting voice communication."

4. Voice communication module

The court is persuaded that Judge Breyer's construction of "voice communication module" in the Nortel case is correct. Accordingly, the court construes "voice communication module" to mean "a module that enables a communication platform to provide voice-over-IP calls."
BACKGROUND

The '301 patent was issued in 1991. It has a single claim, which provides as follows:

1. A payphone which includes a keypad or dial and a digital voice device for providing a user of said payphone voice instructions as to the operation of said payphone; the improvement comprising:

   a directory listing next to said keypad or dial including a list of languages with a corresponding coded numeral found on said keypad or dial;

   and said digital voice device further comprising multilingual voice instructions selectively controlled by the actuation of said keypad or dial such that the numeral actuated on said keypad provides instructions in the language which corresponds in said directory listing.

In 1993, Mr. Maltezos sued AT&T, charging that AT&T's Public Phone 2000 infringed the '301 patent. AT&T moved for summary judgment, arguing that the Public Phone 2000 did not infringe because it lacked a "digital voice device for providing the user of said payphone voice instructions for operating said payphone." The district court granted the motion for summary judgment. The court first ruled that the '301 patent clearly requires the claimed payphone "to have a digital voice device to provide audible instruction in a chosen language." The court then noted that the Public Phone 2000 contains no digital voice device, but instead is capable of presenting readable instructions in languages other than English. The readable instructions, the court held, did not infringe the claim limitation to a "digital voice device," either literally or under the doctrine of equivalents.

Mr. Maltezos took an appeal to the United States Court of Appeals for the Second Circuit, which transferred the case to this court.

DISCUSSION

The first step of an infringement analysis is for the court to determine the scope and meaning of the patent claims asserted. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454, 46 U.S.P.Q.2d (BNA) 1169, 1172 (Fed. Cir. 1998) (en banc). Claim construction begins with the claim language itself. Johnson Worldwide Assocs., Inc. v. Zebco Corp., 175 F.3d 985, 989, 50 U.S.P.Q.2d (BNA) 1607, 1610 (Fed. Cir. 1999). The district court construed the single claim of the '301 patent to require the claimed payphone to have "a digital voice device to provide audible instruction in a chosen language." As a general rule, the words in a claim are to be given their "ordinary and accustomed meaning." Johnson Worldwide, 175 F.3d at 989, 50 U.S.P.Q.2d (BNA) at 1610. We agree with the district court that the ordinary meaning of the claimed "digital voice device" requires that the device provide audible output.

That construction of the claim is entirely consistent with the written description of the patent. For example, the background section notes that "today payphones are using spoken words to instruct the caller how to make and complete a call." '301 patent, col. 1, ll. 16-17. Similarly, the detailed description section discusses "enabling the voice device within the telephone to provide instructional aid," col. 2, ll. 11-12, and discusses the "voice" to be provided by the "voice chip," col. 2, ll. 13-19. We therefore agree with the district court's construction of the claim.

4801

c. "Voice Generator Structure"

The term "voice generator" appears in several of the analysis control system claims at issue, and the limitations containing this term read "voice generator structure coupled through said interface structure for actuating said remote terminals as to provide vocal operating instructions to said individual callers." The parties agree that the term "voice generator structure"
is not subject to means-plus-function analysis because the term connotes a specific range of structures that correspond to the term to those of ordinary skill in the art. The Court concludes that the plain meaning of the term "voice generator" indicates a structure that can produce vocal sounds. The specification of the patents in which this term is found describes the voice generator structure as "a voice origination apparatus may prompt individual callers who (after qualification) provide select digital data to develop a record for further processing." Column 2 lines 4 to 8 of the '707 patent. The specification also provides that the voice generator is incorporated in the interface, Column 4, lines 55 to 58 of the '707 patent, and that "recorded voice messages prompt callers to provide data by actuating the alphanumeric buttons" on their telephones, Column 1, lines 45 to 47 of the '707 patent. Based on the term's ordinary meaning, the claim language, and the specification, the Court concludes that "voice generator" means: a device for generating vocal instructions or prompts to individual callers at the remote terminals.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 
12 The term "voice generator structure" is found in Claim 51 of '309, Claims 33, 104, 117, and 192 of the '707 patent, and Claims 65 and 171 of the '863 patent. In Claim 192 of the '707 patent, the limitation provides that the voice generator structure is also able "to prompt said individual callers to enter data."

2. Voice guidance

This term appears throughout the '330 patent. Plaintiff proposes that it means "spoken words that give accurate directions." Defendant's construction, which I adopt, is more narrowly tailored to the context of the '330 patent: "spoken words that give accurate directions about how to navigate at a particular position."

2 The court rejects defendant's suggestion that "speech synthesis" is inherent in a "voice recognition system." "Voice recognition" is the mechanism by which spoken instructions are input into the robotic surgical system. (Col. 4, Ins. 14-17) "Speech synthesis," on the contrary, is one way in which sound can be output from the robot to the surgeon. (Col. 16, In. 55 - col. 17, In.3) This conclusion is supported by the structure of the claims, which consists of the "voice recognition" limitation in independent claims and "synthesis" as an added limitation in corresponding dependent claims. (See, e.g., claims 13, 15) References to a "speech recognition and synthesis system," therefore, denote the input and output functions of the robotic surgical system. (col. 6, Ins. 23-25, Ins. 48-59) Furthermore, the court finds no support in the specification or claims for defendant's assertion that "voice recognition" and "input device" are means-plus-function limitations pursuant to 35 U.S.C. § 112 P6.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 

- "voice traffic" is construed to mean "transmitted voice packets."
Lucent contends that this term should be construed to mean "packets of voice traffic." (D.I. 396 at 24.) Extreme contends that this term means "voice packets organized into blocks of bits, each block containing bits of a different order of significance, where the bits of lesser significance can be dropped when congestion occurs in the network." In support of its contention, Extreme points to Lucent's statement in the Summary of the Invention section of the specification that "bits in voice packets are organized into blocks according to the order of significance of the bits." (650 patent at 3:33-34.) The Court agrees with Extreme that Lucent describes the organization of voice packets this way. However, the Court does not find that Lucent's description of the way the voice packets are organized amounts to a definition of the term "voice traffic," representing a clear disavowal of claim scope. Further, the Court finds that the parties agree that the ordinary meaning of the term "traffic" is "the information or signals transmitted over a communications system: MESSAGES." (D.I. 379 at 29; D.I. 399 at 21.) The Court finds that the parties also agree that voice traffic is generally comprised of "packets of voice" or "voice packets." (D.I. at 19; D.I. 399 at 18.) Further, the Court finds that the specification references the transmission of voice packets several times in the Summary of the Invention (650 patent at 3:2-16.) Thus, in the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

The Court agrees with Defendants' construction and thus construes "voiceband" as "frequencies in the range of 0 to 4 kHz." Plaintiff tries to support its construction that reads "frequencies in the range of 0 to 4 kHz reserved for POTS services (e.g., analog voice phone services)" by citations to the specification. However, none of the specifications cited by Plaintiff clearly associate "voiceband" with being limited to those frequencies "reserved for POTS services (e.g., analog voice phone services)." Since Defendants agree with the first part of Plaintiff's construction, Defendants' arguments are limited to disputing the additional language in Plaintiff's construction that reads "reserved for POTS services (e.g., analog voice phone services)." First, Defendants argue adding the POTS service acronym would be confusing to the jury because it is technical and not understood by lay persons. Second, Defendants argue Plaintiff's proposal contradicts the express language of the claims that require only certain signals in the claims to be above "voiceband" (the "resume signal" in claims 1, 7, and 24; the "modulated data signal" in claims 7 and 16). Because the 0 to 4 kHz frequency range is "reserved" for only POTS under Plaintiff's proposal, Defendants argue that signals having no express above-voiceband limitation (the "resume signal" in claim 16; the modulated data signals in claims 1 and 24) could nonetheless be required to be above voiceband.

The Court agrees with Defendants' construction. Plaintiff's construction adds language that is unnecessary and there is no strong foundation in the intrinsic record for adding such limitations. Rather, the intrinsic record actually supports "voiceband" as referring solely to a range of frequencies, which, in that case, is best construed as "frequencies in the range of 0 to 4 kHz." See '323 patent, 7:60, Claim 1 ("outside the voiceband frequency range") (emphasis added); 4:46-48 ("filtered to remove frequencies above voice band"); 2:31-37 ("frequency range above voiceband") (emphasis added). Therefore, the Court construes "voiceband" as "frequencies in the range of 0 to 4 kHz."

Plaintiffs propose to construe the term "void" (964 Patent, claim 1) as a space or spaces in the image carried by the input video signal where a change or illumination may be made to cause an improvement of the perceived quality of the image. Defendants argue that the court should construe the term void more narrowly, to be an off pixel or a space between two pixels, but specifically not a defective pixel such as that corrected by United States Patent No. 4,573,070 (’070 Patent), nor part of a jagged edge in an image. Defendants also argue that Plaintiffs' proposed construction is estopped by the prosecution history of the '964 Patent. In addition, Defendants contend that their proposed construction should be adopted since it parallels the PTO's definition of "void" as excluding jagged edges.

A. Scope of Construction

Defendants argue that the term "void" should not include defective pixels. The intrinsic record, which includes the prosecution history and prior claim constructions of the '780 Patent family supports Plaintiff's proposed construction. The
'964 Patent specification provides a range of examples consistent with this construction:

Examples of voids would include such things as defects, unwanted elements, improper elements, corrupted elements, valid but replaceable elements, locations with no image information, and/or other locations or elements which may be in question or need for improvement. The term void is used to cover all these and similar situations for uniformity.

('964 Patent, col. 3, Ins. 38-52, emphasis added). Plaintiffs' construction was also previously accepted by the court in Lexmark. 424 F.Supp.2d at 1089-90. Thus, the specification in the '964 Patent indicates that voids can be defects. This rebuts Defendants' proposal that voids are not defective pixels and supports Plaintiffs' proposal that voids are spaces in the image where a change may be made to cause an improvement.

B. Estoppel

Defendants also contend that Plaintiffs' proposed construction is estopped by the prosecution history of the '964 Patent. Defendants assert that J. Carl Cooper (Cooper), the inventor of the '964 Patent, distinguished another of his patents, the '070 Patent, from the '964 Patent by claiming in a response to a Patent and Trademark Office (PTO) Action that "a defective pixel, such as that corrected by the '070 Patent, is not the same as 'voids' as in the presently rejected claims." (9/5/03 Resp. to 4/8/03 Off Act, 2)(emphasis in original). The court in Lexmark rejected this same estoppel argument. 424 F.Supp.2d at 1089-90. Defendants contend that Lexmark concerned only the '780 and '637 Patents, not the '964 Patent.

The Defendants selectively quote the office action response in support of their argument. It is clear from a more complete reading of the prosecution history that Cooper was not distinguishing the '070 Patent for present purposes, but was instead referring to his earlier use of that argument in prosecuting the '780 Patent. The office action response cited by Defendants reads as follows.

In fact, the '070 patent was used as the basis for a rejection in claims in United States Patent Application 07/355,461 which is the first grandparent application to the present case. (See paper no. 7 to that application, at p. 9, and paper no. 11, at p. 4). In response to that rejection, the applicant overcame his own '070 patent, noting that a defective pixel, such as that corrected by the '070 invention is not the same as "voids" as in the presently rejected claims.

Id. (first emphasis added). In fact, Cooper went on in the cited office action response to reiterate the distinction between the '070 and '780 Patents, characterizing the latter as more comprehensive than the former. Id. at 3 (noting that "the present invention, as called for in claim 61, further allows for filling a void. . ., while the cited portion of the Cooper '070 patent deals with . . .") (emphasis added). Cooper also invoked the expansive dictionary meaning of "void" as an empty space, opening, gap, or the quality of being without something, noting that such a definition "would preclude the filling of voids from being obvious in view of . . . the '070 patent." Id. In addition, we note that Cooper invoked the expansive dictionary meaning of the word "void" in order to characterize the '780 Patent as a more comprehensive version of the '070 Patent and the same is true for the '964 Patent. See Golight, Inc. v. Wal-Mart Stores, Inc., 355 F.3d 1327, 1332 (Fed. Cir. 2004)(stating that although a patentee may have intended to use a term in a manner other than its ordinary and customary meaning, prosecution history may prove this conclusion only by a "clear and unmistakable departure" from the common meaning).

C. Effect of PTO's Definition

Defendants argue that their proposed construction parallels the PTO's definition of "void" as excluding jagged edges. The PTO noted in its reexamination decisions for the '780 and '637 Patents that "smoothing the jagged edges does not fill in voids" and that "eliminating the jaggies is smoothing the edges of an image, and not filling voids." D RE of '637 Patent (Apr. 11, 2008), at 8, 10; D RE of '780 Patent (Apr. 17, 2008), at 13. However, the cited PTO decisions do not support Defendants' position as to reexamination of the '780 and '637 Patents. The PTO's post-issuance statements imposed no obligation on Plaintiffs to reply, and Plaintiffs' decision not to reply did not create a surrender of patent rights. Salazar v. Procter & Gamble Co., 414 F.3d 1342, 1347 (Fed. Cir. 2005)(noting that an "examiner's unilateral remarks alone do not affect the scope of the claim, let alone show a surrender of claimed subject matter"). Defendants argue that the PTO's understanding of "void" in the '780 and '637 Patents is significant to construing claims. However, Salazar governs the underlying weight accorded to unilateral remarks by the PTO. Thus, based on the above, we construe the term "void" ('964 Patent, claim 1) in a manner consistent with Plaintiffs' proposed construction.
The term "void" is used throughout both patents. IP proposes the following definition: space(s) in the image where a change of illumination may be made to cause an improvement of the perceived quality of the image. Lexmark and Dell propose that, with respect to still images, "void" should be construed to mean "an empty space, opening, gap, the quality of being without something between pixels of a displayed image." In the context of moving images, Dell asks for another construction: an empty space, opening, gap, the quality of being without something at all times.

The essence of the parties' dispute is whether "void" refers only to gaps or spaces between pixels or includes image elements and defective or turned-off pixels. Lexmark and Dell advance the former position, averring that Cooper disavowed a broader definition in the course of prosecuting the patent application. Specifically, they point to a statement where Cooper referenced a dictionary defining the word "void" as "empty space, opening, gap, the quality of being without something, etc." See S/N 355,461 O.A. response 6/18/92 at 17; S/N 355,461 O.A. response 6/24/93 at 7. Cooper also stated in these two office action responses that "Applicant believes however that the examiner is incorrect in his assertion that a defective pixel such as corrected by the 070 invention is the same as, and would include, voids in the image as in the present disclosure and claims." Id. Lexmark and Dell believe that these statements show a clear intention on the part of the Cooper to redefine the term "void."

It is axiomatic that the prosecution history of a patent can show that a patentee intended to use a term in a way other than its ordinary and customary meaning, but the proceedings before the examiner must show a "clear and unmistakable departure" from the common understanding of the term. See Golight, 355 F.3d at 1332. If the statements made can reasonably be interpreted in more than one way, no clear and unmistakable departure is shown. See id.

In this case, the statements to which Lexmark and Dell refer can reasonably be interpreted as an attempt on Cooper's part to distinguish his present invention from a prior patent. The prior art patent filled in defective voids only, in contrast to the invention in the 780 patent, which ameliorates artifacts caused by defective pixels as well as by gaps or empty spaces between pixels. Rather than excluding defective pixels or image elements from the types of voids the invention could alter, Cooper illustrated that the 780 patent was more comprehensive. Because the reference to the dictionary definition can reasonably be interpreted in this way, there is no clear departure from the more expansive understanding of the term "void."

Last and most important, IP's position is consistent with the specification and the claims. Both the claims and the specification make reference to the possibility that voids need not be completely empty; claim 110 states that "the void can include at least in part a portion of a space occupied by another image element," and the specification states that "new pixels or pixels used for filling, substitution or replacement may be comprised of . . . a portion of a pixel." U.S. Patent No. 5,424,780, col. 5, Ins. 48-50; see Purdue, 237 F.3d at 1364. To accept Lexmark and Dell's definition, we would in essence read out these portions of the patent. Therefore, we construe this term to mean a space or spaces in the image where a change of illumination may be made to cause an improvement of the perceived quality of the image.

In the context of the 637 patent, Lexmark and Dell contend that this term should have a different meaning, relying on a portion of the specification in that patent that supplies illustrative examples of voids. As explained in the discussion of "display device" above, an illustrative list is not tantamount to an exhaustive description. Thus, Lexmark and Dell's arguments that this term should not be given a consistent meaning for both patents are unavailing, and we attribute the construction addressed here to all appearances of this term in both patents.
the '780 family of patents. Sony, however, argues that with respect to this term, the patentee used one meaning of the term in the '780 patent but explicitly redefined the term in the continuation-in-part '637 patent. The Court considers the term within the context of each patent.

For purposes of both the '780 and '637 patents, IPI defines voids as spaces around or in the image where a change of illumination maybe made to cause an improvement of the perceived quality of the image (e.g., blank areas of the image near a detailed area of the image). Importantly, IPI adds that these spaces may or may not include an unused image element.

Sony contends that a void in an image, as used in the '780 patent, means a physical point in a displayed image that is not addressed by image elements on the incoming signal at any time. Thus, according to Sony, the voids disclosed in the '780 patent reflect an empty space, opening, gap, or the quality without being something in the video information in the signal carrying the image. Sony submits that the patentee redefined the term in the '637 patent, as any location in an image including defects, unwanted elements, improper elements, corrupted elements, valid but replaceable elements, locations with no image information, and other locations or elements which may be in question or in need for improvement.

The term "voids" was not expressly defined in the '780 patent, and thus we must ascertain its meaning from the context of the patent. IPI emphasizes that language used in surrounding claims indicates that "voids" must include locations containing existing image elements. It points out that claim 110, which was added during reexamination of the ‘780 patent, discloses "the method of claim 15 characterized in that the void can include at least in part a portion of a space occupied by another image element." IPI argues that this claim makes it clear that a void can include a space occupied by another element. It also draws the Court's attention to the specification's discussion of how a video fill signal can generate a new pixel or pixels, which may be "used for "filling, substitution or replacement [and] may be comprised of all or a portion of a pixel." U.S. Patent No. 5,424,780, col. 5, lines 48-50. IPI reasons that if a fill signal includes substitution or replacement of old pixels with newly generated pixels, then a void, by definition, must include the possibility that a pixel exists within the space designated as a void.

Other claim language supports Sony's interpretation. The Court counted five claims that refer to a "void between image elements." See claims 3, 11, 12, 96 and 147. Moreover, the claims and specification contain numerous references to "blank areas," a phrase that the patentee appears to use interchangeably with "voids." For instance, claim 135 discloses a "means for changing the shape of at least one element [that] can include generating fill image elements in blank areas of the display." Use of the term blank tends to suggest that the patentee had the ordinary meaning of "void" in mind when drafting the patent. In sum, the claims and specification do not conclusively support one interpretation over the other.

The prosecution history, however, sheds more light on the intended meaning of the term. During prosecution of the '780 patent, the inventor, James Cooper, responded to an examiner's objection of a claim based on obviousness by stating:

Applicant has reviewed and considered the examiner's remarks given in his 35 U.S.C. § 103 rejection over Cooper '070. Applicant believes however that the examiner is incorrect in his assertion that a defective pixel such as corrected by the '070 invention is the same as, and would include, voids in the image as in the present disclosure and claims. The '070 patent generally shows replacing a given pixel with an average of pixels based on the similarity or ranking of pixels. The similarity or ranking of pixels is not related to the absence of elements as the examiner suggests. It might be noted that Webster defines the noun void as empty space, opening, gap, the quality of being without something, etc. Such definition would preclude the filling of voids from being obvious in view of the averaging of similar elements for removal of noise which is disclosed in the '070 patent.

See S/N 355,461 O.A. response 6/18/92 at 17. The Court reads Cooper's remarks, and in fact believes that this is only sound interpretation of his comments, as an unambiguously limit on the scope of "voids."

Moreover, during prosecution of the '780 patent on reexamination, Cooper made amendments to certain claims on March 16, 2001. In this document, he amended then claim 138, which read "the apparatus of claim 1 characterized in that the void can include at least in part a portion of a space occupied by another element" to read "the apparatus of claim 1 characterized in that the void can be filled in part with portions of two image elements." See G15/7422R1F at 9. When Cooper, later in the same document, discussed his interview with the examiner, he noted that

in respect to the "portion of a space occupied by another image element" in claim 138, the undersigned pointed out how
the voids may be filled by all or a portion of a pixel (fig. 5A; col 4 lns 51-52; col 5 ln 50; col 10 lns 26-31; col 12 lns 23-34). This use could utilize a combination of a plurality of pixels for the fill element, thus utilizing a portion of two (or more) elements to fill a given void. The examiner indicated he would again reconsider this rejection with the wording as currently constituted.

Id. at 17. Though the Court was not provided with subsequent excerpts of the prosecution so as to determine later changes made to the above mentioned claim 138, the inventor's remarks are illustrative. Following this reasoning, current claim 110, which reads "The method of claim 15 characterized in that the void can include at least in part a portion of a space occupied by another image element," most likely refers to the newly generated elements rather than image elements already existing in the space.

Because the prosecution history of the '780 patent limits the interpretation of "voids" in a manner that unequivocally excludes IPI's interpretation, see Omega, 334 F.3d at 1324, the Court adopts for that patent Sony's proposed definition of "void" as a physical point in a displayed image that is not addressed by image elements on the incoming signal at any time.

The parties do not truly dispute the meaning of "void" in the '637 patent, aside from their preferred phraseology. Both agree that in the context of the disputed claims in that patent, a "void" may include a space occupied by an image element. Indeed, as Sony highlights, the specification contains the following discussion defining the scope of "void:"

It will be also understood that although the word void is used in this specification, the invention is directed towards replicating new image information utilizing neighboring image elements, which new image information is utilized at a certain location(s). These locations might or might not have previously had image information available therefor. The void may exist at the point of image creation, before/after storage and/or at the point of presentation. Examples of voids would include such things as defects, unwanted elements, improper elements, corrupted elements, valid but replaceable elements, locations with no image information, and/or other locations or elements which may be in question or need for improvement. The term void is used to cover all these and similar situations for uniformity.

U.S. Patent No. 6,529,637, col. 3, lines 33-47. This excerpt clearly demonstrates that the patentee used the term in the '637 patent in a manner outside the bounds of its ordinary meaning. Where the specification contains a definition for a term that differs from the meaning the word would otherwise possess, the patentee's lexicography governs. Phillips, 415 F.3d 1303, 2005 WL 1620331, at *8.

Courts presume that a claim term carries the same meaning throughout a particular patent and related patents, including a continuation-in-part. See Omega Eng'g. Inc. v. Raytek Corp., 334 F.3d 1314, 1334 (Fed. Cir. 2003). But this presumption maybe overcome by evidence that the patentee clearly assigned different meanings to a term that appears in two related patents. In this case the presumption has been overcome.

Thus, with respect to the use of void in the '637 patent, the term is defined as any location, existing at the point of image creation, before or after storage, or at the point of presentation, in or around an image where a change of illumination may be made to cause an improvement of the perceived quality of the image. Such voids may include, but are not limited to, defects, unwanted elements, improper elements, corrupted elements, valid but replaceable elements, locations with no image information, and other locations or elements which may be in question or need for improvement.

4. "Volley code"

The meaning of the term "volley code," which appears in both Claim 1 and 8 of the '002 Patent, is also in dispute. Papyrus suggests that the term means "one or more symbols used for relating one communication or instruction to another communication or instruction." Pl. PCCO 3; Markman Hr'g Tr. vol. 2 at 87. Moreover, Papyrus alleges that volley codes communicate the stage, i.e., the status, of a transaction or instruction. Markman Hr'g Tr. vol. 2 at 88-89. Specifically, the "Detailed Description" section of the patent addresses volley codes, stating that "[t]he system utilizes volley codes to define the present stage of a transaction or instruction." '002 Patent col. 18 l.41-42 (emphasis added). In addition, Papyrus also notes that the definition of the word "code" is "a system of signals or symbols for communication" and "a system of
symbols (as letters, numbers, or words) used to represent assigned and often secret meanings." Pl. App. Ex. 48 at 457; see Pl. App. Ex. 49 at 481.

In the alternative, NYSE suggests a construction where the term means "a code that reflects the current stage of communications for a transaction." Def. PCCO 3. Although NYSE cites claim language which states "said volley code defining a hierarchical relationship among said subset of data packets," it asks that the court construe the term to mean in part, "the stage of the transaction." '002 Patent col.33 ll.38-39, col.34 ll.28-29 (emphasis added); Def. Reply Br. 18.

Papyrus, however, contends that NYSE's proposed definition "restricts volley codes to characters that reflect the 'current stage of communications.'" Pl. Reply Br. 20. According to Papyrus, "nothing in the written description manifests an intent to confine the volley codes to the preferred embodiments . . . ." Pl. Reply Br. 20-21. Indeed, the patent explains that although the preferred embodiment provides for the use of specific symbols as volley codes (e.g., "Q," "O," "M," "E," "S," "A"), the "characters [used] are merely illustrative of the essential function of the system which they represent" and therefore, "other characters or digital means may be used to identify the progression of one communication from one device to another." '002 Patent col.18 ll.60-63; see id. col. 18 ll.53-59. As a result, the specification supposedly teaches that a "volley code" may also broadly identify the progression of a communication. Pl. MHSP vol. 2 at 55; see Fuji Photo Film Co., 386 F.3d at 1106. Moreover, because Claims 1 and 8 expressly provide that volley codes define a hierarchical relationship, the phrase "volley code" should not be construed to repeat that express provision. Pl. Reply Br. 20.

Here, the meaning of "volley code" as explained by the patent language is ambiguous. On one hand, the written description clearly states not only that volley codes "define the present stage of a transaction or instruction" but also that "other characters or digital means may be used to identify the progression of a communication from one device to another." '002 Patent col. 18 II.41-42, 61-63. On the other hand, the claim states that volley codes define hierarchical relationships among a subset of data packets. See '002 Patent Abstract, col.8 II.2-3, col.33 II.38-39, col.34 II.28-29. Nevertheless, the court finds that Figures 12 and 13 are crucial to understanding the purpose and role of volley codes in the method. According to the specification, Figure 12 shows "the progression among several of the principal subtypes [of volley codes] for orders and quote requests as they are disseminated and handled." Id. col. 18 II.65-67 (emphasis added). Figure 13 also depicts the progression, between the programmed computer and the HHD which prompts the invention to use the volley code that corresponds with the stage of the transaction. Based on the language in the specification and the pictorial representations of the invention, the court defines volley codes as "codes that define the present stage of a transaction or which reflect the progression of communications for a transaction." 4810

3. "Voltage Amplifier"

In P3's opening claim construction submission, it argued that the term "voltage amplifier" as used throughout the '850 Patent should mean "any device or combination of devices that changes the amplitude of the voltage input." UPM appears to argue in opposition that this term, like the prior art UPM references, does not amplify the voltage signal but only "attenuate[s]" it in order to be processed by the ADC. In reply, therefore, P3 contends that the parties at least agree that a proper construction of "voltage amplifier" includes "devices that attenuate voltage." P3 further contends that the argument of UPM's expert that the specific limitations found in the specification should be read into this claim limitation should be rejected as improper. The parties having agreed that the term "voltage amplifier" includes at least devices that "attenuate" voltage, and UPM having made no argument in its opposition brief for any different definition of the term, the term "voltage amplifier" shall be construed as a device that at least attenuates voltage. 4811

3. "Voltage Regulator" (Claim 11)

There are two disputes regarding the construction of this term. First, the parties engage in the identical dispute to that described above regarding "amplifier circuit," with Broadcom arguing for the application of P 6 on the grounds that there
are many different physical manifestations of voltage regulators. For the reasons stated above, the Court rejects this contention and holds that the term is not governed by P 6.

Second, Broadcom objects to Agere's construction of the voltage regulator as a device that "controls the voltage supplied to the input of the bandgap voltage supply circuit by the power source so as to maintain the output bandgap voltage between 1.0 and 1.5 volts." Broadcom argues that this language is "vague," in that it could be read to imply, incorrectly, that the voltage regulator directly controls the output bandgap voltage instead of merely regulating its own output. (R. at 239, 245 (May 7, 2004).) The Court notes, however, that Agere's construction is taken verbatim from the claim itself ('817 patent, col. 7, l. 21-col. 8, l. 2) and, rather than being vague, states unequivocally that the voltage regulator controls the voltage "supplied to . . . the bandgap voltage supply circuit by the power source." Thus, there is no question that the voltage regulator directly controls the input to, and not the output from, the bandgap voltage supply circuit, and therefore Broadcom's vagueness argument is meritless. Accordingly, the Court adopts Agere's construction.

A. Voltage Source Means Dispute

The parties dispute whether the limitation "voltage source means providinga constant or variable magnitude DC voltage between the DC input terminals" is a function-plus-means limitation, subject to construction as limited by section 112, P 6. Lighting Ballast argues that "voltage source" connotes sufficient structure to one skilled in the art and that it should avoid treatment as a means-plus-function limitation. In the alternative, Lighting Ballast argues that if the Court determines that section 112, P 6 applies, then the specification discloses the corresponding structure. Universal argues that the term should be treated as a means-plus-function limitation because it is written in means-plus-function format, and furthermore, that the specification does not disclose a corresponding structure, making both claims in which the limitation appears indefinite.

1. Plaintiff's Proposed Construction

Lighting Ballast argues that this limitation, while using the term "means," is not a means-plus-function limitation because the term "voltage source" has an understood meaning in the art when read in the context of the specification. See Pl.'s Opening Br. 14-15, ECF No. 84. Specifically, according to Lighting Ballast, "voltage source means [providing (claim 1), able to provide (claim 18)] a constant or variable magnitude DC voltage between the DC input terminals" connotes the structure of a rectifier to anyone skilled in the art. Id. at 15. As support for this assertion Lighting Ballast points to extrinsic evidence: expert testimony from Andrew Bobel, the inventor, who has several years of experience working on electronic ballast designs, and Dr. Victor Roberts, an expert witness. Id. Both Bobel and Dr. Roberts testify, that as persons skilled in the art, the "voltage source" limitation clearly connotes the structure of a rectifier. Pl.'s Opening App. Ex. 2-A at 226, ECF No. 84-3; Ex. 3 at 7-8, ECF No. 84-7. In the alternative, Lighting Ballast argues that if the Court determines that section 112, P 6 applies, then the specification discloses the corresponding structure. Universal argues that the term should be treated as a means-plus-function limitation because it is written in means-plus-function format, and furthermore, that the specification does not disclose a corresponding structure, making both claims in which the limitation appears indefinite.

2. Defendant's Proposed Construction

Universal argues that this limitation is governed by section 112, P 6 as a means-plus-function limitation. Def.'s Opening Br. 16, ECF No. 85. First, Universal points to the use of the term "means," which presumptively invokes section 112, P 6. Id. Secondly, according to Universal, the limitation itself clearly recites a function only. Id. And third, the claim language does not point to any structure. Id. Thus, Universal asserts, this limitation is a classic means-plus-function limitation and must be construed according to section 112, P 6. Universal then goes on to argue that the specification for the 529 Patent does not disclose any structure, a rectifier or otherwise, for performing the claimed function. Id. 18-20. Accordingly, Universal urges that Claims 1 and 18 should be held invalid because they are indefinite.

3. Court's Analysis and Construction

The Court begins with the presumption that this is a means-plus-function limitation, subject to construction under section 112, P 6 because it uses the term "means," and is written in a classic means-plus-function format. See Kemco Sales, Inc. v. Control Papers Co., Inc., 208 F.3d 1352, 1361 (Fed. Cir. 2000). Lighting Ballast asserts that the presumption should not
apply because, despite use of the term "means," the limitation recites sufficient structure to avoid section 112, P 6. To determine whether the limitation "voltage source means" connotes sufficient structure, the Court must first consider all of the recited claim language, including nouns, adjectival modifiers, and function descriptions, and secondly, determine whether that claim language has an understood meaning in the electronic ballast field when read in the context of the 529 Patent specification. See Linear Tech. Corp. v. Impala Linear Corp., 379 F.3d 1311, 1320 (Fed. Cir. 2004).

The words "voltage source" precede "means," which is followed by the claimed function, "[providing/able to provide] a constant or variable magnitude DC voltage between the DC input terminals." Lighting Ballast argues, as it must in order to avoid section 112, P 6, that "voltage source" connotes sufficient structure, in this case, a rectifier. However, in order to come to this conclusion, Plaintiff uses the recited function along with inventor and expert testimony, that a rectifier would be required where the function is "providing a constant or variable magnitude DC voltage." Lighting Ballast also points the Court to case law stating "it is sufficient to avoid [section 112, P 6] treatment if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the terms identify the structures by their function." Mass. Inst. of Tech., 462 F.3d at 1356.

Universal argues that the term "source" and by extension, the term "voltage source," is insufficient to connote structure and directs the Court to case law. In Nilssen v. Motorola, Inc., the court held that even if the term "source" in "source means" connotes a device that provides power, this alone is not a sufficient structural recitation to remove the limitation from the ambit of section 112, P 6. 80 F. Supp. 2d 921, 928-29 (N.D. Ill. 2000). The difference here is that "source" is preceded by "voltage" obviously meaning that it is a source of voltage. However, the Court is inclined to agree with the Nilssen court, that even assuming "voltage source" connotes a structure, it is not a sufficient structural recitation to overcome the presumption in favor of section 112, P 6.

Lighting Ballast's argument that "voltage source" connotes sufficient structure to avoid means-plus-function construction is problematic for other reasons as well. First, Lighting Ballast does not point the Court to any evidence, intrinsic or extrinsic, that the term "voltage source" is commonly used in the electronic ballast industry to mean a rectifier. Rather, Plaintiff relies on the description of the function, stating that persons of skill in the electronic ballast industry, including Bobel and Dr. Roberts, understand that this function, insofar as it includes supplying a DC voltage, can be and often is performed by a rectifier. Secondly, Lighting Ballast admits that a rectifier is not the only structure capable of providing a DC voltage, pointing out that a battery would also suffice. There is no indication that "voltage source" is often used synonymously with the term "rectifier" by those of ordinary skill in the electronic ballast industry, and Lighting Ballast does not appear to argue as much. In fact, the opposite would seem to be the case, since a rectifier is merely one voltage source. Lastly, neither the language of claim 1 or claim 18 describes the function of a rectifier. Rather, the recited function, "providing a constant or variable magnitude DC voltage between the DC input terminals," refers only inferentially to the function of a rectifier. 2 For these reasons, the quotation from Massachusetts Institute of Technology, supra, does not assist Plaintiff in avoiding section 112, P 6. Therefore, the Court finds that this limitation, even when read in the context of claims 1 and 18, of which it is a part, does not suggest sufficient structure on its face to overcome the means-plus-function presumption, and it must be construed in accordance with section 112, P 6.

--- Footnotes ---

2 Dr. Roberts appears to acknowledge this fact when he states in his declaration that "one skilled in the art would immediately ascertain and implement the structure necessary to supply the DC supply voltage[.]" Pl.'s Opening App. Ex. 3 at 7-8, ECF No. 84-7.

--- End Footnotes ---

In order to construe the "voltage source means" limitation in accordance with section 112, P 6, the Court must determine the claimed function, and then identify the corresponding structure in the written specification of the 529 Patent that performs that function. See Applied Med. Res. Corp., 448 F.3d at 1332. The Federal Circuit has stated that section 112, P 6 represents a quid pro quo by allowing inventors to use a generic means expression for a claim as long as the specification indicates the structure that constitutes the means. See Atmel, 198 F.3d at 1381. The section 112, P 6 "tradeoff cannot be satisfied when there is a total omission of structure. There must be structure in the specification." Id. at 1382. Once it is established that there is a disclosure of structure in the specification, the analysis proceeds to the sufficiency of the disclosure—whether one skilled in the art will know and understand what structure corresponds to the means limitation. Id. Therefore, as long as
there is disclosure of structure, the written description in the 529 Patent need not explicitly describe the structure; rather, disclosure of the structure may be implicit so long as it meets the above test. See id. at 1380. However, the Court must bear in mind that the proper "inquiry is whether one of skill in the art would understand the specification itself to disclose a structure, not simply whether that person would be capable of implementing a structure." Biomedino, 490 F.3d at 953. In other words, if no structure is disclosed, it is not sufficient that a person of skill in the art could implement a structure. See id. As established supra, the claimed function is "providing [or (able to provide)] a constant or variable magnitude DC voltage between the DC input terminals." Thus, the description in the 529 Patent must disclose a structure, either explicitly or implicitly, such that one with skill in the art would understand the disclosure to connote a structure, that performs this function. See Atmel, 198 F.3d at 1382. The parties do not dispute that the 529 Patent does not explicitly disclose the structure of a rectifier. Therefore, the issue turns on whether the specification in the 529 Patent implicitly discloses a rectifier as the structure to perform the above specified function.

The parties dispute this point. Lighting Ballast directs the Court to several references in the 529 Patent to drawing power from a power line source and to DC supply voltages. Pl.'s Opening Br. 16, ECF No. 84. Lighting Ballast, relying on testimony from Bobel and Dr. Roberts, argues that "the only structure that can perform such a function in a lighting ballast is a rectifier, which is implicit, but clear, from the specification's multiple references to 'a power line source' and 'a DC supply voltage.'" Id. Otherwise, Lighting Ballast does not point the Court to any language in the 529 Patent that discloses a structure. See id. Defendant, Universal, argues that the description in the 529 Patent does not disclose a corresponding structure, and that Lighting Ballast may not use expert testimony to suggest a structure that was not disclosed in the patent. Def.'s Resp. Br. 4-6, ECF No. 89.

Lighting Ballast relies on language from Atmel, where the court states that "disclosure of structure corresponding to a means-plus-function limitation may be implicit in the written description if it would have been clear to those skilled in the art what structure must perform the function recited in the means-plus-function limitation." 198 F.3d at 1380. However, this statement must be understood in its proper context. As noted supra, the central issue in the Atmel opinion was not whether there was a disclosure of a structure, the first step in the analysis, but whether the alleged disclosure would connote a structure to one skilled in the art. See id. at 1380-82. The appellant in Atmel argued that a citation to a particular article in the patent's specification, which included the article's title, was a sufficient disclosure of the structure at issue such that a person of skill in the art would understand the nature of the corresponding structure. Id. at 1380-81 ("Atmel specifically directs us to the testimony of its expert . . . that the mere mention of the title of the . . . article in the specification is sufficient for one skilled in the art to envision the structures disclosed in that article") (emphasis in original). The Federal Circuit agreed, holding that "interpretation of what is disclosed must be made in light of the knowledge of one skilled in the art." Id. at 1380. Therefore, when the Atmel court made the statement above, relied on by Lighting Ballast, the court was specifically discussing the second step of the implied-disclosure analysis, the sufficiency of the alleged disclosure.

It is also worth noting that this language was itself used in a quotation in the Atmel opinion. See id. at 1380. The Atmel court was quoting from what were proposed supplemental guidelines from the PTO which were themselves adopted from the Federal Circuit's In re Dossel opinion. Id.; see In re Dossel, 115 F.3d 942 (Fed. Cir. 1997). In Dossel, the court, like the Atmel court, was discussing the sufficiency of the alleged disclosure of the structure corresponding to a means-plus-function limitation in a claim. Id. at 946. The specific structure at issue was a computer, however, neither the written specification nor the claims ever used the word computer. Id. Rather the description described the structure of a computer, by its functions—"clearly, a unit which receives digital data, performs complex mathematical computations and outputs the results to a display must be implemented by or on a general or special purpose computer." Id. at 946-47. The Dossel court then stated that this conclusion was bolstered by the fact that "in the medical imaging field, it is well within the realm of common experience that computers are used to generate images for display by mathematically processing digital input." Id. at 947. Thus, it is clear that the appellant in Dossel had overcome the initial hurdle of pointing to a disclosure of the structure in the patent's specification, and the court's focus was considering whether the disclosure was adequate.

3 Plaintiff does not point the Court to any language in the specification of the 529 Patent describing the function of a rectifier.
Finally, in Biomedino, the Federal Circuit addressed the substance of Lightning Ballast's argument. 490 F.3d at 952-53. In Biomedino, the court considered the claim limitation "control means" and whether the patent's specification disclosed a corresponding structure. Id. at 948-49. The only references in the specification to the "control means" were a box labeled "Control" in a diagram of the invention and a statement that the regeneration process "may be controlled automatically by known differential pressure, valving and control equipment." Id. at 949. The appellant relied on expert testimony to show that from the above statement, one skilled in the art would be able to identify a structure. 4 Id. at 951. The court rejected this argument, stating that the proper inquiry was not whether a person skilled in the art could implement a structure but whether that person would understand the specification to disclose a structure. Id. at 953 (emphasis added). Thus, the Biomedino court held that the "bare statement that known techniques or methods can be used does not disclose structure." Id.

4 Similar to Dr. Roberts's argument in this case, see supra n2 and infra n6.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Here, Lighting Ballast fails to point the Court to any language in the 529 Patent that discloses either implicitly or explicitly the structure of a rectifier. Rather, Lighting Ballast attempts to use testimony from the inventor, Bobel, and an expert, Dr. Roberts, that they understand that the invention covered by the 529 Patent would require a rectifier. In so doing, Lighting Ballast finds itself in same position as the appellant in Biomedino, arguing that one skilled in the art could implement a structure. Lighting Ballast relies on the testimony of Bobel and Dr. Roberts, that they, as persons skilled in the art of lighting ballasts, understand that when the specification speaks of using a DC supply voltage, where power is supplied from a power line source, which they know to supply AC voltage, that a structure to convert AC power to DC power would be required. Furthermore, since the invention is a lighting ballast, Dr. Roberts testifies, a rectifier would be the structure used in the vast majority of applications. While all of this may be true, it ignores the proper inquiry laid out by the Federal Circuit in Atmel and further explained in Biomedino. First, Lighting Ballast must point the Court to the disclosure of a corresponding structure in the specification, and only then, may the Court evaluate the sufficiency of the disclosure and determine whether one skilled in the art would understand the disclosure to suggest the corresponding structure. See Atmel, 198 F.3d at 1381.

Since Lighting Ballast is unable to point the Court to language in the specification disclosing a structure, it seeks to rely on expert testimony that one skilled in the art is capable of implementing a structure after reading the specification. 5 However, the Federal Circuit, in Biomedino, expressly forbids such use of expert testimony. Biomedino, 490 F.3d at 953. At most, the language in the specification to which Lighting Ballast directs the Court requires an inference on the part of one skilled in the art who has read the 529 Patent. The references to a power line source and a DC supply voltage do not connote structure; rather they require the person skilled in the art to implement one. 6 Therefore, the Court finds that Plaintiff, Lighting Ballast, has failed to identify a structure in the 529 Patent's specification that corresponds to the "voltage source means" limitation, contrary the requirements of 35 U.S.C. § 112, P 6.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 The Court notes that in its briefing, Plaintiff admits that the 529 Patent focuses on the energy output rather than the energy input side of the ballast. Pl.'s Opening Br. Cl. Const. 4, n.4, ECF No. 84. This may explain the absence of any disclosure of a structure to match the "voltage source means" limitation in Claims 1 and 18.

6 Dr. Roberts only bolsters this conclusion in his declaration when he states: "one skilled in the art would immediately ascertain and implement the structure necessary to supply the DC supply voltage, based on the particular application of the ballast in question." Pl.'s Opeing App. Ex. 3 at 8, ECF No. 84-7 (emphasis added); see also n2 supra.

IV. CONCLUSION

A determination that a claim is indefinite is a question of law and is part of the court's duty as the construer of patent claims. Personalized Media Commc'n's, 161 F.3d at 705. It is well-established that the determination of whether a claim is invalid as indefinite depends on whether one skilled in the art would understand the scope of the claim at issue when it is read in light
of the specification. North Am. Vaccine, Inc. v. American Cyanamid Co., 7 F.3d 1571, 1579 (Fed. Cir. 1993). Where one employs means-plus-function language in a claim, one must set forth, in the specification, an adequate disclosure showing what is meant by the claim language. Atmel, 198 F.3d at 1378-79 (quoting In re Donaldson Co., Inc., 16 F.3d 1189, 1195 (Fed. Cir. 1994)). If an applicant fails to set forth an adequate disclosure of the structure intended by the claim language, the applicant fails to "particularly point out and distinctly claim the invention," as required by section 112, P 2. Id. at 1379. In order for a claim to meet the particularity requirements of section 112, P 2, the corresponding structure of a means-plus-function limitation must be disclosed in the written specification. Id. at 1382. Where a patent specification fails to disclose a corresponding structure for a means-plus-function limitation in a claim, that claim is invalid for indefiniteness under section 112, P 2. See id; see also Default Proof Credit Card Sys., Inc. v. Home Depot U.S.A., Inc., 412 F.3d 1291, 1302-03 (Fed Cir. 2005).

The Court has held that the "voltage source means" limitation, present in both Claims 1 and 18, is a means-plus-function limitation, subject to construction under section 112, P 6. Applying section 112, P 6 the Court found that the specification of the 529 Patent fails to disclose a corresponding structure for the "voltage source means." Therefore, since the 529 Patent fails to disclose a structure for a means-plus-function limitation in a claim, those claims, Claims 1 and 18, are indefinite under section 112, P 2 because they fail to particularly point out and distinctly claim the subject matter which the applicant regards as his invention. See Atmel, 198 F.3d at 1379; Default Proof Credit Sys., 412 F.3d at 1302-03. Accordingly, the Court finds that Claims 1 and 18 are invalid for indefiniteness and may not be enforced by Lighting Ballast against Universal.

4813

a. "voltage supply"

The term "voltage supply" appears in one of the asserted claims of the '955 patent. Claim 1 of the '955 patent requires "a voltage supply having a coupling to said underlying substrate regions determined by a voltage of said underlying substrate regions." NeoMagic and Trident agree that "power supply" and "voltage supply" are synonymous. Therefore, consistent with its earlier construction of "power supply," the court finds that the term "voltage supply" refers to a source of electrical energy, such as a battery, that requires at least two power supply lines to deliver power in an electrical circuit.

4814

C. Voltage Sustaining Layer

1. Plaintiff’s Interpretation

Plaintiff PMT asserts that "voltage sustaining layer" should be defined as "a structure comprising 'alternating' regions of p-type conductivity and n-type conductivity." (PMT Br. at 13). As with "contact layer," PMT argues that "layer" is used in the Chen Patent to mean a horizontal orientation, and "region" is used to mean a vertical orientation. (R. 37 at 11-13). Thus, the voltage sustaining layer is "a horizontal area containing vertical regions." (Id. at 11). In support of its proposed definition, PMT asserts that the inventor chose to be his own lexicographer and unambiguously defined "voltage sustaining layer" in the patent claims. (Id. at 1-5; 15 to 38 at 3; R. 224 at 8-18; R. 231 at 14-15) (referencing Chen Patent, col. 1, In. 55-col. 2, In. 3; col. 7, In. 62 to col. 8, In. 6). In the specification, the inventor calls the type of voltage sustaining layer disclosed by the patent a composite buffer layer, or CB-layer, and PMT regards "voltage sustaining layer" and "CB-layer" as interchangeable. (R. 89 at 22-25; R. 225 at 6 to R. 227 at 16) (referencing, inter alia, Chen Patent col. 1, In. 55-58; col. 1, In. 67 to col. 2, In. 8; col. 2, In. 22-23). PMT admits that the voltage sustaining layer can contain components other than regions of p or n-type conductivity, but urges that the inventor’s definition of CB-layer (i.e., voltage sustaining layer) requires that all components occur in an alternating arrangement. (R. 90 at 4 to 91 at 16; R. 228 at 23 to R. 229 at 24; R. 230 at 20-25). PMT thus contends that everything below that layer of alternating regions is contact layer. (R. 230 at 24 to 231 at 2).

PMT rejects defendants' proposed interpretation first on the ground that it requires back-loading limitations from the generic
"voltage sustaining layer" described in the specification into the "voltage sustaining layer" defined in the claims. (R. 216 at 14 to 217 at 24). PMT contends that the definition that defendants take from the background is actually only Chen's description of the prior art, i.e., of what his invention is not. (R. 219 at 10-17) (referencing Chen Patent, col. 1, In. 11-15). Finally, PMT argues that all semiconductor devices, including Chen's, will sustain some voltage in areas other than their "voltage sustaining layers"; therefore, it is vague to define that structure in terms of its function alone. (R. 221 at 9-19).

2. Defendants' Interpretation

There is some variation in defendants' proposed definitions of "voltage sustaining layer", but "the lightly doped layer of the device that sustains voltage in the off state" 14 sufficiently incorporates their most recent and relevant arguments. Defendants base their proposed definition directly on the language the inventor used to define the term in the specification. (R. 119 at 20-25; Infineon Br. at 20; R. 176 at 1-16) (referencing Chen Patent, col. 1, In. 11-15). Defendants reject PMT's claim that "voltage sustaining layer" and "CB-layer" are interchangeable, arguing that the inventor explicitly defined "CB-layer" in the claims in a way that makes clear he meant it as one species of the genus "voltage sustaining layer." (R. 119 at 12-23; R. 176 at 1 to 177 at 5) (referencing Chen Patent, col. 1, In. 55 to col. 2, In. 2). Defendants contend that the definition of "voltage sustaining layer" that PMT offers the Court is the definition that should instead be applied to "CB-layer." (R. 120 at 7-8; R. 177 at 4-14). Defendant ST explains further that the phrase "called hereafter" that immediately precedes the first use of the term "voltage sustaining layer" in the specification is used to mean "defined as"; therefore, that preceding language is the inventor's intended definition, not the later language used in association with the "CB-layer." (R. 176 at 1-24) (referencing Chen Patent, col. 1 In. 55 to col. 2, In. 2). According to ST, PMT's definition would impermissibly incorporate limitations from a preferred embodiment, the CB-layer, into the definition of "voltage sustaining layer." (R. 177 at 17-19) (referring PMT to it's own Br. at 5 and citing SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1118-25 (Fed. Cir. 1985) (en banc)). Finally, defendants rebut PMT's characterization of their proposed definition as merely Chen's description of the prior art by pointing out that Chen's CB-layer was also prior art under Coe, U.S. Patent No. 4,754,310. (R. 279 at 11-13).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

14 Defendant Infineon specifically asserts that "voltage sustaining layer" should be defined as "the lightly doped layer between n+ and p+ regions that sustains voltage." (R. 120 at 3-5). Defendant ST specifically asserts that "voltage sustaining layer" should be defined as "the layer of the device that sustains the reverse voltage of the device in the offstate." (ST Br. at 11; ST slide # 26).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

ST separately denies that the voltage sustaining layer must be limited to alternating n and p regions because the drafter specifically used the term "comprising," meaning "including the following elements, but not excluding others," 15 to describe the structure rather than the term "consisting of," meaning "the following elements and nothing more." (R. 178 at 2 to 179 at 6) (referencing Chen col. 7, In. 64). ST argues that it makes no difference that none of the embodiments show any other structures, because "comprising" specifically allows for other structures, even if not disclosed. (R. 179 at 15-17). Therefore, under ST's construction, a "voltage sustaining layer" could include anything that sustains a voltage and forms an interface with the contact layers. (R. 180 at 14-18).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

15 The parties have agreed to this definition of "comprising." (R. 178 at 2-5).

3. Recommended Interpretation

The Special Master recommends that "voltage sustaining layer" also be defined in terms of its function as the "layer that primarily sustains the voltage applied between the terminals of the device." As with "contact layer", "voltage sustaining" is used as an adjective describing the function of this layer within the device. Whether or not this layer can include structures beyond those described as the "CB-layer" can be conclusively determined because the structure of the voltage sustaining
layer is explicitly defined in the claims. 16 (See, e.g., Chen Patent, col. 7, In. 63 to col. 8, In. 6). Chen described the voltage sustaining as "comprising first semiconductor regions of the first conductivity type and..." (Chen Patent, col. 7, In. 64-65) (emphasis added). "Comprising" is a term of art well-known to any patent attorney that is used to mean "including, but not limited to." 17 By using it, the patentee signaled his clear intent that the voltage sustaining layer includes the CB-layer structure, but that it not be restricted from including other layers or structures. Such an interpretation is consistent with the patentee's description of the CB-layer as the point of novelty of the voltage sustaining layer. (Chen Patent, col. 1, In. 55 to col. 2, In. 21). Chen describes the CB-layer as "a new structure of the voltage sustaining layer," but nothing in the disclosure is inconsistent with the idea that the voltage sustaining layer may include structures other than the CB-layer. (Chen Patent, col. 1, In. 55 to col. 2, In. 21). If the patentee had intended to so limit the voltage sustaining layer, he could have easily done so by using "consisting of," meaning "including these elements but no others," 18 rather than "comprising," or he could have used the term "CB-layer" in the claims rather than "voltage sustaining layer," as he did in the original claims, as filed. Instead, his use of "comprising" makes clear that the voltage sustaining layer must contain the alternating regions of the CB-layer, (Chen Patent, col. 1, In. 54 to col. 2, In. 21), but is not limited to those alternating regions. The specific embodiments in the Chen Patent do show the voltage sustaining layer to be just the CB-layer, but to read such a limitation into the term "voltage sustaining layer" would be an impermissible reading of limitations from the preferred embodiments into the claims. Constant, 848 F.2d at 1571. Further, restricting the "voltage sustaining layer" to a particular dopant concentration would be similarly impermissible because of the use of "comprising." (Chen Patent, col. 7, In. 64). The rule against reading limitations from preferred embodiments into the claims remains true even though every embodiment discloses a voltage sustaining layer that is just the CB-layer. Constant, 848 F.2d at 1571. Thus, under the recommended definition, a voltage sustaining layer may also contain additional structures or layers (in addition to the CB-layer), as long as those structures perform the function of sustaining the voltage across the terminals of the device.

--- Footnotes ---

16 Vitronics, 90 F.3d at 1582 (patentee may choose to be his own lexicographer, as long as the special definition is clearly stated); Constant, 848 F.2d at 1571 ("it is the claims that define the claimed invention"). Thus, ST's assertion that the phrase "called hereafter" in the specification signals the inventor's intended definition is incorrect because a clear definition in the claims supercedes any description in the specification.

--- End Footnotes ---

The single use of the term "voltage sustaining region" in, for example, claim 11, confuses the analysis, but does not change the result. (Chen Patent, col. 8, In. 8) (emphasis added). This alternate phrase, voltage sustaining region, is not found in the patent disclosure. There are two possible reasons for the use of this alternate phrase: either it is merely a scrivener's error, 19 or the patentee uses "voltage sustaining region" to mean a voltage sustaining layer plus or minus something else that also sustains voltage. However, such a meaning is nonsensical because, as explained, the definition of "voltage sustaining layer" is already left open by the use of "comprising." Trying to define "voltage sustaining region" as a "voltage sustaining layer" (which may already include other structures) that may then include other layers or structures leads to an absurd result. Thus, the most reasonable explanation is that the alternate phrase "voltage sustaining region" is simply a benign claim drafting error and should be read as "voltage sustaining layer" for claim construction purposes 20

--- Footnotes ---

19 Otherwise, there would be a problem that the term "voltage sustaining region" has no antecedent basis in claim 1.

20 If any meaning is to be attributed to the alternate phrase, it would serve to support PMT's argument that "region" and "layer" are interchangeable.

--- End Footnotes ---
This term is recited or referred to in Claims 1, 5, 17, 20-24, 29, 32, 38-40, 42, 48, 49, 54, 55, 57, 71-77, 80, 82, 85, 94, 96, 102, and 103.

In Claims 1, 5, 20-24, 40, 77, 80, 82, 85, 102, and 103, there is a reference to the voting record and the voting session identifier. In Claims 42, 48, 49, 71-74, 94, and 96, there is a reference to the voting record including the unique voting session identifier. Claims 17, 29, 32, 38, 39, 54, 55, and 57 refer only to the voting record. The parties agree that the term voting record includes the "voter's voting selections/choices." The disagreement is whether the unique voting session identifier should be contained in the definition of the term "voting record."

The description of the invention provides that the memory must store the voting record and the voting session identifier. (Col. 2, ll. 65-67; Col. 3, ll. 1-3.) The separation of these two terms is repeated throughout the description and specification of the invention. (See Col. 3, ll. 13-18; Col. 6, ll. 9-24; Col. 13, ll. 20-24.) The use of the word and indicates that the two terms voting record and voting session identifier -- are different items.

Defendants cite Column 6, lines 9-24 in support of their position; however, the Court finds this citation to favor Plaintiff's argument. "Each voting record PR [tangible voting record]-1, PR-2, . . . PR-n includes the randomly assigned identifying or serial number unique to the particular voting session and a listing of the votes that the voter has cast (the voting record) that is identical to the voting record and identifying number stored in voting machine VM." (Col. 6, ll. 18-24.) (First alteration added.) The citation clearly indicates that there is a difference between the voting record and the voting session identifier. Defendants also cite the prosecution of the patent which provides that "[b]ecause the voting session identifier is stored with or as part of the voting record . . . ." (Def. Ex. 4d, Response to Final Office Action, Aug. 24, 2004, at 24.) This citation is not clear evidence that the voting session identifier and the voting record are the same.

Because the majority of the time the patent refers to the voting record and the voting session identifier as two separate items, the Court will adopt Plaintiff's construction. Accordingly, the Court construes the term "voting record(s)" in Ref. No. 11 as follows: "The voter's voting selections/choices."

This term is recited or referred to in Claims 1, 5, 17, 20, 24, 40-45, 48, 49, 71-74, 76-89, 94, 96, 102, and 103.

Plaintiff proposes that this term be construed as follows: "The time at which a voter makes his or her voting selections on the voting apparatus." The problem with this construction is that Plaintiff does not describe the event in the patent description in that manner. Column 11, lines 46-51 provide that "preferably" the voting machine displays the voting record of the voter requiring at least one confirmation and "preferably" a second confirmation "in order to end a voting session." In even stronger language, the patent provides that "before a voting session is complete the voter confirms the voting selections he has made." (Col. 17, ll. 29-30.)

There should be no dispute here. The language in the specification and description of the patent is clear. The term "voting session" as contained in the above-listed claims is construed as: "The period during which a voter makes his or her voting selections on the voting apparatus, ending when the voter confirms the voting selections."
its construction is simple, yet significant.

Defendants contend that the voter takes away the voter identifier or voting session identifier at the end of the voting session. Plaintiff argues that certain embodiments permit the voter to take the voting session identifier away at the end of the session, but it is not a required element of the contested claims. Plaintiff asserts that each of the four phrases listed above are noun phrases and do not include the verbs "take" or "remove."

In support of their respective positions, the parties cite the background section of the '730 Patent. Column 1, lines 35-43 of that patent explain that previous electronic voting machines did not allow or provide any method by which a voter could personally check his or her vote, thereby increasing voter confidence. Column 1, lines 46-48 further describe the "particular" concern with electronic voting machines that, because of the intangible nature of records stored in electronic and magnetic form, an individual's vote could be altered without "leaving any evidence thereof." These concerns are repeated in Column 2, lines 6-21.

In support of its construction, Plaintiff directs the Court to the third embodiment as set out in Column 3, lines 19-30, describing five steps as an aspect of the invention. Plaintiff argues that there is no requirement in this embodiment for taking the voting session identifier. The last step is "storing the voting record including the voting session identifier and the voting selections in a tangible medium separate from the memory." (Col. 3, ll. 28-30.) The words of the claim themselves contradict Plaintiff's construction.

Additionally, the preferred embodiment section of the patent includes indications that the voting session identifier is to be provided to the voter. Column 6, lines 27-31 provide that there are three separate and independent records of the randomly assigned voting session identifier: "one stored in the memory (memories) of voting machine . . ., one stored in the memory of smart card . . ., and one printed [sic] the voting receipt.]" All three "identify the voting record of the particular voter by the same unique voting session identifier." (Col. 6, ll. 54-59.) And, the voting session identifier is stored after the voting session and is provided to the local printer, which, in turn, provides a tangible record to the voter in the form of a printed receipt. (Col. 7, ll. 9-14.) "Note that where the results are published as individual voting records with the voting session identifier associated therewith, the results are 100% transparent because each individual voter may use the voting session identifier printed on his tangible receipt to check the voting record posted against that on the printed receipt." (Col. 7, ll. 56-62.) (Emphasis added.) Also, the vote results, as explained in the patent, may be made available on the Internet, allowing a voter to log on and use the unique voting session identifying number on the voter's receipt to verify his or her vote. (Col. 8, ll. 27-36.) In Column 14, the patent states that voter may keep the printed record with the voting session identifier for his or her own reference. (Col. 14, ll. 36-43.) There is also a description of a "corrective voting session" which allows an election official to void an individual's voting record and allows the voter to repeat the voting process. (Col. 15, ll. 14-25.) Without a printed receipt containing the voting session identifier, the voter could not confirm that the change was actually made by the official. This is further evidence of the intention of the patent to provide a voting session identifier to the voter after his or her vote is completed.

Column 16, lines 35-41 again provide that the unique voting session identifier may be published or posted in a public location and on the Internet. See also Col. 18, ll. 20-26 (similar provisions). Without the voting session identifier, the voter would have no means to confirm his or her vote. 5 Column 23, lines 5-20 provide that all of the voting records and voting session identifiers are stored and tabulated at the close of voting and are combined at the election headquarters. "All voting records, voting session identifiers, and tallies thereof are made public with reference to each voter's randomly generated serial number (voting session identifier) for 100% transparency of the voting." (Col. 23, ll. 17-19.) "The printed-out receipt . . . is retained by the voter for reference and for checking his or her vote against the final posted voting tallies which include the voters' identifying numbers (voting session identifier)." (Col. 23, ll. 29-36.) (Alteration and emphasis added.)

5 Plaintiff cites Column 7, lines 56-62; Column 16, lines 35-41; Column 18, lines 23-26; and Column 21, lines 59-62 as evidence that publication is optional. The term "publication" as used in these portions of the patent, however, refers to the publication of the voting results, which in turn require the publication of the voting session identifier. This allows the voter to confirm his or her vote by using the voting session identifier provided the voter following the voting session. Column 20, lines 25-33, also cited by Plaintiff, refer to an optional serial number apart from the voting session identifier.
Thus, the description of the patent makes it clear that the inventor intended to create a voting system that promoted confidence in the voting experience. The inventor repeatedly stressed that the use of the voting session identifier retained by the voter is means to gain this confidence. A major tool in the '730 Patent to create this confidence is the ability of the voter to compare or check his or her vote with the published results of the vote. Without some identification number or identifying information on a receipt which is mirrored in the vote tally, the voter cannot confirm his or her vote. To now argue that distribution of the voting session identifier to the voter is optional flies in the face of the description of the invention.

As noted above, "the specification is always highly relevant to the claim construction analysis" and "is the single best guide to the meaning of a disputed term." Honeywell Int'l, Inc., 452 F.3d at 1318 (interim quotations omitted). Moreover, when the patentee "demean[s]" a feature in the description of his or her patent, it can be concluded that the patentee disavows that feature from the scope of the patent's claims. Id. at 1319. Here, the patentee criticizes previous voting events whereby the voter was not provided a means to personally check his or her vote cast. The specification and description of the invention provide the cure to that problem through the use of the voting session identifier on a printed receipt provided to the voter as a way for "personal checking of votes cast." (Col. 1, ll. 42.)

For the foregoing reasons, the Court accepts Defendants' proposed construction of the term "voting session identifier" and construes the term set forth in Ref. No. 6 as follows:

A random or pseudo-random number (or alphanumeric character or symbol) or number randomly chosen from a unique sequence of numbers assigned to a particular voting session which the voter takes away at the end of the voting session to enable the voter to identify her voting record from among the voting results published for that particular election.

7. "Gate"

"Gate" appears in claims 5, 12, 13 and 21 of the 148 patent. UniRAM asserts that "gate" should mean "gate electrode." Jt Cl Const, Ex B at 11. MoSys and TSMC, without providing any reason, contend that the term is indefinite; to the extent the term can be construed, they contend it means "polysilicon gate electrode." Id; TSMC Br (Doc # 99) at 32; MoSys Br (Doc # 103) at 53-54. Because the patentee expressly modified "gates" with "polysilicon" in claim 21 of the 148 patent, not all "gates" must be made of polysilicon. See Phillips, 415 F3d at 1314. Accordingly, the court adopts UniRAM's definition of gate as "gate electrode."

8. "WL-transistor gate" 4T"WL-transistor gate" appears in claim 13 of the 148 patent but does not appear in the specification except in a section paraphrasing the claim. 148 patent at 23:66-24:35. UniRAM contends that it means "the gate electrode in a memory cell transistor, which is connected to the word line (WL)." Jt Cl Const, Ex B at 31. MoSys and TSMC, again without providing any reason, contend that the term is indefinite; alternatively, they assert that the term means "the polysilicon gate electrode of the select transistor." Id.

As demonstrated presently, because "WL-transistor gate" is "amenable to construction," the term is not indefinite. Exxon Research and Engineering Co v United States, 265 F3d 1371, 1375 (Fed Cir 2001). The court rejects UniRAM's construction because it introduces the term "memory cell transistor," which is not mentioned anywhere in the patent. MoSys and TSMC's proposed construction better accords which claim 13, which states in part: "word-line (WL) select transistors each having a WL-transistor gate * * * " 148 patent, at 27:1-3. In construing "gate," the court rejected defining that term using "polysilicon." The court therefore adopts a modified version of MoSys and TSMC's construction and defines "WL-transistor gate" as "the gate electrode of the word-line select transistor."

Pursuant to this Court's Markman Order, the term "wafer" means "a thin, generally cylindrical, slice of semiconductor material used as a base for an electronic component or circuit." The term "a first axially symmetric region" means "a region
that is symmetric about the central axis of the wafer." The term "substantially free of agglomerated vacancy [or interstitial] defects" means "a concentration of such agglomerated defects which is less than the detection limit of these defects, which is currently about 1000 defects/cm³." The term "agglomerated vacancy intrinsic point defects" means "defects caused by the reaction in which vacancies agglomerate to produce D-defects, flow pattern defects, gate oxide integrity defects, crystal originated particle defects, crystal originated light point defects, and other such vacancy related defects." Finally, "agglomerated silicon self-interstitial intrinsic point defects" means "defects caused by the reaction in which self-interstitials agglomerate to produce dislocation loops and networks, and other such self-interstitial related defects."

3. Wafer Cassette (Claims 1 and 21)

Plaintiff argues "wafer cassette" should be construed as "a structure that holds one or more wafers." Defendant argues "wafer cassette" should be construed as "an open structure that holds one or more wafers."

The Court finds "wafer cassette" is properly construed as "a wafer carrier that holds one or more wafers and keeps them separate." 6

6 The Court has not adopted either party's proposed construction. Defendant has failed to show the claimed "wafer cassette" must be "open" at all times. Both parties' reference to a "structure that holds one or more wafers" fails to provide sufficient clarity; both parties agree, however, that a "wafer cassette" is a type of "wafer carrier" that, in addition to holding wafers, keeps them separate. (See Pl.'s Opening Brief on Claim Construction at 16; Gwozdz Decl. PP 23-24, Ex. H.)

6. Step (C): Wager

Plaintiff suggests that "wager" should mean "bet" and provide a dictionary definition for wager: "something (as a sum of money) that is risked on an uncertain event." (Pl. Br. at 22, citing Webster's, Ex. B.) Defendants argue in their Brief that the meaning of "wager" should be limited to a "specific sum of money." (Def. Br. at 21.) Defendants did not allocate much of their time in the hearing to the meaning of "wager," except beyond indicating it should be a monetary amount. Plaintiff did not dispute this argument at the hearing and even proposed that the term "wager having an amount" means "a wager having a numerical currency value."

There is no support in the specification to limit the meaning of "wager" to a "specific sum of money," and indeed, a great deal of support for the proposition that diverse wager amounts are allowed for in the invention. While the preferred embodiment does refer to the "wager amount of a specific bet," this appears to have a distinct meaning from "specific sum of money," namely that an individual bet has a specific amount, but other amounts for other wagers are anticipated. Defining "wager" to mean "a specific sum of money" could limit the invention to allowing only one kind of wager - an unsupported outcome that would destroy the invention's distinction from prior art and invalidate the patent.

However, the parties apparently agree that "wager" involves monetary value. Nevertheless, neither party points to a definition or a means of understanding the term from the specification which we could adopt as a clear definition. Given the lack of limitation presented by the specification and the fact that the extrinsic dictionary definition provided by Plaintiff does not appear to contradict the specification's usage of the term "wager," we adopt the dictionary definition presented by Plaintiff.
The parties dispute the definition of the term "wager" in the context of the patent claims. Specifically, the last step of the "method for automatically accepting a plurality of different wagering formats over a computer system" in every one of the asserted claims of the '865 patent is "requesting said prospective wagerers to enter a wager." Based on that context, Lottotron claims that "wager" is commonly understood to place at risk an infinite variety of things apart from money; such as, pride, bragging rights, avoidance of embarrassment, etc. Lottotron further claims that the breadth of the term is confirmed by its dictionary definition. On the other hand, Gtech submits that pursuant to the intrinsic evidence, "wager" is only limited to denote risking a sum of money.

--- Footnotes ---

--- End Footnotes ---

It is readily apparent from gleaning the '865 patent that "wager" involves risking money. In fact, throughout the patent, references to money are indicated. There is a lack of description in the patent to demonstrate that "wager" places at risk pride, bragging rights, avoidance of embarrassment, and etc. Indeed, other than a definition from a dictionary, Lottotron has failed to identify any intrinsic evidence to show that "wager" involves more than just a sum of money. Accordingly, the Court concurs with Gtech and construes the word "wager" to mean risking a sum of money.

To find support from the intrinsic evidence, the Court first reviewed the "Background of the Invention" section, which makes clear by comparison that the invention involves wagering money:

"None of the aforementioned systems allow a subscriber to call up on a touch-tone telephone, set up an account with a lottery system, place wagers in one or more lotteries available on the system, and charge the account for the wager."

'865 patent, col. 1, ll. 64-67. Next, in the "Summary of the Invention" section, the invention apparently requests "subscriber wagering information," including "a wagering amount for the particular lottery game chosen." Id., col. 2, ll. 24-31. Moreover, with respect to the description of the figures drawn in the patent, references to dollar amount are readily found.

If the caller confirms the date by pressing 1 then the VRU will respond with the message "Enter your two-digit weekly wager amount", else the VRU will again request the expiration month and year. When the caller then enters "10" signifying that on a weekly basis they wager ten dollars ($10.00) on lottery games, the VRU confirms the weekly wager amount by responding with a message "You have entered 10 dollars, press 1 to confirm, 2 to re-enter". In our examples, since the caller pressed '1' to confirm, the VRU then plays the message, "The system will now charge your credit card with 50 dollars, providing you with an open balance to wager."

Id., col. 4, l. 65 - col. 5, l. 9. The patent then describes how the invention prompts the user to enter a wagering amount that will be withdrawn from the credit balance.

The VRU then request the entry of the amount to be wagered during this call. The host compares this amount to the subscriber's open balance to wager to insure that sufficient funds are available for wagering. The system only reduces the open balance to wager as wagers are placed and not by the entry of this wager amount. The VRU plays the message, "Enter 2-digit wager amount". In our example, the subscriber entered '10', and the VRU then responds with, "you entered 10 dollars, press 1 to confirm, 2 to re-enter". As shown the subscriber responded by pressing '1'.

Id., col. 6, ll. 22-32. Ultimately, the system determines whether the user has "sufficient funds to place a wager" by "comparing the subscriber's open balance to wager against the amount which they indicated they would be wagering." Id., col. 7, ll. 19-21.
Clearly, as indicated by the patent language itself, the type of wager contemplated by the specification is monetary in nature, particularly since all the embodiments of the '865 patent require that the user provide information of a credit card from which the system can withdraw money in order to place wagers. See, e.g., id., col.2, ll. 12-18; col.4, ll. 36 - col. 5, l. 45; col.8, ll. 34-39; col.10, l. 45 - col. 11, l.45. Thus, as the meaning of "wager" is apparent from the specification, it is improper for the Court to employ the dictionary meaning as proposed by Lottotron. See C.R. Bird, Inc., 388 F.3d at 862. Indeed, accepting Lottotron's proposed definition would clearly depart from "the true scope and spirit of the invention." '865 patent, col. 11, ll. 60-61. As such, the Court will construe the term "wager" to mean risking a sum of money.

FortuNet argues nothing in the claim language or specification requires that the "additional wager" be a separate wager. FortuNet argues the player could pay a single predetermined amount to cover both the initial and additional wagers, and the "one fee covers all bets" concept is well known in gaming. The Court does not understand Planet Bingo to be arguing the wager has to be physically separate, but that the player simply must be charged an additional price for the second wager. The Court therefore holds "wagering an additional wager" means "placing another wager, either separately or through an increased purchase price, that one or more of the additional lottery elements will be drawn during play of the game." (See JA0206, Col. 19 at 48-51.)

Although the parties discuss other claim terms in their briefs, those arguments revolve around the parties' disputes regarding the need for a "ticket," the "fixed" number of balls called, and the patentee's restriction to Figures 9-12. The Court therefore will not construe these terms individually.

Lottotron proposes that "wagering format" means "the kind of lottery games that are available, such as Keno, Lotto, and 3- or 43- digit lotteries." Gtech, however, submits that construction of "wagering format" is a "wagering game in which the outcome of the game determines the outcome of the associated wager." The Court fails to find support for Gtech's proposed definition from the intrinsic evidence. Rather, the intrinsic evidence properly supports Lottotron's construction.

Gtech's proposed definition of "wagering format" is apparently based upon the logic that for every lottery game, the player places a wager before the outcome of the game is determined, and the outcome of the game determines the outcome of the wager. Thus, the term, Gtech contends, necessarily includes not only the variety of lottery games available on the system but also the ultimate outcome of the wager. To support its reasoning, Gtech cites to certain language of the patent that identifies the different game formats available on the system (e.g., six digit lotto, three digit lotto, keno and four digit lotto), and how a user can access and play these lotto games. However, the language does not mention, let alone describe, the outcome of a player's wager or the game. Instead, the language seems to support Lottotron's definition of "wagering format."

For example, in the "Summary of invention" section, the patentee states that "the invention provides a lottery wagering system comprising . . . second voice responsive means (wager VRU) . . . requesting subscriber wager information . . . including . . . a particular lottery game format chosen from a plurality of lottery game formats available . . . and a wagering amount for the particular lottery game chosen." '865 patent, col. 2, ll. 2-31. The patentee goes on to state with respect to Figure 1 that the system "places a wager" for the caller based on information provided by the caller, including "the particular lottery format of interest, such as 6-Digit lotto, 'keno', 3-Digit lotto." Id., col. 3, ll. 22-30. Accordingly, pursuant to the intrinsic evidence, restricting "wagering format" to "a wagering game in which the outcome of the game determines the outcome of the associated wager" is plainly contrary to the ordinary meaning of the term "wagering format." Thus, the Court construes the term to mean the "kind of lottery games that are available, such as Keno, Lotto, and 3- or 43- digit lotteries."
Indeed, as Lottotron points out, "wagering format" has been constructed, by the United States District Court for the Southern District of New York in Lottotron, Inc. v. Scientific Games Corp., No. 03-0920, 2003 U.S. Dist. LEXIS 15507 (S.D.N.Y. Sep. 9, 2003), as "the kind of lottery games that are available." Id. 2003 U.S. Dist. LEXIS 15507, at *8 n.2. Although Gtech argues that the district court did not analyze the term, and that it merely offered an explanation to provide context for the analysis of the construction for other terms, the district court certainly would not have based its claim constructions on an inappropriate meaning of another term. Nonetheless, this Court finds such interpretation persuasive not only because of the New York court's correct analysis, but also because of this Court's independent construction of the term based upon the intrinsic evidence.

2. "waiting state"

EMC asks the Court to construe this term as: "State of operation of the peripheral device wherein the peripheral device is ready to receive new microcode." HP proposes (in its opposition brief): "A state in which a peripheral device stands ready to receive new microcode." The parties concede that their constructions are the same. Transcript of April 5, 2004 Hearing, 82:3-4; 87:12-16.

The meaning of "waiting state" is unclear from the claim language. The claim indicates that a detector of transfer peripheral device command receives the command and new microcode while in a waiting state and that there is circuitry for entering the waiting state in response to the initiator and transfer command detectors. The specification states:

When an initiator command is detected, a waiting state is entered in which the peripheral device is held ready to receive new microcode. The resident processor also includes a detector for a transfer peripheral device command, which includes the new microcode, received while the peripheral device is in the waiting state.

801:2/36-42; see also 801:2/53 & 6/39-44. Thus, the "waiting state" is equivalent to the state of the peripheral device when it is ready to receive new microcode. Accordingly, the Court construes this term as "a state of the peripheral device in which it is ready to receive new microcode."

C. "warning light signals"

The plaintiff proposes "light signals that convey warning." Defendants propose "a light emission that conveys warning information." The main dispute involves Defendants' inclusion of "information." Both parties agree that "warning" is an adjective that modifies "light signal." The parties, however, make the same arguments as discussed above for the construction of "light signal" and disagree as to whether "light signal" includes messages and images.

For the same reasons as discussed in Section A, the Court concludes that "warning light signals" does not encompass all "information." Accordingly, the Court adopts the plaintiff's construction and "warning light signals" means "light signals that convey warning." The Court incorporates by reference its definition of "light signal."

F. "warning signal light"

The plaintiff proposes "device that generates a warning light signal for identifying a motorized vehicle as an emergency vehicle or as a utility vehicle." Defendants propose "a light that generates a light emission that conveys warning
The plaintiff argues that the specifications and claims do not describe the invention as anything other than a warning signal light for use on emergency vehicles or utility vehicles. In addition, the plaintiff cites to the inventor's deposition stating that purely informational devices on ordinary vehicles would not be a "warning light" because no one would recognize it as an emergency vehicle. The plaintiff further argues that Defendants' construction is too narrow because it covers only one embodiment which can display images, symbols, and characters, in addition to warning light signals, but does not cover the other embodiment where only warning light signals (e.g., flashing, oscillating, etc.) are used with no capability to display messages. The plaintiff also argues that Defendants' construction is too broad because it would cover informational message boards that produce no warning light signals.

Defendants argue that the specifications are broad and discuss warning signal lights other than that attached to a motor vehicle. See '269 patent, 3:19-24, 8:43-45; '865 patent, 7:65-8:2. Furthermore, Defendants argue that under the doctrine of claim differentiation, the claims must have a broad meaning. Claims 1-9 of the '865 patent do not mention a motorized vehicle, while other dependent claims require "an emergency vehicle" or "a utility vehicle." See '865 patent, claim 26, claim 27. Defendants also point out that the phrase "warning signal light" only appears in the preamble and states an intended use, and, therefore, should not limit the claim. Defendants disagree with the plaintiff's contention that one of the embodiments discusses only using warning light signals without the capability to display messages. See '269 patent, 4:37-48, '865 patent, 10:21-33, 10:47-55 (discussing display of images such as arrows).

In reply, the plaintiff argues that the prosecution history clearly limited the invention to warning signal lights on motorized vehicles because the patentee distinguished prior art on the basis that the prior art did not disclose light signals "for use with an emergency vehicle." '871 application, Dec. 20, 1999 Amendment, at 18.

The Court agrees with Defendants that the phrase is not limited to "identifying" the vehicle because this limitation is included in dependent claims. See Phillips, 415 F.3d at 1315 (stating that dependent claim limitations are presumed not to be present in the independent claim). Accordingly, "warning signal light" means "a light that generates warning signals."
involves an element of intent.

The dictionary definition for "waveguide" is:

a device which constrains or guides the propagation of electromagnetic waves along a path defined by the physical construction of the waveguide; includes ducts, a pair of parallel wires, and a coaxial cable.

McGraw Hill Dictionary of Scientific and Technical Terms, supra at 2155. Under this definition, Switchcraft observes that the entire jack can be a waveguide. Therefore, Switchcraft argues, the term, as used in the '378 patent, must have a more specific interpretation. Switchcraft proposes "waveguide" be construed as a "structure positioned to affect impedance matching along the signal transmission through a jack housing."

In support of its proposed construction, Switchcraft argues that if waveguide is interpreted merely as a structure that tunes impedance, any device within a coaxial switching jack that improves impedance matching, regardless of the degree, would constitute a waveguide. Switchcraft argues the prosecution history supports a narrower interpretation. The prosecution history shows that the application that eventually matured to the '378 patent was initially rejected because all pending claims were taught in U.S. Patent No. 5,885,096 ("the '096 patent") in combination with U.S. Patent No. 4,264,115 ("the '115 patent"). See Patent Application File History (Stephens Decl. [Docket No. 46] Ex. C) at 56-99. The examiner found that the '096 patent taught all recited limitations except the housing with a waveguide, which was an obvious variation and shown in the '115 patent. Id. at 51.

The applicant subsequently amended claims 1 and 16 and added other claims to distinguish the '378 patent. For instance, claim 1 was amended to recite "a waveguide projecting from one of said walls adjacent to said movable portion, said waveguide including a planar portion facing said leaf spring portion" (with added limitations in underline). Id. at 101. The applicant argued repeatedly he had improved upon the prior art device "through the addition of structure internal to the jack device which results in an impedance matching at greater frequencies than prior jack designs" and that "the focus of the present invention is the electrical performance (impedance) of the switching jack device so that impedance mismatches are avoided." Id. at 104; see also id. at 105. The applicant also sought to distinguish the waveguides recited in the '115 patent by claiming they served to shield against interference rather than for "impedance matching"as taught by the '378 patent. Id. at 105. Switchcraft argues the measures needed to distinguish waveguides in the '378 patent from prior art limited the scope of "waveguide."

Finally, Switchcraft notes the '378 patent teaches that the geometric shape of the waveguides is not critical. Instead, the specification teaches the waveguide is a structure placed in an empty area of the switch housing to achieve impedance matching. '378 patent at 9:20-27, 9:47-52. For these reasons, Switchcraft argues the term "waveguide" should reflect an intent to position the structure to affect impedance matching.

Conversely, ADC argues "waveguide" should not be construed to include an element of intent. Instead, ADC proposes "waveguide" should be interpreted to mean "structure for tuning impedance in an electrical device for better carrying an electrical signal." ADC argues there is no intent element to direct infringement and it is therefore irrelevant whether the structure was placed or positioned in the device for some other purpose. Under ADC's interpretation, whether or not a structure is a "waveguide" can be determined by testing its affect on the impedance of the device without regard to the subjective intent of the engineer.

The Court construes "waveguide" to be a "structure for tuning impedance in an electrical device for better carrying an electrical signal." In general, intent is not relevant to whether a product directly infringes a patent. See, e.g., Intel Corp. v. U.S. Int'l Trade Comm'n, 946 F.2d 821, 832 (Fed. Cir. 1991); Florida Prepaid Postsecondary Educ. Expense Bd. v. College Sav. Bank, 527 U.S. 627, 645, 144 L. Ed. 2d 575, 119 S. Ct. 2199 (1999). Therefore, whether a structure was placed in the device for some other purpose does not address whether it infringes an existing patent. See Vulcan Eng'g Co. v. Fata Aluminum, Inc., 278 F.3d 1366, 1375 (Fed. Cir. 2002); Northern Telecom, Inc. v. Datapoint Corp., 908 F.2d 931, 945 (Fed. Cir. 1990).

The Federal Circuit has acknowledged, however, that a claim can be written, by including a scienter requirement, in a manner that limits it. Koito Manuf. Co., Ltd. v. Turn-Key-Tech., LLC, 381 F.3d 1142, 1150 (Fed. Cir. 2004). In Koito, the Federal Circuit found a claim teaching "a method of injection molding a plastic product" carried a scienter requirement.
when it taught to inject "a quantity of first plastic into the first mold cavity so that the first plastic follows in the first-layer-defining-mold-cavity-section in a first predetermined general direction." Id. at 1145 (emphasis in original). The Federal Circuit affirmed the district court's interpretation that the claim's use of "predetermined" "required intent or foreknowledge in the fixing of plastic flow direction." Id. at 1150.

The terminology at issue in Koito is distinguishable from "waveguide" at issue in the instant case. First, Koito dealt with a method claim rather than the apparatus claim as in the case at bar. Second, and more importantly, the term "predetermined" inherently requires foreknowledge in a manner completely absent from "waveguide."

Switchcraft argues that, without an intent component, any element that tunes impedance is a "waveguide" and that ADC limited the scope of the term through the prosecution history. While it is true that claims should be interpreted in light of the prosecution history, the statements cited by Switchcraft are in keeping with the interpretation of waveguide as a "structure for tuning impedance in an electrical device for better carrying an electrical signal." Subsequent language in the claim and specifications, describes where these waveguides should be positioned to improve impedance matching. n1 Language defining this structural relationship, rather than an intent requirement, modifies and narrows "waveguide" by describing the position necessary to provide impedance tuning. As a result, "waveguide" should be construed as a "structure for tuning impedance in an electrical device for better carrying an electrical signal."

--- Footnotes ---

n1 For example, claim I recites: ". . . said housing including a waveguide projecting from one of said sidewalls adjacent to said moveable portion, said waveguide including a planar portion facing said leaf spring portion."

--- End Footnotes ---

4830

The parties disputed six terms used in the claims of the '843 patent. The Court has construed those terms as follows:

a) "Waveguiding structure" is used interchangeably with "waveguide" and is defined as: "A structure formed by a waveguiding film and a substrate and containing a diffraction grating";

b) "Waveguide film" means: "A film which, in combination with a sample having a lower index of refraction and a substrate can guide light along a path";

c) "Diffraction grating" means: "Any arrangement in the waveguiding structure that imposes a periodic variation of amplitude and/or phase on an incident wave";

d) "Wavelength" means: "A wavelength of light at which the optical sensor, including the waveguiding structure, waveguiding film, and diffraction grating, detects chemical, biochemical or biological substances in the sample";

e) "Effective index" means: "A number that relates the propagation velocity of light guided in a waveguide to the speed of light in a vacuum";

f) "Measuring the effective index and effective index change" means: "determining the effective index" and "determining the effective index change."

(D.I. 156).

The parties disputed six terms used in the claims of the '843 patent. The Court has construed those terms as follows:
a) "Waveguiding structure" is used interchangeably with "waveguide" and is defined as: "A structure formed by a waveguiding film and a substrate and containing a diffraction grating";

b) "Waveguide film" means: "A film which, in combination with a sample having a lower index of refraction and a substrate can guide light along a path";

c) "Diffraction grating" means: "Any arrangement in the waveguiding structure that imposes a periodic variation of amplitude and/or phase on an incident wave";

d) "Wavelength" means: "A wavelength of light at which the optical sensor, including the waveguiding structure, waveguiding film, and diffraction grating, detects chemical, biochemical or biological substances in the sample";

e) "Effective index" means: "A number that relates the propagation velocity of light guided in a waveguide to the speed of light in a vacuum";

f) "Measuring the effective index and effective index change" means: "determining the effective index" and "determining the effective index change."

(D.I. 156).

The Court construes the term as a “terminal at the end of a communication pathway having a transmitter and/or receiver for wavelength division multiplexing communications.” Ciena initially argued that the term does not need to be construed. Alternatively, Ciena proposes that if the term is construed it should be construed as “terminal that can send and/or receive wavelength division multiplexed (WDM) communications.” Nortel argues that the term should be construed as “an apparatus containing wavelength division multiplexed transmitters and receivers at an end of a wavelength division multiplexed optical communication path.” During the Markman Hearing Ciena proposed a construction that read, “a terminal at an end of a communication pathway that can send and/or receive [wavelength division multiplexing] communications.” Nortel agrees with the “a terminal at an end of a communication pathway” language of the proposed construction but further suggests that the “can send and/or receive language be changed to “having a transmitter or a receiver.” Nortel argues that the term is a structural element and should be construed in terms of structure and not capabilities.

Claim 5 of the ‘115 patent claims “An optical communication apparatus, comprising: a first wavelength division multiplexed terminal . . . .” The term is a structural element and should be construed in terms of structure. Accordingly, the Court agrees with Nortel and construes the term as “terminal at the end of a communication pathway having a transmitter and/or receiver for wavelength division multiplexing communications.”

For the following reasons, this court construes the claim term "wavelength division multiplexed (WDM) optical network environment" in claims 6, 14, 17, and 24 to mean:

An environment having a network for carrying information on a plurality of wavelengths, the plurality of wavelengths multiplexed together as an optical signal.
The specification explains that a WDM network is designed to carry a plurality of wavelengths multiplexed together as an optical signal. First, patent '772's specification states, "[t]he invention . . . pertains to upgrading an in-service wavelength division multiplexed (WDM) optical communication system." ('772 patent, col. 1:15-18.) The specification then goes on to explain:

A WDM system employs plural optical signal channels, each channel being assigned a particular channel wavelength. In a WDM system optical signal channels are generated, multiplexed to form an optical signal comprised of the individual optical signal channels, transmitted over a single waveguide, and demultiplexed such that each channel wavelength is individually routed to a designated receiver.

('772 patent, col. 1:29-34.)

Fujitsu's proposed construction again includes the phrase "highest relative order" as Fujitsu asserted in its proposed meanings of other disputed terms in patent '772. (Dkt. No. 90, Ex. C at 7.) As the court stated earlier, Fujitsu's proposed construction improperly imports a limitation from a preferred embodiment in the specification. See Phillips, 415 F.3d at 1323 (explaining that courts generally should not limit claims to the preferred embodiments in the specification); Astrazeneca AB, 384 F.3d at 1340. The specification only uses the term "highest relative order" once as the specification describes Figure 4 and states that "[t]he line interface is adapted for wavelength division multiplexed (WDM) optical communication signals of the highest relative order." ('772 patent, col. 4:48-50.) To incorporate the requirement that the optical signal be of the 'highest relative order' would limit the claim to a preferred embodiment and, therefore, the court rejects the incorporation of the limitation "highest relative order" into the construction of "optical line interface."

D. '252 Patent Claim 1 - "waveshape the voltage and current in order to efficiently ignite the fuel in the turbine engine"

The Court construed this language to mean that the invention must "produce a current waveform . . . which initially rises relatively slowly, followed by a transition to a fast rising current which quickly peaks and thereafter slowly dissipates." Lucas Aerospace, Ltd. v. Unison Industries, L.P., 890 F. Supp. 329, 1995 WL 362387 at *12. As with claim 1 of the '073 patent, Lucas argued to the Court that the phrase 'waveshape the voltage and current' meant to produce a waveform similar to that depicted in Figures 3b and 4 (Curve A) of the '252 patent. See id. at *9 Lucas now repeats the same arguments which it made with respect to claim 1 of the '073 patent. In essence, Lucas suggests that the Court's claim construction encompasses waveforms demonstrated in Figure 3a and Figure 4 (curves B and C) and that, therefore, the Court's claim construction is "too broad since it would cover prior art and invalidate the claim." D.I. 394 at 33.

Lucas's arguments fail for the same reason they failed with respect to the '073 patent. Figure 3b represents the generalized shape of a saturable core inductor's current waveform. Figure 4 (curve A) represents the preferred embodiment's waveshape in comparison to the preferred embodiment implemented with an air core inductor. Once again, Figure 4 (curve A) is representative of just one permutation of the waveforms that could be created by a network with varying electrical and physical characteristics. The fact that Figure 4 (curves B and C) also have an initially slow current rise does not indicate that the claim construction is over broad; it merely demonstrates that the waveform characteristics of the '073 invention implemented with an air core inductor cannot match the theoretical characteristics of an air core inductor demonstrated in Figure 3a. More importantly, the differences between the two sets of waveforms, particularly in Figure 3, help to define what is meant by the claim language describing the change in the rate of current rise. The differences in the two sets of illustrations, however, do not act as an invitation for alleged infringers to argue that their waveform looks more like one curve than the other curve, thereby ignoring the more important and defining aspect of the invention, the components required in the language of the claim that create the waveform. The Court thus concludes, once again, that Lucas has demonstrated no error in the Court's construction of the '252 Patent claim 1.
Given the Court's previous conclusion that "Web" refers to World Wide Web, it follows that "web browser" refers to a software application that can be used to locate and display Web pages in human-readable form. 2 See, e.g., Def. Ex. 13, Microsoft Computer Dictionary (3d ed. 1997) (defining "Web browser" as a "client application that enables a user to view HTML documents on the World Wide Web"); Webopedia, http://www.webopedia.com/TERM/b/browser.html (defining "browser" as "a software application used to locate and display Web pages."). 3

The Court finds no significance in the fact that "Web," which is elsewhere capitalized in the claim language (thereby more clearly reflecting its use as short-hand for the World Wide Web), is here lower-cased: for its function still relates, on the face of the claims, to locating and displaying pages that the claim language refers to as emanating from "Web sites." 3 Although these definitions were published subsequent to the prosecution of the patents, every indication suggests that these definitions were consistent with that understood by one of ordinary skill in the art in 1996, when the application for the '181 patent was filed.

B. Web Browser (Claims 1, 8, 14, 20, 26, 32, 38, 43, 48)

HP argues that the ordinary meaning of web browser is "software that can be used to retrieve information over a network, including, but not limited to, the Internet." Intergraph contends that the term should be defined as "a program within a client computer that utilizes Hypertext Transfer Protocol ("HTTP") to request services from a remote server connected via the Internet."

HP asserts that its proposed construction is consistent with the definitions found in technical dictionaries available at the time the '028 Patent was issued. See Ex. 19, Peter M B Walker, Chambers Dictionary of Science and Technology at 149 (1999) (defining "browser" as "Software used to retrieve information from the Internet . . . or other network"); see also Ex. 20, Dictionary of Computing at 54 (4th ed. 1996) ("The term browser is used either to refer to a person who is browsing, or to the utility program that allows the user to locate and retrieve information from networked information services."). HP contends that the term "web browser" and "browser" are used interchangeably throughout the '028 Patent, and thus the ordinary meaning of "browser" should control the Court's construction.

Intergraph supports its proposed construction by citing language from the specification. Specifically, the specification provides that "the World Wide Web is a collection of servers on the Internet that utilize the Hypertext Transfer Protocol (HTTP)." '028 Patent, col. 1:23-24. The specification further states that "each local computer system may access the remote web sites with web browser software . . . " '028 Patent, col. 3:56-57. Based on this language, Intergraph concludes that the term "web browser" must imply use of the Internet.

The parties dispute over the proper construction of "web browser" stems from the central disagreement between the parties with regards to the '028 patent - does the '028 patent have applicability to other networks besides the Internet? The Court's analysis must begin with the proposition that disputed terms in a claim "are generally given their ordinary and customary meaning." Vitronics, 90 F.3d at 1582. The Court agrees with HP, based on the provided dictionary definitions, that the term "browser" can be used to retrieve information over a network other than the Internet. The Court also agrees with HP's argument that the patent uses the terms "browser" and "web browser" interchangeably. Compare '028 Patent, col. 5:23 with col. 5:34-35 (referring to "browser 200" and "web browser 200," respectively). During oral argument, Intergraph argued that the patent's file history conclusively establishes that the invention was limited to internet applications. However, after reviewing the file history, the Court cannot agree with Intergraph that the patentee intended to limit the claim scope in this manner. See Inverness Med. Switz. GmbH v. Princeton Biomeditech Corp., 309 F.3d 1365, 1372 (Fed. Cir. 2002) (statements made during prosecution history were not a clear and unambiguous disclaimer of a claim scope). Finally, Intergraph argues that upon examining the diagrams of the preferred embodiments, it appears that whenever a client computer is connecting to a remote server, the Internet is being used. However, the Court should not "limit [] the claimed
invention to preferred embodiments or specific examples in the specification.” Ekchian, 104 F.3d at 1303. Accordingly, the Court adopts HP's proposed construction that defines "web browser" as software that can be used to retrieve information over a network, including, but not limited to, the Internet.

4837

web page

Claims 1 and 16 contain the term "web page." Accolade contends "web page" should be given its plain and commonly understood meaning and does not need construction. Alternatively, Accolade argues that the term means "a page which when opened in a web browser on a computer can display text, images or links to the addresses of other pages or locations on a network, such as the internet or an intranet." Citrix contends that "web page" means "a software created 'object' including an interface written in HTML which permits text and images to be presented via a web browser to a computer system that is coupled to or part of the Internet."

The parties dispute whether a "web page" is "a software created object including an interface written in HTML." The patentee acted as his own lexicographer and defined "web page" in the specification. The specification states, "A web page is a software constructed 'object' including an interface written in HTML which permits text and images to be presented to a computer system that is coupled to or part of the Internet." Col. 6:6-9. Thus the specification defines "web page," and thereby resolves the parties' disagreement.

However, the Court does not construe "web page." The definition for "web page" provided in the specification is consistent with the web page that is commonly known to a layperson. As such, lay jurors would be familiar with "web page," and a construction is not necessary. Furthermore, using the definition for "web page" provided in the specification would only lead to confusion about an already well understood term. Thus, the Court does not construe web page.

4838

1. “Web Page”
“Web page” is utilized in asserted claims 1, 3, 6, 7, 9, and 11 of the ‘554 Patent and 1, 4, 7, and 8 of the ‘335 Patent. The Plaintiff asserts that “Web page” does not need construction. Alternatively, if construed, the Plaintiff contends that the proper construction of the term is “content displayable through a Web browser.” The Defendants assert that the terms should be construed as “an HTML document accessible through a URL.” The Court first notes that the Plaintiff’s original briefing expressed concern that the Defendants’ construction implies that dynamically generated Web pages are not included within the term “Web page.” The Court finds this concern somewhat unfounded, and it is noted that the Defendants clearly referred to “Web page” in their briefing and oral argument as encompassing both static and dynamic Web pages.

The other assertions by the parties primarily revolve around two issues, the inclusion of terms “HTML” and “URL” in the construction. The Plaintiff argues that the term “content” is utilized in the specification at least twice to describe what is displayed on a Web page. Col. 1:47-51; Col. 7:23-26. Further, the Plaintiff points out that in the Defendants’ own briefing Web pages are referred to as containing content. Defendants’ Brief at 11-12. The Plaintiff further asserts that the Defendants are also attempting to read in limitations from the specification and that such a construction would exclude documents formatted in other formats such as SGML, XHTML, XML, and JPG.

The Defendants state that HTML is a software language and argue that as described within the specification HTML documents are what are sent back as Web pages. Col. 1:18-22; Figures 3 and 5. The Defendants also cite a Microsoft Press Computer Dictionary definition which states that “A Web page consists of an HTML file…” Defendants’ Brief at 9. The Defendants further assert that “content” in the specification refers to information included in a Web page and that such content itself does not form a Web page.
The Court notes that the specification does appear to consistently refer to the HTML language and does not mention other software languages. However, the Defendant does not identify persuasive support within the specification that the invention must be limited to only one type of software language. Moreover, Defendants have not persuaded the Court that in light of the specification one skilled in the art would assume a Web page as referred to in the patents could only be generated with the HTML language. Further, upon review of the whole specification and claims, with respect to Web pages the described concepts are not related to the intricacies of what particular programming languages are used to display a Web page but rather merely the higher level differentiation of static pre-existing Web pages verse dynamically generated Web pages. In these circumstances, the Court finds it improper to incorporate the limitation of HTML within the more general term Web page that is utilized in the claims themselves.

With regard to the URL concept, the Plaintiff asserts that the Defendants’ definition adds additional complexity to the claim construction as the meaning and scope of “accessible through a URL” could itself require construction. Further, citing the extrinsic evidence that the Defendants themselves put before the Court, the Plaintiff argues that it is known that when a Web browser sends a request what is actually sent does not match what is commonly known as a full URL. In oral argument the Plaintiff asserted that the Defendants’ extrinsic evidence shows a URL as “http://"/" host [":" port ] [ abs_path] thus requiring four components: a protocol (HTTP), a host, a port and an absolute path. Further the Plaintiffs argue that this same extrinsic evidence shows that a request most commonly is structured for example “GET / pub / WWW / TheProject.html HTTP /1.0” The Plaintiff asserts that this also emphasizes the concern over the ambiguity of the meaning of “accessible through a URL.”

The Defendants turn to the specification, which includes the statement “[a] URL is a Web address that identifies the Web page and its location on the Web.” Col. 1:30-33. The Defendants also note the language that states “[w]hen the appropriate Web site receives the URL, the Web page corresponding to the requested URL is located…” Col. 1:33-34. Further, the Defendants point to other examples in the specification, such as Figure 3, which refer to the Web browser sending the URL request. At oral argument, the Defendants also stated that what is sent by a Web browser does include the URL information.

The arguments of the parties highlight some of the concerns the Court has with the inclusion of the term URL. A definition of the meaning of URL within the usage of the patent would further be necessitated as URL is alternatively referred to as “what is examined by the Web browser,” a URL request is received by the Web server, and a URL request can be sent to a page server. Col. 4:13-14; Col. 8:28-32; Col. 8:38-39. The specification does not make clear what is the particular structure and content that is meant by the use of the term “URL” at each of these stages of the process. Again, as with the HTML term, this is not surprising as the specification and claims as a whole do not focus on the particular type of request that is made or the particular structure/content of a request as it processed through the system beyond the static and dynamic distinction discussed above. Further, to add the term “accessible” to the construction would necessitate further claim construction as to what “accessible” means. As described within the specification, a Web page is a mechanism through which static and dynamic content may be displayed. The particular addressing mechanism at each step of the processing of a dynamic Web page is not noted in the specification to be a requirement or of particular importance to the claimed invention. An inclusion of the term URL would improperly incorporate limitations from the specification for the term Web page which has a meaning that is adequately described within the full context of the specification.2

Thus, the Court construes “Web page” to mean “Web content displayable through a Web browser.”

4839

The Court, having reviewed the relevant briefing, finds the parties’ objections are without merit. In their briefing, the parties address, among other things, the word “mechanism” as used in the Magistrate Judge’s discussion of the construction of the claim “Web page.” See Report and Recommendation at pgs. 8-9 (“As described within the
specification, a Web page is a mechanism through which static and dynamic content may be displayed."")(emphasis added). A Web page may include static or dynamic content. However, the Magistrate Judge’s construction of “Web page” as “Web content displayable through a Web browser” does not include the word “mechanism.” The Court adopts the construction of “web page” as proposed by the Magistrate Judge, and with the exception of the use of the word “mechanism,” the Court also adopts the reasoning of the Magistrate Judge with respect to the construction of “Web page.”

4. “Web Server”

“Web Server” is utilized in asserted claims 1 and 11 of the ‘554 Patent and 1-2 of the ‘335 Patent. The Plaintiff asserts that the proper construction of “Web server” is “a processing system capable of processing an HTTP request and producing a response to such a request.” The Defendants assert that the terms should be construed as “a machine running a Web server executable capable of storing, locating, and returning Web pages in response to Web client requests.” In the claim construction Oral Argument, the Plaintiff stated that it would agree to language including “software” in place of the Plaintiff’s originally proposed “system” language similar to the Plaintiff’s agreement with regard to “page server.”

The focus point of the dispute between the parties is whether the term “Web server” requires a machine or whether the term may merely represent software or a combination of the two. Both the Plaintiff and Defendants cite conflicting extrinsic evidence to support their positions in the form of dictionaries, industry guides, and protocols. Some of the Plaintiff’s extrinsic evidence includes citations to extrinsic evidence first brought before the Court by the Defendants. The conflicting extrinsic evidence presented by the parties fits the rationale presented in Phillips regarding the cautions that should be considered relating to such evidence.

Looking to the specification, the Plaintiff points to passages in which “Web server” is not used to describe a machine. In particular, the Plaintiff points to the statement in the specification that:

The preferred embodiment of the present invention is implemented as a software module, which may be executed on a computer system such as computer system 100 in a conventional manner. Col. 3:55-58.

The Plaintiff also highlights the following passage:

This embodiment is appropriate for Web servers such as NetsiteTM from Netscape, that support such extensions. A number of public domain Web servers, such as NCSATM from the National Center for Supercomputing Applications at the University of Illinois, Urbana-Champaign, however, do not provide support for this type of extension. Thus, in an alternate embodiment, Interceptor 400 is an independent module, connected via an ‘intermediate program’ to Web server 201. This intermediate program can be a simple CGI application program that connects Interceptor 400 to Web server 201. Alternate intermediate programs the perform the same functionality can also be implemented. Col. 4:63-Col. 5:7.

The Defendants counter that the specification uses the terms “Web server,” “Web server executable” and “Web server machine” and that the proper interpretation is that the machine is referred to as a Web server machine, the software is referred to as the “Web server executable” and the combination is referred to as a “Web server.” To support this argument, the Defendants cite to various passages and figures in the specification. Figures 2-4; Col. 4:39-41; Col. 4:59-62; Col. 5:7-36.

While the Defendants may be correct that “Web server” may be utilized at times as indicating a combination of a machine and software, the specification clearly does not require the term “Web server” to include a machine. The passages of the specification noted above by the Plaintiff make clear that the Web server is contemplated to be at least in one embodiment, software. It is also noted that in general in other passages of the specification the term “Web server machine” is more often used when describing the machine component and “Web server” to describe merely the software
component. Thus, for example, it is noted that the “Web servers process each of these requests on a single machine, namely the Web server machine,” “Interceptor 400 resides on the Web server machine as an extension to Web server 201,” and the Dispatcher “can, however, also reside on the same machine as the Web server.” Col. 4:39-42; Col. 4:61-62; Col. 5:20-21. Passages such as these imply a utilization of the term “Web server” as the software module as opposed to the combination of both the machine and software. Thus, some usage of “Web server” implies just software and at other times implies a combination of software and hardware.

The Court construes “Web server” to be “software, or a machine having software, that receives Web page requests and returns Web pages in response to the requests.”

The Court is of the opinion that the findings and conclusions of the Magistrate Judge are correct. Therefore, the Court hereby adopts the Report of the United States Magistrate Judge as the findings and conclusions of this Court.

The parties dispute the meaning of "web server," as used in claim 33 of the '372 patent. NICE contends that the plain meaning of the contested term and the specification support its construction, citing col. 12:18-21 and 12:44-46. Witness contends that NICE's construction reads the word "Web" out of the term, that the ordinary meaning of "Web" indicates "World Wide Web," and that the prosecution history confirms Witness's construction.

The Court construes "web server" to mean "A component that provides access to information accessible from a computer connected to the Internet or an intranet." The specification provides:

[T]he Web server 280 acts as an intermediary between one or more recorders 252 in the recorder stage of the logger, and the users accessing the stored information via, for example, the Internet. . . . It will be appreciated that similar distribution scheme can be provided as part of a corporate intranet.

(col. 12:18-21, 12:44-46.) Further, the prosecution history Witness references supports construing "web server" to include either Internet or intranet. "The prior art of record simply does not disclose, teach or even suggest a method for accessing information in a logger, where users communicate requests for stored data over a 'Web' in the sense of a communications network like the Internet." ('372 Pros. Hist. Amend., 13, dated Sept. 24, 2001 (emphasis added).) The term "like" in the prosecution history accords with the usage of both Internet and intranet in the specification and supports the Court's construction.

The Court construes "web server" as "A web server separated from said image server": "A web server that is a separate computer from the image server." During prosecution, the examiner of the '904 patent rejected claims 9-10 as anticipated by Brown in view of its disclosure of a proxy server with "functionality to construct [a] web page which contains HTML code or embed commands to the browser," that functions "as image server and web server." (D.I. 386, ex. 2 at JA165) In response, the applicants asserted
VirnetX argues that the specifications refers to "web site" as "host," which suggests that "web site" carries the broader protection from what he disclosed to the public as "web site." Thus, the patentee cannot gain broader claim face requires a site on the World Wide Web. The patentee chose to use "web site" in the claims instead of using a more encompassing term like "host," "target computer," or "Internet resource." This would offend the meaning of the claim term itself. "Web site" on its face refers to a "web" Internet resource, which is a web page on the World Wide Web. The specification is consistent with construing "web site" as a web page on the World Wide Web. Examples of web sites in the specification are "Yahoo.com" and "Target.com." Col. 37:25, 45. "Yahoo.com" and "Target.com" are well-known web pages on the World Wide Web. Also, the specification states that a "web browser" can be used to access a "web site." Col. 39:44, 50-51, 55; Col. 40:1, 38. It is well-known that a "web browser" is used to navigate "web pages" on the World Wide Web. Thus, "web site" may be construed as its own claim term.

The Court adopts Microsoft's construction and construes "web site" as "one or more related web pages at a location on the World Wide Web." The parties dispute whether "web site" should be given a construction separate from "secure web site" and whether "web site" is limited to web pages on the World Wide Web.

VirnetX argues that "web site" should not be construed separately from "secure web site" because the '135 patent claims never state "web site" without the preceding word "secure." However, "secure" is separable from "web site" as a modifier of "web site." The claims show that "secure" can be replaced by other modifiers to "web site." Claims 1 and 10 of the '135 patent refer to "web site" preceded by "non-secure" and "secure target." Col. 47:28, 30; Col. 48:10, 14. This demonstrates that "web site" can be separated from its modifier and thus is its own term separate from "secure." Thus, "web site" may be construed as its own claim term.

VirnetX proposes construing "web site" as "a computer associated with a domain name." This construction would broaden the meaning of "web site" beyond how this term is used in the patent. VirnetX's construction does not include the limitations "web page" and "World Wide Web." Without these limitations, the claims would include a right to exclude over computers with network addresses that do not host web pages. This would offend the meaning of the claim term itself. "Web site" on its face requires a site on the World Wide Web. The patentee chose to use "web site" in the claims instead of using a more encompassing term like "host," "target computer," or "Internet resource." Thus, the patentee cannot gain broader claim protection from what he disclosed to the public as "web site."

VirnetX contends that the specification demonstrates a broader meaning of "web site" than what Microsoft proposes. VirnetX argues that the specifications refers to "web site" as "host," which suggests that "web site" carries the broader
meaning of "host." However, the claims and not the specification define the scope of the right to exclude. See Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998) ("the claims define the scope of the right to exclude; the claim construction inquiry, therefore, begins and ends in all cases with the actual words of the claim") (citation omitted). The patentee chose to use "web site" in the claims and thus the claims are limited by that term. Accordingly, the Court construes "web site" as "one or more related web pages at a location on the World Wide Web.

3. "Web site" ( '181 patent, claim 1; '664 patent, claims 1 and 3; '768 patent, claims 1 and 19)

In everyday parlance, "Web" is a short-hand for the World Wide Web, which in turn is a specified subset of the Internet universe. Accordingly, a "Web site" is a location on the World Wide Web. Neither plaintiffs nor their expert dispute that this is the ordinary definition, see transcript ("tr."), Oct. 5, 2001, at 91, but they nonetheless contend that "Web" is being used in the patents in a broader sense to mean the equivalent of the entire Internet. Aside from the fact that the claims themselves do not expressly define "Web" in this unusual way, there is nothing in the function or structure of the claims that compels this unusual definition. By contrast, there is a "heavy presumption in favor of the ordinary meaning of claim language as understood by one of ordinary skill in the art." Bell Atlantic Network Services, Inc. v. Covad Communications Group, 262 F.3d 1258, 1268 (Fed. Cir. 2001). Indeed, to adopt an unusual definition of the familiar term "Web" where the language of the patent did not expressly so define or otherwise compel such usage would undercut the public notice function of a patent. See, e.g. Dayco Products Inc. v. Total Containment, Inc., 258 F.3d 1317, 1324 (Fed. Cir. 2001).

A. "Website"

The term "website" appears in the '945 patent in all three of the asserted claims--claims 3, 4, and 5. 47 ABC asserts that "website" means "one or more servers operating together, that can be provided by a service provider, that can be located on the Internet by use of a Uniform Resource Locator ("URL"), and which can perform services including hosting web pages, validating logon commands and sending, receiving, and processing instructions." 48 WebEx contends that "website" means "a collection of related Web pages maintained by a Web server and retrievable by a Web browser using hypertext transfer protocol ("HTTP") and Hypertext Markup Language ("HTML") interpretation." 49 WebEx further asserts that the claims of the '945 patent must be interpreted to require that the same "website" both receive valid logon commands and receive and send the data that control the remote computer unit. 50

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

47 The term "website" literally appears only in claims 1, 2, and 5 of the originally issued version of the '945 patent. Claims 3, 4, and 5, however, are written in dependent form. Claim 3 depends on claim 2, which itself depends on claim 1. Claims 4 and 5 depend on claim 1. As explained above, ABC canceled claims 1 and 2 during reexamination, but claims 3, 4, and 5 survived reexamination without amendment. Therefore, the text of claims 1 and 2, including the term "website," remains part of the '945 patent because it is incorporated by dependent claims 3, 4, and 5.

1. Web Pages or Servers
The first question raised by the parties' proposed constructions is whether a website is a collection of web pages hosted or maintained by a server or servers, or whether a website consists of the server or servers themselves. In support of its position that the term website refers to servers, ABC points out that the claim language (intrinsic evidence) requires that the website claimed in the '945 patent be able to carry out a number of functions: (1) "allowing and facilitating communication between a remote computer unit and an interface unit via an internet," 51 (2) "receiving . . . a valid logon command," 52 (3) "associat[ing] the valid logon command with the remote computer unit," 53 (4) "receiving . . . data signal instructions from the interface unit," 54 (5) "sending the data signal instructions . . . to the remote computer unit," 55 and (6) "downloading a program . . . to the remote computer unit." 56 ABC argues and submits an affidavit from a purported person of skill in the art stating that web pages, alone, are unable to carry out these functions. Therefore, the term "website" must be understood to refer to a server or collection of servers, which could conduct these functions. 57

57 See ABC's Brief, Docket Entry No. 154, at 12; Affidavit of Ivan Zatkovich, PP 7-10 (May 28, 2009) (included in ABC's Response, Docket Entry No. 165, at Exhibit A).

--- End Footnotes ---

Because ABC's argument is based on the claim language itself, the court finds it very persuasive. See Phillips, 415 F.3d at 1312 (explaining that the claim language itself is "of primary importance" in the claim construction process (quoting Merrill, 94 U.S. at 570)). Moreover, WebEx does not make any counter-arguments based on the claim language itself in support of its position. Nor does it attempt to controvert ABC's assertion that web pages alone cannot perform the functions attributed by the claim language to the website. Instead, WebEx argues only that the ordinary and customary meaning of the term in 1998 encompassed only web pages.

WebEx is unable to muster any persuasive intrinsic evidence to support its position, relying only on prosecution history references. 58 See Phillips, 415 F.3d at 1317 (explaining that having a patent's prosecution history "often lacks clarity . . . and thus is less useful for claim construction purposes" than other forms of intrinsic evidence). WebEx first directs the court to two patents cited as prior art during the prosecution of the '945 patent. The first prior art patent states: "In the preferred embodiment, a web site or 'home-page' is constructed on a secure HTTP . . . server . . ." 59 The second patent states: "A 'web site' on a web server 20 contains one or more web pages where a 'base' or 'home' page is the first or entry page into a desired web site." 60 These references indeed equate a website with a web page, not a server. These unrelated patents, however, do not give the court the same insight into how the '945 patent inventor understood the term website as the text of the '945 patent itself does.

--- Footnotes ---

58 The court acknowledges that WebEx had very little intrinsic evidence to work with. The original application for the '945 patent did not include any claims reciting the term "website." See Original Patent Application for '945 Patent, at 31, 36 (Sept. 30, 1999) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6A). Moreover, the term "website" does not appear anywhere in the specification of the '945 patent. See '945 patent. The originally proposed claim language and the specification speak only in terms of a "computer service control unit" facilitating the connection between the local and remote elements. ABC did not propose claim language including the term website until July of 2004, almost five years after.
the application for the '945 patent was filed and over six years after the patent's effective filing date. See Response to Office Action Dated February 4, 2004, at 13 (July 13, 2004) (proposing a new claim, numbered 22, that would eventually become claim 1). Moreover, when ABC finally proposed the claim language including the term "website," ABC did not attempt to define the term or explain how the utilization of a website was supported by the patent specification. See id. at 25-28 (discussing the new proposed claims). In light of this history, WebEx suggests that the asserted claims of the '945 patent are invalid because the website limitation is not supported by the written description, as required by 35 U.S.C. § 112, ¶ 1.

WebEx further states that it intends to file a motion for summary judgment on this issue at some point in the future. WebEx's Brief, Docket Entry No. 156, at 17. Because the issue is not yet ripe for review, the court does not now decide whether the specification supports the website limitation found in the asserted claims.

59 United States Patent No. 6,138,150 col.3 ll.4-6 (filed Sept. 3, 1997) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 14). This patent was cited during the prosecution of the '945 patent in an Information Disclosure Statement submitted to the Examiner by ABC. See Information Disclosure Statement by Applicant (Apr. 20, 2005) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6E).

60 United States Patent No. 7,007,070 col.8 ll.65-67 (filed Feb. 28, 1997) (included in WebEx's Response, Docket Entry No. 166, at Exhibit 15). This patent was cited during the ex parte reexamination of the '945 patent in a Response to Office Action. See Response to Office Action in Ex Parte Reexamination, at 8-10, Ex Parte Reexamination of U.S. Patent No. 6,999,945, Control No. 90/008,122 (Feb. 19, 2008) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6f).

WebEx also points to statements made by the USPTO Examiner who conducted the reexamination of the '945 patent. In the Final Office Action for the '945 patent reexamination, the Examiner explained his reasons for concluding that claims 1 and 2 of the '945 patent were invalid as anticipated by a particular prior art reference. 61 Quoting a document describing the prior art technology, the Examiner explained that the prior art enabled a user to "control another computer o[r] transfer files over the Internet by initiating [a] connection from any Web browser via HTML hotlinks,' which inherently utilizes a website." 62 The Examiner also stated that the prior art reference "discloses the use of hot-links in a web browser," and concluded that

[a] page in the web browser utilizing hot-links described in the [prior art reference] would fall under the rubric of what one of ordinary skill would have considered a 'website,' a broad reasonable interpretation consistent with the Patent specification . . . given the lack of description of a 'website' in the Patent's specification. 63

ABC submitted a response to this office action in which it stated that it

agrees with the Examiner's statements regarding the proper interpretation of the term "website" and agrees with the Examiner's conclusion that such interpretation is consistent with the specification. Particularly, the Patent Owner agrees with the Examiner's statement that '[]any system that utilizes a website to connect the two computer systems reads on the instant limitations even if the actual controlling data is sent via another route.' . . . The Patent Owner also agrees with the Examiner's statement that this '[]broad interpretation of "website" is consistent with the specification and the requirement that the Examiner give each claim term its broadest reasonable construction consistent with the specification.' 64

62 Id. at 7 (quoting a document referred to by the Examiner as "Symantec Ships").

63 Id. at 10.

64 Response to Office Action in Ex Parte Reexamination, at 5, Ex Parte Reexamination of U.S. Patent No. 6,999,945, Control No. 90/008,122 (Nov. 26, 2008) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6H).
WebEx argues that these documents show that both the Examiner and ABC were in agreement that a website is a web page retrievable by or viewable in a web browser. The court is not persuaded by WebEx's argument. Although the Examiner's statements could be interpreted to indicate that he understood the term website to encompass a web page or pages, they do not foreclose the possibility that the Examiner considered the term to refer to a server or servers hosting a web page or pages. It is not clear whether the Examiner thought the page in a web browser was itself the website or whether the server or servers that provided the functionality of the hot-links on the page constituted the website. Moreover, the Examiner made clear that he was interpreting the term website very broadly. Thus, it is not at all clear that the Examiner understood the term website to exclude servers that host or are otherwise associated with web pages.

As for ABC's statements expressing its agreement with the Examiner's interpretation, the court understands these statements only to express agreement that the term "website" should be interpreted as broadly as possible consistent with the specification. More importantly, the court does not conclude that ABC disclaimed servers as within the scope of the term website. In conclusion, the court finds that the intrinsic evidence more strongly supports ABC's position that a website is one or more servers, as opposed to merely one or more web pages hosted on a server.

Turning to the extrinsic evidence, WebEx cites three dictionary definitions dating from 1999 and 2000. Two of the definitions are from general purpose dictionaries, which define the term website as "a set of interconnected webpages, usually including a homepage, generally located on the same server," 65 and "[a] group of related Web pages," 66 respectively. These definitions are consistent with WebEx's position, but because the Federal Circuit has warned courts not to rely on "non-scientific dictionaries for defining technical words," AFG Indus., Inc. v. Cardinal IG Co., Inc., 239 F.3d 1239, 1247-48 (Fed. Cir. 2001), the court does not find them persuasive.

--- Footnotes ---

--- End Footnotes ---

WebEx also cites a technical dictionary that defines a website as "a group of related HTML documents and associated files, scripts, and databases that is served up by an HTTP server on the World Wide Web. . . . Most Web sites have a home page as their starting point, which frequently functions as a table of contents for the site." 67 Although this definition suggests that a person of skill in the art may have understood a website to consist of more than just web pages, encompassing "scripts" and "databases" as well, the definition clearly does not include servers within the scope of the term. Instead, the definition characterizes a server as something separate that "serve[s] up" the website. Therefore, this definition tends to support WebEx's position.

--- Footnotes ---

--- End Footnotes ---

ABC, however, cites a treatise published in 1997 that defines the term "web site" as a "server that serves the WWW [World Wide Web]." 68 Additionally, ABC cites the deposition testimony of Srinath Anantharaman, a former WebEx engineer who was the named inventor for a patent application that WebEx filed for its allegedly infringing products. During Mr. Anantharaman's deposition he was asked to define HTTP. That question led to the following exchange:

A. That's typically the protocol that's used by web sites to communicate with web browsers.

Q. So the central computer system would be implemented as a web site under the invention?
MR. PANKRATZ: Objection. Mischaracterizes his testimony.

THE WITNESS: Don't know what you mean by web site, but yes, there is a web site that you go to and behind that, is, you know, other servers which are maybe not typically considered part of the web site.

MR. POTTS: Well, what is a web site?

A. It's a very broad term. So a web site, most people would be a machine or a set of machines which host a web server which basically gives you web pages as you ask for it. So that's typically what you would think of as a web site.

Q. That's what the uninitiated would think of as a web site?

A. That's what most people would think of as a web site.

Q. People who create web sites, though, would understand that a web site also includes the other servers, the application servers, the database servers, the communication servers, all of which provide the information through the web server, which can then be accessed over the internet, correct?

A. Certainly. And how a web site is implemented is very wide and different. 69

The treatise and deposition testimony cited by ABC reflects that one of ordinary skill in the art would understand a website to consist of servers, not merely web pages.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

- - - - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

The extrinsic evidence is mixed. It suggests that a person of skill in the art in 1998 could have understood the term website to refer either to a web page or collection of web pages, or to the servers that host web pages. As discussed above, however, the intrinsic evidence in the record would inform one of skill in the art that the inventor of the '945 patent intended the term to refer to a server or servers, and not merely web pages. The court therefore construes website to refer to one or more servers.

2. Web Servers, One or More Servers

The parties further dispute whether the term website, to the extent it refers to a server or servers, refers only to a single web server, or whether it refers to web server(s) and any other server(s) required to carry out all of the services provided by the website. 70 WebEx's proposed definition limits the website to a single web server. 71 ABC, on other hand, argues and presents evidence indicating that many websites, even as early as 1998, provided services beyond simply hosting static web pages and, therefore, required more than just a web server to operate. 72 Therefore, ABC suggests that one of ordinary skill in the art would have understood the term website to encompass more than just a web server. ABC also argues that the '945 patent claims explicitly require that the "website" be able to conduct a number of different functions, which include, inter alia, receiving and checking logon commands, receiving and sending data signal instructions, and downloading a program. 73 Therefore, according to ABC the server or servers that make up the claimed website must be able to carry out all of these functions and, thus, cannot be limited only to a single web server.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

70 From the totality of the briefing it appears that the parties agree that a "web server" is a server that serves web pages.
The court finds ABC's arguments persuasive. The claimed website performs multiple functions besides hosting or serving web pages. Therefore, limiting the server or servers that make up the website only to a single web server, i.e., a server that merely serves web pages, would go against the plain language of the claim. See Phillips, 415 F.3d at 1312 (explaining that the claim language itself is "of primary importance" in the claim construction process (quoting Merrill, 94 U.S. at 570)). Similarly, because the website must perform multiple functions, limiting the number of servers to only one would seem inconsistent with the claim language. Moreover, WebEx's own corporate representative who gave deposition testimony on behalf of the corporation admitted that while many simple websites could operate with only a single web server, at least some websites -- including some commercial websites that have been in operation since around the effective filing date of the '945 patent -- require multiple and different types of servers to operate. 74

WebEx does not deny that, generally speaking, websites may consist of or utilize more than one server. WebEx contends, however, that ABC disclaimed the concept of multiple servers during the reexamination of the '945 patent to overcome a rejection based on certain prior art references. 75 See Computer Docking Station Corp. v. Dell, Inc., 519 F.3d 1366, 1374 (explaining that "a patentee may limit the meaning of a claim term by making a clear and unmistakable disavowal of scope during prosecution" (quoting Purdue Pharma L.P. v. Endo Pharms., Inc., 438 F.3d 1123, 1136 (Fed. Cir. 2006))).

During the reexamination of the '945 patent, the Examiner initially rejected claims 1-4 of the '945 patent as obvious in light of the combination of two prior art references, referred to as "Konrad" and "Broadway." 76 In the Office Action stating the rejection of claims 1-4, the Examiner stated that an element of the Konrad reference known as the "starter server," like the website in the claimed invention, performed the functions of receiving a valid logon command and associating the valid logon command with a remote computer unit. 77 ABC did not dispute this statement, but argued that Konrad's "starter server" could not read onto the claimed website because it did not also perform the functions of receiving data signal instructions from the interface unit and sending the data signal instructions onto the remote computer unit, as required by claim 1. As ABC explained, "the starter serv[er] . . . sends commands and software to the remote hosts allowing the remote hosts to connect directly to the local hosts over the network. The connection over the network allows the local host to operate the remote host." 78 In other words, ABC argued that Konrad's starter server merely initiated the connection between a local element and a remote element. Once the local and remote elements were connected, the starter server did not continue to manage and facilitate the connection by receiving and sending data signal instructions like the claimed website in the '945 patent. Once connected, the local element and the remote element interfaced directly with each other. According to ABC, there was no intermediate element comparable to the website in the '945 patent.
WebEx argues that the "starter server" in Konrad received the logon commands and initiated the connection between the remote and local elements, and then the "network" took over to facilitate the connection. Therefore, WebEx contends that the starter server and the network referenced in Konrad are essentially two "servers," which together could make up a "website" if described in the terminology of the '945 patent. Furthermore, according to WebEx, because ABC differentiated its invention from Konrad on the basis that Konrad's starter server did not both initiate and then continue to facilitate the connection between the remote and local elements, ABC limited its claimed website to being composed of only a single server.

WebEx's argument is not persuasive. Nothing suggests that the "network" described in Konrad is at all comparable to a "server" in ABC's definition of website. The available evidence instead suggests that the "network" in Konrad did nothing more than passively conduct data signals from the local to the remote element. In fact, ABC described the network as a mere conduit for a direct connection between the local and remote element. The '945 patent, on the other hand, requires the claimed website, which is made up of one or more servers, to actively manage and facilitate the connection between the remote and local elements.

The court concludes that ABC differentiated its claimed invention from Konrad not because it described one "server" (the "starter server") that initiated a connection and another "server" (the "network") that continued to actively manage and facilitate the connection, but instead, that ABC differentiated Konrad from the claimed invention because in Konrad nothing continued to actively manage and facilitate the connection after the starter server initiated it. Therefore, ABC did not clearly and unmistakably disavow any website that utilized more than one server to perform multiple functions. See Computer Docking Station Corp., 519 F.3d at 1374.

3. Hosting Web Pages, Retrievable by a Web Browser Using HTTP and HTML Interpretation

Under ABC's definition a website "can perform services including hosting web pages . . . ." Therefore, under ABC's definition, a website need only be capable of hosting web pages, but need not necessarily do so. ABC's definition is silent as to whether the web pages hosted by websites must be retrievable by a web browser and as to whether the web pages must be retrievable using HTTP and HTML interpretation.

Under WebEx's proposed definition a website is made up of "Web pages maintained by a Web server and retrievable by a Web browser using [HTTP] and HTML interpretation." Therefore, WebEx suggests that a website must involve web pages, that those pages must be retrievable by a web browser, and that the protocol and programming language used are limited to HTTP and HTML, respectively.

a. Hosting Web Pages

The only evidence in the record that supports ABC's contention that a website need not involve web pages is a statement in the affidavit of ABC's expert (extrinsic evidence): "In fact, a website is not even required to maintain any web pages." 79 However, the source cited by the expert as allegedly supportive of this statement describes only websites that have web pages.

79 Affidavit of Ivan Zatkovich, P 10 (May 28, 2009) (included in ABC's Response, Docket Entry No. 165, at Exhibit A).
The World Wide Web, A Mass Communications Perspective, by Kaye and Medoff, describe five types of commercial websites. Each type of website described clearly utilizes web pages. In fact, several example web pages displayed in web browser windows are depicted. Therefore, the court is not persuaded by ABC's expert's affidavit.

--- Footnotes ---

--- End Footnotes ---

The other relevant evidence in the record -- both intrinsic and extrinsic -- suggests that websites necessarily involve web pages. As stated above, some intrinsic and extrinsic evidence actually equates the term website with the web pages themselves. Although the court concluded that a website, as the term is used in the '945 patent, consists of one or more servers, as opposed to web pages, the evidence nevertheless strongly suggests that a website necessarily involves or is somehow related to web pages. Accordingly, the court concludes that a website must host one or more web pages.

--- Footnotes ---

81 See United States Patent No. 6,138,150 col.3 ll.4-6 (filed Sept. 3, 1997) ("In the preferred embodiment, a web site or 'home-page' is constructed on a secure HTTP . . . server. . . .") (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 14); United States Patent No. 7,007,070 col.8 ll.65-67 (filed Feb. 28, 1997) ("A 'web site' on a web server 20 contains one or more web pages where a 'base' or 'home' page is the first or entry page into a desired web site.") (included in WebEx's Response, Docket Entry No. 116, at Exhibit 15); Microsoft Computer Dictionary 479-80 (4th ed. 1999) (defining a website as "a group of related HTML documents and associated files, scripts, and databases that is served up by an HTTP server on the World Wide Web. . . . Most Web sites have a home page as their starting point, which frequently functions as a table of contents for the site") (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 10).

--- End Footnotes ---

b. Retrievable by a Web Browser

The evidence in the record also suggests that web pages hosted by a website must be retrievable by a web browser. For example, one prior art patent cited during the prosecution of the '945 patent states that "[t]he WWW [World Wide Web] is a collection of files written using [HTML], commonly referred to as 'Web pages.' HTML files may be accessed and displayed using specialized applications known as 'web' browsers . . . ." 82 Another cited prior art patent states that "Web pages are typically accessed using an HTML compatible browser . . . ." 83 Similarly, the Microsoft Computer Dictionary (extrinsic evidence), which defines website as a collection of web pages, states in the definition of website that "[u]sers need a Web browser . . . to access a Web site." 84

--- Footnotes ---

82 United States Patent No. 5,961,586 col.1 ll.15-21 (filed May 14, 1997) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 8). This patent was cited during the prosecution of the '945 patent in a supplemental disclosure. See Second Supplemental Disclosure (Oct. 23, 2000) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6B).

83 United States Patent No. 6,167,441 col.1 ll.22-25 (filed Nov. 21, 1997) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 9) This patent was cited during the prosecution of the '945 patent in a Notice of References Cited. See Notice of References Cited (May 27, 2003) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6C).

--- End Footnotes ---

Moreover, ABC has not produced any evidence to show or give examples of web pages that are not retrievable by a web browser.
browser. Accordingly, the court concludes that a website, by definition, hosts one or more web pages that are retrievable by a web browser.

c. HTTP and HTML

WebEx asserts that one of ordinary skill in the art in 1998 would have understood the term website to connote the use of HTTP and HTML, but not other protocols or languages. Alternatively, WebEx asserts that ABC disclaimed other protocols and languages during the reexamination of the '945 patent in an attempt to distinguish the claimed invention from prior art, and therefore, narrowed the scope of the term. ABC denies that websites, now or in 1998, are or were limited to using HTTP and HTML. ABC also denies that it ever represented that the term "website," as used in the '945 patent, was limited only to the use of HTTP and HTML.

The parties cite multiple references that allegedly support their respective interpretations. The court, however, need not analyze these in detail because the court agrees with WebEx that ABC disclaimed other protocols and languages during the reexamination of the '945 patent, limiting the term website only to HTTP and HTML.

As explained above, during the reexamination of the '945 patent the Examiner concluded that claims 1 and 2 of the '945 patent were anticipated by a prior art reference that utilized hot-links in a web browser. In response ABC submitted an affidavit by a purported expert, Dr. Alan H. Jones, Ph.D., who distinguished the prior art reference by explaining that clicking on a hot-link in a web browser could trigger a number of actions, including

a) retrieval of a web page from a website through [HTTP] and HTML interpretation (emphasis added);

b) initiation of a directory listing and file transfer from a remote FTP server using FTP protocols and formats;

c) activation of an external program operating independently of the browser to retrieve and interpret data using streaming formats (e.g. RealPlayer window using Real Time Streaming Protocol (RTSP) and interpreting RealAudio format); or

d) activation of a browser plug-in to fetch and interpret multimedia data to be displayed within a child window of the browser (e.g. Macromedia flash player plug-in using Real Time Messaging Protocol (RTMP) and interpreting as ShockWave Flash format). 86

Dr. Jones then stated that "[t]he use of the term hot link within a web browser, thus, does not unambiguously imply access to a website, as it can also relate to the use of protocols such as FTP, RTSP, or RTMP" (emphasis added). 87

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

85 Supplemental Response to Office Action in Ex Parte Reexamination, at 4, Ex Parte Reexamination of U.S. Patent No. 6,999,945, Control No. 90/008,122 (Sept. 16, 2008) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6F).

87 Id.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

Dr. Jones differentiated the claimed "website" from the prior art hot-link because the prior art hot-link did not necessarily utilize HTTP and HTML, but could have utilized other protocols or languages. The clear implication from his statements is that a website, by definition, utilizes HTTP and HTML, while something that does not utilize this protocol and language would not qualify as a website. Accordingly, because of ABC's "clear and unmistakable disavowal of scope during prosecution," the website referred to in the claims of the '945 patent is limited to the use of HTTP and HTML. Computer Docking Station Corp., 519 F.3d at 1374.

4. Located on the Internet by Use of a URL
ABC contends that a website must be capable of being located on the Internet by use of a URL. WebEx counters that "[t]he ability to be located using a URL does not define a website and does not distinguish a website from other entities that can be located by a URL." 88

Importantly, WebEx does not contend that there are any websites that cannot be located with a URL. To the contrary, WebEx implicitly concedes that all websites can be located with URLs. WebEx instead argues that because "other entities" that do not qualify as websites can also be located with URLs, the ability to be located by a URL should not be included in the definition of a website. 89 This is rather like arguing that a bicycle should be not defined as having two wheels because other vehicles, such as motorcycles, also have two wheels. Therefore, the court does not find WebEx's argument persuasive.

Moreover, evidence in the file, including evidence presented by WebEx, confirms that websites are inherently locatable using URLs. For example, a prior art patent cited during the prosecution of the '945 patent states: "The path to a particular Web server is defined by a Uniform Resource Locator (URL)." 90 Additionally, the Microsoft Computer Dictionary (extrinsic evidence) defines the term "Web page" as "an HTML file . . . in a particular directory on a particular machine (and thus identifiable by a URL)." 91 Further, the same dictionary defines the term "Web directory" as "a list of Web sites, giving the URL . . . of each," and, for the term "Web address," the dictionary refers readers to the definition of URL, suggesting the terms are synonymous. 92

WebEx does not argue that a website is not "located on the Internet." Indeed, in its argument regarding the term "established on the World Wide Web," WebEx characterizes the WWW as a "subset of devices on the Internet." 93 Therefore, a website, clearly a part of the WWW, is located on the Internet.

5. Provided by a Service Provider
ABC asserts that a website inherently "can be provided by a service provider." ABC points to several passages in the specification of the '945 patent that describe the preferred embodiment of the invention. 94 The first passage reads: "An example of the preferred embodiment would be an Internet service provider operating much like a phone or cable company, in which a large number of customers can be connected from a large number of different locations to a large number of PC's, at a specific location." 95 The second passage states: "The customer for example could log onto an internet service provider and could click the mouse arrow on the computer service icon . . . for example and the computer service screen would appear and give the customer several options to select from." 96

--- Footnotes ---

94 ABC's Brief, Docket Entry No. 154, at 12-13.
95 '945 patent, col.4 ll.7-11.
96 Id. col.6 ll.5-9.

--- End Footnotes ---

Courts may not limit the invention to the preferred embodiment unless the patentee describes the particular embodiment as "important to the invention." Toro Co., 199 F.3d at 1301. ABC has not directed the court to any representation in the specification or prosecution history of the '945 patent suggesting that the ability to be provided by a service provider is important to this invention. Although the website may be provided by a service provider in some embodiments of the invention, the court is not persuaded that the website must always be adaptable to being provided by a service provider. Accordingly, the court will not include the service provider limitation in its definition.

6. Validating Logon Commands and Sending, Receiving, and Processing Instructions

ABC argues that the term website, as used in the '945 patent, must be capable of "validating logon commands and sending, receiving, and processing instructions." Claim 1 -- upon which the three asserted claims depend -- explicitly states that the website "receiv[es] . . . a valid logon command from the interface unit whereby the website associates the valid logon command with the remote computer unit." 97 It further states that the website "receiv[es] . . . data signal instructions from the interface unit; and send[s] the data signal instructions . . . to the remote computer unit." 98 The court agrees that this claim language supports ABC's position that the website must validate logon commands and send and receive instructions. The claim, however, does not require that the website process these instructions. Therefore, the court's definition will reflect that a website must be able to validate logon commands and send and receive data signal instructions. The court's definition will not include the requirement that the website process the instructions.

--- Footnotes ---

97 '945 patent, claim 1.
98 Id.

--- End Footnotes ---

7. The Same Website Both Receives Valid Logon Commands and Receives and Sends the Data Signals that Control the Remote Computer Unit

WebEx contends that the claims of the '945 patent speak in terms of a single website such that the same website must both receive valid logon commands and receive and send the data signals that control the remote computer unit. ABC, in its response brief, does not dispute this construction, and itself speaks in terms of a singular website "capable of . . . receiving a valid logon command, associating the logon with a remote computer unit, receiving data signal instructions, sending the data signal instructions and downloading a program . . . ." 99 Moreover, such a construction is consistent with plain language of the claims of the '945 patent. The first use of the term appears in claim 1 and recites, "a website capable of allowing and facilitating communication between a remote computer unit and an interface unit via the internet." 100
subsequent references in claim 1 and the remaining dependent claims speak in terms of "the website." 101 Accordingly, the court agrees that the same website both receives valid logon commands and receives and sends the data signals that control the remote computer unit.

--- End Footnotes ---

8. Conclusion

The court concludes that a "website," as the term is used in the '945 patent, is "one or more servers operating together that (1) can be located on the Internet by use of a Uniform Resource Locator (URL), (2) host one or more web pages retrievable by a web browser through hypertext transfer protocol ("HTTP") and hypertext markup language ("HTML") interpretation, (3) validate logon commands, and (4) send and receive data signal instructions." The same website both receives valid logon commands and receives and sends the data signals that control the remote computer unit.

---

7. Current Web site (First appearing in claim 1 at col. 12, l. 56, and as used thereafter in claims 1-31)

Websidestory contends that the term "current website" does not require construction, while Netratings construes the term to mean "the website providing the page requested by the network browser." See Joint Claims Construction Chart at 3-4.

Netratings contends that the use of this term in claim 1 of the '479 Patent requires the adoption of its construction. Websidestory contends that the meaning of "current website" would be clear to an ordinary person skilled in the art in 1999, and does not need to be construed by the Court. If the Court requires construction of "current website," Websidestory proposes that "current" should be construed to mean "belonging to the present," and "website" should be construed to mean "a collection of thematically related, hyperlinked World Wide Web services, mainly HTML documents, usually located on a specific Web server and reachable through a URL assigned to the site." Joint Claims Construction Chart at 3-4.

The term "current website" is neither defined nor mentioned in the specification, and appears for the first time in the second element of claim 1 of the '479 Patent as follows:

- receiving a request from a network browser for a page at a website, the page having at least one graphical element having an image source attribute that specifies a website traffic path analysis data location;
- detecting if the website page request includes a website cookie having website traffic path analysis data from the network browser for the current website;
- producing a website cookie in response . . ., wherein the website cookie contains data . . . for the current website.

Patent at col. 12, ll. 50-61 (Emphasis added.). The term appears in a similar context in other claims. After considering the language of the claims, and particularly the context within which the terms "current website" and "current website visit" are used in the claims, the Court concludes that it would be readily apparent to a person of ordinary skill in the art in question at the time of the invention that the term "current website" is used to refer to the web page which is requested by a visitor's network browser. The Court adopts Netratings' proposed construction for "current website," and concludes that the acquired meaning of "current website" is: "the website providing the page requested by the network browser."

8. Detecting if the website page request includes a website cookie having website traffic path analysis data from the network browser.
browser for the current website (Patent at claim 1, col. 12, ll. 54-57)

Netratings contends that construction of this phrase is necessary to clarify that (a) the website cookie contains the traffic path analysis data, and (b) the website page request contains the cookie. Netratings' proposed construction reads: "detecting if the website page request contains a website cookie for the current website from the network browser, which website cookie has website traffic path analysis data." Joint Claims Construction Chart at 2. Websidestory contends that construction of the phrase is unnecessary, and argues that Netratings is needlessly reordering words. Joint Claims Construction Chart at 2. The terms "website page request," "website cookie," "website traffic path analysis data," and "current website" have already been construed by the Court.

The first dispute in this phrase centers on the word "includes." Netratings' proposed construction substitutes the word "contains" for the word "includes." See Joint Claims Construction Chart at 2. Netratings proposed construction begins, "detecting if the website page request contains a website cookie," while the language of the '479 Patent reads, "detecting if the website page request includes a website cookie." See Joint Claims Construction Chart at 2. Netratings argues that the word "includes" must be replaced by the word "contains" to clarify the meaning of the '479 Patent, however, Netratings does not explain why such a clarification is necessary. Instead, Netratings simply notes in its opening brief that the term "contains . . . is consistent with the ordinary meaning of the word" includes, and is used in the specification. Netratings' Opening Claims Construction Brief at 10. Webster's Third New International Dictionary defines "include" as "to place, list, or rate as a part or component of a whole or of a larger group, class, or aggregate," and "contain" as "to keep within limits . . . to have within." WEBSTER'S THIRD NEW INTERNATIONAL DICTIONARY 490-91, 1143 (1986).

The Court finds that substitution of the word "contains" for the word "includes" does not clarify the '479 Patent. First, a court is not permitted to re-write the claims of the patent. ChefAm., Inc. v. Lamb-Weston, Inc., 358 F.3d 1371, 1374 (Fed. Cir. 2004). Second, the specification states on at least one occasion that, "the browser . . . sends the corresponding cookie along with the request for the page," see Patent at col. 8, ll. 10-15. On the basis of that language, the Court concludes that "includes," with its broader meaning, is more consistent with the specification than "contains." Finally, after reviewing the '479 Patent and extrinsic evidence, there is no evidence that "includes" should be limited to "contains."

Claims construction is "not an obligatory exercise in redundancy," see U.S. Surgical Corp., 103 F.3d at 1568, and while every word in a claim has meaning, not every word requires construction. Orion IP, LLC v Staples, Inc., 406 F. Supp. 2d 717, 738 (E.D. Tex. 2005). After consideration of the parties' arguments and the '479 Patent, the Court concludes that the word "includes" does not need to be construed, and the Court will not substitute the word "contains" in its place. The ordinary and customary meaning of the word "includes" will control.

Netratings' proposed construction also seeks to clarify that the website traffic path analysis data is stored in the website cookie described in this phrase. Netratings' proposed construction reads, "detecting if the website page request contains a website cookie for the current website from the network browser, which website cookie has website traffic path analysis data." Joint Claims Construction Chart at 2 (Emphasis added.). After reviewing the '479 Patent's claims and specification, the Court concludes that there is significant support for the proposition that the website cookie has website traffic path analysis data. See Patent at col. 12, ll. 54-56 ("a website cookie having website traffic path analysis data"); Patent at col. 12, ll. 59-66 ("wherein the website cookie contains an initial set of traffic path analysis data for the current website" and "setting the traffic path analysis data of the website cookie to initial values . . ."). However, the Court finds that the claim language, "a website cookie having website traffic path analysis data," requires that the cookie has the traffic path analysis data, and no construction is necessary.

5. Web site Page Request (First appearing in claim 1 at col. 12, l. 55, and as used thereafter in claims 1-31)

The parties initially disputed this term, but agreed to a meaning at oral argument. Tr. at 95, 105-07, 120-22. The parties agree that the term should be construed as: "a request for a page and its various components." This construction is supported by the '479 Patent's language, and the Court concludes that the construction is consistent with the ordinary and customary meaning of the term to one skilled in the art in 1999. The Court adopts the parties' joint construction. The Court concludes that the acquired meaning of "website page request" is: "a request for a page and its various components."
3. Website traffic path analysis data (First appearing in claim 1 at col. 12, ll. 55-56, and as used thereafter in claims 1-31)

The parties dispute the meaning of the phrase "website traffic path analysis data," which first appears in the '479 Patent at claim 1, col. 12, l. 54. See Joint Claims Construction Chart at 2. Websidestory contends that the phrase means "data used for website traffic path analysis." Netratings contends that the phrase has a more specific and detailed meaning, and proposes "data consisting of the actual sequence of every page at a website visited by a browser during a current visit, the clock time of each page visit obtained from the browser, and cumulative values and statistics."

Netratings contends that the specification and the claims of the '479 Patent detail and define the contents of "website traffic path analysis data," and require the phrase to include a sequence of every page visited, the visitor browser's clock time, and other cumulative values and statistics. Netratings contends that Websidestory's definition renders the word "analysis" meaningless.

Websidestory contends that Netratings' proposed construction improperly imports limitations from the specification, impermissibly limiting the scope of the '479 Patent. Websidestory contends that the claims of the '479 Patent support its proposed, and more general, construction of "website traffic path analysis data," and further contends that it is unnecessary to utilize the specification given the clarity and plain meaning of this disputed phrase. Websidestory disputes Netratings' assertion that the '479 Patent's claims and specification disavow or disclaim the contents of "website traffic path analysis data."

After reviewing the '479 Patent and the parties' arguments, the Court concludes that the phrase "website traffic path analysis data," has an ordinary and customary meaning consistent with Websidestory's proposed construction of "data used for website traffic path analysis." Joint Claims Construction Chart at 2. This construction is consistent with the use of "website traffic path analysis data" in the claims, and supported by those portions of the specification which provide specific examples of "website traffic path analysis data." See Patent at col. 4, ll. 37-40; Patent at col. 5, ll. 2-4. This construction is also consistent with the presence of dependent claims, e.g. claims 2-10, which claim embodiments of the invention where "website traffic path analysis data" must include specific types of data. Patent at col 13, ll. 10-42.

The doctrine of claim differentiation instructs that, ordinarily, (a) each claim in a patent has a different scope, (b) a dependent claim has a narrower scope than an independent claim, and (c) an independent claim has a broader scope than a claim that depends on it. HERBERT F. SCHWARTZ, PATENT LAW AND PRACTICE § 5.1.A.3.d. (5th ed. 2006); see also Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004). "[T]he presence of a dependent claim that adds a particular limitation raises a presumption that the limitation in question is not found in the independent claim." Liebel-Flarsheim Co., 358 F.3d at 910; Phillips, 415 F.3d at 1315. Though that presumption can be overcome where evidence favoring a different construction is "strong, . . . where the limitation that is sought to be read into an independent claim already appears in a dependent claim, the doctrine of claim differentiation is at its strongest." Liebel-Flarsheim Co., 358 F.3d at 910; see also Sunrace Roots Enter. Co. v. SRAM Corp., 336 F.3d 1298, 1302-03 (Fed. Cir. 2003).

The independent claims of the '479 Patent do not require "website traffic path analysis data" to include the actual sequence of every page visited by a browser, clock times, cumulative values, or statistics as proposed by Netratings. Instead, those limitations appear in dependent claims, such as claims 2, 5, and 6 of the '479 Patent. See Patent at col. 13. Accordingly, the Court concludes that there is a presumption against including those limitations in the acquired meaning of "website traffic path analysis data." Liebel-Flarsheim Co., 358 F.3d at 910. Netratings attempts to rebut the presumption with intrinsic evidence from the specification. Netratings contends that "website traffic path analysis data" must be defined to include the actual sequence of requested pages, clock times, cumulative values, and statistics, and cites the following sections of the specification in support of its argument:

In addition, conventional Internet-based traffic analysis tools do not indicate the actual sequence, or path, followed by a website visitor from page to page of a website. The website path taken by visitors can be very important . . . .

For every website page requested by a website visitor, the state of the visitor's browser is recorded. The state includes the clock time and an indication of every page at the website visited by the browser during the current visit. Patent at Summary of the Invention, col. 4, ll. 37-40.

Next the path analysis data is initialized. For example, cumulative data such as elapsed visit time is set to zero . . . . Patent at Description of the Preferred Embodiment, col. 8, ll. 39-43.

FIG. 8 is an exemplary cookie format such as will be passed back and forth between browser and server to track website traffic, in accordance with the invention…. The next cookie field is a site visit count. . . . FIG. 9 is an example of path analysis data stored in a cookie. . . . The next field is for the calculated average time between site visits, a statistic that is maintained by the traffic analysis computer. The time spent is calculated in accordance with the cookie expiration time limit . . . . Patent at Description of the Preferred Embodiment, col. 9, ll. 10-60. Netratings asserts that the inclusion of the actual sequence, cumulative values, statistics, and clock times references in the above descriptions of website traffic path analysis data require reading those terms into the definition of "website traffic path analysis data."

After reviewing the language of the claims, the Court concludes that an ordinary person skilled in the art at the time of the invention would not include clock times and cumulative values in the definition of "website traffic path analysis data." Nor is there evidence that a person skilled in the art in 1999 would interpret "website traffic path analysis data" in that manner. In order for the Court to conclude that the specific interpretations proposed by Netratings are part of the acquired meaning, the '479 Patent would have to define "website traffic path analysis data" in a clear and precise way. See Merck& Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1370-72 (Fed. Cir. 2005) ("When a patentee acts as his own lexicographer in redefining the meaning of particular claim terms away from their ordinary meaning, he must clearly express that intent in the written description."). After reviewing the language of the specification, the Court concludes that the specification does not clearly define the term "website traffic path analysis" as including the actual sequence of pages, clock times, cumulative values, and statistics.

Though the '479 Patent specification makes reference to prior art which included data such as time stamp values, see Patent at col. 3, ll. 55-57, the prosecution history of the '479 Patent, and specifically the notice of allowability, does not indicate that a detailed description of data was necessary for patentability. Though the notice of allowability did reference the current requested page and the complete path of website pages as part of "website traffic path analysis data," it did not define data to include specifics such as clock times, cumulative values, or statistics. Swinton Decl. at Ex. 4, p. 30.

Finally, the Federal Circuit has stated on multiple occasions that it is improper to read limitations from a specification into a claim. Callicrate v. Wadsworth Mfg., 427 F.3d 1361, 1368 (Fed. Cir. 2005); Phillips, 415 F.3d at 1312. The limitations proffered by Netratings appear in dependent claims, and the limitations are often preceded with language such as "for example," "exemplary," or "in the preferred embodiment." The Court recognizes that it is often a "fine line" that separates "proper from improper reliance" on the specification. HERBERT F. SCHWARTZ, PATENT LAW AND PRACTICE § 5.1.A.3.b. (5th ed. 2006); Innova/Pure Water, Inc. v. Safari Water Filtration Sys., 381 F.3d 1111, 1117 (Fed. Cir. 2004). The Court concludes, however, that Netratings' proposed construction which includes the actual sequence of pages, clock times, cumulative values, and statistics as part of the definition of "website traffic path analysis data" improperly imports limitations from the '479 Patent specification.

After considering the parties' arguments, the intrinsic evidence presented, and the '479 Patent, the Court concludes that references to the actual sequence of pages visited, clock times, cumulative values, and statistics are not required in the definition of "website traffic path analysis data." The Court adopts Websidestory's proposed construction, and concludes that the acquired meaning of "website traffic path analysis data" is: "data used for website traffic path analysis."
1. Principles of claim construction

Claim construction of a patent, including terms of art within claims, is exclusively within the province of the court, not the jury. Markman v. Westview Instruments, Inc., 517 U.S. 370, 388-8, 116 S. Ct. 1384, 134 L. Ed. 2d 577, 579 (1996).

It is well-settled that, in interpreting an asserted claim, the court should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history. See Markman, 52 F.3d at 979, 34 U.S.P.Q.2d at 1329. Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language.

The first step is to look to the words of the claims themselves, both asserted and nonasserted, to define the scope of the patented invention. Id. Second, it is necessary to review the specification to determine whether the inventor has used any terms in a manner inconsistent with their ordinary meaning. Id.

The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication. Id.” Claims must be read in view of the specification, of which they are a part." Id. (citing Markman, 52 F.3d at 979). The specification is always highly relevant to the claim construction analysis, and usually, it is dispositive; it is the single best guide to the meaning of a disputed term. Id. The drawings or figures of the patent are considered with the specification in interpreting claim language. Wright Medical Tech., Inc. v. Osteonics Corp., 122 F.3d 1440, 1443 (Fed. Cir. 1997).

Third, the court may also consider the prosecution history of the patent, if in evidence. Vitronics Corp., 90 F.3d at 1582.

In addition, the Court should not read into a patent limitations that do not exist in the claims. As the Federal Circuit recently held, "[t]he danger of improperly importing a limitation is even greater when the purported limitation is based upon a term not appearing in the claim." Amgen, Inc. V. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1325 (Fed Cir. 2003) (internal citations omitted).

Moreover, like contract interpretation, the Court should first give claim terms their ordinary and accustomed meanings.

Claim terms take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic evidence using words or expressions of manifest exclusion or restriction, representing clear disavowal of claim scope.

Apex, Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1377 (Fed. Cir. 2003) (emphasis added).(citation omitted).

In fact, the Federal Circuit has issued a ruling instructive on this issue. In Rexnord Corp. v. Laitram Corp., 274 F.3d.1336, 1343-44 (Fed. Cir. 2001) the Federal Circuit overruled the district court’s holding that the claim term "portion" was to be accorded a meaning narrower than its customary meaning, by finding that the district court had improperly relied on the preferred embodiment, the drawings, and one passage in the prosecution history to overcome the presumption.

Finally, if an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term, it is improper to rely on extrinsic evidence. Id. at 1583. Extrinsic evidence is that evidence which is external to the patent and file history, such as expert testimony, inventor testimony, dictionaries, and technical treatises and articles. Id. at 1584. Extrinsic evidence in general, and expert testimony in particular, may be used only to help the court come to the proper understanding of the claims; it may not be used to vary or contradict the claim language. Id.

This approach was affirmed in the Federal Circuit's most en banc decision, Phillips v. AWH Corp., 415 F.3d 1303, 1317 (Fed. Cir. 2005). In that case, the Court reiterated that "[w]e have viewed extrinsic evidence in general as less reliable than the patent and its prosecution history in determining how to read claim terms." Id.

Following this guidance and framework, this Court finds that the '801 Patent's Claim 5 and the specification only requires
that the microprocessor permits (allows) audio data to leave through the audio reproduction circuit and not that the audio data must always leave that way.

Additionally, nothing in the claim language, specifications, or prosecution history supports a finding that "allows" is limited to an understanding of "enable" meaning to turn on from a previously turned off starting point. As to "when," this term appears multiple times in the '801 Patent and none support an interpretation of "every time." "When" simply means that "at the time."

Here, it is inappropriate for this Court to find that Mediatek's argument is correct, as there is little to support overcoming the heavy presumption that the terms carry their ordinary meaning. As such, for the purposes of Claim 5 and its dependant claims 6 and 7, the plain terms are interpreted as (1) "allows" meaning "to permit" and (2) "when" meaning "at the time" instead of Defendants' more restrictive interpretation.

4851

7. When a DR is identified ('321 patent, claims 1, 47, 185, 190 and 193)

Plaintiffs assert that certain steps take place "when a DR [data reference] is identified" and other steps take place "as the referencing record is created." Although plaintiffs concede that the word "as" requires real-time processing, they dispute whether the word "when" also requires real-time processing. Claim 47 of the '321 patent, for example, provides that:

A method for identifying a referenced record referenced in a referencing record wherein the referenced record is referenced in the referencing record by at least a data reference (DR), the method comprising the steps of:

 as the referencing record is created:

 (i) receiving the referencing record;

 (ii) analyzing the referencing record to identify a DR; and

 (iii) when a DR is identified, associating the DR and the referenced record.

'321 Patent:, at 36, 37-46 (emphasis added).

The parties do not dispute that "receiving" or "analyzing" the referencing record must be performed in real time. The patent examiner's response is clear on this point. See Aff. of Craig Smith, Exh. N, July 3, 2002 Response to Office Action, at 8 ("Applicant has amended each of claims 47 and 137 to now require that the steps of receiving and analyzing are performed in real time.") (Emphasis in original.) However, plaintiffs argue that because the patent examiner failed to mention "associating" in his response ("when a DR is identified, associating the DR and the referenced record" in step three (iii)), this step need not occur in real time. I disagree. In order to overcome a prior art rejection for lack of a real-time element, the inventor amended the '321 patent by adding "as the referencing record is created" and the word "and" between steps two (ii) and three (iii). Thus, the patent examiner required all three steps after the phrase "as the referencing record is created" to occur in real time. Accordingly, in the '321 patent, "when a DR is identified, associating the DR and the referenced record" occurs in real time.

4852

4. "When a subset of the stored terrain information is located within boundaries" 53
When reading this claim language in the context of the invention, it is clear that the patent refers to any piercing of the alert zones, since it does not limit the term subset in either the claim or specification. To hold otherwise would render some of the claim language moot. Thus, for the reasons set forth under "alert envelope," the court will apply Sandel's proposed construction.

Skyline argues that Google's use of "during periods of time when the local computer is not downloading data blocks describing three-dimensional terrain in response to the coordinates received from the renderer." Skyline counters with "when not downloading data for displaying the scene corresponding to the current view."

Skyline next argues that the only blocks "required by the renderer" are those immediately necessary for the display of the current view. This proposed construction overstates the point. Clearly there are at least two types of data blocks -- those required by the renderer, and those that are being downloaded to fill up excess local memory, with the expectation that they might eventually be required for display of a particular viewpoint. To say that those "required by the renderer" are only those immediately needed for the current viewpoint is not wholly accurate.

Because the data blocks are not transferred at the exact moment they are requested (due to network lag, processor delays, etc.), there will often be a backlog of data blocks that the renderer has requested, but not yet received. Cutting down on this
time lag is a purpose of the '189 patent. However, because the lag exists, and the '189 patent allows for a constantly changing user viewpoint, there will often be a queue of data blocks, some of which may not be needed any longer, that have been requested by the renderer, but not yet downloaded. Until these requested blocks have finished downloading, excess blocks will not be downloaded to fill the local memory. See Fig. 8 ("Queue Empty?" No --> Download blocks from queue; Yes --> Download excess surrounding blocks). Therefore, files which are, or were, "required by the renderer" may include data blocks not required for the currently displayed view.

n14 The process diagramed in Fig. 8 does run a check to see if the block in the queue is out of range (which it would be if the viewpoint has changed so dramatically that the block is obviously no longer needed), but excess blocks are not automatically downloaded if the requested block is found to be out of range. Instead, the logic says to go back to the top of the flowchart, and wait for further inputs.

n15 This point becomes particularly clear if one envisions a viewer hovering over a point, say at the top of a hill. The viewer might start by looking north, then turn around in a circle, examining each of the cardinal points. By the time the viewer's attention comes back to the starting point, the resolution of the terrain image should have increased, so that the view is more detailed that it was initially. While the viewer was turning around, data blocks "required by the renderer" to improve resolution at the starting point were being downloaded. However, these blocks were not required for the display when the viewer was looking in other directions (due south, for example).

Construction: (when not downloading blocks required by the renderer) During periods of time when the local computer, or a connection thereof, is not downloading data blocks in response to coordinates received from the renderer

n16 I have eliminated Google's proposed addition of "describing three-dimensional terrain" whenever "data blocks" appeared, because this term has already been construed in a way that makes the additional language unnecessary.
The '382 patent's specification states,

Preferably, a timer 64 is initiated once the OVP exceeds the threshold, thereby initiating a time-out sequence. The duration of the time-out is preferably designed according to the requirement of the loads (e.g., CCFLs of an LCD panel), but could alternately be set at some programmable value. Drive pulses are disabled once the time-out is reached, thus providing safe-operation output of the converter circuit.

Accompanying this language provides no support for MPS's assertion that the timer circuit measures two time periods before the drive pulses are shut down. On the contrary, the specification states that the drive pulses "are disabled once the time-out is reached," which suggests that the "time-out" constitutes a single time period. Because neither the specification nor any other intrinsic evidence indicates that the timer circuit measures two separate time periods, the Court rejects MPS's proposed construction and concludes that the timer circuit measures only one "predetermined duration."

Accordingly, the Court construes this language to mean: "when the above-mentioned first voltage signal exceeds and continues to exceed a voltage value determined beforehand for the above-mentioned time period."

The main dispute concerns the requirement that "the probe generate a trigger signal when said sensing tip contacts an object and said stylus holder is thereby deflected relative to said housing." The district court determined that "when" is defined by reference to this entire claim limitation, such that "when" means as soon as contact is made and deflection occurs. See Renishaw, 974 F. Supp. at 1089. On appeal, Renishaw argues that "when" should receive one of its broader dictionary definitions: "at or after the time that," "in the event that," or "on condition that," so that the claim would read on a device that does not generate a trigger signal until an appreciable amount of time after contact is made and deflection begins. Because infringement of this limitation depends on the meaning of the word "when," we refer to it in the remainder of the opinion as the "when" limitation. We agree with the district court's construction of this claim limitation and, because all limitations must be met for there to be infringement, we need consider only this limitation.

The ultimate issue is the manner in which "when" defines the timing of probe triggering vis-a-vis contact of a stylus with a workpiece. The issue brings into sharp focus the convergence of the two canons of claim construction discussed above. According to Renishaw, the accused probes escape infringement only if a narrowing limitation is read into "when" from the written description. Marposs counters with an argument that the claim is properly construed to require a finding of noninfringement because the correct meaning of the claim term "when" is embedded throughout the specification.

Neither party forwards a technical meaning for "when" in the applicable industry. However, there are several closely-related, but distinct, common meanings for "when," most cited by Renishaw on appeal. These include: at or during the time that; just at the moment that; at any or every time that; at, during, or after the time that. n4 Renishaw asserts that nothing in claim 2 places an outer endpoint on the time at which a trigger signal must be generated, other than that the device be capable of generating some trigger signal. Therefore, contends Renishaw, the trial court's definition of the term was overly narrow, and the claim is properly defined simply as "at or after the time that." For its part, Marposs argues that the '904 patent's written description exhibits a clear intent to provide triggering as soon as possible after contact with a workpiece, not at appreciable times after contact. Marposs argues that in claim 2 the use of "when" provides an entry point into the claim for that intent.

- 5073 -
The explicit language of claim 2 is our starting point. There, the claim states that a signal is generated "when" there is contact with a workpiece "and said stylus holder is thereby deflected." The claim ties the signal to contact and deflection, thus showing that the trigger signal cannot occur until the probe has contacted the workpiece and the stylus has deflected some amount. In other words, contact and deflection are a condition precedent to signaling. Thus, the claim itself precludes us from viewing "when" as requiring signaling at the precise moment of contact, for some deflection must occur before signaling. The district court also recognized this. See Renishaw, 974 F. Supp. at 1071; see also Mantech Envtl. Corp. v. Hudson Envtl. Servs., Inc., 152 F.3d 1368, 1998 U.S. App. LEXIS 18753, No. 98-1079, slip op. at 12-13 (Fed. Cir. Aug. 13, 1998) (looking to other terms in a claim to construe a limitation in dispute); Phonometrics, Inc. v. Northern Telecom Inc., 133 F.3d 1459, 1465, 45 U.S.P.Q.2D (BNA) 1421, 1426 (Fed. Cir. 1998) (same).

Mere recognition that "when" is not limited to the precise moment of contact, however, does not make the term clear, or mandate a meaning of "when" to include any time after contact as long as a measurement is derived from stylus contact. That is because "when" is not a broad and general term when standing in isolation. Instead, it has several meanings, each of which may prevail based on the context. Here, we have bounteous context. Claim 2 does not exist in rarefied air, but rather is surrounded by a patent disclosure of singular purpose. As evidenced by the several common meanings of "when," the term is imprecise as used in the '904 patent. The term is not ambiguous, however, because the written description provides overwhelming evidence to guide a proper interpretation of the term. See Vitronics, 90 F.3d at 1583, 39 U.S.P.Q.2D (BNA) at 1577. Replete with references that indicate that the patentee was preeminently concerned with generating a trigger signal as soon as possible after contact, the written description lends precision to the term "when." The written description shows that the patentee's invention is directed at a machine that produces very accurate, very precise probe readings by maintaining tight control over the position of the stylus. In the context of the invention, such readings can only be obtained if the probe triggers very, very soon after contact.

For example, in describing the invention's place within the prior art, the '904 patent notes: "When the stylus contacts a workpiece surface, a trigger signal is generated by the probe, which is used to trigger the taking of a reading of the instantaneous position of the movable spindle, quill or arm." Col. 1, ll. 36-42. Likewise, the Summary of the Invention states that the preferred embodiment of the probe "includes means for providing a signal when said stylus contacts a workpiece," col. 3, ll. 28-29, and that the movable elements are displaced "out of said rest position when said stylus contacts a workpiece," col. 3, ll. 21-22.

Statements in the "Description of Preferred Embodiments" also use the term "when" to describe a time very close to the precise instant that the stylus contacts the object to be measured and not some appreciable time thereafter:

When the stylus 14 contacts a workpiece, from any direction, the stylus is deflected. For example, if the contact is in a horizontal direction, the stylus 14 tilts, about a point of contact between the surfaces 20 and 22. At this time, the cylinders 34 and balls 36 remain engaged with each other, and the tilting is accommodated by flexing of the planar spring 30. . . .

When the deflecting force on the stylus 14 ceases (i.e. when the probe is moved so that the stylus 14 no longer contacts the workpiece) the stylus member 12 is returned to its axial and lateral rest position by the action of the spring 24.

Col. 4, l. 52 to col. 5, l. 7. This passage refers to "when" as "at this time," i.e., when the planar spring is flexing and the cylinders, or analogously, the legs of the trampoline, have not yet lifted out of their moorings. In other passages, the written description states: "The instant at which the stylus tip 15 first contacts a workpiece can be detected in various possible ways," col. 6, ll. 10-11, that the photoelectric sensor is responsive to motion caused "when the stylus 14 begins to deflect upon contact with a workpiece," col. 6, ll. 33-34, "when the stylus 14 is deflected by contact with a workpiece, the cage 86
initially remains stationary in its kinematic rest position," col. 8, ll. 60-63, "all of the embodiments of FIGS. 4-10 may have any of the arrangements for detecting the instant of contact between the stylus tip and a workpiece," col. 9, ll. 16-20, and:

In operation, when the stylus 14 is deflected by contact with a workpiece, at first the skirt 72 and cage 64 lift or tilt bodily from the surfaces 74. . . . Also for the same reason, when eventually the stylus returns to its rest position, there is little or no hysteresis in its rest position.

However, the above bodily lifting or tilting of the cage 64 upon deflection of the stylus only lasts for a very small amount of stylus deflection.

Col. 8, ll. 11-13 (emphasis added to all quotations). These passages make abundantly clear that "when" in the patent means at the time of, and not some appreciable time thereafter. See Autogiro Co., 384 F.2d at 397, 155 U.S.P.Q. (BNA) at 702-03 ("Words must be used in the same way in both the claims and the specification.").

To the extent that these passages refer to the preferred embodiment, they cannot be read into the claims without some hook. The claim term "when" is that hook. Each of the passages above show that the patentee wanted "when" to mean as soon as possible after contact. In contrast, Renishaw's proferred construction of "when," which would sweep in any time whatsoever after contact, is so broad that it would require us to ignore the abounding statements in the written description that point decidedly the other way.

Renishaw might have us save its claim by placing a functional limitation on the claim such that "when" would permit signaling at any time after contact but no longer than would permit accurate measurement of the workpiece. However, this limitation appears nowhere in the claims; rather, it comes from a concept of operability. To the extent Renishaw must refer to the written description, the patentee's extremely detailed account of his invention in that written description shows that his aim was to generate a signal as soon as possible after contact, not to generate a signal at appreciable times after contact. Any delay in signaling with Renishaw's probes creates an unrecoverable error, because they must equate the position of the probe at the moment of signaling with the position of the workpiece. Therefore, delay in signaling while the probe continues to move creates an error. The patentee strove to eliminate this error, and the entire patent document exhibits his intent to make the delay between contact and signaling as small as possible.

Our construction of "when" matches that of the district court. Although the district court initially construed "when" to mean "at the time that," it recognized that its choice of words could be read out of context to require immediate signaling, a physical impossibility. The district court therefore clarified its construction as follows:

While it is of course true that the laws of nature dictate that no detection device can be "absolutely instantaneous," the claims, specifications, figures, and Mr. McMurtry's testimony confirm that the patented probes signal as soon as possible when the stylus tip contacts the workpiece. The quicker the Renishaw probes trigger, the better their performance. In short, the patents teach the quickest signaling possible, and there is no suggestion otherwise. In fact, Mr. McMurtry stated that he taught good probes with quick signals, "wouldn't do anything but that, but to teach the best."

Renishaw, 974 F. Supp. at 1071. Consistent with this understanding and with the understanding that the claimed probes operate at a micron-level scale, we hold that claim 2 covers probes which signal within a nonappreciable period of time after contact such that the delay in signaling is insignificant when compared to the sensitivity and accuracy of the probe.

The displacing step (c) also provides for "stopping the relative displacement of corresponding contact surfaces when said testing determines said alignment and existence of correct electrical contact." As with displacing, the parties dispute whether stopping can be done manually. They also dispute whether "stopping . . . when" requires stopping as soon as the test is positive or whether the claim embraces a more leisurely stopping as well.

As to whether stopping may be manual, the ALJ concluded that it could be. In the Matter of Certain Removable Electronic
Cards, Inv. No. 337-TA-396 (Initial Determination) [hereafter "ID"] at 55. The Commission disagreed. "We believe that the failure to describe a display element of some kind, or otherwise indicate how the user would know to perform stopping, is significant." ITC at 14. "We find that the specification does not teach that stopping can be performed manually."

This Court also finds that stopping cannot be accomplished manually. The term "stopping" alone does not require this result. But taken in context, the specification clearly contemplates automated stopping. Even in the alternative embodiment allowing for manual displacement, the inventor presumes that stopping will be accomplished by the electric device rather than the card holder. Col. 8, Ins. 26-37. As to the Commission's reasoning, it is not just the absence of a display element but the absence of any means for ensuring that once good electrical contact is achieved, it is maintained during manual stopping. Thomson's reference to the file wrapper is more on point for this purpose, because Moreno did stress to the PTO the non-obviousness and novelty of his invention for performing a electric test to achieve good contact. The Court understands Moreno's statement that in his invention the card is "subsequently aligned[] by an electric device," although appearing to refer to displacing, actually refers to stopping because the card is "aligned" at the point that displacement stops. See Prosecution History at 1100133.

On the question of how quickly stopping occurs, Thomson urges that it be done as soon as possible. Innovatron argues that the term "stopping . . . when" does not mean "stopping . . . as soon as" but "stopping . . . if" good contact has been established, without a temporal limitation. The Commission held that

The phrase 'stopping . . . when' [] mean[s] stopping that occurs as a result of a positive test for correct alignment and electrical contact, and that is instantaneous or nearly instantaneous such that relative displacing is halted before the corresponding contact surfaces are moved from a position of proper alignment and correct electrical contact to a position out of such alignment and contact.

ITC at 15.

This Court concurs in the Commission's reading. The most common use of the term "when" is to indicate a point in time. For example, of the six definitions set forth in one respectable dictionary, the first five have a temporal meaning; only the sixth supports Innovatron's conditional reading. See WEBSTER'S II at 1313; see also Renishaw, 158 F.3d at 1250-53 (construing "when" to mean "as soon as" rather than "upon condition" after extensive discussion). The specification also supports reading "when" to mean "as soon as." When disclosing his invention, Moreno wrote:

(d) Testing . . . and stopping the . . . displacement when the electric contact has been established. This step of the process has as it [sic] purpose, in combination with the preceeding [sic] steps, to facilitate the rapid placement in contact because as soon as this has been done, the process stops.

Col. 2, Ins. 18-24. Either the specification guides selection of which ordinary meaning to ascribe to "when," cf. Renishaw, 158 F.3d at 1251, or, alternatively, even if "when" did not have "as soon as" as its ordinary meaning, Moreno has acted as his own lexicographer and imposed that meaning in the disclosure.

"Calculating . . . When the Animal May Be Released"

Representative claim 1 requires a step of "in response to entry of a selected drug treatment requiring a withdrawal period, calculating in the computer means, for the selected drug treatment, when the animal may be released from the feedlot." Although the term "when" is subject to different shades of meaning, the context of its use in this case does not support the district court's construction. In the phrase "when the animal may be released," the word "when" identifies the point in time at which a discrete act (the animal's release) is permitted. In that context, the term "when" is best understood to refer to the point in time at which release is first permitted, although it does not specify whether that point in time must be identified by hour, day, week, or other temporal reference. By analogy, in the phrase "when the prisoner is in prison," the term "when" would be understood to refer to the entire period of the prisoner's incarceration. But in the phrase "when the prisoner may be released," the term "when" would be understood as referring to the point in time at which the prisoner will be set free, whether it be the day, month, or year of release.
The district court's construction of the term "when," as used in the phrase "calculating . . . when the animal may be released" is also inconsistent with the patent's description of the invention. The Abstract, for example, explains that if a drug treatment has a withdrawal period, "a release date is calculated." And the Summary of the Invention similarly states that if a selected drug treatment requires a withdrawal period, "a release date is calculated for the animal based on the treatment date." One of the embodiments described in the patent's written description states that the computer that performs the calculations recited in the claims "calculates from the treatment data the earliest release date of the animal thereafter." Each of those references supports Lextron's argument that the term "when" in the phrase "calculating . . . when the animal may be released" refers to the point in time at which release is first permitted.

Invoking the doctrine of claim differentiation, Micro Chemical argues that the clause "when the animal may be released" cannot be interpreted as being equivalent to the phrase "earliest permitted release date," because the latter phrase is used in several dependent claims, which would otherwise be identical to the claims from which they depend. The answer to that argument is that the dependent claims add limitations other than the reference to the "earliest permitted release date." Those claims are thus distinguishable from the independent claims without the need to rely on a difference between the clause "when the animal may be released" and the phrase "earliest permitted release date." For example, dependent claim 8 differs from independent claim 1 in that claim 8 requires that the computer compare an animal's earliest permitted release date with the date that the animal is scheduled to be shipped from the feedlot, while claim 1 requires only that the computer calculate when the animal may be released from the feedlot.

Finally, Micro Chemical relies on the prosecution history of the '505 patent to support the district court's claim construction. In particular, it points out that, late in the course of the prosecution, the clause "when the animal may be released" was substituted for the phrase "the earliest permitted release date" in each of the independent claims. That change, Micro Chemical argues, must be regarded as broadening the claims so that they required only that "some withdrawal-related calculation be made."

While the claims as amended may be somewhat broader than they were before the amendment, in that they do not require the calculation of the exact date of permitted release, we find no support for Micro Chemical's assertion that the amendment broadened the claims so much that they would require only that "some withdrawal-related calculation be made," or that the system identify "some date or period of time after the drugs administered to the animal have cleared the animal's system," as Micro Chemical argues. When the claim language was changed, Micro Chemical's patent counsel described the adoption of the "when the animal may be released" clause, along with other changes made at the same time, as designed simply to "clarify [the] coverage." Because the revised claim language does not support Micro Chemical's proposed construction, we are satisfied that the term "when" refers to the beginning of the period in which the animal may be released from the feedlot, which is contrary to the claim construction adopted by the district court.

The dispute between the parties concerns only the meaning of the term "when" in this claim term. Briefly, Defendant contends that in the context of this claim term, the word "when" is used to explain that ticket transfer is completed instantaneously after the ask price equals the bid price. Defendant's construction for this claim term is almost exclusively dependent upon the Court accepting Defendant's proposal that the claims be limited to "exchange type" sales formats.
However, as explained above, the Court declines to limit the claims to "exchange type" formats. The Court will thus not adopt Defendant's proposed construction.

Defendant acknowledges "that 'when' can be either a signifier of causality or proximity in time." (D.I. 57 at 16 (citing Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250-51 (Fed. Cir. 1998).) Likewise, the Federal Circuit has explained that "when" has several meanings and that the particular meaning that prevails depends upon the context. Renishaw, 158 F.3d at 1250-51. Here, the specification explains that "exchange type" transactions are distinguishable from "auction type" formats because, in the former, "sales are made instantaneously when a bid price equals an ask price for a ticket." '809 patent at 4:44-50. Thus, the specification identifies embodiments where transactions are completed the moment a bid price equals an ask price and embodiments where the sale is made at some point after the bid price equals the ask price. In view of this evidence, the Court concludes that the term "when" should be understood broadly, as Plaintiff contends. Accordingly, the Court will construe the claim term "completing a transfer of the paperless tickets when the bid price equals the ask price and the ask quantity is equal to or greater than the bid quantity" to mean "transfer of the paperless tickets is completed at, during, or after the time that the bid price equals the ask price and the ask quantity is equal to or greater than the bid quantity."

1. The "When" Limitation

Zi argues that the district court erred by construing the claim limitation "causing the display means to display the shape of a character . . . when the code numbers entered by the entering means uniquely identify said character" as requiring that the system wait until a unique code is entered to display a character for selection. '352 patent, col. 21, ll. 27-29 (emphasis added); Zi, slip op. at 5-6. According to Zi, the district court applied an incorrect temporal limitation to the claim term "when" by improperly importing limitations from the written description and misconstruing the prosecution history. Zi proposes that the word "when" should be construed to mean "at or during the time that" or "at any and every time that" such that a character is displayed at the time it is uniquely identified. Zi also argues that the court's interpretation excludes two of Zi's preferred embodiments from the claims, i.e., the duplication and compound character features, and results in an inconsistency between claim 1 and dependent claims 7 through 9.

Tegic responds that Zi's proposed broad claim construction is not supported by the written description and prosecution history. In particular, Tegic points to Zi's assertion during prosecution of patentability over Wong's U.S. Patent 4,505,602, in which Zi stated that characters are displayed "as soon as" they have been uniquely identified. Applicant's Resp. to Second Office Action, at 7. According to Tegic, construing the term "when" as broadly as "at any time that" would ignore a critical temporal distinction between Wong and the claimed invention. With respect to the embodiments that Zi asserts display characters before unique identification, Tegic responds that the patent teaches the minimization of the duplication embodiment, which is therefore not within the scope of the claims. Tegic also argues that the duplication embodiment occurs only when unique identification is impossible and therefore does not occur "before" unique identification, a non-event in this context. As for the compound characters embodiment, Tegic argues that compound characters are not displayed until they are in fact uniquely identified and as such are consistent with the district court's narrow claim interpretation.

In interpreting claims, a court "should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history." Vptronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1996). "The words of a claim are generally given their ordinary and accustom meaning, unless it appears from the specification or the file history that they were used differently by the inventor." Carroll Touch, 15 F.3d at 1577, 27 U.S.P.Q.2D (BNA) at 1840. Furthermore, independent claims should be construed consistently with the claims that depend from them. Wright Med. Tech., Inc. v. Osteonics Corp., 122 F.3d 1440, 1445, 43 U.S.P.Q.2D (BNA) 1837, 1841 (Fed. Cir. 1997).

We agree with Zi that the district court interpreted the term "when" too narrowly by requiring that the claimed system "wait until the unique code is entered to display the appropriate character for selection." Zi, slip op. at 5-6 (emphasis added). Under the district court's interpretation, the system cannot display any character that might be the target character unless and until the operator enters code numbers that uniquely identify that character.
The written description does not support this interpretation. The district court referred, inter alia, to the caption to Figure 10 to justify its narrow reading. Zi, slip op. at 6; '352 patent, Fig. 10 ("Keystroke entry continues until the character itself is identified on the 13th stroke. It then appears in the 'pending' area and will be moved to the text line by the space bar, if the operator accepts it as correct.") (emphasis added). However, Zi is correct in asserting that the claims should not be limited by the embodiment described in Figure 10, especially in light of other embodiments of the invention that display candidate characters before unique identification. See, e.g., Laitram Corp. v. NEC Corp., 163 F.3d 1342, 1347, 49 U.S.P.Q.2D (BNA) 1199, 1203 (Fed. Cir. 1998) ("[A] court may not import limitations from the written description into the claims.") (citations omitted).

Tegic points to another discrete statement from the specification to support a narrow claim construction:

Controller 24 identifies each stroke entered with a code number, and determines from a comparison of the string of code numbers entered to strings stored in storage 26 whether a particular character has been uniquely identified. Once this happens, such character is retrieved from the shape storage 28 and displayed in the pending character area 52 on the display screen of monitor 30.

'352 patent, col. 12, ll. 8-15 (emphasis added). That description, according to Tegic, temporally limits the claims to read only on those devices displaying characters after unique identification. We disagree. We read that statement as meaning only that a character must be displayed at the time of unique identification. The "comprising" transition term of the claim opens the claim to covering systems in which characters are displayed at different times according to different retrieval and display protocols, as long as the claimed retrieval and display features are present in such systems. The specification itself describes embodiments in which target characters are displayed for selection before they are uniquely identified.

One such embodiment addresses the problem of duplication, which occurs when a string of entered code numbers corresponds to more than one character. To solve this problem, the specification states:

The most commonly used of these [duplicate] characters will be sent to the screen on monitor 30; at the same time one or more less commonly used alternative characters are shown in parenthesis alongside the most commonly used character so that the operator can make a choice by a single keystroke.

'352 patent, col. 16, ll. 14-20. Two candidate characters are thus displayed for selection before unique identification; the operator then selects the target character for display in the text field. Although Tegic correctly points out that unique identification by a string of code numbers is impossible when a string identifies more than one character, we understand the duplication embodiment to do exactly what Tegic asserts is outside the scope of the claims--it displays a candidate character before unique identification--even if unique identification by a string of numbers never occurs.

We reject Tegic's argument that the claims do not cover embodiments displaying candidate characters because the patent teaches that duplication is a problematic feature to be minimized and it occurs less than 0.5% of the time in its preferred embodiment. '352 patent, col. 16, l. 50. Even if the patent tries to minimize duplication, the "problem" is a result of the claimed invention and the claims should not be construed to exclude its solution, as taught in the written description. We recently rejected a similar argument in Northern Telecom Ltd. v. Samsung Electronics Co., 215 F.3d 1281, 1293, 55 U.S.P.Q.2D (BNA) 1065, 1073-74 (Fed. Cir. 2000). Samsung argued that a statement in the written description that ion bombardment should be reduced or avoided specifically excluded ion bombardment from the scope of the claims. We disagreed:

Indeed, wholly contrary to Samsung's view, that sentence clearly contemplates that ion bombardment may be present in the claimed process, but states that the patentees prefer that it be reduced or eliminated. In other words, the low level of ion bombardment in conjunction with the claimed plasma etching is plainly a preferred embodiment . . . .

Id. Similarly, the statement in the specification that duplication should be minimized contemplates that duplication--and its concomitant display of candidate characters not uniquely identified--is inherent in the claimed system.

Another embodiment displaying a candidate character before unique identification of the target character relates to compound characters, which have a specific meaning created by the conjunction of two or more individual characters. '352 patent, col. 5, l. 65 to col. 6, l. 2. Dependent claims 7 through 9 relate to such a system using compound code strings that
will display a candidate character according to character context information in the database. For example, the characters for "electricity" and "child" mean "electron" when combined. In practicing the claimed invention, when the first string of numbers for "electricity" has been entered and the character displayed, the user need only input two of the three code numbers necessary to uniquely identify the next character for "child" before it appears on the screen for selection. If this candidate "child" character is the target character, the user can select it without entering all three code numbers normally required for unique identification of "child." If "child" is not the target character, i.e., "electron" is not the target compound character, the operator may continue entering code numbers, the candidate compound character for "child" will disappear, and the target character desired after "electricity" will be displayed when it has been uniquely identified according to claim 1. See '352 patent, col. 11, ll. 14-31; col. 16, ll. 1-8.

Tegic asserts that the claimed compound characters are displayed only after they are uniquely identified, in accordance with the district court's claim construction, because the later character in the compound is displayed when the sequence of code numbers matches the string for the compound character. '352 patent, claim 7, col. 22, ll. 4-9. Nonetheless, this embodiment of the invention displays candidate compound characters before they are uniquely identified according to the limitation described in claim 1 for identifying characters individually. If the user's target character is not the displayed compound character, then the compound character disappears and the target character will be displayed at the time it is uniquely identified in accordance with claim 1.

The district court did not take into consideration in its analysis the duplication and compound features of the claimed invention. It stated that "there is nothing in the claims, the specification, or the prosecutorial history to suggest that [the applicant] contemplated, much less invented, a system that was capable of identifying desired characters before a unique code was entered." Zi, slip op. at 6. We disagree. The duplication and compound string features in the '352 patent clearly describe a system capable of identifying and displaying candidate characters before unique individual identification.

We thus construe the term "when" as requiring only that a character be displayed at the time it is uniquely identified, an event that must occur sooner for those characters with trimmed codes than for those characters with untrimmed codes. This construction of the term "when" avoids reading the claims to exclude the preferred embodiments for duplication and compound character context data. It preserves the consistency of claims 7 through 9 with claim 1.

Tegic argues that statements made during prosecution to distinguish the Wong patent limit the claims to systems that wait to display a character until a uniquely identifying code string has been entered for that character. Wong teaches a method with "untrimmed" codes that displays an operator's desired character when the operator has entered in the full sequence of numbers corresponding to each pen stroke. See col. 11, l. 26 to col. 12, l. 1-25. During prosecution, Zi stated:

Wong does not function in the same way to produce the same results as the different elements of claim 1. The different elements of claim 1 cause characters to be displayed as soon as the characters have been uniquely identified. This happens when the user is inputting characters whose strings of code numbers are shorter than the number of strokes in the characters.

Applicant's Resp. to Second Office Action, at 7 (emphasis added). We do not agree with Tegic that the district court's temporal distinction is necessary to distinguish the claimed invention from Wong. To the contrary--the court's reading of "when" as "wait until" in no way distinguishes over that patent. Wong never displayed candidate characters before unique identification; rather, it only displayed characters after they had been identified with a full code sequence. See Wong, col. 11, l. 26 to col. 12, l. 25.

The statement made during prosecution that "the different elements of claim 1 cause characters to be displayed as soon as the characters have been uniquely identified" must be construed in light of the statement immediately following: "This happens when the user is inputting characters whose strings of code numbers are shorter than the number of strokes in the characters." For the claimed invention, the triggering event of "unique identification" usually (but not always) occurs sooner than in Wong, because, for some characters, a partial code string will trigger the event of unique identification when only one possible character corresponds to the partial string. In Wong, the entire code string must be entered for all characters to trigger unique identification and display of the target character. See id. Thus, the statement that the characters of the patent are displayed as soon as they have been uniquely identified distinguishes the invention from Wong because unique identification generally occurs before it does in Wong and the characters appear before they would appear in Wong.

The specification supports this interpretation: "Where uniqueness is established at an earlier point . . . controller 24 causes
the character to be displayed at the monitor 30 even before the entry of the entire string of code numbers for such character is completed." '352 patent, col. 10, l. 66 to col. 11, l. 3. The temporal limitations imposed by the specification and the prosecution history require only that the unique identification and display of characters occur sooner for the claimed invention than for other systems with full-length codes.

We also reach our conclusion by considering what "characters" were referred to by Zi during prosecution to distinguish over the Wong patent: "The different elements of claim 1 cause characters to be displayed as soon as the characters have been uniquely identified." Applicant's Resp. to Second Office Action, at 7 (emphasis added). The characters referred to with emphasis cannot logically include all characters, including candidate characters not yet uniquely identified, in the context of the sentence referring to display of uniquely identified characters. The statement should not be read to exclude systems that display candidate characters--characters that have not been uniquely identified--prior to the triggering event of unique identification. Such a limitation would read out preferred embodiments from the scope of the claims and render claim 1 inconsistent with claims 7 through 9, which depend from it.

We finally note that Zi distinguished the invention over Wong on an additional basis during prosecution. In response to a rejection for anticipation over Wong, the '352 applicant first stated that "for all the characters in the collection, the order of the code numbers in the string is the same as the predetermined writing sequence of strokes so that the string always begins with a code number for the first stroke of the predetermined writing sequence and follows the sequence without interruption until the end of the string." Applicant's Resp. to Second Office Action, at 5. In contrast, Wong's encoding scheme employs exceptions to the traditional writing order sequence. Thus, the claimed invention is distinguishable over Wong in more than one respect. The validity of the '352 patent over Wong does not require Tegic's proposed narrow construction.

12. "SPNAN receives said first responsive information when the first user has reconnected the first network accessible node to the network" ('702 patent)

<table>
<thead>
<tr>
<th>Beneficial's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>No construction is necessary (except for the individual terms that will be separately construed).</td>
<td>&quot;SPNAN receives the first responsive information at the time that the first user reestablishes the ability of the first network accessible node to communicate with the communications network&quot;</td>
</tr>
</tbody>
</table>

Alternatively, "SPNAN receives said first responsive information when the first user has established a subsequent different network connection between the SPNAN and the first network accessible node"

The Court finds that Defendants' proposed construction of the term "when" to mean "at the time that" is consistent with its meaning in the context of the '702 patent. Further, Beneficial acknowledges that Defendants' proposed construction of the terms "when" and "reconnect" are consistent with the ordinary meaning in the context of the '702 patent. Claim 53 explicitly requires that the SPNAN receive the first responsive information when the first network accessible node is reconnected to the network. Thus, the Court rejects Beneficial's proposal to substitute the term "network" with the term "SPNAN." Further, the claim language implies that the network accessible node is actually reconnected with the network, not that the node merely has the ability to connect to the network as Defendants propose. Thus, the Court construes the phrase "SPNAN receives said first responsive information when the first user has reconnected the first network accessible node to the network" to mean "SPNAN receives said first responsive information at the time that the first user reestablishes a subsequent different network connection with the communications network."
Both patents also refer to "when the market changes." Patent '304's claims 1 and 27 use the term, claiming: "displaying the bid and ask display regions in relation to fixed price levels positioned along the common static price axis such that when the inside market changes, the price levels along the common static price axis do not move and at least one of the first and second indicators moves in the bid or ask display regions relative to the common static price axis." Patent '132's claim 14 states: "(A) display device for displaying market depth of a commodity, through a dynamic display of a plurality of bids and a plurality of asks in the market for the commodity, including the bid and ask quantities of the commodity, aligned with a static display of prices corresponding thereto, wherein the static display of prices does not move when the inside market changes...." Although we do not view the parties' constructions as diametrically opposed to one another, we accept plaintiff's construction. "When the market changes" is construed as "at the time that new data reflecting a change in the inside market is received." Plaintiff, and this construction, recognizes that "when" is not synonymous with "instantaneously." Rather, "when" encompasses the concept that the update will not appear on the trader's screen until the software and/or computer receives, processes, and displays the new market information.

2. "whenever" (1[\[b\]], 11[p.3])

(i) Claim Construction

Two issues arise regarding interpretation of the word "whenever" in claim 1 and claim 11 of the '903 Patent: (1) whether claim 1 includes the situation where a condition to enable a vend will not be established, even if there is sufficient credit for the selected product, until the selection switch has been actuated for a sufficient time, and (2) whether claim 1 and claim 11 include the situation where the means under control of the accumulator will not establish a condition to enable a vend operation to take place until a product selection switch has been actuated and additional logic is satisfied. Coinco argues that the word "whenever" should be construed to allow for a determination that the selection switch has been actuated for a sufficient time and that the accumulator's logic to establish the condition may also include actuation of the product selection switch and any additional logic. Mars argues that "whenever" must exclude the situation where a determination must be made that the product selection switch has been actuated for a sufficient time and that the accumulator's logic to establish a vend condition may not include a test for the actuation of a product selection switch and additional logic.

(a) "whenever" does not require the selection switch to be actuated for sufficient time

The Court finds that the language of the claim itself and of the claim in light of the specification does not state any limitation on the length of time that the select switch must be held prior to the establishment of a condition enabling a vend operation. Claim 1 of the '903 Patent describes "means under control of the accumulator whenever an amount accumulated at least equals the amount of a selected vend price for establishing a condition to enable a vend operation to take place." '903 Patent col. 8, lines 28-32.

(b) "whenever" does not permit the output signal to depend upon other logical requirements

The Court also construes the "whenever" language in both claim 1 and claim 11 as a limitation that requires the accumulator to produce an output signal at every time when the amount accumulated exceeds a set price; the output signal may not depend upon any other logical requirements. n24 The claim language does not suggest that any other logic may play a part in determining whether to assert the accumulator's output; in fact, "whenever" appears to exclude other logical requirements. The specification confirms this view:

The selection monitor circuit 58 is constructed so as to be able to establish a circuit condition which has a control effect on the operation of the relay 45. This control effect causes the AND gate 63, when the change maker 56 has sufficient accumulation, to be able to energize the vend relay 45 . . . .

'903 Patent col. 4, line 65 - col. 5, line 3. Again, the only requirement prior to an accumulator output signal is that the accumulator "has sufficient accumulation," which is not related -- in either the claim language or the specification -- to the actuation of a product selection switch and other logic. n25 The '903 Patent's language prohibits any other logical test prior to asserting the accumulator's output.
4864

Claims 21 and 22 are at issue. Claim 21 follows, showing in bold typeface the terms whose construction was in dispute:

21. A method of messaging among at least two remote user terminals ("RUTs") in addition to a host computer ("Host") that uses communication software and hardware to connect to a communication network that supports asynchronous transport mode and serial data transmission, said Host serving as a central messaging information center that provides a plurality of RUTs with data in an integrated application program interface ("IAP") that coordinates the operation for said Host's other sub-systems that comprise a programmable application ("PA") supporting IAP menu functions, system commands, and store-and-forward messaging, an index system reflecting at least one published index that divides broad economic activity into mutually exclusive numbered topics that are used routinely in public and private sectors, a memory configured to correspond to said index system using an operating system, said PA's configuration editor for storage, and PA files, and said method comprises the steps of:

storing in said Host's memory, file capacity calibrated to each subdivision of said index system;

modifying said Host's memory, using said PA to store in a complete series those topic boards identified by multiple-digit numbers that match all multiple-digit numbers in said index system;

storing inside said IAPI sufficient logical progressions of menus with commands for a user at any of said plurality of RUTs to select from said topic boards and enter a topic board matching an index number therein by entering input associated with said index number;

and establishing communications over said network between said Host and said plurality of RUTS to enable said PA to control said Host's processing of said RUTs's commands, and transmit over multiple lines messages and data on a selected topic board;

whereby a trade network supports users at said plurality of RUTs who are each guided by said IAPI to select an economic activity, to identify that index topic that corresponds to said activity, to enter that topic board dedicated to said topic, and who are collectively able to concurrently engage in interactive data messaging on said topic boards.

Mr. Hoffer challenges the district court's construction and definition of several claim terms. We review only the construction of the "whereby" clause, for the "interactive" limitation therein suffices to support the district court's finding of noninfringement.

The "Whereby" Clause

Mr. Hoffer states that the district court erred in holding that the "whereby" clause limits the claims, pointing out that the Federal Circuit has held that "a whereby clause in a method claim is not given weight when it simply expresses the intended result of a process step positively recited." Minton v. NASD, 336 F.3d 1373, 1381 (Fed. Cir. 2003). It is correct that a "whereby" clause generally states the result of the patented process. However, when the "whereby" clause states a condition

n24 Claim 11 has similar language to claim 1: "means for producing an accumulator output signal whenever the amount accumulated therein at least equals the price of a selected vend." '903 Patent col. 9, lines 52-54.

n25 Indeed, the structure of every patent listed as a potential accumulator, including the '255 Patent, has a hard-coded value for what constitutes "sufficient accumulation." Therefore, these accumulators may assert an output indicating sufficient accumulation regardless of the actuation of a product selection switch. Mars' U1 microprocessor does not use a hard-coded value, but only learns that value upon actuation of a product selection switch.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
that is material to patentability, it cannot be ignored in order to change the substance of the invention.

Mr. Hoffer proposes that with elimination of the "whereby" clause, claim 21 would not require that the network have the capability of interactive data messaging among users of the system. He explains that collaborative messaging between two or more users may indeed be implemented by adaptation of known sub-systems to his multimode messaging and conferencing on indexed topics of trade, but that interactive messaging is not required by his invention. He argues that since the whereby clause does not state the mechanics of how to update topic board files or store menu files for navigation, or show what enables host programmable applications to transmit to network services, the whereby clause simply describes the overall objective but does not limit the claim to interactive data messaging.

The district court held that such a construction would be contrary to the fundamental invention, which the specification describes as interactive data messaging. The whereby clause describes a network of users at multiple remote user terminals who are "collectively able to concurrently engage in interactive data messaging." This capability is more than the intended result of a process step; it is part of the process itself. This interactive element is described in the specification and prosecution history as an integral part of the invention. The "Summary of the Invention" recites that "from a remote terminal, the user would enter selected topic boards on a Host Terminal System ('Host System') to address messages to, and receive messages from, other intended users." Col. 6, lines 64-67. Thus, the users communicate with each other. The prosecution history is in accord. Mr. Hoffer points to an amendment during prosecution which made the disclaimer that "newly added [patent claim 21] is an independent method claim . . . that satisfies the Examiner's Statement by solely teaching methods distinct from real-time messaging." Amendment, September 29, 1997. However, there is a difference between real-time messaging and interactive messaging, which can occur in real time or asynchronously.

We confirm the district court's construction of the "whereby" clause as requiring interactive data messaging, and that claim 21 is thereby limited to a method that provides interactive data messaging.

GO BACK

**4865**

a. "Whereby" Clause

Plaintiffs dispute that the clause "whereby data may be selectively transmitted to and received and stored by a remote object only after such remote object has been identified as the correct remote object to receive such data" has been met in the accused products for claims 1 and 4-6. Plaintiffs argue that the accused systems do not infringe the '807 Patent claims because the Plaintiffs' scanner (or interrogator) sends data to a tag both prior to and after identifying the correct tag. In addition, Plaintiffs contend that the accused scanners transmit data to all tags within its range, regardless of whether the scanner has information for that particular tag. Citing to witness deposition testimony, Plaintiffs conclude that contrary to the claim limitations of the '807 Patent, data is transmitted to both correct and incorrect tags.

TransCore, citing to Lockheed Martin Corp. v. Space Systems/Loral, Inc., 324 F.3d 1308 (Fed. Cir. 2003), first responds that the "whereby" clause, although construed by the Court, is not a limitation. Lockheed Martin is inapposite to the facts in this case. In Lockheed, the Federal Circuit found that it was error to consider a "whereby" clause, which merely explained the function of a "means for" clause, since the whereby clause "merely state[d] the result of the limitations in the claim." Id. at 1319. The instant claim in the '807 Patent is not a "means plus function" claim, as was the case in Lockheed Martin. In addition, the whereby clause in the '807 Patent adds additional structure, i.e. limitations, to the claim by further explaining that the data may be selectively transmitted, received and stored to the correct remote object only after it has been identified. As such, TransCore's argument regarding the whereby clause's non-limitation status lacks merit.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 Alternatively, the Court also finds that TransCore is estopped from presenting arguments regarding the non-limitation status of the whereby clause in light of previous representations to the contrary. As pointed out by Plaintiffs, TransCore argued in its opposition for invalidity that the "whereby" clause has structure and therefore should be so construed. Accordingly, TransCore is barred from taking an opposing stance in its brief. See Lewmar Marine, Inc. v. Barent, Inc., 821 F.2d 744, 747 (Fed. Cir. 1987).

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

- 5084 -
TransCore also asserts that Plaintiffs are incorrect in their interpretation of the whereby clause. TransCore specifically argues that the '807 Patent system must at the initial stages inherently send data to all tags that are within range of the RF signal emanating from the interrogator. TransCore points to testimony from Plaintiffs' technical expert that Plaintiffs' system operates in this manner. TransCore states that this Court's claim construction supports its argument when it construed the whereby clause as "the interrogator may selectively transmit, receive and store data to a remote object only after the remote object has been identified as the correct remote object to receive data from the interrogator", i.e. that in order for the remote object to store data to a remote object from an interrogator that has transmitted and received a signal from the same remote object, the correct remote object must first be identified. Thus, TransCore argues that even where incorrect remote objects receive data from an interrogator, such systems would fall within the scope of the claims as long as the interrogator cannot store data to these incorrect remote objects.

The parties, therefore, have a dispute as to the meaning of this Court's claim construction of the whereby clause. This Court, in construing the whereby clause, specifically responded to Plaintiffs' argument that "no data transmitted by the interrogator is stored by the remote object unless and until the remote object has transmitted its entire identity data to the interrogator" by stating that the "plain and ordinary meaning" of the claim refutes their construction. See Doc. No. 211 at 19. Similarly, the plain and ordinary language of this Court's construction of the whereby clause also goes against Plaintiffs' interpretation. This Court construed the whereby clause to mean "whereby the interrogator may selectively transmit, receive and store data to a remote object" only after the interrogator identifies the correct remote object. Id. (emphasis added). The presence of the conjunctive term "and" indicates that the interrogator performs all three functions, i.e. transmits, receives and stores data, only after the correct remote object has been identified by the interrogator. As such, whether an interrogator transmits data but does not store the information to the tag is irrelevant to the infringement analysis, and therefore does not take Plaintiffs' accused device outside the scope of the '807 Patent claims. Accordingly, Plaintiffs' argument lacks merit regarding the whereby clause.

4866

G. "Whereby said vehicle is caused to operate in a protocol selected from at least one alternative available in said preprogrammed memory"

This term means that after a program in the preprogrammed memory is sent to the vehicle's ECM, the vehicle is caused to operate according to the alternate program now residing in the preprogrammed memory. The vehicle must be responsive to the act of selecting a program while the vehicle is moving or while it is stopped, but otherwise in normal operation.

As discussed above, the inclusion of the "in transit" limitation is required by the language from the Brief Summary of the Invention: "The operation of the vehicle is changed by the control while the vehicle is in transit . . . ." (Id. at col. 2, ln. 43-44).

4. Claim 1: Element (b): Part (II)

Text:

... whereby the position of the lesion in the ultrasound image can be compared with a position of the lesion in the radiation therapy plan.

'026 Patent, col. 12, ll. 16-19.

NOMOS's Proposed Construction:

The whereby clause of element (b) of claim 1 should be construed to mean that the system must be structured to compare
the position of the lesion in the two dimensional image generated by the ultrasound probe with the position of the lesion identified in the radiation therapy plan.

NOMOS Opening Brief at 12 (quotation marks and citation omitted).

ZMED's Proposed Construction:

The claimed system must be structured to compare (undefined) the position of the lesion in the 2D image which is the direct output of the ultrasound probe with the position of the lesion identified in the radiation therapy plan.

ZMED Opening Brief at 21.

Construction:

The whereby clause of element (b) of claim 1 means "the system must be structured to compare the position of the lesion in the two-dimensional image generated by the ultrasound probe with the position of the lesion identified in the radiation therapy plan."

D. Ref. No. 59 "Whereby the voting selections marked on each paper ballot are imaged and recorded in accordance with a template corresponding to the jurisdiction identifier for that paper ballot."

This phrase is recited in Claim 1.

According to Defendants' construction of this claim, the voting selections on the ballot are imaged in accordance with a corresponding template and recorded in accordance with the template. Plaintiff construes this term to mean that the paper ballot is imaged and then is recorded pursuant to the identified template. The parties agree that the voting selections are recorded pursuant to the template. The dispute, therefore, is whether the term requires that the voting selections marked on the ballot must also be imaged pursuant to that template.

Comparing Claim 2 with Claim 1's requirements is instructive. Claim 2 provides for a first optical scanner to image the jurisdiction identifier of each ballot and a second optical reader to image the voting selections in accordance with the select template. There is no such language in Claim 1. Moreover, Claim 2 is dependent upon Claim 1, and "[t]he concept of claim differentiation 'normally means that limitations stated in the dependent claims are not to be read into the independent claim from which they depend.'" Nazomi Commune'n, Inc. v. ARM Holdings, PLC, 403 F.3d 1364, 1370 (Fed. Cir. 2005) (quoting Karlin Tech., Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999)) (alteration added). If Defendants' construction is accepted, Claims 1 and 2 would be identical, and the doctrine of claimed differentiation would be vitiated. Moreover, Path 320a in Figure 8 teaches that the ballot is imaged (Step 321), decoded (Step 323), and then a template is selected in Step 325. After that step, the voting selections are decoded in Step 327 and recorded and stored in Steps 330 and 332. (See Col. 15, ll. 16-31.) This is consistent with Plaintiff's construction of Claim 1 requiring only an imaging step. Claim 1 does not require a second optical reader. The specification of the patent support Plaintiff's construction. The ballots are imaged for the jurisdiction identifier and voting selections, and then a processor receiving the jurisdiction identifier selects a template for recording the voting selections. (Col. 2, ll. 3-10; Col. 15, ll. 2-15.)

For the foregoing reasons, the Court construes the term in Ref. No. 59 as follows:

The voting selections on each paper ballot are imaged and the choices/selections are recorded in accordance with a selected template corresponding to the jurisdiction identifier for that paper ballot.

4869
H. "Wherein a Credential is Previously Issued"

The court shall apply the ordinary definition this term. Thus, the term "previously issued" shall be construed to mean "existing or occurring prior to something else in time or order." 4 The preamble of claim 20 (from which claim 27 depends) of the '541 patent states that "a credential is previously issued to at least one of the parties." Thus, the credential must be issued prior to the steps of the claim. 5 The term "wherein a credential is previously issued" shall be construed to mean "the credential referenced in the claim must already be issued before the execution of the steps recited in the claim."

--- Footnotes ---

5 Plaintiff argues that the credential cannot be issued before step one of claim 20 because step one creates the VAN which is included on the credential. Step one of the claim does not state, however, that this is the first time the VAN is created. The patent specifically discusses re-creating the VAN to compare with the VAN from the credential to authenticate the credential. ('541 patent, col. 13, ll. 24-28) This is consistent with the claim language describing a method for securing information.

--- End Footnotes ---

D. "Wherein All the Selected Portions of Said Information Database in Each Tier Are Transmitted at a Corresponding Repetition Rate."

This term is closely tied to the "prioritized system of tiers" construed above. Claim 16 recited "said scheduling step including dividing said selected portions of said information database into a prioritized set of tiers, wherein all the selected portions of said information database in each tier are transmitted at a corresponding repetition rate, wherein the repetition rate for higher priority tiers is higher than the repetition rate for lower tier" (21:51-59). For this term, Comcast urges that the "selected portions" refer to "the part of the database that is scheduled for transmission, which is less than all of the database." It further proposes to limit the term to indicate that "[a]ll of the information in each tier is transmitted at a single repetition rate." Finisar proposes that the term should be defined as "transmitting the selected portions in each tier at a chosen repetition rate." 4

--- Footnotes ---

4 As noted above, the Texas Court construed this term together with "a prioritized set of tiers." It held that "dividing said selected portions of said information database into a prioritized set of tiers, wherein all the selected portions of said information database in each tier are transmitted at a corresponding repetition rate" to mean "placing each part of the information database selected for transmission into one or more groups of information, and transmitting each group at a chosen repetition rate" (Melgar Decl. Exh. B at 12).

--- End Footnotes ---

Claim 16 itself demands that each individual tier be transmitted at a single repetition rate because "all the selected portions of said information database in each tier" have the same repetition rate. This does not mean that the repetition rate for a tier itself cannot be changed to meet the publisher's or provider's needs. For instance, the specification taught that the "particular repetition rates associated with each tier of data and the amount of data allocated to each tier are selectable parameters that will be carefully considered in order to maximize utility of the system to the most subscribers" (col. 14:34-41). For example, during the middle of March of any given year, the provider anticipates a sharp uptick in interest in information about college basketball. The provider places those portions of the database in a higher tier with a more frequent repetition rate. By mid-April, there is less demand for that information, and thus the provider reduces the repetition rate.

Comcast also proposes that the entire database cannot be placed in a single tier. The term itself indicates that "selected portions" of the database are sent at a given repetition rate within a tier. The specification taught that "while a user has
access to perhaps a terabyte, or even 100 terabytes or more, of data, the total amount of data that systems in accordance with the present invention system can transmit in any one day is much more limited . . ." (col. 2:9-13). The aim of the invention was to give subscribers access to a very large amount of information using a relatively modest amount of bandwidth. This was to be done by sending only the data that a subscriber wanted from a virtually omniscient database. Finisar argues that "selected portions" could mean that all portions of the database are selected for a single tier, but it finds no support for this view in the patent. Were the invention able to send all the information in a single tier, there would be no need for the system of indices for accessing parts of the database, or the system of tiers for sending the information at different repetition rates.

Accordingly, the term "wherein all the selected portions of said information database in each tier are transmitted at a corresponding repetition rate" is construed as transmitting the selected portions of the database within a tier at a single, chosen repetition rate, wherein the selected portions per tier are less than the entire database.

Through trial and on appeal, the parties have narrowed the disputed issues of validity to a single point of contention--the placement of the load balancing software at either the DNS servers or the origin server. Therefore, our initial focus in the anticipation analysis is on the construction of claims 1 and 3, in particular whether claims 1 and 3 require the presence of load balancing software at the DNS servers. The issue before us is thus a relatively self-contained one. On the one hand, if claims 1 and 3 require load balancing at the DNS servers, the claims are not anticipated. On the other hand, if the claims do not require this limitation, they are anticipated by the '598 patent.

The only disputed limitation of claims 1 and 3 reads:

wherein in response to requests for the web page, generated by the client machines the web page including the modified embedded object URL is served from the content provider server and the embedded object identified by the modified embedded object URL is served from a given one of the content servers as identified by the first level and second level name servers.

'703 patent, col. 17, ll. 31-37 (emphases added).

Claim 3 is dependent upon independent claim 1 and includes the following additional limitation.

3. The hosting framework as described in claim 1 further including a redundant second level name server.

Id., col. 17, ll. 40-41.

Akamai contends that the '598 patent differs from claims 1 and 3 of the '703 patent in the placement of the load balancing software. Indeed, in its brief on appeal, Akamai stated:

The significant difference between the prior art '598 patent and the '703 patent claims on appeal was acknowledged and admitted by everyone throughout the trial. . . . In particular, C&W counsel told the jury the difference involves the fact that selection of the best computer server to deliver the embedded objects of the web page is done in the '598 prior art patent by "software . . . located at the origin server" whereas selection of the best computer server to deliver the content is done in the '703 patent "by software located at the DNS . . . ."

C&W argues that the location of the load balancing software is not a limitation in claims 1 and 3, and in the alternative, that while the '598 patent does not explicitly disclose the placement of load balancing software at the DNS servers, it is nevertheless inherent in the Internet and the '598 patent.

We agree that claims 1 and 3 do not include a load balancing limitation. While the written description unquestionably contemplates the preferred location of the load balancing software, claims 1 and 3 do not expressly require its presence. To support its reading of independent claim 1, Akamai points only to the term "identifying" in the "wherein" clause of claim 1 which states:

wherein in response to requests for the web page, generated by the client machines the web page including the modified embedded object URL is served from the content provider server and the embedded object identified by the modified
embedded object URL is served from a given one of the content servers as identified by the first level and second level name servers.

This language, however, requires only that the embedded object is "identified by the modified embedded object URL" and is "served from a given one of the content servers as identified by the first and second level name servers." The plain meaning of the claim language does not require any load balancing mechanism. Instead, it simply requires the embedded object to be served from "the content servers as identified by the first and second level name servers." Load balancing, if required at all, could be at either the DNS servers or the content provider server. The ordinary meaning of the term "identifying" in claims 1 and 3 covers standard DNS resolution, without any sort of load balancing. Absent evidence that a "patentee unequivocally imparted a novel meaning to [the] term[] or expressly relinquished claim scope during prosecution," we give the limitation its full ordinary and customary meaning. Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1323 (Fed. Cir. 2003); Teleflex, Inc. v. Ficsa N. Am. Corp., 299 F.3d 1313, 1325-26 (Fed. Cir. 2002); CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366-67 (Fed. Cir. 2002); Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998) ("Absent a special and particular definition created by the patent applicant, terms in a claim are to be given their ordinary and accustomed meaning.").

The only question that remains is whether the written description or the prosecution history unequivocally shows that the inventors imparted a novel meaning to the term "identifying" to include load balancing. Omega Eng'g, 334 F.3d at 1323; Teleflex, 299 F.3d at 1325-26. The written description does not specifically define the term "identifying." Rather, the discussion with respect to load balancing focuses on the DNS servers as performing "special functions," e.g., load balancing functions, without any reference to the term "identifying." See, e.g., '703 patent, col. 9, ll. 31-48. Similarly, the parties have pointed to nothing in the prosecution history with respect to the term "identifying." Akamai's only evidence that supports its special definition of the term "identifying" is the testimony of one of the inventors, Mr. Farber, of the '598 patent. Mr. Farber stated that: "the DNS in our system are a little different because we did the step of identifying . . . which repeater should be used by the browser as part of the, using [sic] the HTTP method instead of the DNS method." 3 This extrinsic evidence is not the unequivocal evidence, Omega Eng'g, 334 F.3d at 1323, indicating the term "identifying" should take anything other than its ordinary and accustomed meaning. While this possibly suggests that the inventors believed the "identifying" step included a load balancing function, "what the patentee subjectively intended his claims to mean is largely irrelevant to the claim's objective meaning and scope." Solomon v. Kimberly-Clark Corp., 216 F.3d 1372, 1379 (Fed. Cir. 2000). It is also not testimony that clearly supports the proposition that the term "identifying" has a special meaning to one of ordinary skill in the art.

3 The "HTTP method" refers to placement of the load balancing software at the origin servers responsible for providing the HTTP container page.

Thus claim 1, as properly construed, does not include the limitation of the placement of the load balancing mechanism. The parties agree that the '598 patent discloses all the remaining limitations of claim 1. Because claim 1 does not require exact placement, it is therefore invalid as anticipated by the '598 patent.

Claim 3 similarly does not require placement of the load balancing software at the DNS servers. Claim 3 only includes the additional limitation that the hosting framework as described in claim 1 further includes "a redundant second level name server." On appeal, Akamai's primary argument echoes that of claim 1, namely that the load balancing software is located at the DNS servers. Akamai's only separate argument with respect to claim 3 is that "because [the] '598 patent did not even mention hierarchical DNS (i.e., more than one level), clearly the jury was entitled to reject the notion that [the] '598 [patent] also anticipated claim 3." This additional argument, however, fails to address C&W's contention that hierarchical DNS is inherent in any Internet system. Indeed, C&W proffered documentary evidence and testimony at trial that redundant domain name servers are inherent in any Internet-based application. See Dayco, 329 F.3d at 1369. Akamai points to no evidence whatsoever that contradicts the evidence presented to the jury at trial. Accordingly, we hold that any inference in favor of Akamai relating to the redundant second level server in claim 3 is unsupported by substantial evidence. The addition of a redundant second level DNS server does not save the validity of dependent claim 3. Claim 3 is therefore also invalid under 35 U.S.C. § 102 as anticipated by the '598 patent. 4
Judge Newman in her dissent specifically points out that the issue of anticipation is a question of fact. Claim construction, however, is a question of law. Before the factual question of anticipation may be addressed, a court must first properly construe the claims before it. Here, claims 1 and 3 were not properly construed by the district court. Therefore, a necessary first step in this court's anticipation inquiry was to properly construe the claims at issue.

Atmel contends that this passage, containing over twenty individual terms, should be construed as a single phrase. See Def.'s Second Brief at 48. Initially, the Court notes that the parties do not cite any case law to support the implicit proposition that it is appropriate for a Court under certain circumstances to provide a construction for a passage in the claims which contains such a large number of individual terms, nor do the parties provide any reasons why, even if permissible, the Court should construe this passage as a single phrase.

At the crux of Atmel's arguments regarding this phrase are two specific contentions. The first actually goes to what Atmel contends should be the construction of the individual terms "self-limiting" and "self-limiting thickness." Atmel contends that such terms would have had no independent meaning to a person of ordinary skill in the art. See Def.'s Second Brief at 48. Furthermore, Atmel contends that the patentee chose to be his own lexicographer and to provide clear definitions for these terms in the specification. See Def.'s Post-Hearing Brief at 19. The Court agrees. The specification states:

The self-limiting effect is characterized by a tungsten formation rate at 10 minutes that is less than 10% of the initial equilibrium rate. The self-limiting thickness is the tungsten thickness under these conditions achieved at 10 minutes.

Atmel goes even further, arguing that the claim language in question should be construed as not covering the use of an environment that includes a cold wall reactor in the temperature range of 250 to 600 degrees C. See Def.’s Post-Hearing Brief at 19-20. Atmel apparently contends that this limitation should be read into the claim language in question as a result of the language appearing in the specification immediately before and after the above-quoted language defining "self-limiting effect" and "self-limiting thickness":

Conditions should be chosen such that a self-limiting effect with a self-limiting thickness smaller than the junction thickness is achieved on the silicon prototype wafer in the 250 [degrees] C. to 600 [degrees] C. temperature range. (The self-limiting effect is characterized by a tungsten formation rate at 10 minutes that is less than 10% of the initial equilibrium rate. The self-limiting thickness is the tungsten thickness under these conditions achieved at 10 minutes.) For example,
when a hot wall, e.g., tube reactor … is employed with tungsten hexafluoride and argon, the self-limiting thickness vs. temperature is shown in FIG. 1. Similarly, when a cold wall reactor … is utilized in the temperature range 250 [degrees] C. to 600 [degrees] C. no self-limiting effect is observed and thus under these conditions this reactor should not be employed. ‘672 Patent at col. 3:64 through col. 4:13. However, the specification language pertaining to the unsuccessful use of a cold wall reactor in the temperature range of 250 to 600 degrees C. simply does not appear in the claim language, nor can this purported limitation be understood as being part of a definition of a specific term or phrase in the claim language. Rather, the specification language indicating that a self-limiting effect is not observed using a cold wall reactor in the temperature range of 250 to 600 degrees C. appears to present merely an illustration of conditions that may not produce the desired result. Thus, it would be improper to read this purported limitation from the specification into the claims. See Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998).

Atmel's second contention with regard to the claim language in question is that 35 U.S.C. § 112, P 6 applies to claim 1, and that, because claim 1 does not satisfy the requirements set forth in 35 U.S.C. § 112, P 6, claim 1 is invalid for indefiniteness. Section 112, P 6 provides:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

35 U.S.C. § 112, P 6. The word "combination" in this paragraph can include a combination of mechanical elements in an apparatus claim, a combination of substances in a composition claim, or a combination of steps in a method or process claim. See O.I. Corp. v. Tekmar Co., Inc., 115 F.3d 1576, 1582-83 (Fed. Cir. 1997). In combination apparatus claims, a patent applicant can claim a specified function without reciting in the claim itself the structures or materials necessary for performing that function. See id.; Apex Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 2003 WL 1725618, at *5 (Fed. Cir. 2003). Such claim limitations are referred to as "means-plus-function" limitations. See Apex Inc., 325 F.3d 1364, 1371, 2003 WL 1725618, at *5. Similarly, in combination method or process claims, a patent applicant can claim a specified function without reciting in the claim itself the acts necessary for performing that function. See O.I. Corp., 115 F.3d at 1583. Such claim limitations are referred to as "step-plus-function" limitations. Apex Inc., 325 F.3d 1364, 1371, 2003 WL 1725618, at *5. Moreover, when an applicant takes advantage of the convenience of employing a "means-plus-function" or "step-plus-function" limitation, such claim is limited to the means or steps specified in the written description, and equivalents thereof. O.I. Corp., 115 F.3d at 1583.

A threshold question is whether § 112, P 6 applies to a particular limitation. Here, there is no dispute that claim 1 is a process claim. In method or process claims, § 112, P 6 "is implicated only when steps plus function without acts are present," i.e., when "an element in a combination method or process claim [is] recited as a step for performing a specified function without the recital of acts in support of the function." O.I. Corp., 115 F.3d at 1583.

Therefore, when the claim language includes sufficient acts for performing the recited function, § 112, P 6 does not apply. Again similar to a means-plus-function analysis, the absence of the phrase "step for" from the language of a claim tends to show that the claim element is not in step-plus-function form. However, claim elements without express step-plus-function language may nevertheless fall within § 112, P 6 if they merely claim the underlying function without recitation of acts for performing that function. Unfortunately, method claim elements often recite phrases susceptible to interpretation as either a function or as an act for performing a function. Both acts and functions are often stated using verbs ending in "ing." … In such circumstances, claim interpretation requires careful analysis of the limitation in the context of the overall claim and the specification.

In general terms, the "underlying function" of a method claim element corresponds to what that element ultimately accomplishes in relationship to what the other elements of the claim and the claim as a whole accomplish. "Acts," on the other hand, correspond to how the function is accomplished. Therefore, claim interpretation focuses on what the claim limitation accomplishes, i.e., it's underlying function, in relation to what is accomplished by the other limitations and the claim as a whole. If a claim element recites only an underlying function without acts for performing it, then § 112, P 6 applies even without express step-plus-function language.

Seal-Flex, Inc. v. Athletic Track and Court Constr., 172 F.3d 836, 849-50 (Fed. Cir. 1999) (J. Rader, concurring).
The Court has considered the threshold issue of whether § 112, P 6 applies to the claim language in question. As stated above, the issue here is whether the language in this combination process claim sets forth an element that is recited as a step for performing a specified function without the recital of acts in support of the function. Atmel argues that the language in question (“wherein said deposition temperature and environment is controlled such that”) contains no guidance as to how the deposition temperature and environment are to be controlled to achieve the self-limiting effect and thickness … . Therefore, despite the absence of ‘step for’ language, the limitation should be treated under § 112, P 6 and construed to cover only the corresponding steps in the specification, and equivalents thereof, for achieving the self-limiting effect and thickness.

Def.’s Post-Hearing Brief at 19. In response to this argument, Agere contends simply that, "because the claim language clearly recites an act -- i.e., controlling the temperature and environment -- Atmel's 'step-plus-function' argument fails." Pl.'s Post-Hearing Brief at 24. Agere also notes that "courts have been extremely reluctant to interpret process claims as employing 'step-plus-function' limitations," citing to Seal-Flex, 172 F.3d at 850 n.5 (Rader, J., concurring). Atmel counters: "The claim implicates § 112, P 6 because the claim does not teach how to achieve the desired outcome by specifying the act; the teaching appears, if at all, only in the specification." Def.’s Post-Hearing Brief at 19 n.12.

The Court agrees with Atmel that § 112, P 6 applies to the claim language in question. During the Markman hearing, the following colloquy transpired between counsel for Atmel and Agere's expert witness:

Q Going back to the claim limitation it says "wherein said deposition temperature and environment is controlled." The claim language doesn't tell you how it controlled the temperature and the environment such that you achieve a self-limiting interaction with a self-limiting thickness less than said junction depth, does it?

A Your question is the claim language does not tell me how to control?

Q Right.

A It tells me that I need to use that temperature and that environment such that the following occurs.

Q What does it tell you, the claim language, about how you control the environment?

A It just simply says that I have to use whatever environment and deposition temperature such that the interaction and so forth occurs.

Q But the claim language doesn't tell you what you're supposed to do to manipulate or vary the deposition temperature in the environment such that you achieve the interaction that is self-limiting with a self-limiting thickness, does it?

A The specification does describe how one would go about or how the inventor suggests one goes about as to obtain those results.

Q So you need to go to the specification to determine how you achieve the result that the interaction is self-limiting with a self-limiting thickness less than said junction depth, correct?

A That's not exactly what I said. I said the specification describes how one finds when interaction would be self-limiting or not. So one can use that to identify how to choose a temperature and environment such that that interaction occurs.

Tr. 12/5/02 at 156-58. Thus, as acknowledged by Agere's own expert witness, and as asserted by Atmel's expert witness, see Tr. 12/5/02 at 225-26, it is only in the specification of the '672 patent that one reading the patent would find the information necessary to allow one to determine the "deposition temperature and environment" that should be used to achieve the desired function. See '672 Patent at col. 3:56 through col. 4:21. Therefore, the Court concludes that although the claim language in question does not include express step-plus-function language, the claim language nevertheless falls within § 112, P 6 because it recites a step (controlling the deposition temperature and environment) for performing a specified function ("such that said interaction is self-limiting with a self-limiting thickness less than said junction depth") without
reciting the acts necessary to perform this step and achieve this function.

Once it is determined that a claim includes a step-plus-function limitation, the Court must then construe the limitation "to cover the corresponding ... acts described in the specification." 35 U.S.C. § 112, P 6; Chiuminatta Concrete Concepts, Inc. v. Cardinal Industries, Inc., 145 F.3d 1303, 1308 (Fed. Cir. 1998). In other words, this Court must now turn to the written description of the patent to find the acts that correspond to the step in claim 1 requiring that the deposition temperature and environment be controlled "such that said interaction is self-limiting with a self-limiting thickness less than said junction depth." B. Braun Medical, Inc. v. Abbott Laboratories, 124 F.3d 1419, 1424 (Fed. Cir. 1997).

The Court concludes that the acts in the specification corresponding to this limitation are set forth in the following passage:

The precise conditions suitable for the tungsten deposition vary with reactor design. Appropriate conditions are determined by performing a control sample in the desired deposition apparatus utilizing 1) a precursor composition including only tungsten hexafluoride and argon and 2) a bare silicon prototype wafer that has been subjected to an implant dose equivalent to the total implant does that is ultimately to be employed in the device. Conditions should be chosen such that a self-limiting effect with a self-limiting thickness smaller than the junction thickness is achieved on the silicon prototype wafer in the 250 [degrees] C. to 600 [degrees] C. temperature range.

'672 Patent at col. 3:56-67. However, the Court does not agree with Atmel that the next passage, referring to the use of hot wall and cold wall reactors, should be included in construing the step-plus-function limitation, since this passage appears to set forth merely illustrative examples and not required limitations. See '672 Patent at Col. 4:4-13 ("For example, when a hot wall reactor ... is employed with tungsten hexafluoride and argon, the self-limiting thickness vs. temperature is shown in FIG. 1. Similarly, when a cold wall reactor ... is utilized in the temperature range 250 [degrees] C. to 600 [degrees] C. no self-limiting effect is observed and thus under these conditions this reactor should not be employed.").

In sum, the Court construes "self-limiting" as "exhibiting an effect that is characterized by a tungsten formation rate at 10 minutes that is less than 10% of the initial equilibrium rate."

The Court further construes "self-limiting thickness" as "the tungsten thickness achieved at 10 minutes under conditions in which a 'self-limiting effect' is achieved, i.e., the tungsten formation rate at 10 minutes is less than 10% of the initial equilibrium rate." The Court also concludes that the claim language in question recites a step-plus-function limitation, and that this limitation should be construed in accordance with the specification language quoted above, see '672 Patent at col. 3:56-67.

8. Wherein said download starts at any point within the data file, exclusive of the start of file and end of file

The Court's Construction: The download cannot resume at the "start of file" or "end of file" indicators/markers. Markman Tr. 55:25-56:2.

Ethos argued that the Court ought adopt the construction: "[t]he download need not resume at the start of file or end of file." Markman Tr. 56:7-25. RealNetworks agreed with the Court's construction and challenged Ethos' construction as contrary to the plain meaning of the term "exclusive of." Id., 57:12-58:11; Def. Br. at 14-15. Ethos contended that "exclusive of" means "not limited to." Pl. Br. at 19. In support of this construction, Ethos referred to an ad for a New Year's Eve dinner at the Ritz Carlton Hotel which states the rate as "$ 95 per guest, exclusive of tax and gratuity," and argued that the use of the term in the ad clearly does not suggest that taxes and gratuities will not be added or expected. Id.; see also Markman Tr. 58:24-59:20 (making a similar argument).

The plain meaning of the phrase "exclusive of" is "[n]ot including: besides." Webster's II New College Dictionary 399 (3d ed. 2005). There is no indication in the specification or the prosecution history that the plain meaning of this term was altered as Ethos suggested. The prosecution history confirmed the propriety of adopting the commonly understood meaning of "exclusive of."

The prosecution history, in distinguishing this invention from prior art, states:
Thus the Miller invention [(the prior art)] may only restart a terminated download at the boundaries of frames/blocks, not at any point between these boundaries as is true with the present invention [this language is cited by Ethos]. Claim 47 specifically excludes Miller's stream of a file of frames, and specifically emphasizes that the resumption of the terminated transfer starts at any point within the data file, exclusive of the start of file and end of file, regardless of the presence of spurious markers, frame boundaries, and other boundaries that may occur within the data file.

... When an unintended termination of transmission occurs, the client may indicate to the server to resume the transfer starting at any point within the data file. The client may indicate to the server the last byte or word successfully received, or the client may indicate to the server from which byte to resume the download. ... "Start of file" and "end of file" indicators are now included for the data file being downloaded. These indicators are included in new claim 47 so that the claim language can specifically exclude those indicators as locations from which the resumption of the download can occur. This is to specifically distinguish prior art, e.g. the Miller reference.

Def. Br., Ex. 8, 11/99 Action at 9-10 (emphasis added); see Pl. Br., Ex. 11; 3/00 Action at 6 (containing similar language).

It is clear from the prosecution history that the inventors intended for that claim specifically to exclude the start of file and end of file indicators as restart locations.

4874

"wherein said first and second switch means assume a non signal-conducting state when said CPU power circuit is not supplied with power"

The Court agrees with Mitchell and construes the term as, "the eleventh limitation describes a further function performed by the first and second switch means. When the CPU power circuit is not supplied with power, the switch means takes on a state in which no current or voltage may be conducted through the switch, and therefore a voltage representing a signal on a line connected to one side of the switch will not be affected by and will not affect a voltage representing a signal on a line connected to the other side of the switch. This also means that a voltage representing a signal on a line connected to the switch will not be transmitted through the switch." Intel's proposed construction is almost identical to Mitchell's except that Intel argues that the words "when" and "assume" should be construed and proposes additional language to construe the two words: "the 'assumption' of a non signal-conducting state occurs in response to, and continues as long as, the CPU power circuit is not supplied with power." Intel argues that the additional language will help the jury understand that "the claim requires the assumption of the non signal-conducting state to be a response to ... the moment when the CPU gains power and sends an 'appropriate' signal to the 'switch means.'" Intel argues that "the purpose of the eleventh limitation is to isolate the elements of the system from each other in the event the CPU is damaged and to remain in that isolated state until receipt of an appropriate signal from the CPU." See Col. 3:5-13; Col. 42:47-53; Cols. 43:65-44:20.

The additional language proposed by Intel is not supported by the claim language and is not necessary. Furthermore, this additional language was not included in Judge Illston's construction. Accordingly, Intel's proposed addition language is not included in the Court's construction of the limitation.

GO BACK

4875

"wherein said lines of said CPU and said contacts assume a non signal-conducting state when said first and second switch means are in said non signal-conducting state"

The Court agrees with Mitchell and construes the term as, "the dedicated memory address data, and control lines of the CPU and the dedicated memory address, data and control lines of each of the three sets of contacts assume a non signal-conducting state when the first and second switch means are in a non signal-conducting state. Accordingly, those lines take on a state in which no current or voltage may be conducted through them, and voltages representing signals on the lines may not be transmitted along the lines, whenever the first and second switch means are also in this state." Again, Intel's proposed construction is nearly identical to Mitchell's except that Intel argues that the words "assume" and "when" should be
construed and proposes additional language that states, "the 'assumption' of a non signal-conducting state by the lines and contacts occur in response to, and continues as long as, the first and second 'switch means' are in a non signal-conducting state," to accomplish this goal.

For the same reasons discussed above with regard to the eleventh limitation, Intel's additional language is rejected and the Court construes the term consistently with Judge Illston's construction.

**4876**

VIII. Primary Memory Interface Means
The term "primary memory interface means" appears in independent Claim 9 of the '846 Patent. The parties agree that the term is governed by Section 112(6) but disagree as to the function and corresponding structure.

A. Function
Intergraph's proposed function is "coupling data between said primary memory and said cache memory." Toshiba's proposed function is 

"(a) coupling data between said primary memory and said cache memory; (b) and selectively transerring data between said primary memory and said cache memory in response to a miss signal." The dispute centers on whether the "wherein" clause in the claim imposes an additional function to the term. Claim 9 contains the clause "primary memory interface means for coupling data between said primary memory and said cache memory," followed several clauses later by the clause "wherein said primary memory interface means selectively transfers data between said primary memory and said cache memory in response to a miss signal." Accordingly, the court must decide whether the latter clause constitutes an additional function which must be performed by the primary memory interface means.

The parties dispute the legal effect of the "wherein" clause. Intergraph asserts that the word "wherein" should be treated the same as "whereby." Intergraph's sole support for this contention is a citation to a section of the Manual of Patent Examining Procedure ("MPEP") dealing with the terms "adapted to," "adapted for," "wherein" and "whereby." Pl's Exh. G, MPEP § 2111.04. Significantly, "adapted to" and "adapted for" are treated as a single type of clause, while "whereby" and "wherein" are treated as separate types of clauses. Id. The MPEP gives these clauses as "examples of claim language . . . that may raise a question as to the limiting effect of the language in a claim." Id. The MPEP further states that "[t]he determination of whether each of these clauses is a limitation in a claim depends on the specific facts of the case." Id.

**Intergraph cites no case where a "wherein" clause was held not to impose a limitation.** Instead, Intergraph cites two cases dealing with "whereby" clauses: Texas Instruments, Inc. v. U.S. Int'l Trade Comm'n, 988 F.2d 1165, 1172 (Fed. Cir. 1993) (holding that "[a] 'whereby' clause that merely states the result of the limitations in the claim adds nothing to the patentability or substance of the claim"); Lockheed Martin Corp. v. Space Sys./Loral, Inc., 324 F.3d 1308, 1319 (Fed. Cir. 2003) (holding that "[t]he function is properly identified as the language after the 'means for' clause and before the 'whereby' clause"). The court in Griffin v. Bertina, 285 F.3d 1029, 1034 (Fed. Cir. 2002), held that "wherein" and "whereby" were two different parts of speech and confirmed that the inquiry as to whether these words create limitations is fact-dependent. There, the court held that a "wherein" clause imposed a limitation because it "expressed[d] the inventive discovery" rather than "merely stat[ing] the inherent result of performing the manipulative steps." Id.

Accordingly, the court cannot consider the word "wherein" in isolation, but must determine whether the "wherein" clause in Claim 9 expresses an inventive component or merely the result of the delineated limitations. Intergraph characterizes Claim 9 as reciting seven separate structural elements, including the primary memory interface means, each with its own clause. The two "wherein" clauses following these seven component clauses, according to Intergraph, simply express how the components are intended to operate together in a computer system. In response, Toshiba argues that treating the "wherein" clause in Claim 9 as non-limiting would force the court to ignore several dependent claims that consist of nothing more than "wherein" clauses. Toshiba's argument misses the mark. As with the specific "wherein" clause at issue in Claim 9, each "wherein" clause elsewhere in the patents must be individually considered to determine whether the clause simply recites a result or sets forth an inventive limitation.

However, the court cannot accept Intergraph's proposed function, because the "wherein" clause at issue does not merely recite a result. Rather, it clearly recites an additional function of the primary memory interface means. Notably, in each of the cases cited by Intergraph, the "whereby" clauses stated pure results rather than actions directly involving the structures or limitations at issue. In Texas Instruments, 988 F.2d at 1169, the result of
the claimed steps was that "the fluid will not directly engage the device and electrical connection means at high velocity, and the conductors will be secured against appreciable displacement by the fluid." Likewise, in Lockheed Martin, 324 F.3d at 1315, the term at issue was "means for rotating said wheel in accordance with a predetermined rate schedule which varies sinusoidally over the orbit at the orbital frequency of the satellite," and the immediately ensuing "whereby" clause set forth the necessary result of rotating the wheel as described, i.e. offsetting the attitude of a satellite in a particular manner. In Griffin, 285 F.3d at 1031, the clause at issue was assaying for the presence of a point mutation in the nucleotides of codon 506 within EXON 10 of the human Factor V gene, wherein said point mutation correlates to a decrease in the degree of inactivation of human Factor V and/or human Factor Va by activated protein C, wherein the presence of said point mutation in said test nucleic acid indicates an increased risk for thrombosis or a genetic defect causing thrombosis.

Because the correlation was the inventive discovery, the wherein clauses were necessary limitations.

Here, the "wherein" clause does not recite a necessary result of arranging the delineated components of the claimed apparatus. Rather, it recites a specific function of the primary memory means. Selectively transferring data between the primary memory and cache memory in response to a miss signal is not a necessary result of coupling data between the primary memory and the cache memory. It is a separate function performed by the primary memory interface means which must be read as part of the limitation.

Accordingly, the court adopts Toshiba's proposed function: "(a) coupling data between said primary memory and said cache memory; (b) and selectively transferring data between said primary memory and said cache memory in response to a miss signal."

The parties disagree on the meaning of the above-stated language.

Dell argued that the ordinary meaning should suffice. Lucent proposed: "the web site includes a web page containing a subset of the managed information that is assembled to suit the needs or preferences of users at the second user Internet point." The court concludes that no construction of this claim term is required.

2. "Whether or Not . . . Approved"

The phrase "whether or not . . . approved" means determining without human involvement whether or not establishment of the financial account was fully approved, not merely reaching a preapproval determination. This means the automated process continues until information is provided to the applicant as to whether the financial account was approved or not approved.

5. "while buffer overflow is threatened, admitting for storage in said buffer cells only on such of said virtual channel connections on which the previous cell admitted was not indicated by the header of said previous cell as being end of transmission on said virtual channel"

The plaintiff contends that no construction is needed because the technical terms ("virtual channel," "cells," "buffet," "header" (appears in the agreed definition of "cells"), and "end of transmission" (synonymous with "end of frame"
indicator") have been defined, and the other terms need no further construction. In the alternative, the plaintiff proposes "while buffer overflow is threatened, admitting for storage in the buffer cells only on such of the virtual channel connections on which the previous cell admitted was not indicated by the header of the previous cell as being end of transmission on the virtual channel." The defendants propose "while buffer overflow is threatened, storing cells from each VCC in the buffer when the previous cell stored in the buffer for that VCC did not contain an end-of-frame designation, and rejecting all other cells." After considering the parties' submissions, the court agrees with the plaintiff that no additional construction of this phrase is warranted.

2. "while maintaining an open association with said first remote device throughout a series of image acquisitions"

Plaintiffs' construction: during the time that a series of images is acquired, the association with the first remote device is kept open

Defendant's construction: wherein the imaging system is configured to continuously maintain an association with the first remote device that allows for transmission of multiple images acquired by the imaging system without any re-opening of the association

The crux of the dispute regarding this term, and the '327 patent as a whole, is whether the "open association" claimed in the patent is limited in any way by the claim language, patent specification or prosecution history. Plaintiffs argue that little construction of the term is necessary or appropriate and that defendant's construction results in a "negative limitation" on the claim language that lacks support in the specification or prosecution history. Defendant contends that the specification and prosecution history require the limitations that: the association remain open continuously, the "open association" operates without "reopening," and the "open association" is the result of a particular configuration.

I agree with defendant. Both the patent specification and prosecution history show that the primary advantage of the invention is that it provides for a continuously open association between the imaging system and the remote devices, rather than an association that is opened and closed as individual images are acquired. In fact, in this regard defendant's construction appears to differ only slightly from plaintiffs' construction, which provides that the association is "kept open" while images are acquired.

The Abstract and Summary of the Invention explain that the association between the imaging system and remote devices is "open throughout the course of an examination of a patient." '327 patent, Abstract; id., col. 5, lns. 38-40. In addition, during the patent prosecution, the patentee distinguished the invention disclosed in the '327 patent from prior art by explaining that it allows for "a continuously open association mode." '327 patent prosecution history, Walkenhorst Decl., dkt. # 45, Ex. 15. at 4. Therefore, I agree with defendant that it is proper to construe this term to include the requirement that the association between the ultrasound system and remote device remain open "continuously."

Next, I will consider whether defendant's proposed addition of the phrase "without any re-opening of the association" to the construction is appropriate. As an initial matter, given that both sides state that the association between the imaging system and remote devices is "kept open" or open "continuously" while images are transferred, it is somewhat perplexing why they disagree about whether the connection must be maintained without the need for "re-opening." When a door or a line of communication is "kept open" or is open "continuously," there is little need for it to be "re-opened."

Plaintiffs contend that the addition of the phrase "re-opening" adds unnecessary ambiguity to the patent language. I agree. The patent specification states that the live imaging feature of the patent "allow[s] more efficient image transfer because the association need not be opened and closed for every image sent to a remote device." '327 patent, Abstract; id., col. 5, lns. 41-43. In addition, in order to overcome an obviousness rejection during patent prosecution, the patentee explained that the live imaging feature "allows more efficient image transfer because the associate need not be opened and closed for every image sent to a remote device." '327 patent prosecution history, Walkenhorst Decl., dkt. # 45, Ex. 15 at 4. Although both of these statements are evidence that the association remains open while images are collected and transferred, the inclusion of the phrase "continuously" conveys this adequately.
Finally, plaintiffs do not appear to dispute defendant's argument that the "open association" is the result of a particular configuration, so I will adopt that portion of defendant's construction with no further discussion.

Court's construction: wherein the imaging system is configured to continuously maintain an association with the first remote device that allows for transmission of multiple images acquired by the imaging system

4881

4. "while said association with said first remote device is open"

Plaintiffs' construction: during the time that the association with the first remote device is open

Defendant's construction: while the association between the ultrasound imaging system and the first remote device has remained open continuously

For the reasons discussed in detail above with respect to the term "while maintaining an open association with said first remote device throughout a series of image acquisitions," I will adopt defendant's proposed construction of this term. Again, the specification and prosecution history for the '327 patent support the understanding that an "open" association between the ultrasound imaging system and the remote device is one that remains open "continuously."

4882

A. "while the amplification reaction is in progress" Applera asks the court to construe this language to mean "during the amplification reaction," which would include either periodic or constant monitoring. Stratagene argues that the term should be construed to mean "for so long as the amplification reaction is taking place," which would require that the instrument be operable to conduct constant monitoring, even if the user wanted to monitor fluorescence only periodically. In the alternative, in its post-hearing brief, Stratagene asks the court to interpret the term to require that the instrument be operable to conduct intra-cycle monitoring.

The claim language itself provides insufficient guidance for resolving the parties' dispute. Both parties' interpretations are consistent with the plain meaning of the words. Accordingly, I consult the specification, which is "the single best guide to the meaning of a disputed term." Phillips, 415 F.3d at 1315 (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)).

The specification does not exclude either parties' interpretation, although Applera's flows more naturally from the specification. As Stratagene notes, the specification contains references to constant monitoring. For example, it teaches that "the continuous detection of fluorescence throughout the amplification provides an amplification profile that reflects the amount of target present at start." (Col. 24, Ins. 9-12.) However, as Applera observes, there are also references to periodic monitoring. For instance, the specification teaches, "It is appropriate to 'read' the microtiter plate before and after thermocycling for determining fluorescence." (Col. 12, Ins. 36-39.) Similarly, it states, "Because fluorescence can be determined between cycles during the course of a PCR . . . . Monitoring fluorescence while PCR is in progress serves to quantitate small amounts of DNA." (Col. 16, Ins. 22-24, 29-32.) This latter quotation is particularly significant because it ties periodic detection to the phrase "while PCR is in progress."

Stratagene argues that the specification's references to continuous monitoring reflect the inventor's understanding that the instrument had to be operable to detect constantly, even if it was only used to conduct periodic monitoring. Although the specification does not exclude this reading, it certainly does not require it either. A more natural reading of the specification is that the inventor did not consider whether the detector had to be operable to conduct constant monitoring. Under this reading, the detector merely has to be operable to detect the fluorescence signal, whether constantly or periodically, so long
as the detection occurs during the amplification reaction. This reading is preferable, particularly given the explicit reference to inter-cycle detection as occurring "while PCR is in progress."

Because the specification does not provide clear guidance, I turn to the prosecution history. The parties discussed the prosecution history at length during the Markman hearing. The discussion centered on the examiner's rejections of the patent as obvious in light of the Haff reference and the inventor's subsequent amendments to the claim.

I understand the Haff instrument to work as follows. Identical amounts of the same target DNA are placed in different reaction vessels. Identical reactions are run within each vessel. The reactions are stopped after various reaction cycles. After a reaction is stopped, the vessel is opened and dye is added. The fluorescence is measured and plotted on a graph. By this process, one can track the amplification reaction for that target piece of DNA. In first rejecting the invention as obvious in light of Haff, the examiner understood Haff to involve monitoring "during the thermal cycling process." (Bio-Rad Ex. 1, at 190.) The Examiner explained that it would be obvious to one trained in the art to optically couple the fluorescence detector to the thermal cycler to measure fluorescence without transferring samples from the cycler to the detector. (Bio-Rad Ex. 1, at 191.)

In response to the obviousness rejection, the inventor explained:

With applicant's invention, the amplification takes place and is detected in a sealed vessel condition. During amplification, a real-time signal indicative of a cycle-dependent change in double-stranded nucleic acid is generated to allow monitoring of the accumulation of double-stranded product while the amplification reaction is in progress, without opening the reaction vessel, without taking aliquots, and without withdrawing samples. Once the amplification reaction is initiated, no further handling or manipulative steps are required.

. . .
. . . Also, by generating a signal that not only gives an indication of the inter-cycle net change of double-stranded product but intra-cycle variations as well, applicant's claimed instrument eliminates any ambiguities regarding the time of sampling. The signal generated by applicant's claimed invention is independent of the time of sampling.

(Bio-Rad Ex. 1, at 204-05.) The Examiner nonetheless rejected the claims, finding these arguments "directed solely to the intended use of the apparatus, rather than the structural features thereof." (Bio-Rad Ex. 1, at 212.) He also stated that it would have been obvious to use sealed reaction vessels to prevent contamination. (Bio-Rad Ex. 1, at 212.)

In response, the inventor explained that "Haff et al. failed to recognize that an indicator reagent could be included in a nucleic acid reaction mixture to allow amplification to be measured over multiple cycles without opening the reaction vessel." (Bio-Rad Ex. 1, at 249.) The Examiner again rejected this explanation, citing other prior art (i.e., Schnipelsky) showing that detection reagents would not interfere with the reaction. (Bio-Rad Ex. 1, at 276.)

Following these communications, the Examiner and inventor had a personal interview. After the interview, the Examiner wrote, "It was generally agreed that structural language requiring operation of the detector over the course of a thermal cycling amplification reaction would define over the art of record." (Bio-Rad Ex. 1, at 302.) Thereafter, the applicant filed an amended claim containing the language, "while the amplification reaction is in progress." He remarked, "During the interview, applicant's representatives summarized prior arguments. The Examiner agreed that the rejection over the art of record would be withdrawn if the claims more clearly recited that the detector was operable to detect during the amplification reaction, in contrast to a detector that was not operable during an amplification reaction." (Bio-Rad Ex. 1, at 317.)

After reviewing the prosecution history in detail, and focusing on the claimed apparatus, as Stratagene urges me to do, I find the prosecution history too ambiguous to support Stratagene's narrower construction.

The claimed invention is distinguishable from Haff in that the dye is present in the reaction mixture as amplification takes place and the fluorescence can be measured without opening the vessels to withdraw samples or to inject dye. As the inventor explained in 2000, one benefit of his invention is that it can generate a intra-cycle signal, whereas Haff's plainly cannot. Until 2002, the Examiner consistently rejected these differences between Haff and the invention and held the
claimed invention obvious in light of Haff and other references.

We do not know exactly what happened in the 2002 interview. According to Stratagene, the Examiner concluded that a key distinction between the claimed invention and Haff was that Haff could constantly detect fluorescence "over the course of a thermal cycling amplification reaction." On this view, "while the amplification reaction is in progress" must be construed to embody the inventor's and the Examiner's understanding that the claimed invention was structurally operable to detect constantly throughout the entire reaction or, in the alternative, within cycles as opposed to only between cycles.

However, Applera's version of what happened at that meeting is equally, if not more, plausible. According to Applera, the personal interview persuaded the Examiner that Haff did not teach detection "during" the amplification reaction, as he had earlier thought. Accordingly, he agreed to withdraw the objections if it was made clearer that the claimed invention was operable to detect fluorescence during the reaction. This interpretation is supported by the inventor's statement that his representatives summarized prior arguments. Importantly, he did not state that they presented new arguments or distinguished his invention on the ground that it was operable to constantly monitor fluorescence. On the basis of the prior arguments, the Examiner agreed to withdraw the objections in exchange for clearer structural language requiring that the detector be operable to detect during the reaction.

The prosecution history is simply too ambiguous to support the narrower construction proposed by Stratagene. This ambiguity manifests itself in the varying language used by the Examiner and the inventor. In his record of the interview, the Examiner used the language "over the course of the thermal cycling amplification reaction." However, the inventor summarized that same conversation using the word "during." Moreover, in a later document, the Examiner contrasted the invention, which would detect "throughout" the amplification reaction, with an instrument that limited "detection to a time immediately following the amplification reaction." (Bio-Rad Ex. 1, at 438.) This suggests that the Examiner understood "throughout" to mean something like "during."

This analysis reconfirms what I said during the Markman hearing. This is an imperfect process. The fact that we have to speculate about what the Examiner and the inventor had in mind underscores the ambiguity of the prosecution history. Given these ambiguities, and given that Stratagene's narrow construction is not compelled by the intrinsic evidence, I find it appropriate to focus on the plaintiff's statements in deciding whether he limited his claim in the way urged by Stratagene. I cannot conclude that he did.

For these same reasons, I reject Stratagene's alternative argument that the detector must be operable to detect within cycles. The inventor did describe his invention as "generating a signal that not only gives an indication of the inter-cycle net change of double-stranded product but intra-cycle variations as well." (Bio-Rad Ex. 1, at 204-05.) But he characterized this as an "advantage" of his system, not as a "structural and functional difference[]." (Bio-Rad Ex. 1, at 204.) This advantage derives from the structural difference that, in the claimed invention, the detectable nucleic acid binding agent is present in the reaction vessel as the reaction takes place. A detector operable to detect intra-cycle variations could be used to take advantage of this structural difference. But this statement does not necessarily mean that the detector must be operable to detect intra-cycle variations, particularly in light of the specification's references to inter-cycle monitoring.

The limited scope sought by Stratagene is not required by the intrinsic evidence. Accordingly, I construe "while the amplification reaction is in progress" to mean "during the amplification reaction."

L. "modifying at least a portion of the user's rule set while the user's rule set remains correlated to the temporarily assigned network address"

The term "modifying at least a portion of the user's rule set while the user's rule set remains correlated to the temporarily assigned network address" is found in claim 25. The plaintiff argues that no construction of this term is necessary in light of other constructions. Alternatively, Linksmart proposes the following construction: "changing at least one of the elements or conditions about the user's session during the session." The defendants contend that "modifying at least a portion of the user's rule set while the user's rule set remains correlated to the temporarily assigned network address" means "changing at least one of the rules in the user's rule set without ending the authorized session."
The primary difference between the parties' proposed constructions is whether termination of the user's session, which may be a form of a rule change, is covered by the patent term. According to the defendants, when the user's session is terminated, the system breaks the correlation between the user's rule set and the temporarily assigned network address. (See '118 patent, 3:21-26 ("When the user terminates the connection with the network, . . . the authentication accounting server . . . sends a message to the redirection server telling it to remove any remaining filtering and redirection information for the terminated user's temporary IP address."); 4:67-5:4 ("When the redirection server . . . receives information regarding a terminated session . . . , the redirection server . . . removes any outstanding rule sets and information associated with the session."). But Linksmart argues that these quoted passages from the specification are preferred embodiments, and the claim should not be construed to exclude modifications that terminate the session.

The court is persuaded by Linksmart's argument. The system may first terminate the user's session, then break the correlation between the temporarily assigned network address and the user's rule set. The court therefore construes "modifying at least a portion of the user's rule set while the user's rule set remains correlated to the temporarily assigned network address" to mean "changing at least one of the elements or conditions in the 'user's rule set' during the session."

E. Wide-Area-Network

The Plaintiff contends that this term does not require construction, but it alternately proposes "a computer network that spans a relatively large geographical area." The Defendants propose the construction "a geographically dispersed communications network." Both parties agree that the network spans or is dispersed over a large geographic area. The dispute is whether the network is a computer network or a communications network.

Neither party argues that the patent explicitly defines this term. The patent states that the method can provide an interface to access the server located on the wide-area-network. Col. 2:2-4. The patent also provides that the Internet is an appropriate environment for processing a laboratory material analysis, which is connected to a server. Col. 3:57. Claim one states that one step of the method is "accessing a server located on a wide-area-network." Claim thirteen requires a wide-area-network with "one or more client computers coupled to the wide-area-network." Thus, it is clear that the network allows for computer access, but the patent does not specify whether the network is a communications network or a computer network.

The Defendants state without evidence that the Internet allows computers to connect to it, but that they are not part of the Internet. Because the patent gives the Internet as an example of a wide-area-network, the Defendants contend that the disputed term means that computers can connect to a wide-area-network but are not a part of one.

The Plaintiff contradicts the Defendants' assertion with evidence. A wide-area-network is defined in one technical dictionary as "a computer network that spans a relatively large geographical area. . . . The largest WAN in existence is the Internet." RANDOM HOUSE WEBSTER'S COMPUTER & INTERNET DICTIONARY 607 (3rd ed. 1999). Another source, dated from the year the patent was filed, defines a wide-area-network as "a geographically distributed network composed of local area networks joined into a single large network using services provided by common carriers." MICROSOFT ENCYCLOPEDIA OF NETWORKING 1329,30 (2000) . That source also defines a local area network as "a group of computers located in the same room, on the same floor, or in the same building that are connected to form a single network. . . . They might use a dedicated backbone to connect multiple subnetworks, but they do not use any telecommunication carrier circuits or leased lines except to connect with other LANS to form a wide area network." Id. at 718. Another source defines a WAN as "a geographically widespread network, one that relies on communications capabilities to link the various network segments. A WAN can be one large network, or it can consist of a number of linked LANS (local area networks)."

From these extrinsic sources, it is clear that neither party is exactly right. The definition of a wide-area-network encompasses both ideas that are being disputed. It is a collection of LANs - a collection of computer networks - but it is also the communications network between those smaller networks.

Construction: A geographically distributed network composed of smaller networks of computers that are joined into a single
4. "a wideband frequency division multiplexer for multiplexing the information onto wideband frequency channels"

The phrase to be construed is "a wideband frequency division multiplexer for multiplexing the information onto wideband frequency channels." "Wideband in this patent document is described in the context of Wideband-Orthogonal Frequency Domain Modulation (W-OFDM or wideband OFDM)." '222 patent, 5:24-26. The specification defines Wideband-OFDM as "OFDM with a K and a [DELTA] f large enough to be able to achieve a specific throughput and large enough to be able to avoid using either a clock or a carrier recovery device without substantially affecting the BER." '222 patent, 6:30-34. The specification of the '222 patent repeatedly states that a "first frame of information is multiplexed over a number of wideband frequency bands at a first transceiver, and the information transmitted to a second transceiver. See '222 patent, Abstract; 2:54-57. The transceiver includes "a wideband frequency division multiplexer for multiplexing the information onto wideband frequency channels." See '222 patent, Abstract; 3:25-28. "To implement wideband modulation, Orthogonal Frequency Division Multiplexing (OFDM) is preferred in which the information, for example encoded speech, is multiplexed over a number of contiguous frequency bands." '222 patent, 7:12-15.

Wi-LAN argues that the term "frequency division multiplexer" means "a device for placing information onto a number of frequencies. Further, Wi-LAN argues that "frequency division multiplexing" is a method for transmitting information simultaneously in the frequency domain by placing information onto a number of frequencies. Thus, Wi-LAN contends that the term multiplexing means "placing." The Court disagrees with Wi-LAN. However, the Defendants do not provide a helpful construction for the term and merely argue that it is "a multiplexer for multiplexing the information" onto wideband frequency channels. The Court finds that the terms "multiplexer" and "multiplexing" are well known in the art. The Court finds that the term "multiplexer" means a device that multiplexes, e.g., combines or merges two or more signals or input channels into a single output signal or single output channel. Likewise, the Court finds that the term "multiplexing" means combining two or more signals into a single output signal. There is nothing in the specification or claim language that dictates straying away from these well known-meanings. The Court finds that one of ordinary skill in the art would understand, in general, frequency division multiplexing as a type of multiplexing where different frequencies are used to combine multiple streams of data for transmission, wherein each signal is assigned a different carrier frequency. The Court finds that one of ordinary skill in the art would understand, in general, orthogonal frequency-division multiplexing as a type of frequency division multiplexing where a number of sub-carriers are used to carry data, wherein the data is divided into several parallel data streams or channels, one for each sub-carrier. These meanings are consistent with the specification of the '222 patent. Wi-LAN's proposed construction conflicts with the well-known meaning of the term multiplexer by redefining "multiplexing" as "placing." The Court finds that "multiplexing" involves more than merely "placing information onto." The Court notes that the term "multiplexing" is used in claim 7 and the parties do not attempt to define the word "multiplexing." Thus, the Court construes the disputed term "wideband frequency division multiplexer" and not the undisputed "multiplexing" term. The Court construes the term "wideband frequency division multiplexer for multiplexing the information onto wideband frequency channels" to mean "a device that combines the information from multiple inputs into a single output for multiplexing the information onto wideband frequency channels."

In regards to the term "wideband frequency channels," the parties essentially adopt the same construction that is supported by the specification, see '222 patent, 6:30-34, with a few notable differences. The Court finds that "wideband frequency channels" means "frequency channels with certain characteristics, and that the Defendants' proposed construction follows the specification more closely than Wi-LAN's proposal. However, the Court agrees with Wi-LAN that K, [DELTA] f, and BER should be described with more than just symbols or acronyms. In the specification K is defined as a "number of points," [DELTA] f is defined as "frequency band," and BER is defined as "bit error probability" or "bit error rate." '222 patent, 1:64-66; 5:26-29; 7:44-46. Thus, the Court construes the term "wideband frequency channels" to mean "frequency channels with a K (number of points) and a [DELTA] f (frequency band) large enough to be able to achieve a specific throughput and large enough to be able to avoid using either a clock or a carrier recovery device without substantially affecting the BER (bit error rate)."
a. "a total width" and "a width greater than"

LGD contends that these limitations mean "the width of the first metal layer, determined by the portion of the first metal layer in contact with the second metal layer together with the portions exposed to the subsequently deposited gate insulating layer, is more than 1 [μm] and less than 4 [μm] greater than the width of the second metal layer." D.I. 367 at Exh. G-6. LGD goes on to clarify that one skilled in the art would understand that the way to determine the "width" of a metal layer of a TFT gate is to measure at the widest portion, meaning the bottom surface, of the layer.

In response, AUO contends that these terms are indefinite. Alternatively, AUO contends that the phrase "a total width of the first metal layer is greater than a total width of the second metal layer by about 1 to 4 [μm]" means "the width of the first metal layer is about 1 to 4 [μm] greater than the width of the second metal layer when measured from a level defined by the top of the first metal layer." Id.

CMO contends that these phrases should be construed as:

The top surface of the first metal layer has a width that is about 1 to 4 [μm] wider than a width of the top surface of the second metal layer to form a double step. A double step is a structure where not all of the top surface of the first metal layer is covered by the second metal layer.

Id. CMO contends that its construction requires the widths to be measured along the top surfaces of the first and second metal layers. CMO contends that its construction is consistent with LGD's responses to an Office Action issued by the British Patent Office asking for clarification regarding the width measurements.

Examining the claim language in light of the specification and the testimony concerning the understanding of one of ordinary skill in the art, the Court concludes that the width terms are not indefinite and are properly defined as proposed by LGD, such that the width measurement is taken at the widest portion of the layer, which in the case of the '321 patent, is the bottom surface of the layer. While the figures of the '321 patent are not necessarily drawn to scale, and thus, create some ambiguity regarding the meaning of width as designated by "w1" and "w2," the Court is persuaded that any ambiguity is rectified by the specification, which explains that the width of a metal layer of a TFT gate is defined according to the photoresist used to pattern the layer. '449 patent, col. 2, ll. 1-8, 12-20; col. 6, ll. 36-39. One of ordinary skill in the art would understand that, according to standard wet etching techniques, a metal layer structure that is patterned by use of a photoresist would not extend outside the cover of the photoresist, or stated another way, would not be wider than the photoresist. Tr. 352:7-354:5 (Rubloff). Dr. Howard also acknowledged that he had never seen a wet etching process that resulted in the metal layer being wider than the photoresist. Tr. 1161:12-15 (Howard). AUO's construction would conflict with this understanding.

Further, the Court notes that in describing the embodiment of the invention shown in Figures 4A through 4F, the specification defines the photoresist used to form the first metal layer of the gate as having the same width, "w1," as the first metal layer discussed in the background section of the patent, which further discusses the related art in the same terms. The '321 patent further states, "[w]hen etching the first metal layer 43 other than the portion of the layer 43 covered with the photoresist 47, the first metal layer 43 preferably has the same width w1 of the photoresist 47." '449 patent, col. 6, ll. 36-39. Because the metal layers in the preferred embodiments of the invention are etched and patterned with only one photoresist, a second photoresist having a width, "w2," defining the width of the second metal layer is not used in the preferred embodiments. However, the '321 patent refers to the width of the second metal layer in the preferred embodiments using the same designation, "w2," used to describe the width of the second metal layer in the background section, which again defines the width of the second layer in terms of the width of the second photoresist. Id. at col. 2, ll. 1-20. Accordingly, the Court concludes that the width terms are defined as "the width of the first metal layer, determined by the portion of the first metal layer in contact with the second metal layer together with the portions exposed to the subsequently deposited gate insulating layer, is more than 1 [μm] and less than 4 [μm] greater than the width of the second metal layer."
To assist in deciding Articulate's summary judgment motion, the court held a claim interpretation hearing pursuant to Markman v. Westview Instruments, Inc., 52 F.3d 967, 34 U.S.P.Q.2d (BNA) 1321 (Fed. Cir. 1995), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). Following that hearing, the court issued its first order, construing the following claim terms at issue:

window - a framing device on the computer screen that displays information and may set the displayed information apart from other information on the screen;

operate on a window - opening, closing, moving or resizing a window without manipulating the data contained within such window;

operate on data in a window - manipulating the data contained within a window without necessarily opening, closing, moving or resizing the window;

help access window - a window that contains one or more controls for accessing information which has been loaded on the central processing unit ("CPU").

* * *

A. Claims 1 and 23

The district court summarily found claims 1 and 23 invalid under 35 U.S.C. § 102(b), stating only that "[Adobe] Photoshop discloses each and every limitation contained in independent claims 1 and 23." On appeal, Apple claims legal error in this finding of anticipation, and in the underlying claim interpretation of the terms "windows" and "simultaneously active." Finding no legal error in the district court's claim construction, we affirm the district court's judgment of invalidity of claims 1 and 23.

1. Apple first asserts that the district court's interpretation of "window" is in error because the court improperly ignored the distinction in the patent specification between "windows" and "menus." According to Apple, the palette of Adobe Photoshop is a type of menu (a "tear-off" menu) and, therefore, not a window within the meaning of the '540 patent. The court's misinterpretation of the term "window," claims Apple, led the court to erroneously find Adobe Photoshop anticipatory.

Apple argues that the '540 patent specification separately refers to both windows and menus, and the specification describes how menus may be included within windows. Therefore, according to Apple, windows and menus are distinguished. Apple further argues that the windows of the '540 patent are limited to windows in which data is displayed, and data cannot include commands. In support of this argument, Apple points to language in claims 1 and 23 requiring the display of "data" and to portions of the specification that distinguish data from commands or functions.

Apple's interpretation of "windows" necessarily excludes menus or palettes, since these graphical features are distinct and since these features display functions, not data. Based on this interpretation, Adobe Photoshop is not anticipatory since it contains only one window within Apple's definition.

We are not persuaded by Apple's arguments. Notwithstanding Apple's arguments to the contrary, the evidence fully supports the district court's construction of the term "window." According to the written description of the '540 patent, "windows" "may take the form of a variety of objects, such as a file folder, loose leaf binders, or simple rectangles." Col. 1, lines 48-50. The written description further teaches that the windows of Apple's invention "include defined areas having window features such as menu bars, command options, text, icons, and/or button functions to be executed by the CPU." Col. 3, lines 8-11 (emphasis added). Taking the language of the '540 patent at face value, a simple icon that performs a button function is a "window." Thus, the palette of Adobe Photoshop, incorporating a number of function keys within a defined area, is surely a "window" for the purposes of the '540 patent.

Moreover, this broad definition of the term "window" is not at odds with the common definition of those skilled in the art.
Indeed, as demonstrated by the very references cited in the '540 patent specification, menu bars or buttons are commonly understood to be types of windows by those skilled in the art.

Footnotes

5 We acknowledge Apple's assertion that a patentee is free to be his own lexicographer, and may define claim terms in ways that differ from the common understanding of those skilled in the art. Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 397, 155 U.S.P.Q. (BNA) 697, 702 (Ct. Cl. 1967). In order to do so, however, a patentee must deliberately and clearly point out how these terms differ from the conventional understanding. Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249, 48 U.S.P.Q.2D (BNA) 1117, 1121 (Fed. Cir. 1998). Apple did not do so here. Instead, Apple described the term "window" in a manner that was consistent with its definition in the pertinent art. Moreover, rather than specifying a narrower meaning for this term, Apple taught that the terms of its claims were to be construed broadly. See Col. 16, lines 25-26.

End Footnotes

Similarly, in light of the clear language of the specification, Apple's argument that the window of its invention must include data in the form of text, as opposed to mere functions or commands, is equally unavailing.

First, we reject Apple's contention that claims 1 and 23 (and the corresponding dependent claims) require windows containing "data" that a user may operate on. This recitation of "data" in the claimed windows appears in the preambles of claims 1 and 23. The body of claim 23 also refers to data in the windows, but only as a possibility, not as a requirement. Thus, if the "windows" of the claimed invention are to be limited to windows containing "data," this limitation must come from the preambles of claims 1 and 23. Language in a claim preamble, however, acts as a claim limitation only when such language serves to "give meaning to a claim and properly define the invention," not when the preamble merely states a purpose or intended use of the invention. In re Paulsen, 30 F.3d 1475, 1479, 31 U.S.P.Q.2D (BNA) 1671, 1673 (Fed. Cir. 1994) (quoting DeGeorge v. Bernier, 768 F.2d 1318, 1322 n.3, 226 U.S.P.Q. (BNA) 758, 766 n.3 (Fed. Cir. 1985)). Viewing the claims as a whole and in light of the written description, the recitation of "data" in the preambles of claims 1 and 23 does not give meaning to these claims nor serve to define the invention. Instead, the term "data" refers to a purpose or intended use of the windows of the claimed invention.

Second, even if we were to find that the recitation of "data" in the claim preambles acts as a claim limitation, we would conclude that this term is used in a broad sense, and that this broad meaning of data is consistent with the district court's interpretation of the term "window." The written description uses the term "data" to include both text and command features:

The access window 130 includes a working area 145 in which the CPU 52 displays instructions, text or command options. The working area 145 includes a vertical slider 148 for scrolling through data displayed within the working area 145.

(emphasis added) Col. 8, lines 14-16. Thus, the term "data" cannot exclude commands, as argued by Apple.

Finally, we also note that the preferred embodiment of the '540 patent further suggests that Apple's narrow interpretation of "data" cannot be correct. Claims 1 and 23 specify that the user may operate on the "data" displayed in the plurality of windows of the invention. In most of the help windows of the preferred embodiment of the '540 patent, however, the only data that may be operated on are icons or command keys, in many instances a command key labeled "HUH?!" Therefore, under Apple's proposed interpretation, there are no data in most of the help windows of its preferred embodiment to be operated on by the user. And while this evidence alone is not necessarily dispositive of the claim construction issue, it further suggests the incorrectness of Apple's proposed interpretation that the "data" displayed in the windows of its invention does not include icons or command keys.

Footnotes

6 The preamble of claim 1 recites that the plurality of windows contains data that may be operated on by the user. The body of claim 23 recites that a user may operate on the windows or data disposed in the windows.
Accordingly, we reject Apple's arguments that the district court misconstrued the term "window.")

3. "Prefix and window circuit" (Claim 11) and "Windowing function" (Claim 25)

Broadcom argues that the claim language is limited such that the "window circuit" and "windowing function" employ a gradual roll-off pattern, which is one particular mathematical pattern of windowing. In contrast, Agere suggests that no construction is necessary because the claim language is broad and can refer to any applicable pattern of windowing. The parties agree that the plain and ordinary meaning of the general terms "window circuit" and "windowing function" can refer to numerous mathematical patterns, including, inter alia, rectangular, gradual roll-off, and triangular shapes. (R. at 131 (May 7, 2004); Goodman Supplemental Rep. P 5 (stating that windowing function "can have various shapes as long as it has finite duration").) Accordingly, neither party suggests that these terms have a customary meaning in the relevant art limited to a specific pattern. Therefore, in order to determine whether Broadcom's proposed limitation is warranted, the Court begins by looking to the intrinsic record to discern whether the presumption of plain and ordinary meaning is rebutted.

The relevant claim language, located in claims 11 and 25, 15 sets up a three-step process whereby: (1) a data stream is partitioned into groups of bits; (2) the bits pass through an inverse Fourier transform circuit ("IFFT"); and (3) the bits pass through a "prefix and window circuit," in the case of claim 11, or are subjected to a "windowing function," in the case of claim 25. ('786 patent, col. 5, ll. 51-67, col. 6, ll. 42-56.) On the basis of these claims, Broadcom presents two arguments in favor of its proposed limitation. First, Broadcom argues that the fact that the windowing occurs after the bits pass through the IFFT compels its construction. 16 According to Broadcom, the symbol is already in a rectangular shape when it leaves the IFFT block. (Cox Supplemental Rep. at 2.) Therefore, Dr. Cox suggests, "no specific windowing circuit would be necessary if the symbol was to remain rectangularly windowed." (Id.) Even if Dr. Cox's statement is accurate, however, it does not compel the conclusion that a "gradual roll-off" pattern must be utilized, as opposed to any other non-rectangular function, and Broadcom provides no support for such a conclusion.

15 These claims are interpreted together because they both describe the part of the invention that performs windowing. Claim 11 is an apparatus claim wherein the "prefix and window circuit" performs windowing, while claim 25 is a method claim wherein the "windowing function" itself is described.

16 In arguing that the terms at issue are not limited to the gradual roll-off pattern, Agere relies on the expert report of Dr. Goodman, in which he states that "rectangular or other types of functions could be used in the invention to accomplish windowing." (Goodman Supplemental Rep. P 8.) The analysis in Dr. Goodman's expert report, however, is based on his misunderstanding that the windowing function in this invention takes place before the IFFT. (See id. P 4 ("Windowing [is] the process of selecting an individual symbol for Fourier analysis.").) Dr. Goodman's belief is plainly contradicted by the claim language, which, as cited above, states that the windowing occurs after the IFFT. At the Markman hearing, Dr. Goodman admitted that, according to the claim language, the windowing functions occur after the IFFT. (R. at 16-17 (May 7, 2004); see also Cox Supplemental Rep. at 1 (explaining that windowing takes place after IFFFT).) Nonetheless, Agere's expert's misunderstanding of the claim language is not, in itself, a basis for this Court to accept Broadcom's contrary construction.

Second, Broadcom claims that the patentee explicitly defined the term "windowing" in the specifications as employing a gradual roll-off pattern:

To reduce spectral side lobes, the cyclic prefixing and windowing block . . . performs windowing on the OFDM symbol by applying a gradual roll-off pattern to the amplitude of the OFDM symbol.
Contrary to Broadcom's assertions, this quoted language does not constitute a clear definition, but rather a description of one particular embodiment. (Id., col. 3, ll. 32-33.) Therefore, it would be inappropriate to import this limitation from the specifications into the broader claim language. Brookhill-Wilk1, 334 F.3d at 1301 ("Absent a clear disclaimer of particular subject matter, the fact that the inventor anticipated that the invention would be used in a particular manner does not limit the scope to that narrow context.").

In conclusion, Broadcom has not provided convincing support to limit the plain and ordinary meaning of the broad claim language. Telegenix, 308 F.3d at 1202 ("Unless compelled otherwise, a court will give a claim term the full range of its ordinary meaning as understood by persons skilled in the relevant art."). Nonetheless, the Court finds that some construction is necessary to assist the eventual trier-of-fact. Accordingly, the Court adopts a modified version of Broadcom's proposed constructions. 17 "Windowing function" is construed as "applying a pattern to the amplitude of the OFDM symbol at the beginning and the end of the symbol." "Prefix and window circuit" is construed as "a circuit that copies the last part of the OFDM symbol and augments the OFDM symbol by prefixing it with the copied portion of the OFDM symbol, and which also applies a pattern to the amplitude of the OFDM symbol at the beginning and end of the symbol."

--- Footnotes ---

17 At the Markman hearing, Agere agreed to these modified constructions. (R. at 122, 125 (May 7, 2004); see also Agere Reply at 25 n.9.)

--- End Footnotes ---

4889

2. "Windows TM operating system environment"; "Windows TM software on the computer" (claims 8, 14-19)

The issue raised by PolyVision regarding this term is whether, because the inventor used the Windows trademark in these claims, this limitation is indefinite and not capable of construction or, alternatively, should be construed as "Microsoft Windows Version 3.0" because that is the operating system disclosed in the specification and because it was the only product at the time of filing that could have been used in the invention disclosed in the ’636 patent. (Col. 11, ll. 20-25, 35-40; Col. 13, ll. 44-58.)

To be valid, claims must comply with the definiteness requirement of § 112, P 2, which "focuses on whether the claims, as interpreted in view of the written description, adequately perform their function of notifying the public of the patentee's right to exclude." Solomon v. Kimberly-Clark Corp., 216 F.3d 1372, 1379 (Fed. Cir. 2000). A claim will be considered indefinite if it does not reasonably apprise those skilled in the art of its scope. See IPXL Holdings, L.L.C. v. Amazon.com, Inc., 430 F.3d 1377, 1383-84 (Fed. Cir. 2005). Because a trademark identifies the source of a product rather than a product itself, see Tumblebus, Inc. v. Cranmer, 399 F.3d 754, 762 n.10 (6th Cir. 2005), the use of a trademark in a patent may render a claim indefinite. The Manual of Patent Examining Procedure ("MPEP") addresses this issue:

The presence of a trademark or trade name in a claim is not, per se, improper under 35 U.S.C. § 112, second paragraph, but the claim should be carefully analyzed to determine how the mark or name is used in the claim. . . .

If the trademark or trade name is used in a claim as a limitation to identify or describe a particular material or product, the claim scope does not comply with the requirements of the 35 U.S.C. 112, second paragraph. Ex parte Simpson, 218 USPQ 1020 (Bd. App. 1982). The claim scope is uncertain since the trademark or trade name cannot be used properly to identify any particular material or product. In fact, the value of a trademark would be lost to the extent that it became descriptive of a product, rather than used as an identification of a source or origin of a product. Thus, the use of a trademark or trade name in a claim to identify or describe a material or product would not only render a claim indefinite, but would also constitute an improper use of the trademark or trade name.

MPEP § 2173.05(u) (2001). n5
n5 Although the MPEP does not have the force of law, it "is well known to those registered to practice in the PTO and reflects the presumptions under which the PTO operates." Critikon, Inc. v. Becton Dickinson Vascular Access, Inc., 120 F.3d 1253, 1257 (Fed. Cir. 1997). As such, the Court will rely on the MPEP to provide the proper framework for dealing with Smart's use of a trademark in its patent.

The United States Patent and Trademark Office Board of Appeals and Interferences has sustained examiners' rejections in several instances upon grounds that inclusion of a trademark rendered the claim indefinite. For example, in Ex parte Simpson, 1982 WL 52193, 218 U.S.P.Q. 1020 (Bd. Pat. App. & Interf. 1982), the matter cited above in the quoted section of the MPEP, the Board rejected the appellants' argument that the use of the trademark "Hypalon" was permissible because the mark was well known and satisfactorily defined in the literature discussing the product, an elastometric chlorosulphonated polythene, or synthetic resin. The Board rejected the argument, noting that the reference to the mark was uncertain in scope because it disclosed nothing about how much chlorosulphonated polythene must be present in the material used in the claimed combination before infringement occurred.

On the one hand, the claim language may be very narrowly construed to a particular chlorosulphonated ethylene having a specific group of additives employed by the owner of the "Hypalon" trademark to produce the desired properties, or on the other hand the claim language might be asserted by appellants . . . to broadly encompass every synthetic resin.

Id. at 1021-22. The Board concluded that the appellant's manner of use of the trademark as merely descriptive of the product not only failed to comply § 112, P 2 by staking out the boundaries of the claim, but was also an improper use of the "Hypalon" trademark. Id. at 1022 & 1022 n.2. See also Ex Parte Schwartz, 1998 WL 1708024, at *5 (Bd. Pat. App. & Interf. 1998) (affirming the examiner's rejection of the claim for indefiniteness because it was not clear "exactly what composition of gelatinous elastomer is encompassed by 'a synthetic polymer gel of the type used in the Kitecko Ultrasound Standoff Pad manufactured by 3M Corporation of St. Paul Minnesota').

Smart contends that its use of"Windows TM " in the claims at issue was not improper because it used the trademark not as a noun to assert a limitation, but rather as an adjective to modify the nouns "operating system environment" and "software." Smart asserts that its use of "Windows TM " in this manner served to distinguish the Windows family of operating systems from other such families, such as MacOS, Sun version Unix, SCO Unix, and HP-UX. The Court rejects this argument because it cannot discern any material difference between using a mark to identify products and using a mark to distinguish Microsoft Windows from other families of operating systems. The fact remains that the claim may still be indefinite because it does not refer to any specific product in the ever-expanding family of Microsoft products. Moreover, Ex parte Kitten, 1999 WL 33134953 (Bd. Pat. App. & Interf. 1999), does not support Smart's claim that its use of the "Windows TM " trademark is proper. In Kitten, the Board noted that although the claim used trademarks to identify the three proprietary products used to produce the subject fertilizer, the appellant filed product sheets in support of the application which identified the makeup and uses of the products. The Board observed: "Based on these product sheets and because claim 13 further limits the fertilizer used in claim 1 to a fertilizer prepared from these well-identified proprietary products, we do not find the use of the trademarks renders claim 13 unclear or confusing." Id. at *2.

In spite of the Court's inclination to conclude that the use of the claims' reference to "Windows TM " renders the claims indefinite, the Court concludes that it is proper to construe the claims as being limited to "Microsoft Windows Version 3.0" as set forth in the specification, in light of the Federal Circuit's admonition that "claims are generally construed so as to sustain their validity, if possible." Whittaker Corp., by its Technibilt Div. v. UNR Indus., Inc., 911 F.2d 709, 712 (Fed. Cir. 1990). It is undisputed that the Microsoft Windows Version 3.0 operating system was the only Windows TM software disclosed in the '636 patent and was the most recently available Windows TM operating system at the time of filing. "The literal scope of the term is limited to what it was understood to mean at the time of filing." Kopykake Enters. v. Lucks Co., 264 F.3d 1377, 1383 (Fed. Cir. 2001). According to PolyVision's expert, Robert Dezmelyk, Windows 3.0 and Windows 3.1 relied on the earlier Microsoft disk operating system, or "MS-DOS," for much of their internal operations. (Dezmelyk Decl. P 4, PolyVision Br. Supp. 3d Mot. Summ. J. Ex. C.) In these systems, Windows was simply a graphical interface that ran on the DOS operating system, and applications programs would run on DOS within the graphical interface of Windows 3.0 or 3.1. (Id.) Dezmelyk further states that beginning with Windows 95, Microsoft eliminated the DOS requirement for its
Windows platform, making Windows a true operating system that is not a mere graphical user interface shell for DOS. (Id. P 5.) See also http://www.webopedia.com/TERM/D/DOS.html (noting that later versions of Windows helped to alleviate some of the DOS limitations for modern computer applications); http://en.wikipedia.org/wiki/History_of.Microsoft.Windows (describing features of Windows 95). Because "Windows TM " includes a number of programs that were not known or released until after Smart filed its patent application and that do not significantly rely upon DOS, Smart may not claim the benefit of those programs, which could not have been known to the inventor or to persons of ordinary skill in the art at the time of the invention in the '636 patent. See Schering Corp. v. Amgen Inc., 222 F.3d 1347, 1353 (Fed. Cir. 2000) (holding that the term "leukocyte interferon" was limited to the understanding of those in the scientific community at the time the application was filed that it meant an interferon polypeptide that originates from leukocytes and not subsequently discovered subtypes of leukocyte interferon). Accordingly, the Court will limit the term "Windows TM " to include Windows 3.0 and Windows 3.1, as well as prior versions of Windows.

2. "Printed board" and "Wire on a printed board"

The parties have asked the court to construe "printed board" and "wire on a printed board." Because construction of these two terms involves the resolution of a single disputed issue, namely, whether a wire on the printed board must be printed or can be discrete, the court will address the construction of these terms together.

Claim 1 of the '641 patent uses these terms as follows:

1. A modular jack to be mounted on a circuit board, said modular jack comprising:

   a printed board containing an electronic element for suppressing noise;
   a contactor for contacting with a plug, said contactor being electrically connected with the electronic element by a wire on the printed board;
   a terminal for contacting with the circuit board, said terminal being electrically connected with the electronic element by a wire on the printed board; and
   an insulating housing for encasing the printed board.

As to "printed board," Murata proposes the following construction:

   A generally flat piece of material typically fabricated from insulating material that provides support and structural integrity for a plurality of interconnected components comprising a circuit. In printed circuit board technology, some or all of the conducting interconnection pattern is formed on the board.

Murata's Opening Brief, at 17. Bel Fuse proposes:

   A flat board made of nonconducting material on which electronic components are adapted to be mounted and electrically connected by a pattern of conductive metal pathways or traces that are printed on the surface of the printed board.

Bel Fuse's Responsive Brief, at 11. Thus, the parties' primary dispute as to the construction of "printed board" is whether all of the wires on the printed board must be printed.

As to "wire on the printed board," Murata proposes: "A conductive metallic element interconnecting various regions, or contributing to the interconnecting of various regions, on the printed board." Murata's Opening Brief, at 20. Bel Fuse proposes: "A conductive metal pathway or trace formed (printed) on a surface of a printed board for electrically connecting components held on the board." Bel Fuse's Responsive Brief, at 11. As with "printed board," the parties dispute whether a "wire on the printed board" must be a printed wire.
The court begins with an examination of the specification of the '641 patent. As part of the summary of the invention, the specification states: "A contactor for contacting with a plug and a terminal for contacting with a circuit board are electrically connected with the electronic element by wires on the printed board." '641 Patent, col. 2, ll. 1-4. The specification also describes three preferred embodiments. As to the first embodiment, it states that "the printed board 30 has printed wires 33 and 34 on both sides," id. at col. 3, ll. 23-24 (emphasis added), and "[i]n order to increase and decrease the number of signal circuits, it is only required to change patterns of the wires 33 and 34 on the printed board 30." Id. at col. 3, ll. 59-62.

"Design of the wires 34 on the printed board 30 is comparatively free, and the pitch P among the holes 32, that is, the pitch among the terminals 36 can be set to 1.02 mm which is the pitch of an ordinary circuit board on which the modular jack is mounted." Id. at col. 4, ll. 11-16. Likewise, the second and third embodiments disclose printed wires. See id. at col. 4, ll. 22-23 ("printed wires 44 and 45 on the board 41 are connected to chip inductors 40."); col. 4, ll. 37-39 ("printed wires 54 and 55 and an earth electrode 57 on the board 51 are connected to the [chip] capacitors 50."). Finally, the specification states:

Although the present invention has been described in conjunction with the embodiments above, it is to be noted that various changes and modifications are apparent to those who are skilled in the art. Such changes and modification are to be understood as included within the scope of the present invention defined by the appended claims.

Id. at col. 4, ll. 50-56.

Thus, the preferred embodiments in the specification of the '641 teach only printed wires on the printed board, but the specification does not expressly exclude the use of discrete wires and states that the invention includes variations to the preferred embodiments that would be apparent to persons of ordinary skill in the art. The question then becomes whether a person of ordinary skill in the art would recognize that some of the printed wires could be replaced by discrete wires.

Murata argues that jumper wires are well-known in the art; jumper wires create "a direct electrical connection, which is not a portion of the conductive pattern, between two points in a printed circuit." The Modern Dictionary of Electronics 532. Murata also cites a photo of an IBM circuit board which includes a jumper wire and the NASA Workmanship Standards which provide standards for the use of jumper wires on printed boards. Exs. 26 and 30 to Murata's Opening Brief. Because the use of jumper wires is well-known in the art and the patent does not specifically exclude them, Murata argues that "printed board" as used in claim 1 of the '641 patent can include discrete wires as well as printed wires and that "wire on a printed board" as used in claim 1 can be either a discrete wire or a printed wire.

Bel Fuse argues that a "wire on a printed board" as used in claim 1 includes only printed wires. Bel Fuse relies on the description of the preferred embodiments in the specification of the '641 Patent, which, as discussed above, include only printed wires. Bel Fuse also argues that one of the objects of the invention of the '641 Patent is that "[a] change in wire patterns on the printed board meets an increase of the required number of signal circuits, thereby never requiring more space." '641 Patent, col. 2, ll. 15-18. Because wire patterns on a printed board are composed of printed wires, Bel Fuse argues that, to achieve this advantage, the invention must include only printed wires. However, Bel Fuse has not explained why this advantage could not be achieved if a discrete wire was used for a connection while the remaining pattern was composed of printed wires, and Bel Fuse does not argue that discrete wires on the type of printed board used in the '641 patent are not known in the art.

Significantly, limiting a "printed board" to one with only printed wires or traces and a "wire on a printed board" to a printed wire would restrict the interpretation of these terms to the preferred embodiments, despite language in the specification saying that modifications apparent to a person of ordinary skill in the art are not excluded. Murata has provided evidence that the use of jumper wires is known in the art, and Bel Fuse has provided the court with no reason to believe that such the modification of using a jumper wire(s) would not have been apparent to a person of ordinary skill in the art. Thus, the court finds that adopting a construction that excludes discrete wires would improperly import a limitation from the specification into the claims. Phillips, 415 F.3d at 1323 (stating that courts should avoid "reading limitations from the specification into the claims"). The court construes "printed board" as "a generally flat piece of material typically fabricated from insulating material that provides support and structural integrity for a plurality of electrically interconnected components comprising a circuit, with some or all of the conducting interconnection pattern formed on the board," and the court construes "wire on the printed board" as "a conductive metallic element interconnecting various regions, contributing to the interconnecting of various regions, on the printed board."
2. Claim Construction for the '553 Patent

The patent consists of forty claims, including independent claims 1 and 22, which are the focus of this motion. Claim 1 sets forth "[a] portable, self-contained hand-carried music performance device for wirelessly transmitting musical accompaniment information stored in a storage medium therein and a voice input from a user, for reception and reproduction by an external receiver and speaker unit." '553 Patent col.10 1.27 (emphasis added). Similarly, claim 22 describes ",[a] portable, hand-carried music performance device capable of transmitting wirelessly both musical accompaniment information stored therein in a storage medium and reproduction by an external speaker unit." Id. at col.13 1.6 (emphasis added). The critical language of these two independent claims for this motion is "wirelessly transmitting" and "transmitting wirelessly." The issue to be resolved is if and how the use of the term "wirelessly" limits the scope of the patent.

a. Plain Language of the Claims

Both parties agree that the ordinary and customary meaning of the word wireless to someone skilled in the art is "without a wire." "Each element contained in a patent claim is deemed material to defining the scope of the patented invention." Warner-Jenkinson Co. v. Hilton Davis Chem. Co., 520 U.S. 17, 29, 117 S. Ct. 1040, 137 L. Ed. 2d 146 (1997). The Court, therefore, must give heed to the use of the term "wirelessly." In the opening clause of both claims 1 and 22, the patent explains that the device wirelessly transmits information. While the focus of the dispute has been the first clauses of these claims, other clauses in both claims also refer to wireless transmission. Indeed, neither claim refers to the transmission process without including the wireless element. Courts can look to other clauses in the claims in question to inform their construction of the claim element "and further define the functions attributed to it by the patentee." Phonometrics, Inc. v. Northern Telecom, Inc., 133 F.3d 1459, 1465 (Fed. Cir. 1998). Plaintiff's repeated and consistent reference to "wireless transmission," as opposed to "transmission" generally or "wired transmission," throughout claims 1 and 22 shows that Plaintiff understood the patent was for a device that "transmitted wirelessly." See id. ("A word or phrase used consistently throughout a patent claim should be interpreted consistently."). Thus "wireless transmission" is an element of the claim that limits the scope of the patent.

Further support for limiting the scope to wireless transmission can be found in the dependent claims, which describe the transmission process. See Phillips, 415 F.3d at 1313 (holding that claim construction requires interpretation in light of entire patent, including dependent claims). All of the dependent claims that describe the transmission process from the device to the FM receivers refer to transmission through an antenna. n2 As an antenna is only necessary for wireless transmission, this repeated description of transmission through an antenna further supports a finding that the scope of the claim is limited to wireless transmission. Thus, the plain language of the claims 1 and 22 in the context of the entire patent indicates that the patent is limited to wireless transmission.

b. Specification

The specification serves as additional support for a finding that the patent scope is limited to wireless transmission. See Aspex Eyewear, Inc. v. Altair Eyewear, Inc., 386 F. Supp. 2d 526, 534 (S.D.N.Y. 2005) (finding that analysis of the specification supported conclusion that claim included eyeglasses with rims). First, in distinguishing the invention from prior art, the specification discusses the disadvantages of the comparative karaoke systems. Within the list of disadvantages such as the size and expense, Plaintiff describes the need for many wire connections, which causes users to be constrained to
certain locations. The specification goes on to say that the invention overcomes the disadvantages of the typical karaoke system. The invention, through wireless transmission, allows users to be mobile - taking and performing their karaoke in any location where a FM receiver is properly tuned. As Plaintiff distinguishes prior art, in part, on the use of wires, the claim should not now be read so broadly as to cover the very aspects of prior art Plaintiff relied on to distinguish the invention. See, e.g., Asyst Techs., Inc. v. Emtrak, Inc., 402 F.3d 1188, 1194 (Fed. Cir. 2005) (holding that the court's construal of the term "mounted on" to mean "fastened into position" based on the ordinary meaning of mounted and rejection of the plaintiff's definition of being electrically connected was supported by the fact that "on occasion the patent distinguishes between features that are 'mounted on' an object and those that are 'connected to' or 'in electrical communication with'"); see also SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1343 (Fed. Cir. 2001) ("[T]he SciMed patents distinguish the prior art on the basis of the use of dual lumens and point out the advantages of coaxial lumens used in the catheters that are the subjects of the SciMed patents. That discussion in the written description supports the district court's conclusion that the claims should not be read so broadly as to encompass the distinguished prior art structure [of dual lumens].").

Second, in describing the embodiment of the device, the specification does not explicitly discuss the use of wires in the invention, or the lack thereof. The specification, however, outlines in multiple places the use of an antenna for transmitting the music and human voice to common FM receivers. See '553 Patent col.5 1.61, col.6 1.19, col.7 1.64. This is material to the analysis. See Watts v. XL Sys., Inc., 232 F.3d 877, 883 (Fed. Cir. 2000) (holding where "[t]he specification only describes one method" of achieving an element of the claim, "the specification actually limits the invention to structures that utilize [that method]," even if a person of ordinary skill would be aware of other methods for achieving the claim element). Again this indicates that the scope of the invention, and Plaintiff's understanding of the scope, was that transmission was wireless. See SciMed Life Sys., 242 F.3d at 1344 ("[T]he written description can provide guidance as to the meaning of the claims, thereby dictating the manner in which the claims are to be construed, even if the guidance is not provided in explicit definitional format."); Phonometrics, 133 F.3d at 1459; Gen Am. Transp. Corp. v. Cryo-Trans, Inc., 93 F.3d 766, 769-70 (Fed. Cir. 1996); Carroll Touch, Inc. v. Electro Mech. Sys., Inc., 15 F.3d 1573, 1577-78 (Fed. Cir. 1993); Minn. Mining & Mfg. Co. v. Johnson & Johnson Orthopaedics, Inc., 976 F.2d 1559, 1566-67 (Fed. Cir. 1992).

Finally, in discussing the steps required for performance, the specification only explains that FM receivers need to be tuned to the correct frequency and adjusted to the proper volume. '553 Patent col.8 1.20. Nowhere does the specification explain that the device needs to be wired or physically connected to a receiver. For the above reasons, the specification confirms a construction of the patent that would limit the scope to wireless transmission.

c. Prosecution History

The '553 Patent's prosecution history does not specifically discuss the inclusion of "wirelessly transmitting," but it nonetheless offers insight into why the term was added to the patent claims. The patent application was twice rejected and amended on the grounds of prior art in the form of the Takao and Mankovitz patents. The PTO explained that the Takao and Mankovitz patents, when considered together, teach the technology used for Plaintiff's invention. (Damoulakis Decl. Ex. B 333) The Takao patent discussed portable devices and the Mankovitz patent discussed transmission means. In Plaintiff's response to the first rejection, Plaintiff commented that the invention was more complex than the prior art. (Damoulakis Decl. Ex. B 350) Plaintiff added elements and details in each of the amendments to distinguish the invention from prior art and to describe more clearly the subject matter of the invention. (Damoulakis Decl. Ex. B 348, 395) In the first amendment, Plaintiff included more details of the invention such as the hand-held and self-contained features, but did not elucidate the "means for transmitting." (Damoulakis Decl. Ex. B 343) These changes, however, were not sufficient to avoid obviousness based on prior art. (Damoulakis Decl. Ex. B 361)

In the final amendment, Plaintiff added the term "wirelessly" to the first and last clauses of claim 1 and introduced claim 22, which describes wireless transmission. While additional changes were made to the patent unrelated to transmission in the second amendment, the Court can nevertheless determine that including the word "wirelessly" was part of Plaintiff's goal to define more clearly the invention in order to achieve patentability. See Phillips, 415 F.3d at 1317. Plaintiff has given no other reason for making the amendments in the remarks. Thus "wirelessly transmitting," as opposed to transmitting generally, was an important detail in achieving patentability. Further, in a declaration submitted during the application process, the Vice President of NAS Electronics, Inc., then the assignee of the device, stated that the device was acclaimed as the "first wireless, hand-held microphone." (Damoulakis Decl. Ex. B 399) Based on the foregoing prosecution history, it is apparent that Plaintiff intended to patent a device that specifically transmitted signals wirelessly from the device to a remote
Plaintiff contends in his opposition papers and at oral argument that the purpose of the inclusion of "wirelessly" was to broaden the scope of claim 1, which originally was limited to RF signals capable of being received only by radio receivers. According to Plaintiff, the addition of "wirelessly" broadened the claim to permit signal receivers other than radios, such as televisions.

Plaintiff mischaracterizes the amendments and their effects on the patent scope. While the amendment did broaden the means of reception, it simultaneously narrowed the means of transmission. On the one hand, the original claim only described the transmission and reception process in one clause, stating a "means for transmitting . . . as an RF signal capable of being received by a radio receiver." (Damoulakis Decl. Ex. B 343) The amended claim, on the other hand, describes the transmission and reception in both the first and last clauses of claim 1. The first clause describes a "device for wirelessly transmitting . . . for reception and reproduction by an external receiver." '553 Patent, col.10 1.28-30. The last clause of claim 1 describes a transmitter "for wirelessly transmitting . . . an RF signal capable of being received and reproduced by said external receiver." '553 Patent, col.10 1.64-7. Thus the first half of the clauses, in both the original and final versions of claim 1, outlines the transmission means and the latter half of the clauses outlines the reception means. Plaintiff blurs the clauses, using the language in the first half, which describes transmission, to support his argument about the second half, which involves reception.

Put another way, prior to the introduction of the term "wirelessly," the '553 patent could have been read to cover both wired and wireless transmission. Plaintiff added the phrase "wirelessly transmitting," thereby narrowing the scope from transmission generally to wireless transmission specifically. Even if the amendments broadened the second half of the clause so that the device could receive more than just RF signals, the change to the first half of these clauses limited the means of transmission to wireless. Therefore, Plaintiff's interpretation of the prosecution history fails.

--- Footnotes ---

n3 On August 9, 2006, Plaintiff submitted an unsolicited letter to the Court seeking to supplement the August 8, 2006 oral argument regarding the addition of the word "wirelessly." Plaintiff did not seek or receive permission from the Court and the Court will not consider the letter. Thereafter, on August 18, 2006, Plaintiff filed a Motion for Leave to File Letter Corroborating Information and Argument of Record or, in the Alternative, for a Telephone or Court Continuation of the Oral Argument. Plaintiff has had ample time since the filing of this Motion to seek leave to submit such a letter or to supplement the record. The Court will not entertain additional submissions or argument. In any event, it does not matter why Plaintiff added the term "wirelessly" to the patent, because as noted below, prosecution history estoppel is not necessary to decide this Motion. The claim says what it says, and does so plainly and clearly.

--- End Footnotes ---

Together, the language of the patent claims, the specification, and the prosecution history require a construction of the patent that is limited in scope by the element of wireless transmission. It is not necessary for the Court to look to extrinsic evidence as no ambiguity remains following review of the intrinsic evidence. Based on this limitation, the Court must now compare the patent claims to Defendants' allegedly infringing devices to determine if wired transmission is equivalent to wireless transmission.

4892

14. Wireless Device: A device that receives and/or transmits electromagnetic signals and can be carried by a person outside of a home or office.

4893

2. Claim 10: "wireless signals" "Wireless signals" is construed to mean "cellular telecommunications transmitted from a
source to a receiver without use of a wire."

4894

9. "First and second wiring segments in a building"

This term appears in Claim 25 of the '538 patent, which describes: "A network for transporting digital data and telephone signals, said network comprising: . . . first and second wiring segments in a building, each comprising at least two conductors for carrying digital data signals. . . ." SercoNet construes this term as "two distinct wiring segments, each consists of 2 or more distinct wires exclusively located in a structure." NetGear's construction is: "The building's conventional telephone wiring which has been modified so as to be split into fully separate segments."

There seem to be two main areas of dispute regarding this term. NetGear argues that the wiring must be telephone wiring and that such wiring is modified and split, whereas SercoNet argues that the wiring is not limited to telephone wiring, and that modification or splitting of that wiring is not required. SercoNet agrees that in its proposed construction, a structure is a building. Starting with the claim language, claim 29 is for a network according to claim 25, wherein at least one of the wiring segments is telephone wiring. Based on this claim language, it appears that wiring segments need not be telephone wiring, unless the wiring is explicitly described as telephone wiring, given the fact that dependent claim 29 limits one wiring segment to telephone wiring. In addition, claim 25 notes that the claimed network transports both digital data and telephone signals. The claim language, therefore, supports SercoNet's broader reading that does not limit the wiring to telephone wiring. Nor does the claim language refer to modification of the wiring.

Turning to the specification to further understand this term, the summary of the invention does not refer to modification of wiring. See '538 patent at 4:55-5:15. Nor does the rest of the specification refer to required modification of the wiring, and NetGear does not point to where the specification refers to this. In fact, NetGear seems to abandon this argument in its opposition.

As to whether the specification limits "wiring" to telephone wiring, NetGear's argument that the specification supports construing wiring as "telephone" wiring is persuasive, as the wiring is described as such throughout the specification and abstract. See, e.g., '538 patent at 1:5-8, 3:40-44 (describing network using telephone wiring, telephone lines, and telephone line wiring system). In fact, the invention is summarized as one that "provides a method and apparatus for using the telephone line wiring system within residence or other building for both analog telephony service and a local area data network." However, the abstract also refers to wiring in a more general sense -- as "electrically-conducting media." See also '538 patent at 11:34-38 (referring to wires and conductors generally). In addition, the specification also refers to ethernet wires. See id. at 9:30-38. Therefore, although the specification makes clear that the invention predominantly uses telephone wiring, it is not limited to such wiring.

In sum, and for all the reasons set forth above, the court adopts SercoNet's proposed construction of "first and second wiring segments in a building" with a minor modification (keeping the term "building" rather than changing it to "structure") and construes the term as: "two distinct wiring segments, each consists of 2 or more distinct wires exclusively located in a building."

3. "with"

The parties disagree about the meaning of the term "with" in the phrase "transmitting said control signal with said television program signal" of claim 21. Echostar argues that "with" requires that the control signal be transmitted at "the same time as" the program signal, whereas IPPV contends that "with" requires a close "association in time" between the transmission of the control signal and the "program (i.e. video) signal."

In support of its proposed construction, Echostar initially argues that the meaning of "with" is not clear from the language of
the claim. It then turns to the specification, and refers the court to an example that discloses that the control signal modifies the vertical rest interval portion of the continuous program signal. The modification is the change in amplitude that results from the combination of the signals. Based on this example, EchoStar asserts that the control signal becomes part of the program signal, and therefore, because the program signal is continuous, the only way for the control signal to be transmitted "with" the program signal is simultaneously. It also argues that if "with" is construed as "near in time to," the claim will be invalid for indefiniteness.

IPPV counters that "with" has several plain and ordinary meanings, and the context of the claim shows that the term means "a close association in time." As further support, IPPV points to a portion of the specification that, in referring to the placement of codes, states that "they are preferably inserted in the blanking so as not to appear as video." It then refers the court to a portion of the specification stating that "the transmitting end of the encoding system includes a program source . . . which generates a composite video signal comprising video information and synchronizing signals . . . ."

IPPV's argument focuses on the location of the control signal relative to the "program (i.e. video) signal." As previously explained, however, program signals and video signals are different types of signals. This distinction is evident from the language of the patent where claim 21 refers to "television program signals" and claim 13 concerns "video signals." In light of this difference, the portions of the specification relating to the placement of signals relative to the video signal are irrelevant to the construction of "with," which concerns the relationship between the control signal and the program signal.

The program signal is constant, and as result, any signal that travels with the program signal must have been transmitted at the same time as the program signal. The context of the claim therefore requires that the court construe "with" as meaning "at the same time as."

The parties dispute the meaning of the words "with the information transmissions" in the phrase "transmitting within at least one allocated television channel frequency band, together with the information transmissions a cost signal indicating the magnitude of the charge for access to the information in the transmissions." EchoStar argues that "with the information transmissions" requires that the cost signal must be placed inside the program signal, while IPPV contends that "with the information transmissions" requires that the cost signal be closely associated in time to the information transmission.

In support of its proposed construction, IPPV refers the court to a portion of the specification stating that "each scrambled program capable of impulse purchase is transmitted with data including the cost of the program in a part of the television signal, which does not convey program information (e.g., the vertical or horizontal interval or an unused portion of the audio frequency band)." Based on this statement, it contends that program information is the data transmitted in an "information transmission," and that the cost signal is not transmitted at exactly the same time as the program information. IPPV therefore concludes that the cost signal is not necessarily transmitted at the same time as the "information transmission." EchoStar simply responds by arguing that the cost signal must be placed inside the program signal.

The parties are focusing on two different relationships: (1) EchoStar wants the court to define the relationship between the cost signal and the program signal; and (2) IPPV wants the court to define the relationship between the cost signal and the information transmission. The court begins with the understanding that the information transmission and the cost signal are components of the continuous program signal. Thus, the cost signal is placed inside the program signal, and due to the continuous nature of the program signal, it is transmitted at the same time. Within the program signal, however, the court finds no reason why the cost signal and the information transmission must be transmitted at the exact same time. As a result, the court concludes that to the extent "with the information transmissions" refers to the relationship between the cost signal and the information transmissions, the words mean closely associated in time.
c. "Within a range"

Each asserted independent claim except Claim 36 states that NSMs must be located "within a range" of at least two RCNs. See CellNet's Memorandum in Support of Its Motion for Non-Infringement at 22-24; Itron's Memorandum in Opposition to CellNet's Cross-Motion for Summary Judgment of Non-Infringement at 25. This limitation allows the '094 patent to achieve one of its central design goals, that of path redundancy. See '094 Patent, Col. 3, 11. 27-30 ("[An] object of the invention is a communications network for collecting data from network service modules that … has inherent communication redundancy to enhance reliability and reduce operating costs."). The specification describes the important role redundancy plays in the patented system:

The remote cell nodes 112 are arranged in an array with the spacing between the remote cell nodes 112 relative to the network service modules 110 so that each network service module can transmit to at least two and preferably four of the remote cell nodes 112. Thus, the remote cell nodes 112 are provided in significantly larger numbers than is absolutely necessary for each network service module 110 to be received by a respective one of the remote cell nodes 112. The remote cell nodes 110 theoretically receive high levels of duplicate information. In a normal residential situation, the location of the remote cell nodes 112 so that each network service module 110 can be received by four such remote cell nodes 112 would lead to an array in which each remote cell node 112 would be responsive to approximately 1,000 of the network service modules 110.

Col. 15, ll. 42-57. Itron contends that the phrase "within a range" does not require that an actual functioning communication link exist between an NSM and two or more RCNs. Rather, it argues, the patent requires only the possibility of such a link. As CellNet points out, however, this proposed construction is contradicted by other aspects of the patent. First, because path redundancy is the central mechanism for assuring data integrity in the '094 patent design, it follows that actual redundancy should be considered a system requirement, not merely an option. Second, the specification language quoted above expressly contemplates actual links between an NSM and at least two or more (and preferably four) RCNs. Third, Claim 36 uses the phrase "within a range" in stating its limitation that only one RCN be within a range of an NSM. If "within a range" were interpreted as requiring only a possible functioning link between an NSM and an RCN, a crucial aspect of the '094 system, as described in Claim 36, would be inoperative. Therefore, according to the well-established rule of claim construction that the same limitation appearing in different claims must be interpreted consistently, see American Permahedge v. Barcana, 105 F.3d 1441, 1446 (Fed. Cir.1997); Southwall Technologies, Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995), "within a range" must be interpreted as describing an actually functioning communications link.

In its claim construction Memorandum Opinion, the Court addressed the DMOS issue raised by Defendants and provided a claim construction for the terms "MOS transistor" and "substrate." At that time, the Court considered the DMOS-related issue to be relevant to equivalence and prosecution history estoppel, and therefore, the Court was not persuaded that the DMOS issue was properly before it.

However, by their letter, Defendants have raised the DMOS issue again. Plaintiff has not alleged infringement under the doctrine of equivalents with respect to the '075 patent and has only pursued its infringement allegations based on literal infringement. Therefore, the Court finds any DMOS issues related to equivalence are moot.

As for prosecution history estoppel, the Court of Appeals for the Federal Circuit has recognized that prosecution history estoppel is irrelevant to literal infringement. See Fromson v. Advance Offset Plate, Inc., 720 F.2d 1565, 1571 (Fed. Cir. 1983). To the extent that Defendants rely on the doctrine of prosecution disclaimer, the Court concludes that the doctrine does not apply here. Like the doctrine of prosecution history estoppel, prosecution disclaimer requires "the alleged disavowing statements to be so clear as to show reasonable clarity and deliberateness, … and so unmistakable as to be unambiguous evidence of disclaimer." Omega Engineering, Inc. v. Raytek Corp., 334 F.3d 1314, 1325-1326 (Fed. Cir. 2003). In this case, the Court is not persuaded that Plaintiff's statements distinguishing Colak were sufficiently clear and unambiguous to amount to a disclaimer of all DMOS devices. In the Court's view, Plaintiff's statements were only relevant to distinguish the type of DMOS device shown in Colak, and not all DMOS devices. Indeed, the specification expressly notes that the invention can be embodied in either an MOS or DMOS structure. '075 patent, col. 3:6-9. Accordingly, the
Court declines to import DMOS limitations into its claim construction by reinterpreting the term "MOS transistor" and defining the term "within a substrate" in the manner suggested by Defendants. 1

--- Footnotes ---

1 As the Court has noted, the term "substrate" has already been defined, and the Court is not persuaded that the term "within" requires special construction beyond its ordinary meaning.

--- End Footnotes ---

In sum, the Court has provided a claim construction for the terms "MOS transistor" and "substrate," and the Court concludes that revisiting its interpretation of those terms is not warranted. Accordingly, the Court will deny Defendants' request for new and/or additional claim construction rulings.

J. "Within the call pod"

Defendants claim that "within the call pod" means "the structures for forming the voice path are inside the call pod." Callpod claims that construction of the term "within the call pod" is not necessary because it is clear and unambiguous.

Defendants offer their interpretation to clarify that "[t]he phrase 'within the call pod' cannot refer to the headsets, because they are outside the call pod and connected to it." However, the phrase "within the call pod" does not need further clarification. See U.S. Surgical Corp v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997) (noting that claim construction "is not an obligatory exercise in redundancy."). The headsets and everything else that are outside of the call pod are already necessarily excluded by the phrase "within the call pod." Further construction of the term would only introduce confusion and ambiguity into a clear and unambiguous phrase. Therefore, the Court finds that the term "within the call pod" does not require further construction.

3. without direct control of the processors of the processing elements

The third disputed term (actually, a phrase) appears in independent Claim 1 and dependent claims 4, 7, and 8. Claim 1 of the '201 Patent reads in relevant part:

A parallel processor array comprising:

said input/output means comprising:

means for broadcasting information received from a parent processing element to said child processing elements, such that common information is distributed to each processing element of the binary tree or a subtree thereof without direct control of the processors of the processing elements;

and

means for determining a priority among respective values of information received from said child processing elements and information received from the processor with which said input/output means is associated without direct control of the processors of the processing elements.

Plaintiff construes the disputed claim term to mean that "the main processor at a node is not burdened with controlling all aspects of an operation." 3 Pl. Br. at 9. Defendant, in contrast, construes it to mean that the "[broadcasting]/[determining a priority] function is performed independently by the I/O device without receiving instructions from its associated processor." Def. Br. at 11.

3 Plaintiff originally construed the term to mean that "the main processor at a node is not interrupted such that very little computational overhead is required for controlling the operation," but proposed the alternative construction in its briefs for the Markman hearing. See Def. Reply at 7 n.6.

The parties thus chiefly dispute the amount of control meant by the words "direct control," and both assert that their respective constructions reflect the ordinary, plain meaning of the words. See Pl. Reply at 9; Def. Br. at 11-12. Resolution of this issue requires focusing on the relationship of the I/O device to its associated processing element. In prior art, the processing elements also handled communication of data to other processing elements, and therefore "propagation times of the query and the result through the binary tree introduce significant delays in overall throughput comparable to those of a serial computer." '201 Patent at 3:29-33. The patent specification establishes that the patent's novel contribution, in part, was that the I/O device "communicates data and queries from the root processing element to all other N processing elements in the array" so as to "minimize propagation delays in the binary tree computer." '201 Patent at 5:10-16. Communication from the root processor to the processing elements is the broadcast function. The specification also provides that "the I/O Circuit of the present invention also provides a high speed function resolve and report function that determines a most favorable value of a set of values stored in the processing elements and reports this value." '201 Patent at 5:56-59. This resolve and report function is the determination of a priority from a data set. In short, the patent specification establishes that the purpose of the I/O device was to increase processing speed by allowing it to handle broadcast and resolve functions, leaving the processing element to perform other tasks.

The dispute over the instant term (or phrase) turns on whether the processor controls, even indirectly, the I/O device during the broadcast and resolve functions. Plaintiff's construction attempts to capture the implication of "no direct control" by stating that the "main processor" is "not burdened with controlling all aspects of an operation," yet the term "main processor" appears nowhere in the patent nor does plaintiff's construction clearly indicate how much of a burden is shifted to the I/O device. Worse still, this construction would permit plaintiff to claim that the processor directly controls some aspects of the broadcast and resolve functions, in contradiction of the claim language "without direct control."

Although plaintiff's construction is not persuasive, plaintiff argues that defendant's construction erroneously requires that the processor have "absolutely no control" over the "broadcast" or "priority" functions and that intrinsic evidence supports the claim that the processor has some control over the state of the I/O device. 4 Pl. Reply at 9. For example, the processor's low level routines send instructions to the I/O device, thus controlling the resolve function by having the bus drivers transmit data back up the binary tree. Pl. Reply at 10 (citing '201 Patent at 28:32-37). Thus, while the I/O device may execute the broadcast and priority functions independently of the processor, according to plaintiff, the processor nevertheless exercises some control because it must send instructions to have the I/O device initiate those functions. See tr., 08/20/09, at 69.

4 Plaintiff goes so far as to claim that the processing element "operates to 'greatly assist the I/O procedure.'" Pl. Reply at 9, citing '201 Patent at 9:15-16. This citation takes the phrase out of context, however, as the full sentence indicates that the processor "is provided with four parallel, 8-bit ports which simplify interconnection between processors and greatly assist the I/O procedure." '201 Patent at 9:13-16. Thus, it is not quite the case that the processor itself "greatly assists" the I/O device.

Although there is no doubt that the processor communicates with the I/O device, see tr. 08/20/09 at 99, the disputed claim language here focuses on the execution of these particular functions, i.e., how "common information is distributed to each
processing element" and how "determining a priority among respective values of information" is handled by the I/O devices. '201 Patent at 70:64-65, 68-69. As the patent specification suggests and the patent prosecution confirms, these functions are performed independently from the associated processor. The '201 Patent applicants originally omitted the phrase "without direct control," and the United States Patent and Trademark Office ("USPTO") rejected the claims as obvious in light of prior art, specifically U.S. Patent No. 4,583,164 ("Tolle"). See '201 Patent Prosecution History, Def. Br., Ex. F, at FBC 829-30. The applicants subsequently sought to distinguish their contribution from prior art by emphasizing that while "broadcasting" was directly controlled by the processors, here "once the broadcast operation is initiated . . . it proceeds independently of the processors . . . . [T]he 'means for determining priority' in each processing element is not under the control of the processor therein." Id. at FGC 793-94. After a second rejection, the applicants modified the claim language to include "without direct control." Id. at FGC 843-44. The applicants asserted that their system handled broadcasting faster than prior systems because it did not have to wait for the execution of processor instructions:

Because 'broadcasting' in Tolle is directly controlled, by the processors of the cells of the binary tree through the execution of a storage management algorithm rather than through cooperation among input/output means within each cell . . . , the time required to move data through the binary tree in Tolle is on the order of the number of cells in the binary tree multiplied by the execution time of the instructions required for moving information from a parent cell to its left and right child cells.

Id. at 852.

Hence, by shifting the execution of the functions to the I/O devices, and away from the processors, the propagation delays were reduced. The prosecution history thus dictates that the execution of the broadcast and resolve functions are performed "independently" by the I/O devices. See Gillespie v. Dywidag Systems Intern., USA, 501 F.3d 1285, 1291 (Fed. Cir. 2007) ("The patentee is held to what he declares during the prosecution of his patent.").

It follows that "without direct control of the processors of the processing elements" means that the [broadcasting] / [determining a priority] function is performed independently by the I/O device without receiving instructions from its associated processor.

C. The '969 Patent - "Without Installing New Software on the Wireless Terminal"

After considering the parties' proposed constructions, the Magistrate Judge recommended that the term "without installing new software on the wireless terminal," as used in Claim 16 of the '969 patent, should be construed to mean "without installing an application program, other than the parsing software, to provide user interfaces." (D.I. 133 at 15-18.) For the reasons set forth in the Report and Recommendations, the Court will adopt this construction.

J. "Without the Need for Human Analysis"

This term is included in all claims of the '382, '617, and '694 patent, as well as claims 1-5 of the '511 patent and claims 1 and 16-25 of the '392 patent. In the '511 patent, the term is used to describe a step that uses a driver to obtain information about the data structure of a data source "without the need for human analysis" of the data source. '511 patent, Col. 19:46-51.
In the joint claim construction chart, Timeline argues that this term is "a fragment of a phrase and cannot be satisfactorily defined out of context; attempts to do so inevitably distort the meaning." Alternately, Timeline proposes:

"A second step for using said first driver to automatically obtain first information about the data structure of said first data source without the need for human analysis of the first data source" means that it is possible (though not always required) to perform the "second step" without human analysis. In other words, the second step has the characteristic that human analysis is not needed for performance of the step, although human analysis or other involvement may be provided for if desired.

Pl.'s Opening Br. at 18. ProClarity's proposed construction is more straightforward: "Not requiring any evaluation or choice by a human."

ProClarity's proposed construction generally reflects the ordinary meaning of this term, which is not difficult to discern. "Without the need for human analysis" obviously means that human evaluation or choice is not required. The parties' dispute over this term appears to be based on an assumption that ProClarity's proposed construction would mean that human analysis is prohibited. However, the court sees no reason why ProClarity's construction, when read literally, would mandate such a result. Simply because human evaluation or choice is not required would not mean that human evaluation or choice is never allowed.

Therefore, the court construes the term "without the need for human analysis" to mean “not requiring evaluation or choice by a human.” The court does not include the word "any" from ProClarity's proposed construction because it is not necessary to reflect the ordinary meaning of the term.

(i) A system for storing digital data words, each data word having a plurality of multi-bit data portions, and for storing said data words in response to a storage request received over a parallel data bus said system comprising . . .

The key disputed term in this part of the definition is "data word." TM contends, without any particular intrinsic evidence to back its contention, that "data word" is no different than "data block" in the '342 patent. The question that arises is why the inventor would use a different phrase to convey the same concept. The issue becomes more acute because the term "word" has a specific and particular meaning in computerese. It is a term of computer architecture, referring to the amount of data that can be transferred to or from input or output devices in one memory cycle. See S. Handel, A Dictionary of Electronics 392 (2d Ed. 1966). The term "block of data," as I have interpreted it in connection with the '342 patent, contains no such specialized meaning and no such restriction. Therefore, I am unpersuaded that the two terms should be construed interchangeably.

IBM would have me construe "data word" even more narrowly, as encompassing only groups of bits that are "small multiples of 32 bits," on the ground that the largest "word" shown in the patent specifications is 256 bits, or 8 times 32 bits. IBM offers no persuasive reason why I should insert this limitation into the term "word," although its counsel -- while agreeing at oral argument that a "word" is indeed the amount of data that can be transferred in one memory cycle -- suggested (without evidentiary support) that only a small amount of data could be transferred in a single memory cycle using current technology. This may or may not be true, but it is not necessary to interpolate so precise a limitation into the patent claim.

Of course, I must interpret this limitation in light of the next following limitation, which specifically states that each data storage unit shall store "a respective one" of the several multi-bit data portions for each data word. (See below, page 32.) Thus, to fall within the literal patent claim, there must be an equivalent number of multi-bit data word portions and data storage units. That does not, however, mean that there may only be 32 data portions and corresponding 32 storage units in order to fall within the limitation. It is not inconceivable that a system could contain several hundred, or even thousand, data storage units, which would therefore be capable of storing a corresponding number of multi-bit word portions in parallel, one data portion to a memory unit.

IBM would also have me declare that the bits of data within the word must be logically related in the sense that they are part
of the same unit of information sent from the computer, and will be part of the same unit of information when returned to
the computer. To illustrate its point: IBM contends that "Mary had a little lamb" could be a data word, because all the "bits"
(that is to say, all the letters) are logically related; but "Mary had a little lamb and the Yankees are World Champions" could
not, because this statement contains two ideas that are not logically related. TM argues that there is no such limitation in the
patent claim, and points out that imposing any such limitation would exclude the preferred embodiment from the scope of
the patent -- a highly disfavored way of construing a patent, one that is "rarely, if ever, correct." See Vitronics, 90 F.3d at
1583. TM is correct, and I decline to impose this restrictive definition on the claim.

The parties agree that the term "parallel data bus" means a system containing more than one conductor within a computer
along which information is transmitted from a source within the computer to a destination within that computer. And the
term "multi-bit data portions" necessarily means data word subsets of two or more bits, because a system described in prior
art could read only one bit at a time. (A 605.)

I will thus describe this first limitation for the jury in the following terms:

We are dealing in this '979 patent with a system for storing something called digital data words. Digital means comprised
or made up of digits, which as we already know can be either 0 or 1. And data, as we already know, means information -- in
this case, information that is encoded into digital form. Now exactly what is a data "word"? Well, the term "word," in
computerese, means the amount of data, or the number of bits (binary digits, or 0s and 1s), that can be transferred to or from
input/output devices in a single memory cycle. It is not a specific number of bits; rather, it is whatever number of bits can be
transferred to or from input/output devices in one memory cycle. We will hear a lot more about input and output devices and
memory cycles as the trial wears on.

In this particular system discussed in the '979 patent, each digital data word is made up of two or more sub-parts, and
each of those sub-parts contains more than one bit, that is, two or more bits. For example, if you had a data word that was 64
bits long, it might have 8 multi-bit data portions consisting of 8 bits each. Or it might have 32 multi-bit data portions
consisting of 2 bits each. But however these sub-parts, these data portions, get whacked up, each one must have at least 2
bits.

Now our system, to be comprehended within the '979 patent, must have the capacity to store the data words in a particular
way. The system has to be able to store the data words in response to a storage request that is received over something called
a parallel data bus. When you think about a data bus, I want you to think about a Bee Line bus, or a city transit bus, or a
school bus. Those are devices for transporting people from one place to another. Well, in a computer, a bus is a device for
transporting data from one place to another. It consists of one or more conductors, along which information is transmitted
from a source to a destination. And a parallel data bus is more or less exactly what it says: it is a data bus that has multiple
conductors, or more than one wire, if you prefer, which can transmit data at the same time -- in parallel, so to speak -- from
one place within a disk system to another.

7. "word line driver circuit"

The parties dispute whether the "word line driver circuit" can provide a driving voltage to a word line or a group of word
lines.

Defendants assert that there can only be one word line for each word line driver circuit. Defendants contend that the
ordinary meaning of the term "word line driver circuit" indicates that it is limited to a single word line. Defendants rely on
MOSAID's definition of "driver" to support this alleged ordinary meaning. "Driver" is defined as "an electronic circuit that
Defendants argue that this definition supports their construction that a "word line driver circuit" supplies an input (i.e.,
voltage) to a word line.

Although Defendants are correct that this definition supports their construction, the Court finds that this definition is also
consistent with MOSAID's broader construction. Nothing in the definition limits a driver to supplying an input to only one

- 5121 -
circuit. On the contrary, it appears that a circuit that applied an input to multiple circuits would still be a driver. Since the Court is required to "give a claim term the full range of its ordinary meaning as understood by persons skilled in the relevant art," the ordinary meaning of "word line driver circuit" will include "one or more word lines."

Next, the Court turns to the claim language to determine whether the ordinary meaning is consistent with the claims. The phrase "word line driver circuit" is found in multiple claims in the '253 and '643 patents. The '253 patent is representative of how the term is used:

- "a word line driver circuit which applies the controlled high voltage V[pp] from the high voltage supply to a word line" '253 patent, claim 15 (emphasis added);
- "a word line driver circuit which applies the controlled voltage from the voltage supply to a word line" '253 patent, claim 22 (emphasis added);
- "a word line driver circuit, which applies the controlled high voltage V[pp] from the V[pp] supply to a selected word line" '253 patent, claim 29 (emphasis added).

Defendants contend that these relevant excerpts demonstrate that a "word line driver circuit" applies a voltage to a single word line. MOSAID counters by arguing that the word "a" before "word line" means one or more and thus the "word line driver circuit" is not limited to only one word line.

Defendants have the better argument. The word "a" in the '253 claims does not limit the word line driver circuit to only one word line. See KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000) ("This court has repeatedly emphasized that an indefinite article 'a' or 'an' in patent parlance carries the meaning of 'one or more' in open-ended claims construing the transitional phrase 'comprising.'") (citations omitted). Since the claims do not require that the "word line driver circuit" work with only one word line, its plain and ordinary meaning includes one or more word lines.

Defendants contend that the broader meaning of "word line driver circuit" is not supported by the specification. Defendants argue that nothing in the Lines patents states or even hints at the possibility that the word line driver can drive more than one word line. Defendants argue that one of ordinary skill in the art reading the Lines patents would believe that a secondary decoder's only function would be as an alternative voltage source for that one word line. Thus, according to Defendants, the "word line driver circuit" would be limited to the embodiment shown in Figure 1 of the Lines patents.

For the reasons stated above under the "means for applying" section, see Section 2 supra, Defendants' arguments are unconvincing. The secondary decoder is clearly contemplated as a circuit that can be used in conjunction with the "word line driver circuit" to select and drive more than one word line. Accordingly, the specification does not limit the ordinary meaning of "word line driver circuit" to the embodiment set forth in Figure 1 of the Lines patents.

In sum, the plain and ordinary meaning of "word line driver circuit" is unambiguous and means "a circuit that applies a driving input voltage to a single word line or a group of word lines."

19 This construction determines how the Court construes the disputed claim terms "word line selection signals" ('253, '640 and '643 patent claims), "select signals" ('253 claim 29), "word line control signals" ('253, '640 and '643 patent claims) and "control signals" ('253 and '643 patent claims). The only dispute between the parties concerning these terms is whether they are limited to a single word line or could apply to a group of word lines. Having found that the Lines invention contemplated an embodiment including a group of word lines, the Court adopts MOSAID's proposed constructions for each of those claim terms.
Claims 1, 25, 27, 28, and 31 of the '819 Patent contain the term "word vector." IPI contends that "word vector" means: "A representation corresponding to co-occurrence patterns and relationships between words. The word vectors represent co-occurrence patterns and relationships between word neighbors." Google contends the term means "a column or row of numbers with each number representing the number of times a particular word co-occurs with each other word within a range of words in a corpus of documents; also known as a 'thesaurus vector.'" The parties' dispute centers around whether the term "word vector" is used in a strict mathematical sense in the specification.

IPI's proposed construction is derived from the '819 Patent Abstract: "The word vectors represent global lexical co-occurrence patterns and relationships between word neighbors." IPI argues that "[a] 'word vector' is simply a representation of the co-occurrence patterns of the words in a document" and nothing in the specification requires that this representation be limited to a number or "the number of times a particular word co-occurs" with another word. IPI's Opening Brief, at 6-7. Google argues that IPI's proposed construction is overly broad in that it would cover representations of co-occurrence patterns that have nothing to do with the patented technology, such as a representation of co-occurrence patterns in prose (e.g., "[I]n this brief, 'claim' occurs more frequently with 'construction,' than with debtor."). Google's Responsive Brief, at 11. Further, Google argues that IPI's proposed construction "would result in 'word vectors' that would simply not work to perform the claimed methods" because "as the claims and specification make clear, the co-occurrences are counted." Id. at 12.

Indeed, Google argues that the term "vector" has a precise mathematical definition and thus, one of ordinary skill in the art would understand "word vector" to be numeric in nature. Google supports its assertion with both the claim language and the specification. Claim 1 recites in part, "recording a number of times a co-occurring word co-occurs in a same document . . ." and "generating a word vector for the word based on every recorded number." In addition, the specification states:

"The first preferred embodiment requires the formation of a co-occurrence-based thesaurus, which is formed by computing and collecting a (symmetric) term-by-term matrix C. Each element c[ij] of matrix C records the number of times that words i and j co-occur in a window of size k."

'819 Patent, col. 14:39-43 (emphasis added). Further, Google argues that Dimensions of Meaning, the inventor's article cited in the '819 Patent, explains how vectors representing the relationship between words are generated from a matrix or array of numbers based on co-occurrence patterns.

The Court agrees with Google that IPI's proposed construction is overly broad in referring merely to a "representation" because the specification indicates that a "word vector" is a particular form of representation of lexical co-occurrence patterns. In addition, IPI's use of the phrase "word neighbors" in the second sentence of its proposed construction serves to confuse rather than clarify the construction. On the other hand, contrary to Google's basic premise, although the term "vector" has a generally understood meaning of a variable quantity that can be resolved into components, such as a matrix of numbers, it is not used in that strict of a mathematical sense in the specification. However, from the claim language and the specification, it is clear that the term "word vector" is numerical in nature. Accordingly, the Court rejects both parties' proposed constructions and construes the term "word vector" to mean "a variable numerical quantity, which can be resolved into components, that provides a representation of a lexical co-occurrence pattern."

H. "Established on the World Wide Web"

The term "established on the World Wide Web" appears in claim 16 of the '253 patent. The term imposes an additional limitation on the remote system controller required by that claim. In other words, the remote system controller described in
claim 16 must be "established on the World Wide Web." 219

---------- Footnotes ----------
219 '253 patent, claim 16 (as amended).
---------- End Footnotes ----------

ABC asserts that "established on the World Wide Web" means "that is accessible as a service on the Internet and can be located by a URL." 220 WebEx contends that the term means "able to be communicated with through a browser using HTTP and HTML interpretation." 221

---------- Footnotes ----------
220 ABC's Brief, Docket Entry No. 154, at 21.
221 WebEx's Brief, Docket Entry No. 156, at 12.
---------- End Footnotes ----------

1. Accessible as a Service

ABC asserts that a device that is "established on the World Wide Web" must be "accessible as a service." ABC, however, cites no evidence, intrinsic or extrinsic, that supports this aspect of its definition. None of the cited evidence describes the WWW or devices associated with the WWW as "accessible as a service" or as necessarily providing a service. Therefore, the court will not include this limitation in its definition of "established on the World Wide Web."

2. Accessible on the Internet and Locatable by a URL

ABC contends that a device that is established on the WWW is accessible on the Internet and can be located by a URL. WebEx does not deny that devices that are established on the WWW are accessible on the Internet. In fact, WebEx specifically admits in its response brief that devices established on the WWW are a "subset of devices on the Internet." 222 Nor does WebEx deny that devices that are established on the WWW are locatable by a URL. To the contrary, WebEx admits that devices on the WWW can be located using URLs. 223 Furthermore, the available evidence, both intrinsic and extrinsic, supports ABC's position that a device that is established on the WWW is accessible on the Internet and can be located by a URL. 224

---------- Footnotes ----------
222 WebEx's Response, Docket Entry No. 166, at 14.
223 See id. at 15 ("[W]hile a URL can be used to locate devices on the World Wide Web, a URL also can be used to locate devices that are not on the World Wide Web. . . . ABC's proposal to define devices established on the World Wide Web as those that can be located with a URL fails to distinguish those devices from others that can be located with a URL but are not established on the World Wide Web.").
224 See, e.g., United States Patent No. 6,167,441 col.1 ll.20-22 (filed Nov. 21, 1997) (intrinsic evidence) ("The World Wide Web, or simply 'the web,' is the Internet's multimedia information retrieval system. It is the most commonly used method of transferring data in the Internet environment. . . . The path to a particular Web server is defined by a Uniform Resource Locator (URL).") (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 9). This patent was cited during the prosecution of the '945 patent in a Notice of References Cited. See Notice of References Cited (May 27, 2003) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6C). See also, e.g., Microsoft Computer Dictionary 479 (4th ed. 1999) (extrinsic evidence) (defining "Web page" as "[a] document on the World Wide Web . . . in a particular directory on a particular machine (and thus identifiable by a URL)," defining "Web directory" as "a list of Web sites, giving the URL . . . of each," and for the term "Web address," referring readers to the definition of URL, suggesting that the terms are
Despite its own admissions and the available evidence, WebEx argues that the definition of the term "established on the World Wide Web" should not mention the characteristics of being accessible on the Internet and locatable by a URL because other devices that are not established on the WWW also have these characteristics. The court is not persuaded by WebEx's argument. Even if certain devices that are not established on the WWW are accessible on the Internet and locatable by a URL, that does not mean that these characteristics should be excluded from the definition of "established on the World Wide Web." The court concludes that a device that is "established on the World Wide Web" is accessible on the Internet and can be located by a URL. The court will include these characteristics in its definition of "established on the World Wide Web."

225 To the extent that WebEx argues that the characteristics of being accessible on the Internet and locatable by a URL alone are not sufficient to define being established on the WWW, the court agrees. As explained below, at least one additional limitation is required.

226 WebEx made a similar argument with respect to the definition of the term "website," and the court found it equally unpersuasive.

3. Able to be Communicated with through a Browser Using HTTP and HTML Interpretation

WebEx asserts that a device that is established on the WWW may be communicated with through a browser using HTTP and HTML interpretation. ABC contends that a browser using HTTP and HTML interpretation is not the only means of communication with a device established on the WWW and, therefore, is too narrow a limitation.

a. Communicated with through a Browser

The evidence provided by the parties suggests that devices established on the WWW may be communicated with through a browser. For example, one prior art patent cited during the prosecution of the '945 patent (intrinsic evidence) states that "[t]he WWW is a collection of files written using [HTML]. . . . HTML files may be accessed and displayed using specialized applications known as 'web' browsers . . . ." Another prior art patent (intrinsic evidence) similarly explains that

[t]he World Wide Web (WWW) is one of the most popular information services on the Internet. The WWW uses browser software to decipher hypertext links to other documents or files located on remote computers all of which are connected through remote computers. Browsers therefore provide a user-friendly graphical interface which allows users to easily navigate or surf from site to site or file to file around the Internet. 227 Another prior art patent (intrinsic evidence) similarly explains that

The same patent explains that a browser provides a user the ability to both send and receive data to and from servers. 229
ABC points out in its response brief that the USPTO Examiner, during the reexamination of the ’253 patent, described certain devices disclosed in a particular prior art reference -- specifically, routers, switches, and cards -- as established on the WWW. 230 ABC then asserts that “[i]t is indisputable that a router, switch, or card is not ‘communicated with through a browser using HTTP and HTML interpretation.’” 231 Although ABC may believe this fact to be "indisputable," it provides no evidentiary support for it. The affidavit of ABC’s expert witness, which ABC cites, does not mention routers, switches, or cards, nor does it identify any other sort of device that is established on the WWW, but which cannot be communicated with through a browser. 232 Therefore, based on the available evidence, the court concludes that a device that is established on the WWW can be communicated with through a browser.

b. HTTP and HTML

WebEx further contends that a browser used to communicate with a device established on the World Wide Web is limited to using HTTP and HTML interpretation. In support of this contention, WebEx cites two prior art patents. 233 The first patent ("the ’586 patent") states that "[t]he WWW is a collection of files written using [HTML] . . . . Servers hosting HTML files can communicate using [HTTP]. HTTP is an application protocol that provides users access to files . . . using the HTML page description language." 234 The second prior art patent ("the ’441 patent") provides that "[i]n the Web environment, clients request Web pages from Web servers using the [HTTP]. HTTP is a protocol that provides users access to files which include text, graphics, images, [and] sound, using a standard page description language known as the [HTML]." 235
236 See Office Action in Ex Parte Reexamination of U.S. Patent No. 6,360,253, Control No. 90/008,052 (Dec. 19, 2007) ("Broadway specifically discloses the benefit of a split personal computer system operating using [HTTP] over the World Wide Web . . . and thus the means for permitting bi-directional communication between the remote and local hosts is 'established on the World Wide Web.'"); id. at 15 ("[O]ne of ordinary skill would have been motivated to add HTTP to Crawford . . ., thus creating a system controller 'established on the World Wide Web.'"); id. ("[A]ny host computer 104 or router/switch that runs HTTP for the connected computers would read on [the 'established on the World Wide Web'] limitation."); id. at 18 ("[O]ne of ordinary skill would have been motivated to add HTTP to pcANYWHERE . . . thus creating a system controller 'established on the World Wide Web.'"); id. ("[A]ny modern ISP controller that runs [HTTP] for the members of the subnet would read on the ['established on the World Wide Web'] limitation; for example, if the remote host also had the ability to run Mosaic or another browser popular at the time and the ISP interfac ed web data for the remote host via HTTP, it would read on the claim even despite the fact that the pcANYWHERE software itself is not taught as being web-based.").

238 TCP/IP, or "transmission control protocol/internet protocol," 239 is a different protocol than HTTP. The '586 patent also discusses the limitations of HTML, noting that it "is a 'display only' language." 240 The patent then explains that the limitations of HTML may be overcome by embedding within HTML files "applications" written in other programming languages. 241 As an example, the patent cites the JAVA programming language. 242

238 United States Patent No. 5,961,586 col.1 ll.29-33 (filed May 14, 1997) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 8).

240 United States Patent No. 5,961,586 col.1 ll.47-50 (filed May 14, 1997) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 8).

241 Id. col.1 ll.50-59.

242 Id.

The '441 patent also describes that use of other programming languages to communicate on the WWW. It explains that web browsers may support not only HTML, but also "dynamic HTML, XML, Java, [and] JavaScript." 243

243 United States Patent No. 6,167,441 col.1 ll.60-66 (filed Nov. 21, 1997) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 9).
Furthermore, the '253 patent itself mentions the use of the JAVA programming language. The specification explains that 
"[t]he system of the present invention can be implemented by utilizing a programming language called JAVA . . . . The 
JAVA language is ideally suited to allow communication between the Graphical User Interface (GUI) requirements of a 
local portion . . . and the remote portion of the split personal computer system." 244

ABC also points out that although the Examiner believed that any device that communicates utilizing HTTP would read 
onto the "established on the World Wide Web" limitation of claim 16, none of the Examiner's statements indicated that 
communication on the WWW is limited only to HTTP. More importantly, ABC made no representations limiting the 
invention to utilizing only HTTP.

Considering all the available evidence the court is persuaded that a browser communicating with a device that is established 
on the WWW is not limited to using HTTP and HTML interpretation. The evidence indicates that browsers communicating 
with devices established on the WWW may utilize other protocols and programming languages.

4. Conclusion

The term "established on the World Wide Web" means "(1) accessible on the Internet, (2) can be located by a Uniform 
Resource Locator (URL), and (3) can be communicated with through a browser."
phrase "at least a part of," intended that each of the above terms should include only complete compositions.

Although the issue is close, the court adopts the plaintiff's proposed construction. The defendant's claim differentiation argument fails because the relevant dependent claims of the '345 patent add additional limitations other than the limitation of a "partial work." These dependent claims also require, for example, that the partial works be "previewed" as well as selected from either the lists or a media inventory. As a result, the scope of the dependent claims referred to in the '345 patent are narrower than the independent claims from which they depend. Accordingly, the court construes the relevant terms to mean "audio and/or video compositions, e.g. songs, movies, music videos, advertisements."

4909

(1) Working Data Code

Square D argues that the term "working data code" should be construed to mean "the machine representation of information used by the processor during the execution of its quantifying and reporting functions." At the Markman hearing, it offered an alternative construction, which is a bit simpler: "the machine representation of information being worked on." EI argues that "working data code" should be construed to mean "software or firmware that executes using working data."

At the Markman hearing, counsel for Square D explained that "the difference is, aside from the exact language, is the working data code we're saying is actually the data itself. It's the working data that is in there. They're saying it's the program that uses the working data. And we're saying that that is just inconsistent with the claim." Transcript of Proceedings from December 3, 2009, pp. 43-44.

The Court agrees with Square D that "working data code" means the data itself, not the code that is run on that data. First, the patent's title - "Intelligent Electronic Device with Assured Data Storage on Powerdown" - makes clear that the invention is concerned with storing data, not storing the codes that will execute on that data. The abstract is consistent with this construction:

An IED includes a power monitoring circuit operative to monitor a parameter of a portion of a power distribution system and generate an analog signal representative thereof. A processor couples with the power monitoring circuit and operates to receive the analog signal and at least one of quantify and report the monitored parameter. The processor further includes an integrated circuit, the integrated circuit having a non-volatile memory operative to store program code for the processor. A digital processing core couples with the non-volatile memory and operates to execute the stored program code to implement the quantifying and reporting functions. A volatile memory couples with the processing core and operates to store working data code for the digital processing core during execution of the stored program code.

The stored program code is executed; the working data code is not.

Similarly, the language of Claim 1 makes clear that there is a distinction between working data code and program code. Indeed, the claim itself uses "working data code" and "working data" interchangeably: Claim 1 discloses "a method for storing working data code," U.S. Patent No. 6,745,138 B2, col. 29, line 11, and the final step in that method involves the period transfer of "said working data from said volatile memory to said non-volatile memory." Id., col. 29, lines 28-30. It is not a program that's being stored; it is data.

Claim 19 is consistent: it discusses storing working data code for said digital processing core during execution of said stored program code. Id., col. 30, lines 38-40. Again, it is the data that's getting stored, not the program. Accordingly, the Court construes "working data code" to mean "the machine representation of information being worked on."

4910

L. First Workspace Data/Second Workspace Data
Visto asserts that the term "workspace data" as used in claims of the '221 patent, means "data that may include e-mail data, file data, calendar data, user data, etc. Workspace data may also include other types of data such as applications programs."

Seven asserts that the term "workspace data" means "a plurality of workspace elements or independently modifiable copies of workspace elements, including corresponding version information, but not including external status indicators that indicate whether workspace elements or independently modifiable copies of workspace elements have been viewed or deleted."

The parties appear to agree that the term "workspace data" had no commonly understood meaning in the art. The court therefore turns to the specifications for guidance. In doing so, the court observes that Visto's proposed definition comes almost verbatim from the specification. See '221 Patent, Col. 5, ll. 45-47: "The LAN comprises a client 165, which includes a base system 170 for synchronizing workspace data 180 (e-mail data, file data, calendar data, user data, etc.) with the global server 115 .... Those skilled in the art will recognize that workspace data 180 may include other types of data such as applications programs." It is clear also from the drawings of the various patents that workspace data includes the corresponding version information for each of the workspace elements in workspace data. See '192 and '131 Patents, Fig. 2, Blocks 250 and 255; Fig. 3 Blocks 180 and 350; '708 Patent, Fig. 2, Blocks 250, 255; Fig. 3, Blocks 144, 350; '221 Patent, Fig. 7, Blocks 180, 782. The court therefore adopts Visto's proposed definition of the term "workspace data" but adds the additional limitation that workspace data includes the corresponding version information. The term means "data, including corresponding version information, which may include e-mail data, file data, calendar data, user data, etc. Workspace data may also include other types of data such as applications programs."

B. Legal Issues

Before construing any of the terms or phrases of the patents at issue, the Court addresses two legal issues that are pertinent to this claim construction: (1) whether the Court should defer to the claim construction of Judge T. John Ward of the Eastern District of Texas; and (2) whether the specification for the '708 patent can be used to construe the claims of the '192 and '131 patents.

1. Judge Ward's Claim Construction Order

Visto brought suit against Seven Networks, Inc. in the Eastern District of Texas for infringement of the same four patents at issue in the instant case. On April 20, 2005, Judge Ward issued a claim construction ruling which addressed many of the same terms and phrases at issue in the instant case. Visto argues that, although Judge Ward's order is not binding on Sproqit because it was not a party in the Texas litigation, the Court should nevertheless adopt the definitions of the terms and phrases construed by Judge Ward. See Op. Br. at 5. Visto suggests that this approach is appropriate under stare decisis and for reasons of judicial efficiency.

Stare decisis, of course, does not literally apply. This Court is not bound to follow the decision of another district court. See Texas Instruments, Inc. v. Linear Techs. Corp., 182 F. Supp. 2d 580, 589 (E.D. Tex. 2002) (stating that stare decisis "does not precisely apply"). However, according to Visto, the Supreme Court in Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996), "noted that stare decisis favors promoting uniformity in claim construction." Op. Br. at 5.

Visto's characterization of Markman is not entirely accurate. In Markman, the Supreme Court's concern was whether claim construction should be within the province of a jury or within the province of a judge. The Supreme Court provided several reasons as to why claim construction should be a matter for a judge, one of them being "the importance of uniformity in the treatment of a given patent." Markman, 517 U.S. at 390. The Supreme Court explained:

Uniformity would . . . be ill served by submitting issues of document construction to juries. Making them jury issues would not, to be sure, necessarily leave evidentiary questions of meaning wide open in every new court in which a patent might be litigated, for principles of issue preclusion would ordinarily foster uniformity. But whereas issue preclusion could not be asserted against new and independent infringement defendants even within a given jurisdiction, treating interpretive issues as purely legal will promote (though it will not guarantee) intrajurisdictional certainty through the application of stare
decisis on those questions not yet subject to interjurisdictional uniformity under the authority of the single appeals court

Id. at 391 (emphasis added). In other words, while Visto is correct that the Supreme Court took note of the importance of uniformity of claim construction, Visto ignores the fact that the Supreme Court also made a distinction between intrajurisdictional uniformity and interjurisdictional uniformity. In the instant case, there is no issue of intrajurisdictional uniformity because Judge Ward's opinion issued from a different district court. See Verizon Cal. Inc. v. Ronald A. Katz Tech. Licensing, L.P., 326 F. Supp. 2d 1060, 1069 (C.D. Cal. 2003) (“Furthermore, the AT&T Order has limited stare decisis effect, given that it emanates from a Federal District Court in a separate jurisdiction.”); Texas Instruments, 182 F. Supp. 2d at 588 (noting that the Supreme Court in Markman praised “intrajurisdictional harmony”). As for interjurisdictional uniformity, there is no indication that Judge Ward's opinion has been appealed and, even if so, that the Federal Circuit has made any decision as to the appropriateness of his claim construction.

As for the other authorities cited by Visto in support of its position, it is largely distinguishable or, as above, of limited support. For example, in Zoltar Satellite Systems, Inc. v. LG Elecs. Mobile Communications Co., 402 F. Supp. 2d 731 (E.D. Tex. 2005), the court did say that "inconsistent claim constructions of the same claims by different courts can create serious problems,” which "especially deserve consideration when the same patent is simultaneously being litigated in another district." Id. at 737. However, the court in Zoltar made this statement in connection with its decision as to whether the case before it should be transferred to another district where a judge had already done substantial work on a patent infringement case involving many of the same patents. In Atmel Corp. v. Silicon Storage Tech., Inc., No. C 96-0089 SC, 2001 U.S. Dist. LEXIS 25641 (N.D. Cal. June 20, 2001), the court did rely on a claim construction ruling that issued from the plaintiff's lawsuit against another party but that claim construction ruling had issued from another court in the same district. In other words, intrajurisdictional uniformity was at issue. Moreover, the court indicated that it was appropriate to rely on the claim construction ruling because the defendant in the case at bar had called that claim construction ruling well reasoned and correct and even sought to have it adopted in litigation before the U.S. International Trade Commission. See id. at *22. Finally, in KX Indus., L.P. v. PUR Water Purification Prods., Inc., 108 F. Supp. 2d 380 (D. Del. 2000), the court did make note of deference to a previous claim construction ruling but that was a ruling that had issued from the very same judge. Moreover, the court highlighted that it would defer to the prior ruling only "to the extent the parties do not raise new arguments," id. at 387, and the court actually revisited at least one of its earlier constructions and corrected it. See id. at 389 ("After reviewing Degen and the specification of the '311 patent, the court finds that its earlier opinion . . . about the scope of Koslow's disclaimer was wrong.").

Taking into account all of the above, the Court concludes that it will take into consideration Judge Ward's claim construction order as, per Markman, uniformity in claim construction is important. However, because Judge Ward's order is outside of this jurisdiction, this Court has discretion in determining the degree of deference accorded his order. The Court concludes that order such as Judge Ward's is entitled to "reasoned deference," with such deference turning on the persuasiveness of the order; "in the end, [however, the Court] will render its own independent claim construction." Innovations, L.P. v. Intel Corp., No. 2:04-CV-450, 2006 U.S. Dist. LEXIS 41453, at *13 (E.D. Tex. June 21, 2006) (stating that claim construction ruling from outside the jurisdiction would be taken into account "as a thoughtful and thorough analysis of the parties' arguments involving the same patent and the same claim" but that court would "in the end . . . render its own independent claim construction"); see also Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 2003 U.S. Dist. LEXIS 13900, at *8-9 (N.D. Ill. Aug. 8, 2003) (stating that, even though claim construction order from outside the jurisdiction was "persuasive," at times, the court might "not agree with that court and Markman . . . is not to the contrary").

2. Use of '708 Specification to Interpret '192 and '131 Claims

In its claim construction brief, Sproqit contends that the specification for the '708 patent cannot be used to construe the claims of the '192 and '131 patents. In response, Visto argues that Sproqit's argument has no merit because the '708 patent is related to the '192 and '131 patents. See Reply Br. at 4. The '708 patent states that it is related to and incorporates by reference the '192 patent. The '131 patent in turn is a continuation of the '192 patent. In addition, the specification for the '708 patent has a great deal of overlap with the specifications for the '192 and '131 patents (which are identical).

There is no doubt that the three patents are all related in some fashion. Moreover, Sproqit probably would not contest the use of the '192 and '131 specifications to construe the claims of the '708 patent because the '708 patent specifically states that it is related to the application for the '192 patent and the specification for the '131 patent is identical to that for the '192 patent. But the issue presents the converse - i.e., whether the specification for the '708 patent can be used to construe the
claims of the '192 and '131 patents.

In Goldenberg v. Cytogen, Inc., 373 F.3d 1158 (Fed. Cir. 2004), the Federal Circuit stated that, "[i]n the absence of an incorporation into the intrinsic evidence, this court's precedent takes a narrow view on when a related patent or its prosecution history is available to construe the claims of a patent at issue and draws a distinct line between patents that have a familial relationship and those that do not." Id. at 1167. In the instant case, although the '708 patent incorporates by reference the application for the '192 patent, neither the '192 patent nor the '131 patent makes any reference to the '708 patent or its application. Moreover, the '708 patent was not part of the parentage or the prosecution history of the '192 or '131 patents. See id. at 1168 (examining whether there was a "formal relationship" between two patents or whether one patent incorporated the other during prosecution). In fact, (1) the application for the '708 patent was not filed until after the application for the '192 patent and (2) the specification for the '708 patent contains new matter not contained in the specification for the '192 patent (and therefore the identical specification for the '131 patent). n1 In Goldenberg, the Federal Circuit addressed the issue of subsequently added new matter.

--- Footnotes ---

n1 For purposes of convenience, for the remainder of this section, the Court focuses on the relationship between the '708 patent and the '192 patent only. The '131 patent does not need to be discussed because it, as noted above, is a continuation of the '192 patent and has the same specification as the '192 patent. Therefore, it should not matter that the '708 patent came before the '131 patent.

--- End Footnotes ---

The patent at issue was the '559 patent. The '559 patent issued from the '662 patent application, which was a continuation of the '261 patent application. At the time the patent holder filed the '261 patent application, it also filed the '262 patent application. The '262 patent application led to the '729 patent application, which then resulted in the '744 patent. In short:

'261 patent application --> '662 patent application (continuation) --> '559 patent

'262 patent application --> '729 patent application (continuation in part) --> '774 patent

See id. at 1161. Notably, after the patent holder filed the '261 and '262 patent applications, the PTO - in a first office action - rejected certain claims of the '261 patent application on the grounds of double patenting over the '262 patent application. See id.

One of the issues in Goldenberg was whether the district court erred in relying on the '744 patent and its prosecution history when construing the claims of the patent at issue, i.e., the '559 patent. The Federal Circuit said both "yes" and "no."

According to the court, it was proper for the district court to rely on the '262 patent application as it existed when the patent holder distinguished the '262 application from the '261 application in response to the PTO's office action. This was because the response "constitutes part of the prosecution history of the '261 application, which is a parent application to the '559 patent, and therefore part of the '559 patent's prosecution history." Id. at 1167 (emphasis in original). However, the district court erred in relying on the specification of the '744 patent to construe the claims of the '559 patent because

...[the relevant passages from the '744 patent] ... were added during a continuation-in-part of the '262 application. These passages are therefore new matter added to the content of the '262 application subsequent to when it was distinguished in the [patent holder's] office action response. While the content of the '262 application at the time it was distinguished from the '261 application constitutes part of the prosecution history of the '559 patent, subsequently added new matter is not similarly incorporated.

Id. (emphasis added).

In the case at bar, no part of the '708 patent or its prosecution history is part of the '192 or '131 prosecution history. Under Goldenberg, the '708 patent would, in the first instance, have no bearing on the construction of the '192 or '131 patents.

To be sure, there may be narrow circumstances where a later patent may be looked to in construing an earlier subject patent
even where it is not part of the subject patent's prosecution history. In Microsoft Corp. v. Multi-Tech Systems, Inc., 357 F.3d 1340 (Fed. Cir. 2004), the Federal Circuit concluded that it was permissible for a court to rely on the prosecution history of a sibling patent to construe the claims of another patent even though the subject patent was issued earlier and its prosecution history did not reference the sibling patent. However, in that case, the specifications for the two patents were exactly the same, and it was the accused infringer who was trying to use the later-issued sibling patent to limit the scope of the earlier-issued patent. Evidently, when identical language is used and there is no new matter, the identical nature of the specification provides a basis for seeking parallel constructions. However, particularly in connection with the phrase at issue in this Order, the specifications for the '192 and '708 patents differ in material respects. The '708 addresses translation across formats; the '192 does not. Moreover, unlike Microsoft, in the instant case, it is Visto as the patent holder, not the accused infringer, who is trying to use the later-filed '708 patent to expand the scope of the earlier-filed '192 patent.

B. Construction of "an independently modifiable copy of the first workspace element" n2

Having addressed the legal issues above, the Court now turns to construction of the claim phrase "an independently modifiable copy of the first workspace element." Claim 1 of the '192 patent is a representative claim with respect to the use of this phrase. It provides as follows:

1. A computer-based method comprising the steps of:

   (a) establishing a communications channel through a firewall using an HTTP port or an SSL port;

   (b) generating first examination results from the first version information which indicates whether a first workspace element stored at a first store within the firewall has been modified

   (c) generating second examination results from second version information which indicates whether an independently-modifiable copy of the first workspace element has been modified, the copy being stored at a second store on a smart phone outside the firewall;

   (d) initiating steps (b) and (c) from within the firewall through the communications channel when predetermined criteria have been satisfied;

   (e) generating a preferred version from the first workspace element and from the copy based on the first and second examination results, wherein if only one of the first workspace element and the copy has been modified, then the step of generating includes selecting the one as the preferred version; and

   (f) storing the preferred version at the first store and at the second store.

Khaliq Decl., Ex. K ('192 patent reexamination certificate, cols. 2-3) (emphasis added). Like the parties, the Court shall address the claim phrase in two parts: (a) workspace element and (b) independently modifiable copy.

a. "workspace element"

"[T]he person of ordinary skill in the art is deemed to read [a] claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Phillips, 415 F.3d at 1313. Here, with respect to the claim term "workspace element," the specifications for the '192 and '131 patents state:

It will be further appreciated that the e-mail data 165, file data 170, calendar data 175 and user data 180 are exemplary and collectively referred to herein as "workspace data 185. Those skilled in the art will recognize that "workspace data" may
include other types of data such as application programs. It will be further appreciated that the e-mail data 165, file data 170, calendar data 175 and user data 180 may each be divided into workspace elements, wherein each workspace element is identified by particular version information 255. . . . Accordingly, each e-mail, file, calendar, etc. may be referred to as "a workspace element in workspace data."

'192 patent, Col. 3; "131 patent, col. 3.

The specification for the '708 patent is similar, stating:

It will be appreciated that the e-mail folder 138, file folder 142, calendar folder 140 and bookmark folder 144 or portions thereof may be stored at different locations such as on the desktop computer 134. The e-mail folder 138, file folder 142, calendar folder 140 and bookmark folder 144 are exemplary, grouped by like information and are collectively referred to herein as "workspace data" 136. Those skilled in the art will recognize that the workspace data 136 may include other types of data such as an application program such as Microsoft Work 6.0.1 TM word processor and the documents created using them. It will be further appreciated that the e-mail folder 138, file folder 142, calendar folder 140 and bookmark folder 144 may each be divided into workspace elements, wherein each workspace element folder or each workspace element individually is identified by particular version information 255. . . . Accordingly, each e-mail or e-mail folder, file or file folder, calendar or calendar folder, bookmark or bookmark folder, document or document folder, etc. may be referred to as "a workspace element."

708 patent, col. 3.

The parties agree that, per the specifications, a workspace element can be an e-mail, a file, a calendar, and so forth. For the '708 patent, a workspace element can also be an e-mail folder, a file folder, a calendar folder, and so forth. The parties disagree, however, as to whether a portion of an e-mail (or file, calendar, etc.) can be a workspace element. According to Sproqit, a workspace element must be, e.g., the entire e-mail, that is, each and every field making up the e-mail. According to Visto, a workspace element can be any part of an e-mail, even a single field of an e-mail. Visto relies on Judge Ward's order to support its position, see Ward Order at 22 (defining the term "workspace element" as "a subset of workspace data such as an e-mail, file, bookmark, calendar, or applications program which may include version information") (emphasis added), as well as a dictionary definition for the term "element." See Op. Br. at 10 (noting that Merriam-Webster's Collegiate Dictionary (10th ed. 1993) defines "element" as "simply 'a constituent part'"). As the Court previously indicated in its order denying Visto's motion for a preliminary injunction, each party has taken an extreme position.

Visto's claim that any part of an e-mail (or file, calendar, etc.) can be a workspace element is untenable. First, Visto's reliance on a dictionary definition for the term "element" is not appropriate. The problem with Visto's approach is that it "focuses the inquiry on the abstract meaning of [a] word[] rather than on the meaning of [a] claim term[] within the context of the patent." Phillips, 415 F.3d at 1321. Visto would have the Court look at the term "element" in isolation but the actual term to be construed is "workspace element." Second, Visto's reliance on Judge Ward's order is unavailing because Judge Ward's construction of the term "workspace element" was not intended to -- nor did it address -- the specific issue here, i.e., whether a portion of an e-mail can be a workspace element.

Furthermore, Visto's preferred construction of the term "workspace element" is not supported by the specifications of the patents at issue. Nowhere in the specifications is it suggested that a portion of an e-mail can be considered a workspace element. Simply because the specifications state that workspace data may be divided into workspace elements does not mean that a workspace element may be divided into bits. In discussing a workspace element, the specifications repeatedly refer to the larger -- and complete -- data structure of an e-mail.

"[E]ach e-mail, file, calendar entry, etc. may be referred to as 'a workspace element in workspace data,'" '192 patent, col. 3 (emphasis added); '131 patent, col. 3 (emphasis added).

. "[E]ach e-mail or e-mail folder, file or file folder, calendar or calendar folder, bookmark or bookmark folder, document or document folder, etc. may be referred to as 'a workspace element.'" '708 patent, col. 3 (emphasis added).

. "Therefore, a system and method are needed for providing users with data consistency, and more particularly for synchronizing multiple copies of a workspace element such as a document in the secure network environment." '192 patent,
col. 1 (emphasis added); '131 patent, col. 1 (emphasis added); '708 patent, col. 1 (emphasis added).

Cf. Honeywell Internat'l, Inc. v. ITT Indus., Inc., 452 F.3d 1312, 2006 WL 1703376, at *5 (Fed. Cir. 2006) (concluding that claim term "fuel injection system component" was limited to a fuel filter in light of the specification, which referred to the fuel filter at least four times as "this invention" or "the present invention"); adding that the fuel filter was not "merely a preferred embodiment" as it "was the only component of an EFI system that the written description disclosed as having a polymer housing with electrically conductive fibers interlaced therein").

Moreover, given the nature of the inventions claimed in the '192, '131, and '708 patents, it is implausible that any subpart or element (including, e.g., a single e-mail field) that is insufficiently complete to make the invention useful could itself be a workspace element. As indicated above, all three patents are designed to address the problem of data inconsistency, more specifically, when multiple copies of "a document" are maintained at different network locations. See '192 patent, col. 1 ("[W]hen maintaining multiple independently-modifiable copies of a document, a user risks using an outdated version. . . . [P] The problem of data inconsistency is exacerbated when multiple copies of a document are maintained at different network locations."); '131 patent, col. 1 (same); '708 patent, col. 1 (same). As Sproqit argues, "[t]he copies are intelligible and can be independently accessed and modified because they are complete and are not simply data fragments." Resp. Br. at 8 (emphasis added); see also Honeywell, 452 F.3d 1312, 2006 WL 1703376, at *5 (noting that "[t]he written description's detailed discussion of the prior art problem addressed by the patented invention, viz., leakage of non-metal fuel filters," supported limitation of the claim term "fuel injection system component" to a fuel filter). The nature of the invention as described in the specifications clearly contemplates that a workspace element be sufficiently complete and independently coherent so that there is utility to the synchronization of the workspace elements contemplated by the patents.

On the other hand, Sproqit's argument -- i.e., that anything less than an e-mail complete with all its fields and ancillary data is not a workspace element -- is equally unpersuasive. Under Sproqit's reasoning, if an e-mail were missing just one field, no matter how insignificant relative to all the other information, the e-mail could not be a "workspace element." Again, the nature of the invention revealed by the specifications is not necessarily defeated simply because a single field is not synchronized and replicated as between a remote device such as a smart phone and a local area network. As Visto pointed out at the hearing, a local area network is likely to have a much larger capacity (and thus is capable of accommodating more fields) than a remote device.

For the foregoing reasons, the Court rejects both extreme positions taken by Visto and Sproqit. Moreover, as noted above, the Court does not adopt Judge Ward's construction of the term "workspace element" because his construction does not address the issue at bar. In addition, under Judge Ward's construction, a workspace element could be an application program even though the specifications for the '192, '131, and '708 identify an application program as a type of workspace data, not a type of workspace element. As for Judge Ward's construction that a workspace element "may include version information," the Court shall address the relationship between a workspace element and version information when it construes the term "version information."

Accordingly, for the '192, '131, and '708 patents, the Court is inclined to construe the term consistent with this Court's order denying the preliminary injunction (and along the lines implicitly recognized by Visto's expert Dr. Head who stated that "the term 'e-mail' refers to the message headers, the message body, [and] status indicators (such as opened/unopened, deleted/undeleted, and other parameters such as urgency, and other message or system dependent parameters, etc.)"). Head Decl. P 28 (located at Docket No. 100).

For the '192 and '131 patents, the tentative construction for the term "workspace element" is as follows: A basic unit of workspace data such as an e-mail, file, bookmark, or calendar. While a portion of a basic unit is not necessarily a workspace element, a basic unit is still a workspace element so long as all significant or important components of that unit are present. For example, a single field of an e-mail is not a workspace element, but an e-mail is still a

For the '708 patent, the tentative construction is as follows: A basic unit of workspace data such as an e-mail or e-mail folder, file or file folder, calendar or calendar folder, or bookmark or bookmark folder. While a portion of a basic unit is not necessarily a workspace element, a basic unit is still a workspace element so long as all significant or important components of that unit are present. For example, a single field of an e-mail is not a workspace element, but an e-mail is still a
workspace element even if it does not contain each and every field present; in other words, an e-mail is still a workspace element so long as all significant or important fields are present.

The Court orders the parties to meet and confer regarding the above tentative constructions to determine whether they can agree on those constructions or on other similar constructions. If the parties are able to come to an agreement, then they should file a joint letter by August 14, 2006, stating what the agreement is. If the parties cannot come to an agreement, then each party should provide a brief (no longer than 5 pages) which (1) states whether the party will agree to the tentative constructions; (2) if not, provides comments on the tentative constructions; and (3) submits alternative constructions. Each brief should also comment on the alternative constructions (if any) proposed by the opposing party. (Such alternative constructions should be discussed at the meet and confer.) The briefs should be filed by August 14, 2006.

M. Workspace Element/First Workspace Element

The claims of the '192, '131 and the '708 patents include the term "workspace element." Visto proposes that the term means "a subset of workspace data." Seven proposes that the term means "an email, file, bookmark, or calendar, but not including external status indicators indicating whether the email file, bookmark or calendar as been viewed or deleted by a user." Notwithstanding Seven's proposed definition and arguments, the specification calls for a broader definition of workspace element. For example, in Col. 3 of the '192 patent, ll. 20-32, the patent refers to emails, files, calendars and "user data" and also to "application programs" all of which are further subdivided into workspace elements. Seven's definition is therefore too limited.

At the claim construction hearing, Seven's counsel urged that, whatever the court's construction of "workspace element," the definition should exclude version information because the specification repeatedly referred to workspace elements and version information as distinct subsets of the broader term "workspace data." The court has carefully reviewed the specifications of the various patents and disagrees with this argument.

In the '192 patent, the description states "It will further be appreciated that the e-mail data 165, file data 170, calendar data 175 and user data 180 may each be divided into workspace elements, wherein each workspace element is identified by particular version information 255 … . Accordingly, each e-mail, file, calendar, etc. may be referred to as "a workspace element in workspace data." The court therefore defines "workspace element" consistent with the breadth of the term permitted by the specification to mean "a subset of workspace data such as an e-mail, file, bookmark, calendar, or applications program which may include version information."
I. "workstation"

The term "workstation" appears in the claims of the '654 and '547 patents. Claim 11 from the '547 patent is representative:

11. A teleconferencing system, for conducting a teleconference among a plurality of users, comprising:

(a) a plurality of workstations

   (i) each associated with at least one user,

   (ii) each workstation including

       (1) a video display device, and

       (2) associated audio reproduction capabilities;

   (b) audio and video (AV) capture capabilities configured to capture

       (i) video images and

       (ii) spoken audio

       (iii) of a workstation user; and

   (c) at least one unshielded twisted pair of wires defining

       (i) a UTP data path

       (1) along which data can be shared

       (2) among the workstations, and

       (ii) a UTP AV path,

       (1) along which AV signals

       a. representing user video images and audio

       b. can be transported among the workstations.

wherein the system is configured to

(i) interactively display images

   (1) based on the shared data,

   (2) on at least two of the video display devices, and

(ii) reproduce video images and spoken audio

   (1) based on the AV signals,
CPI argues that "workstation" should be construed to mean "a position for an operator or user that is equipped with capabilities for computer data processing in combination with audio and video interaction." Tandberg argues that "workstation" should be construed to mean "a general purpose computer." At oral argument, CPI acknowledged that the "position" in its proposed construction must contain one or more devices. The parties' constructions thus differ in only one respect: whether the device or group of devices must include a general purpose computer.

The claims themselves place certain requirements on the workstation. Claims 1 and 8 of the '654 patent require that the workstation have "first and second monitors." Id. at 41:38-40; see id. at 42:34-41. Claims 1 and 8 also require that the workstation have "AV capture capabilities." Finally, both claims require that the workstation be "configured to control . . . the reproduction of images, based on the data signals, on the first monitor" and "the reproduction of participant video images, based on the AV signals, on the second monitor." Id. at 41:49-55, 42:42-50. Similarly, claim 11 of the '547 patent requires a workstation which includes "a video display device" and "audio reproduction capabilities." '547 patent at 42:54-58. In addition, the workstation must be able to share data with other workstations, and must be "configured to . . . interactively display images . . . based on the shared data" and to "reproduce video images and spoken audio . . . based on the AV signals . . . on at least one of the video display devices." Id. at 42:64-43:11. Taken together, the claims suggest that a workstation must at a minimum have the abilities to process AV signals, to process data, and to control the processing and reproduction of the AV signals and data.

Other than the specific physical components listed above, the claims do not expressly limit the type of system that can be used to implement the required capabilities. Tandberg's argument that the workstation must consist of a "general purpose computer" is therefore based on uses of the word "workstation" and descriptions of the CMW in the specification.

Tandberg argues that the specification expressly defines "workstation" to be a general purpose computer. Column 2, lines 34-37 states that "audio and video capture and processing capabilities have recently been integrated into desktop and portable personal computers and workstations (hereinafter generically referred to as 'workstations')." Although the cited passage purports to establish a uniform meaning of "workstation," the Specification and claims continue to use the word "workstation" in two different senses.

In the first sense, "workstation" refers to a particular type of high-performance computer, most commonly running some variant of UNIX. See Spec. at 14:63-15:1 ("Currently available personal computers (e.g., an Apple Macintosh or an IBM-compatible PC, desktop or laptop) and workstations (e.g., a Sun SPARCstation) can be adapted to work with the present invention."); id. at 15:33-41 (describing certain AV-enabled computers, including "Silicon Graphics' Indy workstations."). For purposes of clarity, the court will use the phrase "UNIX workstation" to indicate the narrower sense.

In the second, broader sense, "workstation" refers to the CMW, which includes AV capabilities above and beyond what were found in contemporaneous computers and UNIX workstations. Although the Specification is somewhat clumsy in its use of a single word to describe two different concepts, certain passages make clear that the CMW "workstation" is broader in its functionality than the UNIX workstation on which it may be based. For example, the sentence "[t]he currently available personal computers and workstations serve as a base workstation platform" uses both senses of the word workstation; a UNIX workstation may serve as the platform on which the multimedia-enabled CMW is based. Id. at 15:11-12. "The addition of certain audio and video I/O devices to the standard components of the base platform . . . enables the CMW to generate and receive real-time audio and video signals." Id. at 15:12-19. Tandberg's argument that the word "workstation" as used in the claims is strictly synonymous with "desktop and portable personal computers and workstations" as used in the Specification is therefore incorrect.

The proper question is whether the "base workstation platform" upon which the CMW is based can be anything other than a desktop computer or workstation. Under CPI's construction, any device with "capabilities for computer data processing" could serve as the base platform.

The statements distinguishing the invention from the prior art in the Summary of the Invention preclude CPI's broad construction. As Tandberg notes, "[s]tatements that describe the invention as a whole, rather than statements that describe
only preferred embodiments, are more likely to support a limiting definition of a claim term." C.R. Bard v. United States Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004). In C.R. Bard, the Federal Circuit relied on language in the Abstract and Summary of the Invention in concluding that the claimed prosthesis was required to have "a pleated surface." Id. at 863-64. The Abstract stated that the "implantable prosthesis includ[es] a pleated surface." Id. at 864. The Summary of Invention also stated that "[t]he implant includes a pleated surface." Id. Because the patentee consistently stated that the invention had a pleated surface, the Federal Circuit found that the claim term was limited. Id.

Although the court does not embrace a categorical rule that statements made in the Abstract, Summary of the Invention and Background of the Invention necessarily limit claim scope, the statements at issue here are particularly significant because they distinguish the patented invention from the prior art:

It has been proposed to extend traditional videoconferencing capabilities from conference centers, where groups of participants must assemble in the same room, to the desktop, where individual participants may remain in their office or home. Such a system is disclosed in U.S. Pat. No. 4,710,917 to Tompkins et al. for Video Conferencing Network issued on Dec. 1, 1987. It has also been proposed to augment such video conferencing systems with limited "video mail" facilities. However, such dedicated videoconferencing systems (and extensions thereof) do not effectively leverage the investment in existing embedded information infrastructures -- such as desktop personal computers and workstations, local area network (LAN) and wide area network (WAN) environments, building wiring, etc. -- to facilitate interactive sharing of data in the form of text, images, charts, graphs, recorded video, screen displays and the like. That is, they attempt to add computing capabilities to a videoconferencing system, rather than adding multimedia and collaborative capabilities to the user's existing computer system. Thus, while such systems may be useful in limited contexts, they do not provide the capabilities required for maximally effective collaboration, and are not cost-effective.

Spec. at 2:12-33 (emphasis added). This language unambiguously disclaims systems which do not "add[] multimedia and collaborative capabilities to the user's existing computer system." See also id. at 3:53-57 ("The present invention thus provides a distributed multimedia collaboration environment that . . . leverages ('snaps on to') existing computing and network infrastructure to the maximum extent possible.").

The invention disclosed in U.S. Pat. No. 4,710,917 (the "'917 patent"), which is cited and distinguished in the passage quoted above, illustrates the way in which CPI's construction is overbroad. The '917 patent covers "a video conferencing network for providing video, audio and data communication between remotely disposed video terminals." '917 patent at 2:54-56. Each video terminal ("MATE") contains a Central Processing Unit ("CPU") for data processing as well as equipment for recording and displaying audio and video data. Id. at 6:62-65, 5:26-34. The MATE described in the '917 patent is thus "a position for an operator or user that is equipped with capabilities for computer data processing in combination with audio and video interaction," which falls squarely within CPI's broad proposed construction.

At oral argument, CPI noted that the invention of the '917 patent differs from the claimed invention in other respects, including the lack of data conferencing capabilities. The Specification, however, distinguishes the invention of the '917 patent on the grounds that it is a "dedicated video conferencing system" that "does not effectively leverage the investment in existing embedded information infrastructures," and on the grounds that it "attempt[s] to add computing capabilities to a videoconferencing system." Spec. at 2:19-33. This language serves as an express disclaimer of dedicated videoconferencing systems with added data processing capabilities.

A passage from the lengthy "remote expert" scenario at the end of the Specification also strongly supports this construction, as it refers to the "invention" rather than any preferred embodiment:

It should be noted that the above scenario involves many state-of-the-art desktop tools (e.g., video and information feeds, information filtering and voice recognition) that can be leveraged by our Expert during videoconferencing, data conferencing and other collaborative activities provided by the present invention -- because this invention, instead of providing a dedicated videoconferencing system, provides a desktop multimedia collaboration system that integrates into the Expert's existing workstation/LAN/WAN environment.

Id. at 41:18-26 (emphasis added).

The Specification's discussion of the outer limits of what might be viewed as a workstation further supports a narrower
construction than CPI proposes. As already discussed, the CMW consists of a base workstation platform, augmented with audio and video capabilities. The capabilities can be added in a variety of ways. At one extreme, the capabilities can be completely incorporated into the base platform: "Add-on box itself can be implemented as an add-in card to the base platform 100. Connections to the audio and video I/O devices . . . can be implemented internally (e.g. via the system bus) rather than through an external RS-232 or SCSI peripheral port." Spec. at 16:17-22. At the other extreme, "Side Mount unit 850 can become virtually a standalone device that does not require a separate computer for services using only audio and video. This also provides a way of supplementing a network of full-feature workstations with a few low-cost additional 'audio video intercoms' . . ." Id. at 18:9-14. This second passage is notable because it defines the outer limits of a workstation; a device which "does not require a separate computer" is referred to as an "intercom" rather than a "full-feature workstation." Consequently, the court finds that "workstation" means "a position including a device or group of devices, which are equipped with capabilities for computer data processing in combination with audio and video interaction, and which are based upon or include a conventional desktop or portable computer."

4914

Writable Memory

The Court construes the term "writable memory" to mean "memory that is capable of having data written to and read from." First, for memory to be of any use, it must have the ability to be read from. And thus the "read from" limitation is inherent in the term's construction. Second, the Court declines to accept ST's proposed definition, "a read-write memory," due to Motorola's objection that it is ambiguous. Third, the Court also rejects Motorola's proposed definition 6 because it unnecessarily complicates the definition. Motorola's proposed language requiring "writing information into the cells of the array" is included in other claim language describing the writable memory as "a high density memory array," and thus it is not necessary to include the "array" limitation in the term "writable memory." '092 Patent, 49: 22-24.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

6 Motorola's proposed construction is: "memory capable of writing information into the cells of the array."

</tr>
</tbody>
</table>
access at any time to any of said memories"

Claim 11

The parties dispute the meaning of the language "at any time." Defendants argue that this limitation requires that each signal processor have read access and write access "without latency" or, in other words, "without delay." They further argue that Saxon reads the "at any time" language out of the term. Saxon argues that the "at any time" limitation refers to asynchronous operation of multiple processors, i.e. the idea that the processors need not all write at the same time or all read at the same time.

In addition to the Figure 1b embodiment discussed above, the patent also discloses an embodiment containing multiple processors, in which each processor does not have its own designated memory. '394 Pat. at 5:5-6. This embodiment is shown in Figure 1a:

[SEE FIG. 1a IN ORIGINAL]

The Figure 1a embodiment contains a bus arbiter 110 which controls access to the bus. If, for example, both signal processors 106 and 102 need to access system memory at the same time a collision will occur. '394 Pat. at 4:1-3. During a colliding access request, Bus Arbiter 110 assigns priority to one of the processors and only that processor will be able to access system memory. '394 Pat. at 4:8-13. In the meantime, the other processor remains stalled until it has access to the bus. '394 Pat. at 4:13-15. One of the benefits of the Figure 1b embodiment is that it avoids this stalling, i.e. it allows each processor to access memory "without latency." '394 Pat. at 5:18-26.

Defendants argue that the "at any time" limitation of this term refers to the Figure 1b embodiment and the fact that this embodiment allows write access and read access for each processor without latency. Saxon argues that this limitation refers to a more fundamental distinction over the prior art. Specifically, Saxon argues that the "at any time" limitation merely requires that the multiple processors be able to operate asynchronously. Saxon bases its argument on the prosecution history.

During prosecution, the patentee distinguished a prior art reference that also contained multiple processors ("Cutts"). See '394 Pat. Amendment at 1 (June 6, 1995). The patentee argued that Cutts disclosed a system in which each processor may have access to designated memories, but all of the processors operate on identical instruction streams. Thus, they would all read at the same time or write at the same time. '394 Pat. Amendment at 2. The patentee described Cutts as requiring synchronous operation. '394 Pat. Amendment at 3. In contrast, the patentee explained that "in the present invention, a processor's ability to write to any memory location in its area at any time allows the processors to execute entirely different and unrelated streams of instructions and to operate asynchronously of each other." '394 Pat. Amendment at 3. Furthermore, "[t]his ability for a processor to write to any of its memory locations at any time eliminates data write latency." '394 Pat. Amendment at 2-3. Based on this prosecution history, Saxon argues that the "at any time" limitation distinguishes systems that require synchronous operation, not systems that have data write latency.

Viewed in isolation, the phrase "at any time" could refer to asynchronous operation, but in the context of the entire claim, Saxon's position cannot stand. Phillips, 415 F.3d at 1314("the context in which a term is used in the asserted claim can be highly instructive"). Claim 11 requires that each signal processor have write access or read access at any time. The Figure 1a embodiment does not satisfy this limitation because each processor has read or write access only when no other processor has access. Cutts does not satisfy this limitation because each processor has read or write access only when every processor has read or write access. Thus, Saxon's argument that the "at any time" limitation was only meant to distinguish Cutts does not account for the fact that this limitation excludes systems with data read/write latency. Furthermore, while Saxon is correct that Claim 11 distinguishes systems that require synchronous operation, it distinguishes those systems by requiring that "at least one of said signal processors in said plurality operates independently of other signal processors."

To summarize, the parties have presented two different contexts in which data read/write latency may arise: (1) when bus access is limited, e.g. the Figure 1a embodiment, or (2) when multiple processors operate on identical instruction streams, e.g. Cutts. The Court finds that the "at any time" limitation excludes both embodiments. As explained above, neither the Figure 1a embodiment nor Cutts allows read and write access for each processor "without latency." Because Saxon's proposal does not account for the "at any time" limitation, it must be rejected. Defendants proposal, on the other hand,
appropriately describes this limitation as "without delay." 5 Accordingly, the Court adopts Defendants' proposed construction.

5 Saxon also argues that this "without delay" limitation is inappropriate because it is not physically possible. Saxon is correct that no processor can read or write to memory instantaneously. See, e.g., Paragon Solutions, LLC v. Timex Corp., 566 F.3d 1075, 2009 WL 1424443 at * 11 (Fed. Cir. 2009) (finding that "real time' cannot mean instantaneous"). Nonetheless, at the hearing, Defendants explained that they will not argue that this limitation requires an accused product to defy the laws of physics. Markman Hr'g Tr. at 117:18-118:6. Thus, Saxon's concern is unfounded.

GO BACK

4916

The term "write instruction" appears in claim 27 of the '226 Patent and claim 15 of the '244 Patent; it does not appear in the contested claim of the '136 Patent. Claim 27 of the '226 Patent describes "[a] method for accelerating access to data on a network comprising the steps of . . . intercepting a write instruction to one of said plurality of I/O devices from said computer." (226 Patent, at 28:24-25) (emphasis added). Claim 15 of the '244 Patent describes a caching system "wherein at least one of said cache drivers further includes executable interception code for intercepting a write instruction to one of said plurality of I/O devices. . . ." (244 Patent, at 27:5-7) (emphasis added).

The specifications in the patents-in-suit do not use the term "write instruction." Only the claims to the patents-in-suit use this term. However, the specifications refer to several write instructions that are intercepted by the cache driver software for the disk I/O device. For example, the specifications refer to the cache driver as intercepting a write data I/O access, write I/O data function, or write I/O data transfer. Specifically, the specifications state as follows:

When the Open VMS system (14) performs a write data I/O access to a disk (12) the cache driver (10) software intercepts the I/O. The cache driver (10) will search for possible matching TCMB (24) bucket control structures with their corresponding cache data buckets (22) in all three TCH (26) cache control structures, for the disk and the range of disk blocks in the write data I/O access. Using the write data I/O access disk block as a pointer into the disk block value hash table (30) of each of the three TCH's (26), the cache driver (10) attempts to locate matching TCMB (24) bucket control structures. For each TCMB (24) bucket control structure found, the TCMB (24) and its corresponding cache data bucket (22) are invalidated.

If the Open VMS I/O function is 'io_writelblk' (write logical blocks of disk I/O data), or 'io_writepblk' (write physical blocks of disk I/O data) or 'io_dse' (write data security erase pattern) (437), the program dispatches to the "write data" (572, FIG. 5K) program flow.

Referring to FIG. 5K, the "write data" (572) program flow . . . checks that the byte count for the intercepted write I/O data function is a non-zero positive value (574). . . . The program records the positive byte count of the intercepted write I/O data function in the TCB (16, FIG. 1) disk control structure for the disk I/O device.

The program checks whether the intercepted disk I/O device is currently subject to mount verification on the OpenVMS system (582), indicating that the OpenVMS system is checking the integrity of the volume mounted in the disk I/O device. If so, the program exists via the "I/O function exit" (564, FIG. 5J) program flow, allowing the write I/O data to go directly to the disk I/O device.

Referring to FIG. 5L, the "cache data invalidate" program invalidates the cached data blocks in all three caches, small, medium, and large, that match the disk block range in this intercepted write I/O data transfer for the disk I/O device. . . . If this TCMB is associated with the disk I/O device in the intercepted write I/O data transfer, the program checks whether the
In broader terms, the specifications refer to the cache driver software as intercepting an I/O operation. Specifically, the specifications provide that "[w]henever any I/O operation is performed on a disk I/O device, that I/O operation will be intercepted by the cache software of the invention and the program will commence running at the 'process io' (400) entry point." (Id. at 15:57-61) (emphasis added). The specifications refer to Figures 5A-50 of the patents-in-suit, when describing the I/O operations and the "program flow performed by the active data caching of a disk I/O device in the cache software of the invention." (Id. at 15:55-57). Figures 5A-50 describe the "process io" entry point (FIG. 5A), "cache on" program flow (FIG. 5B), "read data" program flow (FIG. 5C), "read cache miss" program flow (FIG. 5F), "read complete" program entry point (FIG. 5H), "read hit" program flow (FIG. 5I), "I/O function exit" program flow (FIG. 5J), "write data" program flow (FIG. 5K), "cache data invalidate" program flow (FIG. 5L), "write invalidate" program flow (FIG. 5M), "message receive" entry point, "remote invalidate" program flow (FIG. 5N), and "basic statistics" program flow (FIG. 5O). (Id. at 15:55-24:48).

Each of the various program flows commence running upon intercepting an I/O operation (i.e., read I/O data function, read I/O data transfer, write I/O data function, or write I/O data transfer). Thus, the term "I/O operation" is not limited to a write instruction, rather the term "I/O operation" encompasses read instructions as well. Because the specifications use the term "operation" instead of "instruction," the term "write instruction" is accurately described by the broader term "operation."

The IEEE DICTIONARY also confirms that a "write instruction" is accurately described as an "operation." The IEEE DICTIONARY does not define the term "write instruction." However, the IEEE DICTIONARY defines "instruction" as "[a] statement or expression consisting of an operation and its operands, if any, which can be interpreted by a computer in order to perform some function or operation." IEEE DICTIONARY at 528. (Instrument No. 69, at 22; Instrument No. 77, at 28) (emphasis added). The definition of "write" is "to record data in a storage device or on a data medium." IEEE DICTIONARY at 1210. (Id.). Thus, the IEEE DICTIONARY is consistent with the specifications of the patents-in-suit, which indicate that a "write instruction" is an "operation." The IEEE DICTIONARY is also consistent with the interpretation that the "write instruction" is used to transfer data to storage. However, the IEEE DICTIONARY does not describe the process by which a particular function (i.e., transferring data to storage) is to be completed.

In this case, the specifications provide that the "I/O operation will be intercepted by the cache software of the invention and the program will commence running at the 'process io'" (226 Patent, at 15:57-61) (emphasis added). The specifications make clear that the program goes through a step-by-step process of checking different specifications before allowing the transfer or invalidation of data. (Id. at 21:53-23:59). The specifications further indicate that the program flow uses information contained in the "write instruction" to assign different values, ranges, and sizes for the transfer of data. (Id.). Thus, the "write instruction" or "operation" does not immediately transfer the data to storage, it merely provides the necessary information to commence or initiate a process that eventually allows the transfer of data. Accordingly, the Court finds that an accurate construction of the term "write instruction" is "an operation that initiates a transfer of data to storage."
The parties' dispute over "writing . . . simultaneously" is similar to the "program" dispute. Lexar simply proposes that the claim phrase should be construed as "initiating a write command to two or more blocks at the same time." Toshiba, however, like its proposed construction of "program," suggests that "writing . . . simultaneously" means "issuing a write command, followed by address and data for two or more sectors at the same time and exactly coincident."

First, the Court notes that again, Toshiba's proposed "followed by address and data" language is superfluous and need not be included in the construction of the term. Second, the "exactly coincident" language proposed by Toshiba is a limitation that is not required by the "simultaneously" portion of the disputed claim term. Lexar is right that while the initial issuance of a write command must occur simultaneously in both write cycles, each and every step of the write cycles need not occur simultaneously. Specifically, as Lexar persuasively explained at oral argument, the programming phase of the write cycle, represented by the cross hatches in Figure 9, can take varying amounts of time depending on what is being programmed. Each phase of the write cycle, therefore, need not occur simultaneously. The cycles need only start at the same time.

The parties' proposed constructions also differ in that Lexar suggests that the write command is issued "to two or more blocks," while Toshiba suggests the write command is issued "for two or more sectors." Neither party addressed this particular difference between their proposed constructions in their briefs or at oral argument and therefore, the Court, in construing this term, opts to include a portion of the language used by the claim itself. The language represented by the ellipsis, as it appears in the claims themselves, is "writing two or more sectors of information to a row of the nonvolatile memory unit simultaneously." Therefore, the Court construes "writing . . . simultaneously" as follows: initiating a write command to two or more sectors within two or more (row) blocks at the same time.

The parties dispute the meaning of "writing the audio data from the buffer onto a digital audio tape and a random access storage device," as used in claim 1 of the '371 patent. NICE contends that, contrary to its plain meaning, Witness seeks to read into this language two improper limitations - that the transfer of audio from a buffer to the DAT and RAS device occurs "directly" and "simultaneously." Witness contends that the claim language, specifically the step after this disputed term, and the specification confirm the simultaneity requirement. NICE responds that the reference to "simultaneous" in the specification does not relate to information being transferred to the DAT and RAS, but to the transfer of data to one of those devices while the buffer is downloading data. With respect to proposed language "directly," Witness contends that the term "writing" inherently includes a subject or agent that performs the act of transferring data to the DAT and RAS, which in this case is the buffer. As the subject doing the transfer, Witness contends that the transfer has to be direct, rather than through an intermediary. Witness cites Figure 1 of the patent to support this interpretation.

The Court construes the disputed language to mean "transferring audio data from the buffer directly to both a digital audio tape and a random access storage device." After reviewing the claim language, specification, and Figure 1, the Court concludes that the disputed language includes directness component but not a simultaneity element. The specification, under the "summary of the invention" heading, states "a digital audio tape (DAT) and a random access storage (RAS) device are in communication with the buffer to simultaneously receive data when the buffer downloads data." (col 1:50-53.) The Court agrees with NICE that "simultaneously" in this context goes to reception and download, not to reception by DAT and reception by RAS. Figure 1 of the claim supports Witness's contention that the transfer of audio data to the DAT and RAS is direct.
1. "yield"

Defendant argues that the determination of "yield," even when read in light of the specification and prosecution history, does not permit a person of ordinary skill in the art to determine its meaning. D's. Brief. at 2. Defendant suggests that the "word 'yield' in the semiconductor field customarily refers to the 'percentage of finished products leaving a process compared to those entering the process.'" Id. at 3; Hurwitz Delc., Ex. 3. In other words, though the parties agree that "yield" refers to some criterion of successful or acceptable junction performance, the criterion itself is undeterminable from the patent language. Id. The specification language that includes the term "yield" is equally unhelpful, claims Defendant, articulating only that a relationship between temperature, self-limiting thickness, and yield exists without identifying how to determine said yield. Id. citing '672 Patent at col. 4:28-37, 49-59. Defendant suggests that the other specifications provide no guidance as they recite certain parameters related to junction performance that "cannot be combined into a pass/fail criterion" from which an understanding of "yield," can be gleaned. Id. at 5-7. Finally, Defendant disputes Plaintiff's suggestion that the definition of "yield" would vary according to manufacturer acceptance requirements, arguing that a flexible definition is unworkable in the semiconductor production industry. Id. at 9.

Plaintiff suggests that, consistent with general usage of the term in the semiconductor industry, a person skilled in the art would easily conclude that the claim term "yield" as applied to junctions, describes "the percentage of device junctions that retain satisfactory electrical properties following contact formation, typically characterized by a contact resistance less than 10 ohms and a junction leakage current less than 10-7 amps/cm2." Pl's. Brief at 5; '627 Patent col. 1:16-21. According to Plaintiff, the Defendant's definition of "yield" more properly corresponds to a "product yield;" the treatise on which Defendant relies explains numerous "yields" all of which share one commonality in that they measure a portion of operational units as a fraction or percentage of the total units. Id. at n.1. Because the specification identifies two specific metrics, the term 'yield' is clearly defined. Id. at 6 citing E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433 (Fed. Cir. 1988) ("It is entirely proper to use the specification to interpret what the patentee meant by word or phrase in the claim."). When viewed in context of the specifications, the term "yield" does establish some criterion by which a manufacturer can measure junction performance. Defendant's critique is valid, though the conclusion that "yield" is indefinite for lack of guidance is unsupported. However, Plaintiff's definition, which depends largely on the specification, goes too far. Therefore, the Court construes "yield" as "the percentage of device junctions that retain satisfactory electrical properties following contact formation." But, this does not end the inquiry.

An exemplar use of the term "yield management system" is seen in claim 1 of the '691 patent, stating in part, with the disputed term in bold:

1. A method for inventory management, comprising the steps of: . . . .

(d) generating a price quotation associated with the selected inventory item using the price forecasting system, which price quotation has been predetermined by a yield management system using a pricing strategy.

Grantley suggests that this term means, "software or any hardware programmed to calculate prices for remaining inventory based upon historical information such as past trends and performance data, available inventory and a pricing strategy. A 'system' does not include a human being attempting to perform the task or function manually." Clear Channel proposes "a software module that calculates and recalculates prices using each reservation and each order and designed to recalculate prices prior to the next price quote." The specification describes:

a yield management system which produces a pricing forecast used to determine prices for sales of commercial time
based on factors such as past trends and performance data which are updated periodically in order to maintain an accurate pricing model. See generally Pricing & Rate Forecasting Using Broadcast Yield Management, B. Shane Fox, published by the National Association of Broadcasters, 1992, and Broadcast Revenue Management: Pricing Inventory Management in Today's Broadcast Environment, B. Shane Fox, published by the National Association of Broadcasters, 1997.

'691 patent, col. 2, ll. 8-18. The referenced books have similar definitions of yield management. Normally such books would be extrinsic evidence which should be used with care in determining how one skilled in the art would define a term; however, these volumes are incorporated into the patent by reference, see '691 patent, col. 8, ll. 50-56, and are therefore a form of intrinsic evidence.

"Incorporation by reference provides a method for integrating material from various documents into a host document...by citing such material in a manner that makes clear that the material is effectively part of the host document as if it were explicitly contained therein." Cook Biotech Inc. v. Acell, Inc., 460 F.3d 1365, 1376 (Fed. Cir. 2006)(internal quotation omitted). In order to incorporate material by reference, "the host document must identify with detailed particularity what specific material it incorporates and clearly indicate where that material is found in the various documents." Id. (internal quotation omitted). In making such a determination, "the standard of one skilled in the art should be used to determine whether the host document describes the material to be incorporated by reference with sufficient particularity." Zenon Envtl., Inc. v. United States Filter Corp., 506 F.3d 1370, 2007 U.S. App. LEXIS 25892 at *17 (Fed. Cir. Nov. 7, 2007). "Ambiguous terms within the patent can sometimes be interpreted in light of disclosures made in the material incorporated by reference." Neutrino Dev. Corp. v. Sonosite, Inc., 410 F. Supp. 2d 529, 537 (S.D. Tex. 2006).

The parties agreed that "system" should be defined as inelegantly stated by the patentee - "software or any hardware device which has been programmed to perform the same function, but does not include a human being attempting to perform the task or function manually." '691 patent, col. 5, ll. 24-27. The opposing experts agreed that software without hardware does nothing. Except for certain limited purpose devices, hardware needs software to accomplish anything. Tr. at p. 101, l. 18 - p. 103, l. 6. Nevertheless, one skilled in the art would understand this definition of "system" to refer, in the context of these patents, to an appropriately programmed computer and not a person. Since "system" is so defined in the patents, and the definition comports with the understanding one of ordinary skill would have of computers, the court will incorporate that wording into the definition of the phrase. Similarly, the parties agree, and the specification states, that the "system" calculates and recalculates prices.

Given the parties' agreement that this term describes a computer or computer program that calculates and recalculates prices, it becomes clear that the real dispute concerning this term, as with the next term to be considered, is not its meaning, but rather what the claims using the term teach. See, e.g., Tr. at p. 95, l. 9 - p. 96, l. 3, p. 105, l. 4 - p. 106, l.1, p. 109, ll. 10-20..

Clear Channel wants the information used for the calculations to necessarily include "each reservation and each order." They argue that reservations are part of customer requests, which the yield management system calculates and recalculates. See, e.g., '691 patent, col. 1, ll. 10-13; col. 3, ll. 1-10; col. 12, ll. 1-62. However, Clear Channel disregards the fact that dependent claim 4 of the '691 patent is narrower in scope than independent claim 1, and further requires "recalculating pricing data in [claim 1(g)] in a manner that takes both orders and reservations into account." '691 patent, col. 17, ll. 21-22.

Were the court to accept Clear Channel's construction that "yield management system" requires reservations because reservations are always part of the recalculation that the yield management system performs, it would run afool of the doctrine of claim differentiation. While such canons are guides and not inflexible mandates, unless there is good reason to find otherwise, each claim defines a separate invention. See, e.g., Jones v. Hardy, 727 F.2d 1524, 1528 (Fed. Cir. 1984). A claim interpretation which would result in two claims having the same scope is presumptively unreasonable. See Beachcombers v. Wildewood Creative Prods. Inc., 31 F.3d 1154 (Fed. Cir. 1994). If, as Clear Channel argues, reservations are always part of the recalculations performed by the yield management system, the limitation of claim 4 is meaningless because the recalculation would already take reservations into account.

Clear Channel also argues that the court's construction of this term should require the method or system to "recalculate prices prior to the next price quote," and points to several places in the specification which supposedly support this argument. See, e.g., '691 patent, col. 3, ll. 40-50, 59-64; col. 4, ll. 7-11. However, Clear Channel does not include in their recitation the phrase from col. 4, ll. 54-55 which precedes the language they quote: "According to a preferred aspect of this
A court should avoid importing limitations from the specification into the claim terms, absent a clear disclaimer of claim scope. Phillips v. AWH Corp., 415 F.3d 1303, 1323 (Fed. Cir. 2005)(en banc)(citation omitted), cert. denied, 546 U.S. 1170, 126 S. Ct. 1332, 164 L. Ed. 2d 49 (2006); Gillette Co. v. Energizer Holdings, Inc., 405 F.3d 1367, 1375 (Fed. Cir. 2005). Where the specification uses language of preference, rather than requirement, the specification describes a preferred embodiment rather than an essential step or element of the claim. See Andersen Corp. v. Fiber Composites, Inc., 474 F.3d 1361, 1372-73 (Fed. Cir. 2007), Honeywell Int'l v. ITT Indus., Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006). The language Clear Channel references is a preferred embodiment, in which the yield management system recalculates prices before the next price quote is generated. What Clear Channel cannot point to is any description in the specification that would tend to show that this is the only embodiment the invention was intended to encompass. There simply is no clear language of requirement.

Patent claims recite the outer boundaries or parameters of the invention. S3 Inc. v. NVidia Corp., 259 F.3d 1364, 1369 (Fed. Cir. 2001). The purpose of claim construction is to determine what those outer boundaries are by construing disputed terms. United States Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997)("claim construction is a matter of resolution of disputed meanings and technical scope, to clarify and when necessary to explain what the patentee covered by the claims, for use in the determination of infringement."). Arguments calculated to establish that an accused device does not infringe, or that a claim is obvious, are better presented at a later date during an infringement and/or invalidity analysis. The definition of every word and phrase does not have to incorporate all of the other limitations set out in a claim. On the other hand, there is no need to add language to the definition of a term which would expand the scope of the claim beyond the limitations it actually teaches. Each claim sets out what factors are included in the calculation or recalculation performed by the yield management system. The court will define these terms as follows:

"Yield management system" means: "a computer with a program that produces a pricing forecast used to determine prices for sales of commercial time based on factors such as past trends, performance data, and available inventory, updated with data from recent transactions in order to maintain an accurate pricing model. A system does not include a human being attempting to perform a task manually."

"Yield management program logic" means "software that produces a pricing forecast used to determine prices for sales of commercial time based on factors such as past trends, performance data, and available inventory, updated with data from recent transactions in order to maintain an accurate pricing model."

5. "0-order" and "non-0-order" diffracted beams

In the photolithographic process, when the "first" and "second light beams" strike a mask pattern, some light diffracts directly back along the same axis; some does not. Claim 1 places these different types of diffracted light into two categories--viz., "0-order diffracted beams" and "non-0-order diffracted beams"--noting what role these beams play in the microlithographic projection procedure. Claim 1 does not otherwise define the "0-order diffracted beam" and "non-0-order diffracted beam" terms, and Nikon now asks the court to construe the "0-order diffracted" and "non-0-order diffracted" terms to mean "light beams, rays or components formed when light from respective localized areas of relatively higher light intensity diffracted by a mask pattern." Before the ITC, Nikon offered an identical construction, and, at that time, ASML apparently acceded to it.

Before this court, however, it appears that ASML has altered its position, asking the court to define "0-order diffracted beams" and "non-0-order diffracted beams" as nothing more than "0-order diffracted ray[s] of light and other higher order diffracted rays of light such as the 1st-order, 2nd-order," and the like. The court is mindful that the "0-order diffracted" and "non-0-order diffracted" terms carry, in certain contexts, purely descriptive, adjectival meaning, though not necessarily the circular meaning ASML suggests. In reference to a light beam, for example, "0-order diffracted" means simply that the beam is not diffracted to a particular (or any) order of magnitude. Since "diffraction" has a readily ascertainable meaning in the art (namely, the phenomenon exhibited by wave fronts that, passing the edge of an opaque body, are modulated, thereby causing a redistribution of energy), it follows that a "0-order diffracted beam" is a beam in which the energy has been..."
modulated and redistributed to the "0-order." In the context of claim 1, moreover, the "0-order diffracted" and "non-0-order diffracted" modifiers are used only vis-a-vis specific light beams, specifically those formed when light from localized areas of higher-intensity light is diffracted by a mask pattern. See '041 Patent at 18:21-26.

Specification language buttresses this understanding of the claim terms, and it allows the court to avoid resort to ASML's largely tautological approach. See '041 Patent at 3:31-50 & 9:32-41. "0-order diffracted beams" and "non-0-order diffracted beams" have specific meaning in the context of the claim, and the court must construe the terms to this end. See Pitney Bowes, 182 F.3d at 1311. For these reasons, the court construes "0-order diffracted beam" to mean "a light beam or ray formed when a mask pattern diffracts light back directly along the illumination axis"; in turn, "non-0-order diffracted beam" means "a light beam or ray formed when a mask pattern diffracts light off the illumination axis."
