'263 patent, cl. 15, 11. 57-60. As this passage illustrates, the access time register changes the amount of time in which a memory device returns data depending on the value stored in the register. Murphy Reply Decl. P 25. The critical technical aspect of this concept, that is not necessarily included in Hynix's proposed construction of "access time," is the injection of a potential and variable delay in the device's response.

Second, the specification reveals that it would be improper to limit the delay time, or the value stored in the access time register, to any single value. The specification states:

The configuration master should choose and set an access time in each access-time register 173 in each slave to a period sufficiently long to allow the slave to perform an actual, desired memory access. For example, for a normal DRAM access, this time must be longer than the row address strobe (RAS) access time. If this condition is not met, the slave may not deliver the correct data. The value stored in a slave access-time register 173 is preferably one-half the number of bus cycles for which the slave device should wait before using the bus in response to a request. Thus an access time value of 1' would indicate that the slave should not access the bus until at least two cycles after the last byte of the request packet has been received. The value of AccessReg0 is preferably fixed at 8 (cycles) to facilitate access to control registers. '263 patent, cl. 15, 11. 51-65.
Thus, the patent contemplates that the user can set the delay time to any desired value. The preferred embodiment takes steps to teach what the patentee believed to be the optimal delay times for the various access modes. However, the consistent use of terms such as "should," "preferably," and "choose" demonstrates the user is not required to set the delay time to any fixed or pre-determined value. Therefore, this court will not read such a limitation from the preferred embodiment into the construction of "access time register."

Similarly, it would be improper to limit the measurement of the delay time to ending at any specific pre-defined event. The specification explains:

[A] slave should preferably respond to a request in a specified time, sufficient to allow the slave to begin or possibly complete a device-internal phase including any internal actions that must precede the subsequent bus access phase.

'263 patent, cl. 8, 11. 39-42 (emph. added).

This passage demonstrates the patent contemplates the possibility that the delay time could be set to end either before or after the completion of a device internal phase. Rambus, however, agreed at the hearing that the time can be limited to commencing when the device receives a transaction request. Tr. 118:21. 19

--- Footnotes ---

19 In the construction of "access time register" the court adopts below, the court uses the phrase "receiving a transaction request" to describe the starting point of this time delay. To the extent this phrase contains any ambiguity, the court notes that the claims using "access time register" often describe the starting and ending events used to measure this delay time code. The court intends for its construction to be interpreted as a generic term which is further defined by the specific claims at issue. Tr. 117:2-118:4.

--- End Footnotes ---

iv. Rambus's construction is ambiguous

Rambus proposes the value in the access time register be construed as representing "access time delay." JCCS, Ex. A at 24. Hynix objects that this construction is circular and ambiguous. Notably, Rambus made similar objections to Hynix's proposed construction of "access time." Those same objections undermine the soundness of using "access time delay" in the construction. Having found that the ordinary meaning of "access time" does not necessarily equal the delay time, the court finds "access time delay" provides little guidance when evaluating possible infringement.

In searching for a clearer way to define the value stored in the access time register, the court finds the specification's description to be accurate and clear. Therefore, "access time register" is construed as "a data storage element to store a value representative of a time a device must wait from receiving a transaction request before responding to a transaction request." Tr. 118:18-20.

c. Delay Time

Hynix proposes "delay time" be construed using the same definition it proposed for "access time." For the reasons discussed in reference to the "access time register," "delay time" cannot be limited to equaling any fixed access time, nor can it be precisely measured in the fashion Hynix proposes. In addition, Hynix includes in its definition of delay time, "the availability of data at the outputs." Yet, the claims using "delay time" separately already set forth the action that occurs after the delay time expires. For example, claim 1 of the '263 patent involves "a programmable register to store a value which is representative of a delay time after which the memory responds to a read request." (emphasis added) Adopting Hynix's construction of delay time would render the representative claim 1's expression of the subsequent action (emphasized in quotation) superfluous.

Since each claim in which "delay time" is used as a separate term (as opposed to "delay time code") provides sufficient context to ascertain the purpose and functionality of the concept, "delay time" shall simply be construed "as an amount of
time that must transpire before commencing an action." The court finds this construction to comply most closely with the term's ordinary meaning. See OXFORD ENGLISH DICTIONARY (2d ed. 1989).

b. Delineating a set of factory operating rules

ITI contends that the limitation "delineating a set of factory operating rules" means to set forth a group of prescribed guides for conduct or action in manufacturing. According to defendants, the language should be construed as meaning to set forth in detail a group of prescribed guides for how a manufacturing plant works. The sole point of contention is the phrase "in detail" inserted by defendants, who argue that this is necessary to give the word "delineating" its ordinary meaning. See Pl's Reply at 5 ("The defendants' proposal is acceptable without the words 'in detail.'"). In its reply, ITI maintains that the meaning of delineating is straightforward and that substituting an everyday word with its definition is pointless.

The term "delineate" fits within the category of non-technical terms that have widely accepted meanings and do not require elaborate interpretation. See Phillips, 415 F.3d at 1314. In such situations, the Federal Circuit has approved the use of general purpose dictionaries to help determine the ordinary meaning of the terms. Id. Defendants provide the Court with Webster's definition of "delineate": to describe, portray, or set forth with accuracy or in detail. Webster's Ninth New Collegiate Dictionary 336 (1986). The definition ITI cites also includes the language "set forth with accuracy or detail." See Pl's brief at 5. Because the parties agree on the appropriate definition of delineate, and ITI points to no intrinsic evidence showing that the patentee intended a different meaning for the term, the Court adopts the following construction of the limitation: setting forth with accuracy, or in detail, a group of prescribed guides for how a manufacturing plant works.

2. "Demodulated Aural Signal"

Comark argues that the term "demodulated aural signal" means "an aural signal that has been amplitude or frequency demodulated." Harris contends that the term means "an aural signal that has been FM demodulated."

Step two of Claim 14 provides for "demodulating the commonly amplified television transmission signal to provide a demodulated aural signal[]" (Ex. DMX-1 at col. 8, lines 4-6.) Step three of Claim 14 provides for "performing a spectral analysis of the demodulated aural signal to determine the presence and frequency of unwanted aural signal noise resulting from unwanted aural carrier modulation[]." Id. at col. 8, lines 11-16.)

One of ordinary skill in the art, upon reading the '904 patent, would understand that there are both amplitude and phase components of unwanted noise that have been cross-modulated onto the aural signal. (Tr. 10/21/96 at 106, 127.) To identify the amplitude components of the unwanted noise, one of ordinary skill in the art would perform an amplitude demodulation of the aural signal. Id. at 106, 127. To identify the phase components of the unwanted noise, one of ordinary skill in the art would perform a frequency demodulation of the aural signal. Id. at 106, 127.

The court will adopt Comark's proposed construction.

3. "Non-Linear Phase Domain Video Signal"

In Part II.B.3. supra, the court stated that it will adopt Comark's proposed construction. Thus, the term "non-linear phase
domain video signal" means a video signal which is distorted in a non-linear way and fed to a phase modulator in order to phase modulate another signal.

* * *

The term "demodulated aural signal" in Claim 14 means an aural signal that has been amplitude demodulated or frequency demodulated.

A. Parties' Construction Arguments

The terms "demodulation" and "demodulator" do not appear in the specification of the '323 patent, and the term "demodulate" does not appear in the patent at all. Nevertheless, Plaintiff claims the intrinsic evidence clearly supports Plaintiff's construction of "demodulation circuitry" as "circuitry used to reconvert modulated data into its original, pre-modulated form." The most relevant intrinsic evidence is Claim 24 which provides that "demodulator circuitry" receives a "modulated data signal on the loop." Plaintiff also argues that the extrinsic evidence supports Plaintiff's construction, but Plaintiff's citations to extrinsic evidence, such as an IEEE Standard dictionary definition, reflect Defendants' construction nearly as much as Plaintiff's construction. The IEEE Standard Dictionary of Electrical and Electronics Terms 270 (6th ed. 1996) ("demodulation — (4) The reconversion of a modulated signal into its original form by extracting the data from the modulated data signal on the loop").

Defendants argue that when considering Claim 24 states that "demodulator circuitry" receives a "modulated data signal on the loop" and that the parties have agreed that "not a modulated data signal" means "not a signal conveying data through variation of amplitude, frequency, and/or phase," this broad construction and language supports Defendants' construction of "circuitry that extracts data from a modulated carrier." Defendants then cite a number of dictionary definitions for support, including the definition Plaintiff cites, that define "demodulate," for example, as "to extract (information) from a modulated carrier wave" or "to extract the information from (a modulated signal)." See American Heritage Dictionary of the English Language 483 (4th ed. 2000); Merriam-Webster's Collegiate Dictionary 332 (11th ed. 2003).

B. Analysis

The Court believes that both of the parties' constructions constitute the partial definition of the "demodulation circuitry" or "demodulator circuitry." There is little intrinsic record aside from Claim 24, which states that "demodulator circuitry is coupled to the connector to receive a modulated data signal on the loop," '323 patent, 10:5-6. So the intrinsic record only makes clear that the demodulator circuitry does something with respect to a "modulated data signal on the loop." Thus, since the intrinsic record is not clear by itself regarding the "demodulator circuitry," the Court also considers the extrinsic evidence. Both parties cite, and presumably agree with, the definition from the IEEE Standard Dictionary that states "demodulation — (4) The reconversion of a modulated signal back into its original form by extracting the data from the modulated carrier." The IEEE Standard Dictionary of Electrical and Electronics Terms 270 (6th ed. 1996). There are two parts of this definition that are separated by the word "by." Plaintiff's construction focuses on the first part and Defendants' construction focuses on the second part. As indicated from the word "by," the first part of the definition explains what demodulation is and the second part explains how the process of demodulation is performed. Hence, Plaintiff seeks a construction that explains what is occurring in the demodulation circuitry and Defendants seek a construction that explains how it occurs.

The Court believes that the construction should explain both what demodulation circuitry is and how it occurs in order to be most helpful to the jury. Therefore, the Court's construction uses parts of both Defendants' and Plaintiff's constructions, which are partially derived from the IEEE Standard Dictionary, and then supplements them with the information in the intrinsic record from Claim 24. So the Court construes "demodulation circuitry" as "circuitry used to reconvert a modulated data signal back into its original form by extracting the data from the modulated data signal on the loop."
7. "Demographic Conditions"

Claim 15 of the '150 patent recites "[a] process according to claim 11 wherein said step of fetching control data includes fetching data to specify demographic conditions." The parties disagree over the construction of the term "demographic conditions." The plaintiffs argue that "demographic conditions" refers to conditions based on the geographic location of the caller. The defendants contend that "demographic conditions" pertain only to the area code of the caller.

It is clear from the specification that the term "demographic conditions" does not have its ordinary and common meaning in the context of the Katz patents, as both parties agree. In the context of discussing various tests or conditions that may be imposed, the specification provides that "moving from the historic considerations, demographic tests may be specified as in relation to the geographic area manifest by the area code of the calling number." Column 6, lines 24 through 27 of the '150 patent. See also Column 12, lines 19 through 25 of the '150 patent. Katz lists several examples of "demographic conditions" in Column 7, lines 61 through 68 of the '150 patent. While all of the examples are conditions limiting calls based on a particular area code, one of the examples is a condition that limits calls to ANIs from a particular area code with particular prefix numerals.

The Court concludes that although the specification discusses demographic conditions in terms the area codes of the calling numbers, there is nothing in the specification that indicates that an area code can be the only basis for a demographic condition. Indeed, in one of the examples provided in the specification by Katz, the callers' area codes are used in conjunction with the prefix numerals of the calling numbers to indicate the callers' geographic area and limit the calls from a particular area. This convinces the Court that "demographic conditions" are not restricted to conditions based on the callers' area codes only. Thus, the Court construes the term "demographic conditions" to mean: conditions used to limit a call based on the caller's geographic area.

2. "demographics"

The parties dispute the construction of the term, "demographics." "Demographics" is a term that appears in each of the independent claims of the '025 Patent. (Herbst Decl. P 5, Ex. 3.)

Plaintiffs' proposed construction of "demographics" is "characteristics of human populations and population segments, especially when used to identify consumer markets." Defendants proposed construction of the term is "physical characteristics of human populations and population segments, such as age, occupation, income, sex, and marital status, to identify consumer markets." Thus, the parties' proposed constructions are similar to the extent they both define "demographics" in terms of "characteristics of human populations and population segments" that can "identify consumer markets." However, the parties proposed constructions are different to extent that Defendants' construction proposes the use of additional terms. Defendants use the additional term, "physical," as a method of limiting the meaning of the subsequent phrase, "characteristics of human populations." Defendants also use the additional phrase, "such as age, occupation, income, sex, and marital status," as means of providing examples of "characteristics of human populations and population segments." The Court now turns the parties' arguments in support of their respective constructions.

Initially, in support of their construction, Plaintiffs attack Defendants' construction on grounds that it adds unnecessary terms thereby rendering Defendants' construction internally inconsistent and confusing. In addressing Defendants' use of the term, "physical," Plaintiffs emphasize that none of the intrinsic evidence make reference to the term as a way of describing the "characteristics of human populations." Plaintiffs also argue that Defendants' use of the examples "age, occupation, income, sex, and marital status" is internally inconsistent because some of the examples are non-physical in nature, such as occupation, income, and marital status.
Next, Plaintiffs point to the prosecution history wherein Keithley consistently defined "demographics" in exact accordance with Plaintiffs' proposed construction. In April 1995, Keithley stated, "[t]he term demographics has a clear and definite meaning, based on standard dictionary usage and the explanations in the instant application. Demographics means the characteristics of human populations and population segments, especially when used to identify consumer markets. (American Heritage Dictionary.)" (Herbst Decl. ¶ 9, Ex. 7, Amendment After Final, submitted April 11, 1995 at p. 15.) In July 1995, Keithley again stated that "demographics" meant the characteristics of human populations and population segments, especially when used to identify consumer markets. (American Heritage Dictionary.)" (Id. ¶ 10, Ex. 8, Second Preliminary Amendment, submitted July 20, 1995 at p. 6.)

Conversely, in support of Defendants' construction, Defendants accuse Plaintiffs of ignoring critical statements made by the applicants during the prosecution history. Defendants argue that Plaintiffs' definition "was insufficient to obtain allowance of the '025 Patent" and that Plaintiffs ultimately submitted four articles 2 to the examiner that provided "additional information and examples of demographics." (Def.'s Claim Construction Br. 10:3-8; Pluene Decl. PP 4, 7, 8, 11, 13-16, Exs. C, F, G, J, L, M, N, O.) Pointing to the express demographic examples taken from the four articles submitted by Plaintiffs, Defendants argue that similar examples should be included in the construction of the term at issue. Defendants fail to provide factual citations that would support the importation of the demographic examples found in Defendants' proposed construction. However, the Court's independent review of the prosecution history reveals that the cited articles generally describe "demographics" as including such dimensions as age, sex, family size, income, occupation, education, family life cycle, religion, race, nationality, and social class. (Pluene Decl. PP 15, 16, Exs. N, O.)

In examining the parties' respective constructions of "demographics," the Court finds that Defendants' additional limitation ("physical") and extra exemplary language ("such as age, occupation, income, sex, and marital status"), are both unnecessary. The Court now addresses Defendants' proposed constructions in turn.

a. "physical"

Defendants' proposal of limiting the "characteristics of human populations and population segments" to only those that are "physical" fails for two reasons. First, it would effectively require the Court to read in an unsupported additional limitation. Defendant has not cited, and the Court has not located, any support for such a limitation in the claim language, the specification, or the prosecution history. Because neither the claim language, the specification, nor the prosecution history include such a specific limitation, the Court shall not impose one. See e.g., Cargill, Inc. v. Sears Petroleum & Transport Corp., 334 F. Supp.2d 197, 214 (N.D.N.Y. 2004) (quoting Cornell Univ. v. Hewlett-Packard Co., 313 F. Supp. 2d 114, 126 (N.D.N.Y. 2004)); Innova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 289 F. Supp. 2d 1347, 1351 (M.D. Fla. 2003), vacated & remanded, 381 F.3d 1111, 72 USPQ 2d 1001 (Fed. Cir. 2004) ("Adding limitations neither required by claim terms nor unambiguously required by either the specification or the prosecution history of a patent is impermissible."); Bristol-Myers Squibb Co. v. Teva Pharmaceuticals USA, Inc., 288 F. Supp. 2d 562 (S.D.N.Y. 2003); Intertrust Technologies Corp. v. Microsoft Corp., 275 F. Supp. 2d 1031, 1056 (N.D. Cal. 2003) ("the Court is wary of reading into claims a limitation that is not expressly there."); ICN Pharms., Inc. v. Geneva Pharms. Tech. Corp., 272 F. Supp. 2d 1028, 1039 (C.D. Cal. 2003) ("while the specification and prosecution history may provide interpretive context for the claims, the court may not read limitations into the claims.").

The second reason that Defendants' proposed limitation fails is because it creates a facial inconsistency when read in conjunction with the rest of Defendants' proposed construction. In particular, Defendant urges the Court to limit the "characteristics of human populations and population segments" to only those that are "physical" in nature. Defendant then encourages the Court to include a list of examples of such characteristics. However, Defendants' own proposed list includes examples that are non-physical in nature, such as occupation, income, and marital status.

For these reasons, the Court finds Defendants' proposed construction of limiting "characteristics" to only those that are
"physical" in nature to be unconvincing.

b. Exemplary language--"such as age, occupation, income, sex, and marital status"

Defendants' proposal of further describing the "characteristics of human populations and population segments" with a non-exhaustive list that includes "age, occupation, income, sex, and marital status" could create unnecessary confusion. While Defendants' examples are certainly within the dimensions of the term, "demographics," their list is by no means exhaustive of what the term encompasses. By including such a list, a jury could mistakenly interpret the scope of the term to be narrower than intended by: (1) finding the list of examples to be exhaustive; or (2) finding that the term is somehow limited to a subset of the items on the list. Defendant fails to explain how the proposed exemplary language would aid in the determination of infringement. Accordingly, the Court finds that Defendants' proposed exemplary language is superfluous.

Having considered the claims, the specification, and the relevant patent prosecution history, the Court construes "demographics" as "characteristics of human populations and population segments, especially when used to identify consumer markets."

4. "demographic(s) information"

The parties dispute the construction of the term, "demographic(s) information." The term appears in claim elements 1(f), 1(g), 2, 4, and 5, of the '025 Patent. (Herbst Decl. P 5, Ex. 3.)

--- Footnotes ---

3 Plaintiff identifies the term in plural form as "demographics information," while Defendant identifies the term in singular form as "demographic information." At the outset the Court notes that the parties are referring to the same term and that the term's construction does not depend on the Court adopting one form of the term over the other. (See Joint Claim Construction Stmt. at 41) (referring to singular and plural form of the term as the same term at issue.)

--- End Footnotes ---

The parties appear to agree that the term, "demographics information," generally refers to the information that populates the database that is subsequently made available to a second end user. (Id.) However, the parties do not agree on how to define such "demographic information." Plaintiffs' proposed construction of the term is "information from which interests or preferences can be assessed." Defendants proposed construction of the term is "a collection of analyzed and processed user inquiries that identify distinct trends or profiles regarding certain physical characteristics of human populations and population segments, such as age, occupation, income, sex, and marital status, to identify consumer markets. Such a collection results in something more than a time period, count of the length of time, or number of user inquiries." In support of their respective constructions, both parties primarily rely on the specification and the prosecution history. However, before turning to the parties' reliance on the specification and the prosecution history, the Court first addresses the claim language.

In examining the claim language, a claim term is to be given its ordinary meaning unless the patentee has explicitly redefined the term, or the term itself is so ambiguous it is incapable of being understood without reference to the specification. See Johnson Worldwide Assocs., Inc. v. Zebco Corp., 175 F.3d 985, 990, 991 (Fed. Cir. 1999) ("A court must presume that the terms in the claim mean what they say, and, unless otherwise compelled, give full effect to the ordinary and accustomed meaning of claim terms."). Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims. See Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001); CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1159 (Fed. Cir. 1997). Here, the Court notes that it has previously construed the claim term, "demographics." The Court construed the claim term in accordance with its ordinary meaning as, "characteristics of human populations and population segments, especially when used to identify consumer markets." As such, the Court is compelled to build on its previous construction of "demographics" unless there is evidence the patentee has otherwise redefined "demographics information" as having a wholly independent and unrelated meaning. In order to determine whether the patentee has done so here, the Court now
Turning to the '025 Patent specification, Plaintiff argues for a broad definition of "demographic information." Plaintiff points to portions of the specification whereby the patentee has described the invention as relating to a broad array of consumer trends such as, "design trends, new housing development, and competitive practices," (Herbst Decl. P 5, Ex. 3 at col. 5 ll. 51-55), "market trends and research as well as targeting advertising messages," and "increasing demand for housing . . . which could bring new deposit account relationship as well as the opportunity to book new mortgages," (id. at col. 11, ll. 37-46). Plaintiff contends that these examples are evidence that the term, "demographic information," relates broadly to trends that reflect market interest and preferences of the end user. 4

4 After a review of the '025 Patent specification, the Court does not find any evidence that the inventor intended the term, "demographics information," to be wholly independent from the previously defined term, "demographics."

Defendants do not address the specification's impact on the construction of the term at issue. Instead, Defendants focus on the '025 Patent's prosecution history.

Turning to the '025 Patent prosecution history, the Court denotes that the parties have differing interpretations regarding its impact in construing, "demographics information." Defendants aver that the patentee made certain relevant representations in an effort to avoid prior art. Specifically, Defendants point to the patentee's March 1995 remarks wherein he described the invention as one that "analyzed," "processed," and "created profiles of," "inquiries." (Pluene Decl. P 8, Ex. G; P 11, Ex. J.) According to Defendants, the patentee expressly carved out certain functions that are not "demographics information"--such as the "maintaining a time record, a count of the length of time, or the number of user inquiries." As such, Defendants insist that the construction of the term at issue must be narrowed to include only such information that is "analyzed, processed, and created" from the first end user inquiries.

Plaintiffs disagree that prosecution history requires such a limited definition of the term at issue. Plaintiffs maintain that "demographics information" is broad so as to include "the trend in popularity of houses in a particular price range, or style or location, or type of windows, or types of appliances," (Herbst Decl. P 9, Ex. 7 at p. 16), and "consumer trends," (id.), and "forecast[s] [of] demand for public goods and services," (id. at p. 22). Accordingly, Plaintiffs argue that the limitations in Defendants' construction are unnecessary.

To the extent, Defendants' construction consists of a second attempt to add a "physical" characteristic limitation, or to add exemplary language to the term at issue, the Court finds Defendants' construction unavailing. However, in light of the patentee's descriptions of the term in the prosecution history, the Court finds that Plaintiffs' construction is similarly unavailing. In the prosecution history it is evident that the information at issue was more than a report of the time spent, or number of inquiries made by, the first end user. Accordingly, the construction "demographics information" lies somewhere between the parties' competing interpretations.

Having considered the claim terms, the specification, and the relevant patent prosecution history, the Court construes "demographics information" as "characteristics of human populations and population segments, especially when used to identify consumer markets, that are created from the collection of first end user inquiries that identify distinct trends in interests or preferences."

The phrase "selecting a set of stored functions in dependence upon a received format identifier and said read user information" means selecting one or more functions based upon a received format identifier and said read user information. "Set" has a plain meaning of "one or more." As explained above, a "function" is an identifiable set of computer instructions, and a "type of formatting" is a layout or presentation of text and/or graphics on a page. Dow Jones proposes that "a set of stored functions" means "a particular stored and indexed function string." This construction accurately describes the meaning of "set of stored functions" in the preferred embodiment, but it ignores the second, "template" embodiment, '737
Patent, Col. 11, ll. 21-26. Moreover, there is no indication in the specification that the applicants attempted to limit the meaning of "function" or disavowed any other meaning. See Phillips, 415 F.3d at 1323 ("[P]ersons of ordinary skills in the art rarely would confine their definitions of terms to the exact representations depicted in the embodiments.").

8 Dow Jones also seeks to add the phrase "wherein the selection is dependent on both a received format identifier and said read user information, which are separate and distinct, and the format identifier is included in said identified request for specified content data." Dow Jones Opening Br. at 36. As discussed above, although the format identifier is included in the request under the preferred embodiment, this limitation of the claim scope is not justified by the claim language, specification, or prosecution history.

Consistent with the above construction of "network monitor," software is configured and hardware is installed.

The specification describes the formation of an active layer by deposition of GaAs and InAs with no post-growth steps. See col. 5, l. 9-17 (describing the deposition of InAs after a deposition of GaAs); col. 5, l. 33-35 ("After each deposition of inclusions in a plane, the epitaxial growth of GaAs is again performed so as to form another active sub-layer"). Further, the preferred embodiment discloses sub-layers deposited one on top of another, right after each other. The specification mentions other heterostructures besides the one discussed in the preferred embodiment. Col. 6, l. 19-21. However, the specification does not describe a deviation from the method employed to create the sub-layers with the inclusions. Col. 6, l. 25-26 ("InAs inclusions can be fabricated here according to the method embodying the invention.").

In addition, to overcome prior art references, the patentee indicated that the deposition of inclusions "is realized during semiconductor crystal growth." Pl. Br., Doc. # 53, Ex. 5 (Prosecution File History), Response to First Office Action at 4-5. The prior art references used post-growth steps, such as masking, annealing, and injecting ions, to create quantum boxes which serve the same function as the inclusions. Id. at 4-5.

Therefore, the court will construe the term as follows:

"sub-layers deposited successively during growth of said one layer, each of said sub-layer having . . . inclusions" means "the layer is formed by growing sub-layers, each of which has inclusions, one at a time, with each sub-layer forming on the
The parties agreed with this definition, subject to their dispute over the definition of "sub-layer," which is discussed above. Tr. at p. 158, l. 20-25; Tr. at p. 161, l. 9 - p. 162, l. 2.

D. Claim 21 of the '092 Patent

Claim 21 provides:

The device of claim 20 wherein said at least one memory further contains a depth parameter D and where said processor is configured to select said at least one cryptographic transformation based on the current value of said index parameter and said parameter D.

The parties dispute the construction of the phrase "depth parameter D." The written description discusses the D parameter:

An additional parameter is an index depth D. The value of D may also be non-secret, and (for example) may be client-specific or may be a system-wide global constant. The value of D determines the cycle length of the key update process. ('092 Patent, Col. 3:54-60.)

In the context of Claim 21, the reference to parameter D concerns the usage of parameter D in the key update process of the client device, not the server device. 6 The specification states, "D determines the cycle length." The parties dispute whether the inventor's use of the word "determines" means that D is used in the process of the secret key transformation operation to determine the cycle length or whether D is the cycle length value. In this regard, the specification provides:

In the client cryptographic update operations parameter D is used for two purposes:

Note that each iteration of the process of FIG. 2 corresponds to moving down one level in the drawing of FIG. 1, until the correct update operation is determined. Thus, the number of iterations of the loop cannot exceed D. ('092 Patent, Col. 6:38-41.) Thus parameter D represents the maximum number of iterations a transformation operation may have to iterate until a new updated secret parameter is found.

6 The Court declines the constructions of the parties which apply this claim to the "receiving device." The Court finds that the claim applies to a client device.

In addition, parameter D is also used to determine which update function to use during the transformation operation:

At step 230, the device tests whether the variable V is equal to the quantity 2.sup.N -3. If equal, function F.sub.A.sup.-1 should be applied, and processing proceeds to step 235 where the device increments C and updates K.sub.C by computing K.sub.C.rarw.F.sub.A.sup.-1 (K.sub.C). Otherwise, at step 240, the device tests whether the variable V is equal to the quantity 2(2.sup.N -2). If equal, function F.sub.B.sup.-1 should be applied, and processing proceeds to step 245 where the device increments C and updates K.sub.C by computing K.sub.C.rarw.F.sub.B.sup.-1 (K.sub.C). . .

('092 Patent, Col. 6:8-16.) A person of ordinary skill in the art reading the patent documents at the time of the invention would understand that the inventor used the word "determines" to mean that D is used in the cycle length calculation and that D itself is not the cycle length.

Accordingly, the Court construes "depth parameter D" in the context of Claim 21 to mean: a system parameter used to...
determine which transformation function to use in the secret state transformation process, and a parameter whose value is
greater than or equal to the number of transformation iterations in a transformation operation.

6. "value derivable from said secret state"

The "applying step" contains two substeps. Substep (I) discloses performing the "applying" step: "having associated
therewith an updated secret cryptographic value derivable from said secret state." The parties dispute the construction of the
word "derivable" as it is used in substep (I).

The word "derive" and the related term "derivable" have plain and ordinary meanings; they are: obtain or obtainable from a
source. See Webster's New Twentieth Century Dictionary, 491 (2d ed. 1983). This broad definition does not exclude
copying or any other means for deriving a value.

In the '092 Patent, the word "derive" is used with its plain ordinary meaning. For example, the "Summary of the Invention"
states:

The server then performs a series of operations to determine the sequence of transformations needed to re-derive the
correct session key from the client's initial secret value. These transformations are then performed, and the result is used as a
transaction session key (or used to derive a session key).

* * *

Using methods that will be described in detail below, such update functions are applied by the client in a sequence that
assures that any single secret value is never used or derived more than a fixed number of times (for example, three).

('092 Patent, Col. 2:48-65.) Since the patentee did not define derive or derivable, the Court finds that the plain and ordinary
meaning controls. Accordingly, the Court declines to construe the word "derivable."

d. "Derived Element"

Macromedia contends that the phrase "derived element" should be construed to mean "an element that is generated based on
one or more defining elements." (D.I. 470 at 6). Adobe contends that the phrase "derived element" should be construed in
accordance with the definition expressly provided in the specification, namely "an element which is calculated from the
defining element(s) via a present mathematical relationship." (D.I. 479 at 13).

In construing the phrase "derived element," the Court has considered the specification of the '443 Patent. ( '443 Patent, Col.
2, lines 39-43). Because the specification expressly defines the phrase "derived element" as Adobe contends, the Court
construes the phrase "derived element" to mean "an element which is calculated from the defining element(s) via a present
mathematical relationship."

(a) "Deriving" 28

Footnotes

28 In its Motion for Summary Judgment, Defendant Ion Beam refers to a larger phrase, "Deriving a beam path configuration
signal," and argues the entire phrase is indefinite (Ion Beam P.&A. at p. 23:14-18.). However, Ion Beam rests its argument on a bald assertion, with no argument, facts or legal citation supplied in support. (See id.) Accordingly, Ion Beam has not carried its burden on this point as a matter of law. See, e.g., Celotex, 477 U.S. at 322-325; see also Matsushita, 475 U.S. at 586.

Moreover, the claim term "beam path configuration signal" has already been defined, leaving only the term "deriving" to adjudicate.

Finally, Ion Beam argues the term "means for deriving a beam path configuration signal from said beam request signal" is indefinite. But that argument is rejected for the same reasons. (See Ion Beam P.&A. at 23-24.)

--- End Footnotes ---

Plaintiff Optivus argues "deriving" has the ordinary meaning of "arriving at." (Optivus P.&A. at p. 24.) In support of its argument Optivus relies on the definition found in Random House: "to receive or obtain from a source or an origin." (Airhart Decl. Ex. H. at 129.) Optivus also relies on the definition found in Webster's Third: "to obtain or gain through heredity or by transmission… 3. to gather or arrive at (as a conclusion) by reasoning and observation a to obtain inductively <<ideas <ITALICS>derived from nature>[.]" (Id., Ex. N at 211.) Similarly the Oxford English Dictionary defines "derive" as "to hand down" or "pass by descent or transmission," and more pertinently "[t]o draw, fetch, get, gain, obtain (a thing from a source);" as well as "[t]o obtain (a compound) from another, as by partial replacement;" and "to obtain by some process of reasoning, inference or deduction"; and finally "[t]o arise, spring, come from something as its source; to take its origin from." OXFORD ENGLISH DICTIONARY (2d ed. 1989) (emphasis in original).

In light of the common dictionary definitions, and the context of Claim 1, it appears "deriving" means "to obtain something from another thing or source." The relevant portion of Claim 1 recites "deriving a beam path configuration signal from said beam request signal." (Rosenberg Decl. Ex. 3, the '642 Patent at 15:6-7.) In other words, a beam path configuration signal ("x") is derived or obtained from the (previously mentioned) beam request signal ("y"). (See id.)

The court therefore rejects Plaintiff's proffered construction of "arriving at" for the term "deriving" because Plaintiff's construction does not make sense in the context of the claim term, and otherwise does not correspond with the common meaning of the term "to derive" or "deriving." On the other hand, Defendant Ion Beam's construction is overly limited. (See Ion Beam P.&A. at 25:3-4.) Ion Beam proposes the term "deriving" be defined as "computing or obtaining data from other data by application of a specified procedure." (Id.) While it appears the term "deriving" means "to obtain something from another source," the court is not persuaded it should import the limitations suggested by Defendant Ion Beam, i.e., "by application of a specified procedure."

The patent specification reinforces the court's conclusion that "deriving" be defined as "to obtain something from another source." (See, e.g., Rosenberg Decl. Ex. 3, the '642 Patent at 2:30-34, and 6:37-46.) For example, the specification describes "a method of radiation beam security [that] comprises receiving a beam request signal from a selected treatment location. The specification goes on to state "[a] beam path configuration signal is derived from the beam request signal and used to select the switchyard and beam transport system configuration." (Id. at 2:30-34.) More specifically, the specification also teaches:

a beam request is provided by control computer 52 and transferred to the dipole switch controller via interface 51. The dipole switch controller 60 encodes the beam request address into digital command signals specifying the selected dipole switch positions. Switch instructions are transferred via the interfaces…. The instructions are communicated to … the switches so that the switches are connected in the preselected orientations….

( Id. at 6:37-46.) Accordingly, the court hereby finds the claim term to mean "a beam path configuration signal is obtained from a beam request signal," wherein the term "beam path configuration signal" means "a detectable message indicating the arrangement of beam elements or physical properties of the beam"; and the term "beam request signal" means "a detectable message indicating a desire for the beam."
8. Deriving a Reference Cell Value

The term "deriving a reference cell value" means generating a value solely from the words comprising a cell, which value represents the words of the cell.

A. "a set of menus describing the database" 1

1 This term "a set of menus describing the database" is used in claim 1 of the '195 patent. See Declaration of Matthew Rawlinson ("Rawlinson Decl."), Exh. 4 ('195 patent). In their papers, the parties both assert that the disputed term is "a set of menus describing the stored database." Motion at 4:5-7; Opposition at 2:15-26. However, the word "stored" does not appear in the disputed term.

The Court has already construed the term "database" to mean "a conventional hierarchical database in which data [is] organized into records, known as segments, that represent nodes in a hierarchy or tree." April Order at 9:16-17 (emphasis added). Necessary to the Court's construction of the term "database" was a finding that the "set of menus"--which describes the "data"--is also hierarchical. 2 Thus, "describing" is the only word in the disputed term that remains unresolved.

2 The April Order states: "Specifically, Defendant points to the fact that the inventor sought to overcome prior art by providing 'a set of hierarchical menus describing the data, and for accepting selections from the menus.' Jefferson Decl., Ex. 3 at CA 00414 (quotation omitted). During the hearing on this matter, Defendant argued that the "set of menus" is directly related to the type of 'database.' The Court agrees." Id. at 9:1-5.

Plaintiff argues that the parties stipulated to a definition of "set of menus" that was not necessarily hierarchical--"a collection more than one menu." See Joint Claim Construction, Exh. A at 5. However, in light of the Court's prior construction of "database" this fact is of no moment.

Plaintiff contends that the ordinary meaning of "a set of menus describing the database" is a "'set of menus' that includes items descriptive of portions of the stored 'database'" Motion at 4:18-20 (emphasis added). Defendant, on the other hand, asserts that the term is properly defined as "a set of menus in which the individual menus and menu selections correspond with segments of the stored hierarchical database." Opposition at 2:13-15 (emphasis added).

Defendant argues that Plaintiff's definition allows too loose a relationship between the "database" and the "set of menus." Specifically, Defendant contends that, under Plaintiff's construction, the "set of menus" would not necessarily have to describe the entire "database." Opposition at 3:12-14 ("[i]n [Plaintiff's] view, if just two items in a set of menus are 'descriptive' of two pieces of data in the database, the limitation is met, no matter how many other items are included in the menus, and no matter how small a part of the database those two pieces of data constitute") 3 The Court agrees.

3 Defendant also implies that there is a substantive difference between "describing" (used in the disputed term) and
"descriptive" (used in Plaintiff's proposed construction). The Court disagrees. See Declaration of Susan Baker Manning ("Baker Decl."), Exh A (American Heritage College Dictionary (Third Edition), Houghton Mifflin Company) at 376 ("describe…1. [t]o give an account of in speech or writing. 2. [t]o convey and idea or impression of; characterize…"); "descriptive…1. [i]nvolved or characterized by description; serving to describe.") (emphasis added).

Because the term "describing" is not modified by any limiting language, it implies that the "set of menus" must collectively describe the entire database. Although Plaintiff's proposed construction can be read in a manner consistent with this requirement (i.e., each "portion of the stored database" is described by an "item" from the "set of menus"), it is not limited to such a reading. However, Defendant's proposed construction is also problematic in that the word "correspond" (used in Defendant's proposed construction) is not synonymous with "describing." Therefore, the Court must fashion its own construction.

4 Although menu items must necessarily correspond with portions of the database, the term is not limited to the "one-to-one" relationship suggested by Defendant's proposed construction.

Because the word "describing" is not a term of art, the Court may look to standard English dictionaries for the word's ordinary meaning. Texas Digital Systems, 308 F.3d at 1202-3. The American Heritage College Dictionary defines "describe," in the relevant context, as (1) "[t]o give an account of in speech or writing;" or (2) "[t]o convey and idea or impression of; characterize." Baker Decl., Exh. A. Similarly, the Oxford English Dictionary Online (Oxford University Press, 2003) defines "describe" in the following manner: "[t]o set forth in words, written or spoken, by reference to qualities, recognizable features, or characteristic marks; to give a detailed or graphic account of." Rawlinson Decl., Exh. 15.

Because nothing in the specification or prosecution history manifestly excludes, or even puts into question, the ordinary meaning of the word "describe," the Court construes "a set of menus describing the database" to mean the following: "a set of menus that, when taken as a whole (i.e., collectively), give an account, or convey an idea or impression, of the entire database."

d. Describing the parameters in terms of data structures of the chosen model

ITI proposes that the limitation "describing the parameters in terms of data structures of the chosen model" means: a data structure is a table of data including structural relationships, or an organizational scheme, such as a list or record or array, applied to data so that it can be used. Defendants suggest that the Court adopt the following construction: representing the parameters by a table of data including structural relationships, or an organizational scheme, such as a list or record or array.

The parties' constructions are virtually identical; no true dispute exists. The only term either party defines with any elaboration is "data structures," and the parties appear to be in full agreement on the appropriate meaning of this term. Thus, the Court construes the limitation to mean describing the parameters using a table of data, including structural relationships or an organizational scheme, such as a list, record, or array.
16 The term "description of a product" is in claim 1.

Plaintiff's Proposed Construction
information sufficient to identify a product or service

Defendants' Proposed Construction
information sufficient to identify a particular product

"data representing a plurality of products" 17

Plaintiff's Proposed Construction
data sufficient to identify two or more products or services

Defendants' Proposed Construction
data sufficient to identify two or more particular products

Plaintiff argues that the only difference between the parties' proposed constructions--the insertion of a single word by Defendants--is not supported by the claim language. OPENING at 30. Defendants argue that as a matter of logic, the claims require that a particular product be selected. RESPONSE at 22-23. Defendants also point to portions of the specification which refer to "the product," in support of their argument that a particular product must be identified or selected. Id. at 23-24.

Claim 1 of the '253 patent discloses:

1. A method of doing business over a global communications network comprising the steps:

   communicating to a buyer via the global communications network, a description of a product;

   accepting a first request from the buyer to buy the product for a price to be determined within a price range;

   accepting a second request from the buyer to allow the price to be determined based upon a performance of the buyer while participating in a Price-Determining-Activity (PDA);

   receiving data from the buyer over the global communications network, said data representing the performance of the buyer during the PDA; and

   determining the price of the product based at least partially upon the data received, said price being within the price range and scaled to the performance of the buyer.

'253 patent at 9:31-49 (claim 1). Claim 18 discloses:

18. A method of determining a price of a product using a global communications network, comprising the steps:

   communicating to a buyer via the global communications network, data representing a plurality of products available, said plurality of products including a first product;

   accepting acknowledgment from the buyer representing an intent of the buyer to buy the first product at a price to be determined upon a performance of the buyer while participating in a Price-Determining-Activity (PDA), said acknowledgment being communicated over the global communications network;
determining the performance of the buyer; and

assigning a price to the product, said price being scaled to the performance of the buyer.

'253 patent at 10:34-47 (claim 18). Neither of these claims indicate that a "particular" product is identified. Moreover, claim 1 recites "a description of a product." It is a fundamental principle of patent law that the term "a" in a patent claim means "one or more." See Baldwin Graphics Sys., Inc. v. Siebert, 512 F.3d 1338, 1343 (Fed. Cir. 2008); Free Motion Fitness, Inc. v. Cybex Intern., Inc., 423 F.3d 1343, 1350-51 (Fed. Cir. 2005); Scanner Techs. Corp. v. ICOS Vision Sys. Corp. N.V., 365 F.3d 1299, 1305-1306 (Fed. Cir. 2004); Crystal Semiconductor Corp. v. TriTech Microelectronics Intern., Inc., 246 F.3d 1336, 1347 (Fed. Cir. 2001). Absent the indication of a clear intent to limit the article, this language can be read as "one or more descriptions of one or more products." Thus, to construe this term to require a "particular" product could be misleading to the jury. Further, the specification fails to indicate that a "particular" product must be identified. The specification refers to identifying "a product" or "the product," but there is no support for Defendants' proposal. Therefore, the Court finds that the proper construction of the term "description of a product" is "information sufficient to identify a product or service." The Court finds that the proper construction of the term "data representing a plurality of products" is "data sufficient to identify two or more products or services."

1227

3. "a descriptor signal which corresponds to data stored within memory"

3Com proposes "a descriptor signal which describes data stored within host memory." Doc # 81 (05-0098) at 34. Realtek proposes "a signal indicating where the corresponding data is in the host memory." Doc # 81 (05-0098) at 34.

3Com argues that this term should be given its ordinary meaning. Doc # 340 (03-2177) at 15. Realtek, however, criticizes 3Com's proposal as "so broad as to be meaningless." Doc # 333 (03-2177) at 28. The court agrees that this definition is likely too broad to be helpful.

Realtek argues that "the specification uses 'descriptor signal' and 'descriptor' as synonyms." Doc # 333 (03-2177) at 26. Realtek compares claim twenty-six's statement of "using said descriptor signal to generate a frame segment descriptor using a segmentation circuit" with claim one's statement that "said segmentation circuit utilizes said descriptor to generate a frame segment descriptor." '446 patent at 12:51-53; 14:18-19. This evidence shows that the "descriptor" and "descriptor signal" are closely related. It is not, however, sufficient to show that the "descriptor" and "descriptor signal" are synonyms.

3Com argues that the "first signal" from claim fifteen is the same as the "descriptor signal." Doc # 340 at 16. Given the common designation "signal," the lack of any other signal and the similar function performed by these two signals, the court finds this argument is persuasive. Further, 3Com's position that the "descriptor signal indicates where a descriptor is stored within the host memory" is consistent with the observation above that the descriptor signal and descriptor are closely related. '446 patent at 13:35-36. 3Com's argument, however, appears to support Realtek's proposal. If the "descriptor signal indicates where a descriptor is stored within the host memory," the descriptor signal surely corresponds to the descriptor. Further, the descriptor is stored in host memory. Accordingly, the descriptor signal is "a signal indicating where the corresponding data are in the host memory."

The court is, therefore, in the strange position of accepting 3Com's argument and Realtek's proposal. The court adopts the construction "a signal indicating where the corresponding data are in the host memory."

F. "Design or style standards"

Claim 62 of the '025 patent states, "The computer system of claim 45, wherein the presentation rules of the internet media venue comprise design or style standards, further comprising a computer program design filter to automatically apply or
compare the internet media venue design or style standards to the information input by the seller or the advertisement to
to control look and feel of the advertisement to be displayed on the internet media venue. FM proposes that
"design or style standards" should be construed as "presentation rules which control the look and feel of an advertisement."

Google
Enhanced Coverage Linking
Google -Search using:

* News, Most Recent 60 Days
* Company Dossier

does not offer a proposed construction because it contends that the claim is indefinite. The claim is indefinite, according to
Google, due to the multiple cascading "or"s in the claim language and because the proposed construction is purely
functional.

To support its multiple "or"s argument, Google cites In re Archbold, 151 F.2d 350, 33 C.C.P.A. 725, 1946 Dec. Comm'r Pat.
63 (C.C.P.A. 1945), which held that the use of multiple "or"s in the term "volatile solvent of the class of a lower alcohol,
ketones, acetone, or ethyl acetate, benzene, or ether" rendered the claim indefinite because it "introduced the element of
uncertainty as to the scope to be attached to the members of the group." Id. at 351-52 (emphasis added). Archbold is
distinguishable from the present case, because the disputed claim term in Archbold was a Markush group; the multiple uses
of "or" introduced uncertainty as to which elements were members of the group. Id. at 352. In claim 62, the use of "or" in
"design or style," "apply or compare," and "the information . . . or the advertisement" presents a binary choice between two
options--an ordinary skilled artisan would not find any uncertainty in these choices. Thus, the court finds no indefiniteness
due to the use of the word "or."

Google also contends that the claim is indefinite because it uses purely functional language. But "apparatus claims are not
necessarily indefinite for using functional language." Microprocessor Enhancement Corp. v. Tex. Instruments Inc., 520 F.3d
1367, 1375 (Fed. Cir. 2008). Functional language may be used as a limitation in an apparatus claim. K-2 Corp. v. Salomon
S.A., 191 F.3d 1356, 1363 (Fed. Cir. 1999). Similarly in this case, the functional language modifies an apparatus, "the
computer system," which was defined in previous claims. The court is not persuaded that the claim's use of functional
language renders it indefinite. The court defines "design or style standards" as "presentation rules which control the look
and feel of an advertisement."

5. "designating a combinations [sic] of a plurality of but less than all of said multiple sectors to be erased" ('808 pat., cl. 16)

For this claim term, the parties disagree about whether the claimed "designation" requires setting a tag in a dedicated
register for each sector. Defendants say it must, relying in part on their view that the claim requires the ability to designate
"any combination" of sectors. The parties disagree on whether this limitation applies.

As to the question whether the device must be capable of setting "any combination" of sectors for erase, defendants have the
better argument. The claim language calls for only "a combination[1][n]" of more than one but less than all sectors. However, at
times language used in the specification may require a particular limitation to be read into the claim language, such as when
the specification includes "repeated and definitive remarks" that a particular limitation applies to the claims. Computer
Docking Station Corp. v. Dell, Inc., 519 F.3d 1366, 1374 (Fed. Cir. 2008). Moreover, describing a limitation as part of "the
present invention" or "the invention" is strong evidence that the claims should be so limited. Trading Technologies
International, Inc. v. eSpeed, Inc., 595 F.3d 1340, 1353-54 (Fed. Cir. 2010); see also Honeywell International, Inc. v. ITT
Industries, Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006) (four references to a fuel filter as "this invention" or "the present
invention" warranted limiting the invention to a fuel filter). This case includes precisely such limiting language in the
specification. For example, the specification states that "[t]he invention allows any combination of sectors among the chips
to be selected and then erased simultaneously," '808 pat., col. 1, ins. 65-66, and "allows any combination of sectors selected
for erase to be deselected," id., col. 2, ins. 3-4. The specification later repeats this sentiment:
In the present invention, the Flash Eeprom memory is divided into sectors where all cells within each sector are erasable together. Each sector can be addressed separately and selected for erase. One important feature is the ability to select any combination of sectors for erase together. This will allow for a much faster system erase than by doing each one independently as in prior art.

Id., col. 4, lns. 51-55. Plaintiff responds that the specification describes the "present invention" in permissive terms ("the present invention allows"), so it should not be considered a limitation. This is a misreading of the specification. The cited language does not suggest that the present invention may include the "any combination" feature, it says it does. What makes the language appear permissive is the fact that the feature itself is a description of what the system is capable of doing (selecting any combination), not what it is actively doing (selecting a given combination). Because the specification repeatedly describes "the present invention" as one capable of selecting any combination of sectors for erase together, this limitation must be part of the claim.

It is a separate question whether the claimed designation requires setting a tag in a dedicated register for each sector, as defendants contend. According to defendants, this limitation is warranted both because there is no other way to insure erasure of "any combination" of sectors and because the only embodiment disclosed in the patent uses designated registers. As to the first point, defendants fail to establish that tagging designated registers is the only possible method for selecting any combination of sectors. More important, there is no need to decide this question. If defendants are correct, the question of infringement of their products should rise or fall according to whether they are capable of designating "any combination" of sectors.

As for the argument that the only embodiment disclosed uses registers, defendants fail to tie the embodiment to any intent to limit the claims to the contours of the embodiment. Indeed, the specification refers to the embodiment, Fig. 3A, as merely "illustrat[ing]" the claimed feature. Defendants add that the dedicated erase register was a "novel inventive concept" identified by an inventor of the '808 patent, but this is irrelevant; the inventors received a patent describing the invention in broader terms.

Moreover, as plaintiff points out, requiring designation to include setting tag bits in a dedicated register would make some of the language in dependent claim 18 superfluous. Claim 18, which depends (indirectly) from claim 16, adds "setting a tag bit for individual ones of the sectors to be erased"; if claim 16 already included this limitation, it would make no sense to repeat this limitation in claim 18.

In conclusion, "designating a combinations [sic] of a plurality of but less than all of said multiple sectors to be erased" requires the ability to designate "any combination" of sectors for erase but does not require setting a tag in a dedicated register for each sector to be erased.

Designating at least one category
The Court agrees with Sklar that the term has its plain ordinary meaning and does not require construction. Microsoft argues the term should be construed to mean "making each of one or more categories an open category." As an alternative to its position that no construction is necessary, Sklar proposes "the processor designates at least one category." Microsoft objects to Sklar's proposal that this step be performed by a processor. The specification does mention a processor determining which categories to open. '843 patent, Col. 10:54-60. The claim language, however, does not require such a limitation. Defining this term will very likely cause more confusion than it will solve. Any attempted construction will amount to defining the word "designate," which is a common and simple enough term that a lay juror would easily understand its meaning. Therefore, the Court does not construe this term.

Designing
The dispute over the meaning of the word "designing" concerns whether it should be read as meaning only automatic designing. First Graphics argues that "designing" should be given its ordinary meaning, which it claims is simply "to prepare the plans for something." Plaintiff's Claim Construction Brief at 15-16. M.E.P. asserts that "designing," as used in the claims, does "not include use of an object oriented computer aided drafting program where the user has input as to the relative location of an object, or group of objects, with a cursor, such as a mouse." Defendant's Claim Construction Brief at 4. Rather, it argues, the invention is a computer program "which automatically computes a layout through a series of steps limited to the practical application of checking for compliance with the requirements of a building standard during the design, without: (1) user input as to the relative location of the objects, or group of objects, in the drawing; (2) user input as to the route that the piping will take; or (3) the use of a list of objects to [be] placed in the drawing." Id. at 5. This interpretation is buttressed by citations to the specifications of all three patents. By way of example, the specification of the '983 patent states in relevant part that the

invention is a method and apparatus for designing a distribution system for a building. The distribution system can be any system used in a building including plumbing, electrical, sprinkling, ventilating and related systems or any combination of such systems. Information about the distribution system elements and various standard requirements is stored into a memory of a computer. Information about the building elements and adjuncts including location of walls and similar obstructions are entered into a computer... The user also selects the particular standard which is applicable to the building being constructed... The computer program then computes the layout needed for the distribution system based upon the selected standard. '983 patent, col. 2, l. 57 - col. 3, l. 13.

First Graphics notes, correctly, that limitations should not be read into the claim language from the specification, Vitronics, 90 F.3d at 1582, and it points out that some of the claims specifically contemplate user input. It cites to claim 27(f) of the '537 patent, which covers a method of "designing a layout for the sprinkler system in each section to comply with the selected standard, the designing including:... (4) notifying a user when no unobstructed position is determined so that the user can manually edit the position of the heads or pipes or one of the elements or adjuncts of the building." '537 patent, claim 27, col. 38, l. 11-24.

Though we agree with First Graphics that reading limitations from the specification into the term "designing" would be inappropriate, there is no question that the claims, read in their entirety, contemplate that the designing of the distribution system will be done, at least to a large extent, electronically or automatically after the software user inputs certain data. This understanding of the claims comes not just from the specification, but also from the prosecution history. For example, during the prosecution of the '537 patent, First Graphics distinguished a patent cited by the examiner (Watanabe, U.S. Pat. No. 4,700,317), on the grounds that that patent "does not teach electronically designing a layout automatically as recited in amended claim 1." As M.E.P. argues, First Graphics may not obtain in claim construction features that it previously disclaimed--whether by amendment of claims or by arguments made to obtain allowance of claims--during the prosecution of its patent application. E.g., Pharmacia & Upjohn Co. v. Mylan Pharmaceuticals, Inc., 170 F.3d 1373, 1376-77 (Fed. Cir. 1999).

But this description of the patents in toto does not control the meaning of the single word "designing," the particular term that the parties have asked the Court to construe. Indeed, "designing" is consistently used in the claims of the '983 and '537 patents together with the word "electronically" and/or "automatically." To read "designing," standing alone, as including those concepts would render those terms superfluous, contrary to the rules governing claim construction. E.g., Wright Medical Technology, Inc. v. Osteonics Corp., 122 F.3d 1440, 1444 (Fed. Cir. 1997) (noting that a claim construction rendering ordinary terms "mere surplusage" would eviscerate them).

The plain meaning of designing is "to plan out in systematic, usually graphic form." American Heritage Dictionary of the English Language (4th ed. 2000). The Court finds that "designing," as used in the claims, means to prepare the plans for something such as a fire sprinkler system. 1

--- Footnotes ---

1 M.E.P. points to prior art in the form of software called FireSolutions. The Court previously excluded this evidence, see March 20, 2001 Order, as M.E.P. failed to produce the prior art software in accordance with the schedule set by the Court. Accordingly, it is not part of the record and we decline to address it. In any event, prior art that was not relied considered during prosecution of the patent cannot be used in claim construction. Karsten Manufacturing Corp. v. Cleveland Golf Co.,
B. "the spectral light distribution of a desired daylight"

TLI argues that the term "the spectral light distribution of a desired daylight" should be given its ordinary and customary meaning in the art. See TLI's Br. at 9. 3 Specifically, TLI contends that the term "desired" is known in the art as "a selection or reference" and should be accorded its ordinary and customary meaning. See id. Moreover, TLI asserts that the term "daylight" should be construed according to its ordinary and customary meaning. See id. at 11. According to TLI, daylight spectral light distributions have been standardized and are known in the art, which is why it requires no construction. See id.

3 TLI contends that the term "spectral" has its ordinary meaning of, relating to, or made by a spectrum. Further, the term "distribution" has its ordinary meaning as the frequency of an occurrence over a range. In addition, the term "light" has its ordinary meaning as "any radiation capable of causing a visual sensation directly." See Id.

Sylvania contends that nothing in the '017 patent provides any indication as to how a "desired daylight" may be objectively determined or selected. See Sylvania's Br. at 7. Further, Sylvania argues that the term "desired" is dependent on a particular person's subjective opinion 4 and when it is used to modify the term "daylight," it results in a purely subjective choice of infinite possibilities. See id. at 8. As a result, Sylvania asserts that the term "desired daylight" cannot be construed, and is thus indefinite. See id.

4 TLI contends that Sylvania's argument that the term "desired" is a subjective term, is without merit and disingenuous. See TLI's Br. at 10. According to TLI, a search of U.S. Patents and U.S. Patent Applications published by the U.S. Patent and Trademark Office filed on or after January 1, 2005 shows that almost 15,000 patents and patent applications contain the term "desired" in at least one claim. See id. Further, Sylvania is listed as an assignee on more than a dozen patents and patent applications containing the word "desired" in at least one claim. See id.

Finally, the last element of Claim 1 is the "desired format" for viewing the television programming information: "a subset of at least said updated television programming information being output to said mixer so as to provide on the television screen television programming information desired by the viewer in a desired format." Defendants maintain the format is limited to that chosen by the viewer and may not include preselections determined by the service provider. SuperGuide and Gemstar claim the format includes selections by the user, the system designer or the service provider. SuperGuide bases this
conclusion on the fact that the system is preprogramed for a full screen, window or overlay format. Thus, it argues the system designer has "selected" those formats.

The specification provides the following:

Indeed, if desired, mass media advertising could be accomplished according to the invention. An advertiser could arrange to have a message included in information downloaded into the RAM of microcontroller 60. The message might be accompanied by digital sound information [...]. In this manner, a jingle or theme song might accompany the advertising message.

The next command of the viewer at 105 might indicate whether the viewer wished to see all of the information contained in the RAM, e.g., a complete dump of the RAM, or whether a subset of that information was desired. If a complete dump was requested, the microcontroller would direct the viewer to choose a format of display. [...] [If] the viewer has directed the microcontroller to perform [a] subset search, the viewer is directed to determine the format output of the information found. Thus, at 145, the viewer is asked whether an entire screen format is desired. If not, at 150, the viewer is asked whether a window format is desired. If not, the viewer is supplied at 155 with a television overlay format. [...] In addition, at 160 and 165, the mixer is told by the viewer, via instructions of the microcontroller, whether to scroll the desired information, or whether and when to display new full windows or screens of information.

Id., at Col. 5 ll. 45-54, 67-68; Col. 6 ll. 1-5, 29-36, 48-51. Thus, the invention provides at least three formats: entire screen, window or overlay. The viewer must select one of the first two options or the third "overlay" is provided. Thus, by not selecting one of the first two choices, the viewer in fact selects the "overlay" format. The undersigned does not construe this language so broadly as to encompass other formats, as opposed to additional information, preselected by the service provider. The specification clearly states that although additional information may be included in RAM, such as the advertising jingle, the format in which it is viewed is selected by the viewer.

This invention was designed for viewer selection of the format in which he desired to view the television programming information. The choice of formats of necessity is included within the system by the system designer. The fact that the system designer provides certain choices does not mean that it "select" a desired format. The term "desired format" means a user selected format for the display of the results of the search performed by the system. Although additional information may be provided to the system by the service provider, the format for viewing that information is viewer directed.

The court next considers the term "desired input," which is found in step four of Claim One: "selecting keys on the keyboard to provide the desired input." It is also found in step five, but the parties have agreed to a construction of that step that includes the term without alteration. The principal dispute over construction of "desired input" is whether the user or the computer is the actor doing the desiring. Plaintiff says it is the computer and suggests construing the term as "information requested by a computer application or program for processing." Defendants say it is the user and suggest construing the term as "user's complete input in the plurality of data input fields."

As support for their proposed constructions, both sides rely on language from the patent specification that they believe shows the word "desired" being used as they define it. Abbott Labs v. Sandoz, Inc., 566 F.3d 1282, 1288-89 (Fed. Cir. 2009) ("The Federal Circuit's emphasis on the importance of the specification has been repeatedly stated."). The patent specification uses some form of the word "desired" in six places. In some uses, it is obvious that the user is the actor doing
the desiring. ('873 Patent, col. 2, ll. 50-53) ("Computers with touch-screen displays, allowing a user to simply press on a desired location."). In others, it is obvious that the computer is the actor doing the desiring. (Id. col. 3, ll. 30-32) ("[I]f the software in which user input is desired is primarily financial software, the keyboard may include only numbers.") And in others, it is ambiguous just which actor is doing the desiring. (Id., col. 1, ll. 49-50) ("An on-screen keyboard may be necessary to provide the desired input."). The parties' references to the specification, therefore, do not answer the question of which actor is doing the desiring in step four of Claim One.

Looking only at the language of the Claim, Plaintiff argues that the antecedent of "desired input" in step four is "user input is sought" in step one. (Pl's Resp., at 11.) The parties agree that the computer program is the actor in step one, so the computer is the one seeking the input there. Thus, according to Plaintiff, it follows that the computer is the one "desiring" the input in steps four and five as well. Defendants argue that the antecedent of "desired input" is "user input" only, so the Claim links "desired input" and "user." (Def's Br., at 12.) A link between the user and the input does not necessarily mean that the user is the one doing the desiring in step four, though. Indeed, the specification's discussion of "software in which user input is desired" links user and input but, in that context, the software is the actor doing the desiring. ('873 Patent, col. 3, ll. 30-32.) Accordingly, the court finds that Plaintiff's reading of the claim is the better one.

Plaintiff's reading is further bolstered by considering how "desired input" is used in step five. Paragon Solutions, 566 F.3d at 1087 (presuming that when same term is used in different portions of the claim it has the same meaning). Step five reads as follows: "automatically terminating the graphical keyboard area after the desired input is received in the input area." ('873 Patent, col. 2, ll. 50-53.) In most cases, the user and the computer program desire the same input, but when the user misunderstands what input the computer program has requested, she may try to terminate the keyboard before providing that input. Allowing the user to mistakenly close the input area in such a situation is one of the problems that the invention is meant to solve. ('873 Patent, col. 2, ll. 27-29.) Thus, treating "desired input" as user's desired input would contradict one purpose of the invention.

For all these reasons, the court accepts Plaintiff's argument that it is the computer program doing the desiring in steps four and five. Nevertheless, the court does not adopt wholesale Plaintiff's proposed construction because Plaintiff provides no support for adding "for processing" to the end of its construction. The court adopts the following construction for "desired input:" "information requested by a computer application or program."
X. "a plurality of despreading devices for detecting, at each receiver antenna of the plurality of receiver antennas, the first spread-spectrum signal and the second spread-spectrum signal, as a first plurality of detected spread-spectrum signals and a second plurality of detected spread-spectrum signals, respectively" 

24 The term "a plurality of despreading devices for detecting, at each receiver antenna of the plurality of receiver antennas, the first spread-spectrum signal and the second spread-spectrum signal, as a first plurality of detected spread-spectrum signals and a second plurality of detected spread-spectrum signals, respectively" is contained in claims 9 and 33.

Plaintiff's Proposed Construction

The phrase "despreading device" means "a device in the receiver that reverses the spreading operation that occurred in the transmitter."

The phrase "detecting, at each receiver antenna of the plurality of receiver antennas" means "process of determining the presence of, and recovering the multipath spread spectrum signals received at each antenna port."

Defendant's Proposed Construction

This phrase is a means plus function claim element. The corresponding structure that performs the function of "detecting, at each receiver antenna of the plurality of receiver antennas, the first spread-spectrum signal and the second spread-spectrum signal" is a plurality of matched filters matched to the plurality of pseudonoise (PN) chip sequences.

Linex does not believe that the construction of this phrase should be governed by 35 U.S.C. § 112(6).

Plaintiff notes that in the preferred embodiment, the matched filters detect the presence of the transmitted spread-spectrum signals and despread the signals. OPENING at 22. However, Plaintiff argues that the design implementation for the detector is not so limited. Id. Plaintiff also argues that Defendant attempts to import a means-plus-function analysis from claim 33 to claim 9, based solely on a mistaken representation by Linex's prosecution counsel. REPLY at 10. Further, Plaintiff and Defendant both present the same arguments discussed in the previous section.

As previously noted, Linex's prosecution counsel explicitly noted that "claims 33 and 41 employ means plus function, as elements in the claims." RESP., EXH. C at 219. Based on this representation, Defendant argues that claims 9 and 33 both include a means-plus-function claim limitation because they both recite the "plurality of despreading devices . . ." term. Having previously concluded that claim 33 is not in means-plus-function format, Defendant's attempt to extend this argument to claim 9 is also rejected. Therefore, for all the same reasons set forth in section IX, supra, the Court finds no justification for construing this term as being in means-plus-function format. Therefore, the term "a plurality of despreading devices for detecting, at each receiver antenna of the plurality of receiver antennas, the first spread-spectrum signal and the second spread-spectrum signal, as a first plurality of detected spread-spectrum signals and a second plurality of detected spread-spectrum signals, respectively" is properly construed as "a plurality of devices in the receiver that reverses the spreading operation that occurred in the transmitter for determining the presence of and recovering both the first multipath spread-spectrum signal and second multipath spread-spectrum signal received at each antenna port."
Finally, Vonage challenges the district court's failure to construe the term "destination" in the phrase "destination address" in asserted claims 15 and 20 of the '711 patent so that it refers only to a final destination, and not an intermediate destination. The district court did not instruct the jury with respect to the meaning of this term, and did not adopt Vonage's proposed construction. Vonage proposed the following construction: "Destination address means an identifier of an endpoint in the public packet data network." 3 J.A. at 68, 2727. Vonage argues that, because of the district court's failure to construe the term "destination," Verizon was able to argue to the jury that intermediate points in Vonage's system (e.g., RTP relays) qualify as destinations within the meaning of the '711 patent.

3 The asserted claims of the '711 patent refer to a "destination address" multiple times:

15. A method comprising:

receiving a name translation request at a server coupled to a public packet data network;

executing a conditional analysis in response to the name translation request;

if the conditional analysis produces a first result, translating a name included in the name translation request into a first destination address;

if the conditional analysis produces a second result, translating the name included in the name translation request into a second destination address; and

transmitting a response message containing the first or the second destination address to a calling device for use in establishing communication at least partially through the public packet data network.

20. A method as in claim 15, wherein:

the first and second destination address includes a numeric Internet Protocol address; and

the second destination address further includes information relating to call routing via a public switched telephone network.

'711 patent (emphasis added).

We see no error in the district court's decision not to adopt Vonage's proposed construction. Vonage principally relies on a passage in the specification that it claims defines "destination address" to mean a final endpoint, and not an intermediate destination. See '711 patent col.2 ll.26-37. That passage is excerpted not from a description of the invention of the '711 patent, but rather from a description, in the "Background Art" section of the patent, of how the internet works in general. Moreover, the cited passage describes how a "packet [of data] bearing a destination address" is forwarded through the internet until it arrives at a "destination computer." There is no reason to think that the same packet of data cannot then be forwarded again to another destination, until it reaches its final destination. Vonage's interpretation assumes that the "destination computer" must be a final endpoint. But it could just as easily be an intermediate endpoint, and the packet of data could then be forwarded to another "destination computer." Thus the cited passage does not redefine "destination" to mean "final destination." The cited passage also does not address the meaning of "destination address" within the patented invention, but only within the context of the general operation of the internet, and is of limited utility. Further, the ordinary meaning of the term "destination" is not limited to a final destination. In fact, Webster's Dictionary defines "destination" as "a place which is set for the end of a journey or to which something is sent: place or point aimed at [, e.g.,] when buying your plane tickets always buy through to your farthest [destination]." Webster's Third New International Dictionary 614 (2002) (emphasis added).
Finally, Vonage's proposed construction of "destination address" fails for another reason. As Verizon points out, Vonage's proposed construction requires that the destination be part of the "public packet data network," i.e., the internet. This reading would exclude several examples in the specification where the "destination address" is a telephone number only, and thus not a point in the internet. '711 patent col.10 l.67 to col.11 l.3 (destination address "may be . . . [a] telephone number"); col.5 l.52-54 ("In the preferred embodiment, the domain name server transmits different destination address information (IP address and/or telephone number).") (emphasis added). We normally do not interpret claim terms in a way that excludes disclosed examples in the specification. MBO Labs., Inc. v. Becton, Dickinson & Co., 474 F.3d 1323, 1333 (Fed. Cir. 2007) ("[A] claim interpretation that excludes a preferred embodiment from the scope of the claim is rarely, if ever, correct.") (internal citation omitted). Since Vonage's proposed construction was wrong by failing to account for the possibility that telephone numbers could be destinations, Vonage has failed to show error in the district court's failure to adopt it. See Biodex Corp. v. Loredan Biomed., Inc., 946 F.2d 850, 854 (Fed. Cir. 1991) (holding that the party challenging jury instructions must "demonstrate . . . that the requested instruction was proper") (emphasis added); see also Advanced Display Sys., Inc. v. Kent State Univ., 212 F.3d 1272, 1281 (Fed. Cir. 2000) ("A party seeking to alter a judgment based on erroneous jury instructions must establish that [the proposed instruction] would have remedied the error.").

--- Footnotes ---

4 Vonage proposed the following construction: "Destination address means an identifier of an endpoint in the public packet data network." J.A. at 68, 2727 (emphasis added).

--- End Footnotes ---

7. **Destination Processor**: Any one of the constituent processors in an electronic mail system to which information is transmitted by the system. Said processor is identified by an address, in order to initiate the transmission of the originated information from the originating processor.

**Claim Term** | **Plaintiff's Proposed Construction** | **Defendants' Proposed Construction**
--- | --- | ---
"destination signal" | "a data signal providing passenger conveying information that identifies the boarding floor and/or the destination floor" | The claim term is indefinite and cannot be construed.

('861 Patent, claims 1 and 11) | ('465 Patent, claim 1)

Plaintiff's position is that the specification supports a construction of "destination signal" as a signal that directs movement of the elevator car to a boarding and destination floor. Plaintiff cites the following language in support:

The control signal comprises at least one first destination signal which is communicated by way of the data bus 37 to the device 36, 36'. According to this first destination signal the device 36, 36' issues by way of an electrical line a first call report to the elevator control 14, 14'. According to this first call report the elevator control 14, 14' controls the drive 12, 12' and moves the elevator car 11, 11' to the boarding floor. After the elevator car 11, 11' has reached the boarding floor, the user boards the elevator car. The control signal comprises at least one second signal which is communicated by way of the data bus 37 to the device, 36, 36'. According to this second destination signal the device 36, 36' issues a second call report to the elevator control, 14, 14' by way of an electrical line. According to this second call report the elevator control 14, 14' controls the drive 12, 12' and moves the elevator car 11, 11' from the boarding floor to the destination floor.
Plaintiff contends that reading the term "destination signal" in the context of this specification makes clear that it constitutes a signal conveying data as to boarding and destination floors.

Defendants respond that the language relied upon by Plaintiff relates to two distinct destination signals, one which is associated with the boarding floor and one which is associated with the destination floor. Defendants contend that the term "destination call reports" (which the parties agree means "a data signal providing passenger conveying information that identifies the boarding floor and the destination floor") requires both the boarding and destination floor, and therefore, a destination signal would necessarily require both the boarding floor and the destination floor. Because the language of the specification cited by Plaintiff contemplates two distinct destination signals, then either the boarding floor or destination floor information is missing from the term "destination signal," therefore Defendants assert the claim is rendered indefinite.

Defendants argue that the claim language itself describes a "destination signal" as an output from the computing unit, ('465 Patent, col. 11:17-18); which the modernization device reads and converts the destination signal into a call report. (Id. col. 11:19-25.) Defendants contend that the definition is limited by this basic description and therefore does not contain any explanation of what information the signal contains. Thus, the term is too indefinite and cannot be construed.

11 The full text cited provides:
[INSTALLING AT LEAST ONE COMPUTING UNIT AND CONNECTING THE AT LEAST ONE COMPUTING UNIT TO SAID FLOOR TERMINALS FOR AT LEAST ONE OF EVALUATING THE DESTINATION CALL REPORTS AND ASSOCIATION OF DESTINATION FLOORS WITH RECOGNIZED ONCE OF THE IDENTIFICATION CODES AND FOR THE OUTPUT OF AT LEAST ONE DESTINATION SIGNAL.

(Id.) (emphasis added).

12 The full text cited provides:
[INSTALLING AT LEAST ONE MODERNIZING DEVICE AND CONNECTING THE AT LEAST ONE MODERNIZING DEVICE TO SAID FLOOR TERMINALS AND SAID AT LEAST ONE COMPUTING UNIT FOR READING THE DESTINATION SIGNAL, FOR CONVERTING THE DESTINATION SIGNAL INTO AT LEAST ONE CALL REPORT AND FOR CONTROLLING THE ELEVATOR CONTROL BY WAY OF THE CALL REPORT.

(Id.) (emphasis added).

The Court disagrees with Defendants' indefiniteness argument. Where the meaning of a claim is discernible, even if reasonable persons may disagree over the conclusions, the claim is sufficiently clear to be deemed definite. Power-One, Inc. v. Artesyn Techs., Inc., 599 F.3d 1343, 1350 (Fed. Cir. 2010) (citation omitted). The specification cited above clearly implies that the signal that is the output from the computing unit and converted into a call report contains the boarding and/or destination floor information for a particular passenger. Plaintiff's proposed construction, although not derived from the plain language of the claims themselves, is supplemented by the meaning provided in the specification. Accordingly, the Court will adopt Plaintiff's proposed construction that "destination signal" means "a data signal providing passenger conveying information that identifies the boarding floor and/or the destination floor."
A path oriented routing method for packet switching networks, wherein said network is comprised of a plurality of interconnected packet switches wherein at any given period of time each said packet switch can be functioning as a destination switch, an originating switch, a tandem switch, or any combination of the preceding, . . .

arguing that the preamble’s use of the word “comprised” indicates that the path oriented routing method includes non-path-oriented switches. Col. 5:37-43.

Ciena contends that the Nortel has coined the terms “path-oriented switch” and “non-path-oriented switch.” As the preamble to claim 1 indicates, the patent discloses a path-oriented routing method for “packet switches.” See Col. 5:37-39. The patent discusses the method’s use of packet switches in significant detail. See Cols. 6:10-13; 6:10-13; 6:27-29; 1:30-31. However, the term “path-oriented switch” does not appear anywhere in the patent. The Court rejects Nortel’s use of the term “path-oriented switch” because its use is not supported by the intrinsic record. See Phillips, 415 F.3d at 1315. Furthermore, the language of claim 1 indicates that any packet switch in the network can function as a destination switch at any given time and does not support the distinction between path-oriented and non-path-oriented switches. See Col. 5:37-43.

Ciena argues that the clear language of the specification supports its construction. In support of its argument, Ciena cites Column 2, Lines 8 through 10 that state, “the preferred path identifier to use to send messages to it destined ultimately for the destination packet switch,” and Column 2, Lines 15 through 18 that state, “a path identifier being associated with each packet at the source packet switch and carried by the packet as it traverses through the network to the destination switch.” The Court agrees with Ciena and construes the term “destination switch” as a “packet switch for which a packet is destined.”

### 3. Detectable Series

Claims 1-12 describe each particular object as being associated with unique authorized information comprised of machine-readable code elements "coded according to a detectable series." n88 The specification does not define "detectable series" and discusses "series" in the context of a binary embodiment. n89 While the inventors did not define "detectable series" explicitly during prosecution, they listed "sequential serial numbers" as an example in several places. n90 Further, they contrasted the term with the results of "secret algorithms" and noted that in McNeight, which uses a secret algorithm as its means of counterfeit detection, "serial numbers are of no value." n91

n88 See '422 Patent at 49:41-51:14. Claim 16 describes the designation method of Claim 15 "wherein said n sets of unique information are a detectable series." Id. at 52:40-41.

n89 See generally id.

n90 E.g., '422 File History, Tab 8 at 2, 4, 6, 7.

n91 Id. at 5.

Against this intrinsic evidence, CIAS offers its expert's opinion that, to one skilled in the art, "detectable series" means "information in which a pattern, relationship, or arrangement may be detected through examination of a practical number of samples in the context in which the invention is used." n92
Accordingly, the term "detectable series" is construed to mean "information in which a pattern, relationship, or arrangement may be detected through examination of a practical number of samples in the context in which the invention is used." This definition is consistent with the inventors' description in the prosecution history, including the inclusion of "sequential serial numbers" and the exclusion of the results of "secret algorithms." n97

n97 See id. at 1317.

3. "detected phase angle signal"

GK contends that the phrase "detected phase angle signal" means "representation of the actually occurring phase angle between the shafts." CVE responds that it means "the representation corresponding to the relationship between the phase angles present on different rotating shafts."

Initially, GK's construction seems apt: it comports with language in the claim that a "detected phase angle signal correspond[s] to real time phase angle existing between said first and second shafts." But other language in claim 5 strongly implies that the phase angle signal reflects the relationship of phase angles on different shafts. First, elsewhere in claim 5 the "predetermined phase angle signal" is said to represent "a value of a phase angle relationship between said first and second phase elements." (763 patent col. 8, lin 21-24.) Second, claim 5 explains that the resultant vibratory force is determined by that "relative phase angle relationship," and that it can be substantially the same as the predetermined vibratory force if the "detected" and "predetermined" phase angle signals are approximately the same value. In other words, each phase angle signal corresponds to a relative phase angle relationship.

The specification also supports CVE's construction. The portion of the specification upon which GK relies explicitly says that the controller receives the "position information" of the rotating shafts and then "generates a real phase angle signal corresponding to the phase angle difference of the shafts." (763 patent col. 4 lin. 46-50) (emphasis added). Although the difference between two angles is an angle itself, GK's construction unhelpfully suggests that the signal corresponds to a
shared angle, rather than a comparison of angles. The court agrees with DiEuliis that CVE's construction captures this nuance, while GK's does not. CVE's construction therefore comports best with the language of claim 5, the rest of the specification, and, again, DiEuliis's testimony. Accordingly, the court adopts CVE's construction.

C. "Detecting"

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiffs' Construction</th>
<th>Defendants' Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;detecting&quot;</td>
<td>Discovering or ascertaining the presence of.</td>
<td>Applying a DC voltage potential across the working and counter electrodes and then going to an open circuit or delay period, during which no potential is applied, after a blood sample contacts the working and counter electrodes and gives rise to a current response.</td>
</tr>
</tbody>
</table>

The dispute between the parties is whether the "detecting" step of the claims requires the use of a "DC voltage potential" followed by a "delay period" (Defendants' position) or not (Plaintiffs' position). Every embodiment disclosed in the patents-in-suit sets forth a detection step involving the application of a DC potential followed by a delay period. See, e.g., '146 patent at 23:60-24:23. However, this does not justify limiting the claims. See, Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) ("Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction.") (quotations omitted).

As noted above, a patentee may disavow claim scope "by clearly characterizing the invention in a way to try to overcome rejections based on prior art." Computer Docking Station Corp., 519 F.3d at 1374. Defendants contend that Plaintiffs did this by arguing during prosecution that, in an obviousness analysis, prior art disclosing amperometric detection methods could not be combined with prior art disclosing coulometric because the former methods require a delay period while the latter methods do not. (See, D.I. 359 at 25-27.) On reviewing the relevant sections of the prosecution history (see, D.I. 362, Exh. U at 12, 20; id., Exh. V at 24; id., Exh. W at 8; id., Exh. Z at 21), the Court concludes that while the patentee argued that coulometric methods and amperometric were distinguishable on the basis of amperometric methods requiring a delay period, the patentee did not state that the invention was limited to only amperometric methods. Accordingly, the patentee did not limit the claims to only detection methods that require a delay period.

In addition, the Federal Circuit has explained that "[d]ifferences among claims can also be a useful guide in understanding the meaning of particular claim terms." Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005). As Plaintiffs note, dependent claims of both the '146 and '147 patent include an explicit "delay period" requirement. See, '146 patent at Claim 58; '147 patent at Claim 64. Thus, the doctrine of claim differentiation counsels against limiting all the claims of the patents-in-suit to the use of a delay period. Accordingly, the Court will construe the term "detecting" to mean, as Plaintiffs contend, "discovering or ascertaining the presence of."
Trademark Office Board of Patent Appeals and Interferences, affirming the examiner's rejection of claims 1-3, 5-9, 11-15, 17-20, and 22-24 of Chatani's application, No. 10/211,128 (the "128 application"), as anticipated by U.S. patent number 6,560,636 (the "636 patent") to Cohen et al. Ex Parte Masayuki Chatani and Glen Van Datta, Appeal No. 2006-2251 (Oct. 18, 2006). Because the board properly construed Chatani's claim and found it anticipated by Cohen, we affirm.

BACKGROUND

The '128 application claims a method for a multi-user application that manages participants in an online session so that if the first participant (the "host") exits the session, the system detects the departure, notifies the other participants, and re-assigns host functionality to a remaining participant so the session continues without interruption. The crux of the parties' dispute is whether the steps in representative claim 1, reproduced here, must be performed sequentially.

1. A method of managing participants in an online session of a multi-user application, comprising:

- initiating an online session of the multi-user application, the online session including two or more participants comprised of network computers that are communicatively linked to a computer network;
- detecting that a first participant has disconnected from the online session, wherein the first participant is responsible for managing certain managerial functionality associated with the running of the multi-user application;
- broadcasting a notification to existing participants of the online session over the communication network, thereby notifying the existing participants that the first participant has disconnected from the online session;
- re-assigning the functionality associated with the first participant to an existing participant of the online session.

The board relied on the disclosure of Cohen as a single prior art reference disclosing each and every element of the claimed invention. Cohen likewise teaches a method for transferring managerial responsibility from an exiting host to a remaining participant in an online session. Chatani asserted a difference between his invention, which detects that a first participant has disconnected from the online session, and Cohen's invention, which requires that a host change packet be sent to other participants before disconnection. The board appreciated the difference between the two inventions, but nevertheless found the claimed condition was drafted broadly enough to read on the other condition.

On appeal, Chatani reiterates that his invention is novel because it solves the "unexpected departure problem" by alerting online participants to the host's departure without requiring any affirmative action on the part of the host. He argues that the claim requires performance in the order written, and because Cohen does not require each element in the '636 patent to be performed in a particular order, the claim is not anticipated by Cohen. The Solicitor disagrees, arguing that (i) the method's steps do not recite an order, (ii) the logic and grammar of the claim language does not require performance in the order written, and (iii) the specification neither requires nor suggests such a narrow construction of the claim.

DISCUSSION

Claim construction is reviewed de novo on appeal. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454 (Fed. Cir. 1998) (en banc). During prosecution, claims must be given their "broadest reasonable interpretation," In re Hyatt, 211 F.3d 1367, 1372 (Fed. Cir. 2000), so this court reviews the board's interpretation of disputed claim language to determine whether it is "reasonable" in light of the evidence before the board. In re Morris, 127 F.3d 1048, 1055 (Fed. Cir. 1997). There is no dispute that the claimed method does not recite an order of performance, and we agree with the board that Chatani's claim need not be read sequentially.

The board correctly determined that the claimed condition broadly recites detecting disconnection from the online session. The claim does not dictate whether a non-human system or online participants perform the "broadcasting" or "detecting" steps. An artisan in the field could read the claim to include a scenario in which the host sends a broadcast notification that he or she "has disconnected" to the other participants and then disconnects; receipt of the notification leads the other participants to detect or discern that the host composition has changed. So the claim language on its face does not require sequential performance, and we decline to infer what should have been made explicit in the claim during prosecution. To arrive at Chatani's proposed construction would require improperly reading limitations into the claim.

GO BACK
Detecting the existence of concurrencies in instructions stored in said dispatch stack (claim 6); detecting the existence of a plurality of instructions which are concurrently executable from those instructions stored in said dispatch stack (claim 15)

The parties agree that these are "method" claims. Defendant defines the terms as follows:

Scanning the Dispatch Stack from top to bottom to identify instructions for which the sum of all [alpha] and [beta] dependencies, called the Issue Index (I<2>), is determined to be equal to zero and verifying that the required functional unit for each identified instruction is available using a reservation circuit, where reservation circuit is defined as a component that has OP, Issue Index, and Functional Unit Status inputs, and an Issue output.

Defendant's construction includes I<2>, and, because defendant defines I<2> as counting both essential and false dependencies, defendant's construction includes false dependencies as well as essential dependencies.

The Court agrees with plaintiff that the two terms under consideration, "detecting the existence of concurrencies in instructions stored in said dispatch stack" and "detecting the existence of a plurality of instructions which are concurrently executable from those instructions stored in said dispatch stack," simply mean "determining the existence of a plurality of dependency free instructions stored in the dispatch stack." The Court further agrees that nothing in the patent requires the inclusion of I<2> and/or false dependencies in the definition of these two terms. As discussed above, I<2> is not necessarily a counter, but rather a computed value derived from the values [alpha](Si) (essential dependencies), and, if false dependencies are being tracked, [beta] (D) as well.

Further, for the reasons set forth above in the discussion of the phrase "concurrently executable instructions," the Court finds that the two terms do not require that the instructions be free of any particular type of dependency or that any particular type of dependency have previously existed and been removed. Therefore, there is no basis to construe the terms as teaching a dispatch stack which necessarily has a field for false dependencies. The doctrine of claim differentiation supports the conclusion that false dependencies are not a limitation in claims 6 and 15; false dependencies, while not limitations in independent claims 6 and 15, are specified as limitations in dependent claims 7 and 16.

Moreover, defendant improperly reads a reservation circuit into the detecting function. As discussed above in connection with claims 1 and 14, the reservation circuit serves an issuing function, not a detecting function. Thus, the Court rejects defendant's position and reads the terms as meaning "determining the existence of a plurality of dependency free instructions stored in the dispatch stack."

4. "detecting whether buffer overflow is threatened by the storage of further cells arriving for transmission on said virtual path"

The plaintiff contends that no construction is needed because all the technical terms ("buffer," "cells," and "virtual path") have agreed definitions. In the alternative, the plaintiff proposes that the phrase, as a whole, means "detecting whether buffer overflow is threatened by the storage of further cells arriving for transmission on the virtual path." Defendants have proposed three different constructions, set forth, below.

a. Nortel, Lucent, and Alcatel's construction

Defendants Nortel, Lucent, and Alcatel propose that the phrase means "detecting whether the storage of arriving cells would exceed a selected level of occupancy less than the maximum capacity of the buffer for that VPC." The court has previously rejected the argument that the claim limitation should be construed to require a "buffer for that VPC." With respect to the remaining portions of the definition proposed by these defendants, the plaintiff argues that limiting the claim to detecting "a
selected level of occupancy less than the maximum capacity" is too restrictive because the specification allows for detecting 1) whether a ceiling has been exceeded, and 2) whether the number of unoccupied locations has fallen beneath a floor. The plaintiff also invokes the doctrine of claim differentiation, urging that because dependent claims 2 and 3 describe assessing the number of unoccupied locations falling below a threshold, the court should construe claim 1 broadly enough to cover the situation of falling below a floor.

b. Cisco's construction

Defendant Cisco proposes that the phrase means "determining whether the storage of cells arriving on the specified VPC might cause the buffer to exceed its maximum storage capacity." Cisco contends that this construction applies the ordinary meaning of "threatened," which means that a possible future adverse event is likely to occur. In addition, Cisco contends that this limitation requires an assessment of whether the buffer for that virtual path is likely to overflow.

The plaintiff, argues that Cisco is rewriting "detecting" with "determining." According to the plaintiff, there is no ambiguity in the claim that would necessitate a rewriting. Furthermore, the plaintiff argues that Cisco's construction improperly adds a limitation about the connection on which the cells arrive, i.e., "the specified VPC." The plaintiff contends that there is no basis for adding this requirement.

c. Juniper's construction

Finally, Juniper suggests that the claim limitation means "detecting whether the storage of arriving cells would exceed a selected level of occupancy less than the maximum capacity of the buffer storage for that virtual path whereby the level is selected to allow for storage sufficient to accommodate the continuation of frames that have cells which were already stored in the buffer at the time the threshold is exceeded." Juniper argues that the threat of buffer overflow cannot simply be indicated by an arbitrary threshold below the maximum capacity of the buffer, but sufficient space must be available to, admit cells from a frame already admitted into the buffer.

In response, the plaintiff argues that the attempt to tie buffer storage to a particular VPC and restricting the detection to a "ceiling" is improper. Furthermore, the plaintiff argues that Juniper is attempting to limit the claim unnecessarily with language from the specification. See '499 Patent, 9:26-29.

d. Conclusion

The court has previously rejected the defendants' attempt to limit the claim language to a buffer assigned to a particular VPC. In light of the parties' constructions of the technical terms, the court concludes that no additional construction of this phrase is appropriate. In doing so, the court rejects the defendants' efforts to restrict the "detecting" step to a particular manner of detecting, such as detecting "a selected level of occupancy less than the maximum, capacity." As the plaintiff observes, dependent claims 2 and 3 call out 'additional limitations that restrict the manner in which the detecting step must be performed.

2. Detection Means (Claim 2)

Matsushita argues that "detection means" is not subject to means-plus function construction, and should be construed as "a detector." Alternatively, Matsushita argues that, if the term is subject to means-plus function construction, the structure corresponding to the function recited in Claim 2 is the "detection circuit" identified in the specification. Mediatek argues that "detection means" is subject to means-plus function construction and that the specification does not sufficiently disclose any structure corresponding to the function recited in Claim 2.

The Court finds, for the reasons stated by Mediatek, that "detection means" is subject to means-plus function construction. The Court further finds, for the reasons stated by Matsushita, that the structure corresponding to the function "outputting a reset signal in response to a predetermined condition" is the "detection circuit" identified in the specification, specifically, a "detection circuit" that sets a "reset signal [ ] at a low level only when it detects a predetermined condition," which
predetermined condition "includes a condition where a clock having a frequency one-hundredth or less of the frequency of the base clock (for example, 25 kHz) is input into the PPL circuit [] and a condition where all function blocks in a semiconductor device do not need a clock, " see 249 Patent col. 10 II. 39-47, and equivalents thereof. See, e.g., Linear Tech. Corp. v. Impala Linear Corp., 379 F. 3d 1311, 1320 (Fed. Cir. 2004) (holding that because "circuit" is "structure-connoting term," where specification identifies "circuit" by "language reciting [circuit's] objectives or operations," such language constitutes sufficient disclosure of structure to person of ordinary skill in art). 2

2 The Court provides this citation, as it was not referenced in the briefing submitted by the parties.

GO BACK

C. Claim Construction of "Detector"

Claim 1 of the '454 Patent claims an "apparatus for chemical polishing (CMP) of a wafer comprising: . . . (c) an endpoint detector." Defendants seek to have the term "detector" construed as the detection component of a laser interferometer because the specification only uses the term "endpoint detector" to refer to the detection component of a laser interferometer. Plaintiff's argue that the term "detector" should be given its plain and ordinary meaning as a device used in determining when the polishing or planarization process should be terminated.

To construe the term "detector," Plaintiff points to the Background section of the '454 Patent that discusses the early devices and methods used in prior art to perform in situ detection of endpoints during the CMP process. None of the discussed devices or methods involve the use of lasers. ('454 Patent, Col. 2, lines 23-43). On the other hand, Defendants argue that the summary section of the specification expressly describes the "endpoint detector" as a component of CMP that includes a laser interferometer.

The intrinsic evidence does not provide much guidance as to the proper construction of the term "detector." A "detector" is only mentioned in Claims 1 and 22 without much description. As Defendants point out, the specification describes the endpoint detector as a component of the laser interferometer. However, as with the construction of the term "light," the term "detector" cannot be narrowly construed based on the preferred embodiment of the patent. Phillips, 415 F.3d at 1323. Accordingly, the Court deems it proper to consult extrinsic evidence to define the term "detector." Defendants' expert, Dr. Gutmann, agreed that "a person of ordinary skill in the art would understand from reading the '454 specification that there were other end-point detector devices other than a laser interferometer device." (Gutmann Transcript at 210.) Additionally, Merriam-Webster defines "detector" as a device for detecting the presence of electromagnetic waves. Both of these sources provides broader definitions than that proffered by Defendants. Accordingly, the Court FINDS that the term "detector" refers to a device for detecting the presence of electromagnetic waves and is not confined to the detection component of a laser interferometer.

GO BACK

3. Detector

The parties also disagree as to whether the "detector" elements of claims 4, 8, 11, and 15 should be construed as structural or means-plus-function claims. Trilithic argues that the elements are written in structural form and that it has adequately described the detector structure. In contrast, Wavetek contends that "detector" is a generic term that fails to connote a structure, and therefore, the "detector" elements are written in terms of what a detector does instead of what a detector is. As a result, Wavetek believes the "detector" elements should be construed under 35 U.S.C. § 112, P 6, as a means-plus-function limitation and accordingly limited to the leakage detector described in the specification and its equivalents. All of the listed claims read:
the improvement of claim . . . further comprising a detector for receiving a signal representative of leakage from the communication circuit, for extracting from the signal representative of the leakage the variably attenuated, program material-modulated carrier frequency, for detecting in the variably attenuated, program material-modulated carrier frequency the oscillator output signal frequency, and for producing an indication of detection of the oscillator output signal frequency.

'428 patent, col. 9, ln. 43-50.

In Personalized Media, the Federal Circuit reviewed an initial determination made by an Administrative Law Judge ("ALJ") of a patent regarding systems used in television broadcasting. 161 F.3d at 698, 700. The ALJ had determined that the claim limitation "a digital detector for . . . ", which appeared in all the asserted claims, constituted a means-plus-function limitation that needed to be construed under 35 U.S.C. § 112, P 6. Id. at 700. After consulting dictionaries and determining that the definitions of "detector" and "digital" and "digital circuit" did not resolve the issue of whether the "digital detector" conveyed an ordinary meaning to a person of ordinary skill in the art, the ALJ determined that the specification lacked specific structure and was only described in functional terms. Id.

The Federal Circuit reversed the ALJ's decision and held that the "digital detector" limitation was a structural limitation and therefore not subject to 35 U.S.C. § 112, P 6. Id. at 704. First, the court noted that because the limitation did not include the word "means," the presumption was that 35 U.S.C. § 112, P 6 was not implicated. Then the court confirmed that neither intrinsic nor extrinsic evidence rebutted that presumption. Id. The court held that "detector" is not "a generic structural term such as 'means,' 'element,' or 'device'; nor is it a coined term lacking a clear meaning such as 'widget' or 'ram-a-fram.'" Id. Explaining that "detector" has a well known meaning to a person of ordinary skill in the art that is connotative of structure, the court reasoned that the definiteness of the "detector" structure is not detracted from because "detector" is neither defined by its functions nor "connote[s] a precise physical structure in the minds of those of ordinary skill in the art." Id. at 705. In coming to this conclusion, the court accepted the definitions the ALJ noted including "(1) a device for determining the presence of a signal; (2) a rectifier of high-frequency current; (3) a device for extracting intelligence from a signal; (4) DEMODULATOR 1." Id. at 705 n. 12. The court found the claim sufficiently conveyed to a person of ordinary skill in the art a variety of structures known as detectors, even though it did not describe a particular detector structure. Id. at 705. Placement of the word "digital" in front of "detector" did not alter the court's analysis, as it noted that "digital" only "further narrows the scope of those structures covered by the claim and makes the claim more definite." Id.

Faced with a claim similar to the one found in Personalized Media, the Court comes to a similar conclusion; the "detector" language in the disputed claims is not means-plus-function language. The claim language at issue here does not contain the word "means." Again, the Court notes the means-plus-function limitation presumption; if the word "means" is not used in the language of the claim, the presumption is that 35 U.S.C. § 112, P 6 is not applicable. Here, the intrinsic evidence does not overcome that presumption. The claim does contain functional language. The detector will serve the function of "receiving a signal representative of leakage . . . extracting from the signal . . . the variably attenuated, program material-modulated carrier signal . . . detecting . . . the carrier frequency the oscillator output signal frequency and . . . producing an indication of detection of the oscillator output signal frequency." '428 patent, col. 9, ln. 43-50; col. 10, ln.23-30; col.11, ln. 7-14; col.12, ln.18-25. However, using functional language does not automatically mean the claim is a means-plus-function limitation. As previously discussed, if the claim contains functional language, but also discloses the structure within the language of the claim, 35 U.S.C. § 112, P 6 is not applicable. As the Federal Circuit determined in Personalized Media, "detector" has a meaning for those of ordinary skill in the art. According the McGraw-Hill Dictionary, a detector is "the stage in a receiver at which demodulation takes place; . . . also known as demodulator, envelope detector." Pltf.'s Ex. 9 at 550. These definitions are similar to the ones accepted by the Federal Circuit in Personalized Media. See 161 F.3d at 705.

Wavetek's argument that without the functional language a person of ordinary skill in the art cannot determine the meaning of detector is misplaced for two reasons. First, the Court must look at the claim as a whole. Though both Silva and Large may have agreed that if the functional language was covered up, a person knowledgeable in the art may not know which type of detector to use, the fact remains that the functional language is there to assist a knowledgeable person in determining which type of detector would be appropriate. See Tr. at 155-56 (Silva), 226-28 (Large). Both experts acknowledged that upon reading the text of the claims in their entireties in the context of a patent, a person of ordinary skill in the art would know what type of detector is being referenced in the claims. Tr. at 98-99 (Silva), 272 (Large). Secondly, as the Personalized Media court noted, the use of the term "detector" indicates a structure, and the fact that the claim does not evoke a specific detector does not mean the patentee failed to disclose a structure. See 161 F.3d at 705. The term "detector" provides a
sufficient description of a type of structure. The functional language that follows "detector" is not a detriment to the structural definition but instead narrows the scope of possible applicable detectors, such as the term "digital" did in Personalized Media. Id. In fact, here the patentee has provided greater functional detail than did the patentee in Personalized Media. The claim discloses both a structure and the function of the structure and therefore may not be construed under 35 U.S.C. § 112, P 6.

The plain and ordinary meaning of "detector" may apply to the claim because the specification does not provide an indication that any special meaning was to be given to the term "detector." The specification states that "the detection system of the present invention will now be discussed with particular references to FIGS. 2a-c. FIG 2a illustrates to a substantial extent a presently commercially available SEARCHER+ leak detector available from Trilithic . . . ." '428 patent, col. 4, ln. 23-27. The specification continues to explain the detection system as noted in the figures. Though the claim needs to be construed in light of the specification, the description of the detection system as a leakage detection system does not limit the scope of the claims to a leakage detection system. The limitations from the specification are not to be imposed on the claims. Comark, 156 F.3d at 1186. Moreover, as was discussed, the "detector" claims are not in means-plus-function format and therefore are not limited to the corresponding structure of the leakage detector that is disclosed in the specification and its equivalents. A person of ordinary skill in the art would know that the SEARCHER + leakage detector described in the patent performs in the same manner as the detectors described in claims 4, 11, 18, and 25. Tr. at 99. The "detector" claims are structural claims and their scopes are not limited by the leakage detector description in the specification.

E. "detector operable to detect a fluorescence optical signal"

In its claim construction brief, Stratagene urged the court to construe "operable" as meaning "capable of being used." However, the claim is perfectly clear on its face, and there is no significant disagreement between the parties as to its meaning. Stratagene has done little to argue that this term needs to be construed, and it does not press this point in its post-hearing brief. Therefore, it is unnecessary to construe this term.

b. determinator for determining an output brightness level

AUO contends that this term means "logic, such as a circuitry, for determining an output brightness value. D.I. 376 at Exh. M--3. LGD contends that this phrase should be defined as "circuit or logic that determines the output brightness level by applying an offset to the next brightness level that is predetermined based on a difference in quantity of light between the actual and ideal response characteristics of the liquid crystal cell. D.I. 1388 at P 395.

The parties are in agreement that this term refers to logic or circuitry. Their disagreement arises from LGD's additional limitations which purport to limit the manner in which the determinator determines the output brightness. The Court has reviewed the claim language in light of the specification, and concludes that such additional limitations are not required. Accordingly, the Court adopts AUO's proposed construction of the phrase "determinator for determining an output brightness level" as "logic, such as a circuitry, for determining an output brightness value."

1. Determining - Claim 8(a)

(a). The Parties' Proposed Constructions.

Neither party contends that the word "determining" is a term of art in speech recognition or that any technical expertise is
required to construe this word. Indeed, their experts agree that the word "determine" should be accorded its ordinary meaning in everyday speech; that is, to identify or ascertain, as after "consideration, investigation, or calculation." (Docket Nos. 182, Ex. Q at 7 (Groner) and 193 P 39 (Stern).) Despite this apparent agreement, the parties do dispute the appropriate construction of this term as it applies to claim 8.

Although plaintiff patent holders typically advance the broadest possible construction of a claim term, here Davis contends that he expressly restricted the "determining" step of claim 8(a) to "consciously identifying actual sources of false-acceptance error." (See Docket Nos. 169 at 2, 8-9; and 182 Ex. D). In other words, Davis urges that the "determining" step requires prior observation of the occurrence of a specific matching error. Under this proposed construction, one could not meet the "determining" step by applying knowledge of error sources gained while working on other systems or by analyzing the research of others working in the field of speech recognition to identify incoming speech patterns that tend to cause errors.

SWI seeks a broader construction that is not limited to empirical observation of prior errors, but allows for analysis, computation and consideration of a variety of sources of information. In advancing this construction, SWI points to the "determining" and "creating" steps of claim 8, which both discuss "incoming pattern templates which tend to be erroneously matched" to reference templates ('231 patent, col. 8:63-67), and to the specification, which states that "]o]nce those words which are potentially a source of error are identified, their patterns can be intentionally introduced into the system as error templates . . . " (Id., col. 3:6-8). Those modifiers, SWI argues, do not support a construction requiring specific observation of a prior error, which would result in a known, rather than a potential, erroneous match. n4

--- Footnotes ---
n4 SWI describes Davis' proposed construction of "determining" as the "has caused error" definition and its own proposed construction as the "can cause error" definition.

--- End Footnotes ---

Davis contends that his narrower proposed construction is supported by the specification, which first teaches that the introduction of "random" error templates actually increases the number of false rejection errors and then directs the reader away from their use toward those error templates that are "consciously identified." In addition, he claims that he explicitly narrowed the scope of the "determining" step during prosecution. Davis' proposed construction is rejected for the reasons stated below.

(b). The Court's Construction.

With regard to the specification, "claim terms take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate from [such a] meaning . . . by redefining the term or characterizing the invention in the intrinsic record using words or expressions of manifest exclusion or restriction, representing a clear disavowal of the claim scope." Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002). To act as his own lexicographer, a patentee must "define[] the specific terms used to describe the invention 'with reasonable clarity, deliberateness and precision.'" Id. at 1325 (quoting In re Paulsen, 30 F.3d 1475, 1480 (Fed. Cir. 1994)). If he does not, there is a "heavy presumption" in favor of a term's ordinary meaning. Id. at 1327.

Davis argues that the following passage from the specification limits the scope of the claim 8 "determining" step because it teaches away from the use of "random" error templates:

In a speech recognition system which is designed to recognize a finite number of words through the mechanism of template matching, the error rate can be dramatically reduced by introducing one or more "Error Templates" which correspond to speech patterns that are not within the system vocabulary. Consider, for example, a system having a one-word reference vocabulary. If another word, randomly chosen, is introduced as an error template, then each word would have an equal chance of being matched to a third, randomly chosen, incoming word. As more randomly chosen error templates are introduced into the system, the probability (P) that an incoming word will match the reference word decreases proportionally as
P = \frac{1}{1 + \text{NET}}

where NET is the number of error templates.

Once those words which are potentially a source of error are identified, their patterns can be intentionally introduced into the system as error templates to shunt incoming words which would otherwise be mismatched.

Since language words fall into a finite number of sets, the error templates should be chosen from as great a variety of these sets as possible. The number of error templates may be reduced by combining them together in such a way as to retain in the composite a significant amount of the unique features of the individuals.

'231 patent, col. 2:54-3:18 (emphasis supplied).

First, this Court notes that the foregoing passage is of limited relevance to the extent Davis suggests that an error template "determined" by any means other than empirical observation is "random." A random occurrence is one without aim, reason or pattern. Such a definition does not comport with SWI's proposed construction of "determining," nor does it comport with any common understanding of either term.

Moreover, the passage on which Davis relies does not, as he contends, teach that the use of "random" error templates increases the number of false rejection errors. In Davis' example, a false acceptance error n5 occurs when a randomly chosen incoming word is incorrectly matched to the reference vocabulary word. Based on the cited formula, the chance of such a false acceptance error occurring decreases continuously with the introduction of each additional random error template. Indeed, that is precisely what Davis posits in the introductory sentence; "the error rate can be dramatically reduced" (col. 2:56-57).

--- Footnotes ---
n5 The '231 patent uses the term "External Positive Substitution," defined as the error that occurs when "an incoming word that is external to the system's vocabulary erroneously matches to a vocabulary word." Col. 2:42-44.

--- End Footnotes ---

Contrary to Davis' assertion in his opposing memorandum (Docket No. 169 at 5), this passage does not address false rejection errors n6 at all; that is, where the incoming word is the same as the vocabulary word and should be recognized as a match, but is not. In sum, this passage does not, as Davis claims, teach away from the use of error templates that are created from any source of knowledge other than empirical observation.

--- Footnotes ---
n6 The '231 patent uses the term "Non-Recognition," defined as the error that occurs when "an incoming word which is internal to the system's vocabulary does not match any vocabulary word." Col. 2:41, 49-51; Docket No. 169 at 7.

--- End Footnotes ---

Reading the claims and specification as a whole, as this Court must, there are numerous other references that weigh strongly against narrowing the construction of "determining" as Davis suggests. For example, as highlighted above in the passage on which Davis relies, he speaks of identifying words which are potentially a source of error, thereby indicating that such identification is not limited to empirical observation of a known error. Similarly, Davis notes that language words fall into finite "sets" (something that he presents as a given and known in the art), and encourages the reader to choose error templates from a variety of sets. This, too, suggests a "determination" of sources of error based on something other or more than empirical observation.

A bit further in the specification, Davis explains that:

[I]n order to generate error templates to protect reference templates from the largest variety of non-matching words, it is
desirable to have error templates which deviate from the reference template in a given direction and by a given distance in generalized template space. Since such a template may not correspond to a known, or even utterable word, it poses some problem as to how such a template may be formulated.

'231 patent, col. 5:24-32 (emphasis supplied). Concepts of direction and distance in template space, deviation, generation and formulation, do not remotely suggest the limitation on "determining" that Davis urges.

Having reviewed the patent in its entirety, this Court concludes that Davis did not act as his own lexicographer here, and that "determining" should be accorded the ordinary meaning advanced by SWI unless a limitation is apparent from the prosecution history.

The prosecution history consists of the complete record of the proceedings before the Patent and Trademark Office ("PTO") and includes the prior art cited during the examination of the patent. Phillips, 415 F.3d at 1317 (citation omitted). "[B]ecause the prosecution history represents an ongoing negotiation between the PTO and the applicant, . . . it often lacks the clarity of the specification and thus is less useful for claim construction purposes. Id. (citing Inverness Med. Switz. GmbH v. Warner Lambert Co., 309 F.3d 1373, 1380-82 (Fed. Cir. 2002)). Nevertheless, the prosecution history can inform the meaning of the claim by revealing, among other things, whether the inventor limited the invention in the course of prosecution, making the claim scope narrower than it would otherwise be. Vitronics, 90 F.3d at 1582-83.

This Court first notes that Davis has not made the entire prosecution history part of the record, but only the portion he believes will assist him on this question. Apparently, Davis' patent application initially was rejected by the PTO as being anticipated by three prior art references. n7 Davis argues that in distinguishing his invention from one of those references, U.S. Patent No. 4,713,778 ("the Baker patent"), he expressly disclaimed any interpretation of the "determining" step that would cover "guessing, conjecture or speculation." (Docket Nos. 169 at 8-9; 182, Ex. D.)

This Court again points out that, "guessing, conjecture or speculation" is not the construction of "determining" advanced by SWI, nor does it comport with any common understanding of that term. The question then, is whether Davis limited the "determining" step of claim 8 so as to include only knowledge gained from empirical observation. In support of his argument, Davis provides his letter response to the PTO's rejection of his application and highlights certain phrases which he contends narrows the scope of the patent. n8 (Docket No. 170 at 13-14.)

n7 Davis provides his response to the PTO's rejection, but not the underlying PTO communication.

n8 Davis directs the Court to two phrases, emphasized as follows:

. . . in accordance with the present invention, error templates corresponding to erroneously matched features or words are created and stored along with the usual reference templates . . . ; and

Thus, the Baker recognition system is more typical of the prior art approach in that it increases recognition accuracy by better defining patterns being looked for rather than defining those patterns which cause errors, as does the present invention.

In addition to the obvious concern over the unavailability of the complete prosecution history, this Court finds Davis' argument to be without merit. It is readily apparent from Davis' response to the PTO that he sought to distinguish his invention from the Baker patent on the ground that his uses error templates to improve speech recognition while the Baker patent does not. Based on this very rudimentary distinction--error templates versus no error templates--there was no need for Davis to describe in detail or distinguish how his error templates work, much less the manner in which they are
"determined." This Court is unwilling to read a purported limitation that does not comport with the patent language from a generalized description of the invention that appears in a single, isolated communication with the PTO.

For all of the reasons stated, this Court finds that the intrinsic record does not reveal any special definition for the term "determining." Beyond that, the parties' experts agree that the term should be construed in its ordinary sense. Therefore, it is accorded its ordinary meaning here--to identify or ascertain, as after consideration, investigation, or calculation.

n9 Indeed, Davis' expert, Gabriel Groner, acknowledged that a "determination" "would have to include knowledge of how errors occur, but it may not necessarily have to include knowledge of specific errors." (Docket No. 195, Ex. 2 at 194.) (emphasis supplied).

Because the remaining disputed terms do not factor into the parties' validity arguments, this Court will move on to that analysis and will construe the remaining terms further herein, as necessary.

9. "determine"

Power-One seeks no construction of this term, while Artesyn proposes that the term be construed as "calculate." The Court agrees with Power-One that the term needs no construction. The parties have agreed that the term "calculate" as used in the patents means "ascertain based on calculations." Artesyn fails to adequately explain why the term "determine" should have the same definition as "calculate." Further, the passages from the '999 patent Artesyn cites, col. 2:28-34 and col. 4:23-33, do not support narrowing the meaning of "determine." See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (noting that courts will not impose additional limitations from the specification onto the claims). Both passages actually use the term "calculate" showing that "calculate" means something different than "determine."

C.3.a.1. "to determine said individual caller's credit"

Verizon alleges that "to determine the individual caller's credit" means "to determine whether the caller has enough available account resources to access the format." Verizon Brief at 92. Katz asserts that "credit" enjoys a much broader meaning than determining the amount of credit associated with a given caller. Katz Brief at 93.

The limitation "to determine the individual caller's credit" means "to determine the caller's credit standing," and is not limited to determining whether a caller has sufficient account resources. The plain meaning of credit appears to enjoy a broad range of meanings, many of which are consistent with the use of "credit" in claim 41 of the 762 patent. See Moore 1/14/03 Decl. Ex. 26 ("1 a: the balance in a person's favor in an account; also: an amount or limit to the extent of which a person may receive goods or money for payment in the future . . . STANDING . . . financial or commercial trustworthiness") (emphasis in original); see also Texas Digital, 308 F.3d at 1203 ("If more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all such consistent meanings."). The Court's interpretation is consistent with the 762 patent specification which discloses determining a caller's credit without determining an amount of available credit. See 762 patent, Col. 11:26-35 (checking credit card account against negative file).
6. "user's role determined from the request"

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>FotoMedia's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;the user's role is determined from the request&quot;</td>
<td>Role is determined from information related to the request</td>
<td>the user's role is determined from a user ID, class ID, group ID or information about access type contained in the request</td>
</tr>
</tbody>
</table>

The defendants argue that the scope of the term should be limited to the only "types" of information that is disclosed in the specification. They point out that the specification indicates that the user ID, the class ID, the group ID and the information about access type are all information "from the request" that are used to determine a user's role. See '231 Patent, at col. 3, ll. 61-65, col. 4, ll. 64-67. Defendants argue that Fotomedia's proposed definition encompassing any "information related to the request" is too broad. The claim language uses the words "from the request," not from any information that is somehow "related."

Fotomedia points out that the specification describes that "[i]n response to receiving a request for access to the metadata by a particular user, the user's role is determined from the request and the user's role is compared to the roles associated with the metadata elements to determine which metadata elements to make available to the user." '231 Patent, col. 2, ll. 3-5. Therefore, Fotomedia argues, a user's role is not limited to being determined from a particular type of data. Fotomedia further argues that because claim 1 states that the user's role is determined "from the request," the Court should not limit the construction of this term to information "in" the request.

After considering the parties' positions, the Court concludes that the role information is contained within the request itself and should be limited to at least the categories of identifiers listed in the specification, rather than the broad construction that Fotomedia seeks. The user's role is determined from a user ID, class ID, group ID or information about access type contained in the request.

The phrase "the user's role is determined from the request" means that "the user's role is determined from a user ID, class ID, group ID or information about access type contained in the request."

F. "if the at least a portion of the received funds transfer information and the VAN are determined to be authentic"

<table>
<thead>
<tr>
<th>Term</th>
<th>Plaintiff's Definition</th>
<th>Defendants' Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;a third party for determining whether the at least a portion of the received funds transfer information is authentic by using the VAN; and transferring funds from the first account of the first party to the second account of the second party if the at least a portion of the received funds transfer information and the VAN are determined to be authentic.&quot;</td>
<td>If the at least a portion of the received funds transfer information and the VAN are determined to be unchanged.</td>
<td>(1) A verification that the received funds transfer information has not changed or is unaltered; and (2) verifying the identity of the first party.</td>
</tr>
</tbody>
</table>

This limitation appears in claim 41. Continuing with the authentication disputes, the parties dispute whether this limitation requires verifying the identity of the first party. Plaintiff argues that requiring verification of a party's identity would import a limitation from the specification. Defendants argue that the language "and the VAN" means nothing in this claim if it does not authenticate the party. The Court has construed VAN such that it is "used in verifying the identity of a party or the
integrity of information or both." The claim already recites authenticating the funds transfer information that is included within the VAN. If, in this claim, the first party is not required to be authenticated, this claim would disclose authenticating the funds transfer information twice. Defendants argue that authenticating the VAN means that the identity of the first party is authenticated.

Plaintiff's argument is convincing. The Court agrees that this claim does not require party authentication. Verifying that the VAN is unchanged, however, as Plaintiff proposes, does little if the VAN was created fraudulently. By requiring the VAN to be authentic, this limitation requires the VAN to represent what it purports to represent. The Court construes this limitation to mean, "if the at least a portion of the received funds transfer information is unchanged and the VAN is not fraudulent."

H. "determines the size of the pits and particles" and "groups the pits and particles based at least in part on the determination of size" 33

Although the parties identified the phrases "determines the size of the pits and particles" and "groups the pits and particles based at least in part on the determination of size" as contested claim terminology, they limited their argument to a construction of the word "size" as it appears in these phrases. (See D.I. 594 at 22, D.I. 613 at 19-20.) Accordingly, the Court will also focus its discussion on the word "size."

1. ADE's Position

ADE proposes that the Court construe "size" "to mean that, 'the size may be actual size, PSL equivalent size or size based on some other scale or measure.'" 34 (D.I. 613 at 19.) In support, ADE argues that this construction is consistent with the plain meaning of the word and asserts that the '259 specification does not use the word inconsistently. (Id.)

2. KLA's Position

KLA counters by suggesting that the Court construe "size" to mean "determining a PSL (polystyrene latex) equivalent size of the pits and particles." (D.I. 594 at 22.) KLA argues that this is the appropriate construction of the word since the '259 specification is silent as to the meaning, this was the common art understanding of the word in the surface inspection industry at the time of the '259 priority date, and the inventors understood the word "size" as referring to a PSL equivalent size when using the word in the claims of the '259 patent. (Id.)

3. Analysis

The word "size" has a readily understood, ordinary meaning. As to the '259 patent and its inventors, the specification and prosecution history not use the word inconsistently with its ordinary meaning, and the Court is not persuaded by KLA's
arguments for altering that ordinary meaning. Accordingly, the Court construes the word to mean a physical magnitude or
dimension. See MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY 1095 (10th ed. 2002). Thus, the phrase
"determines the size of the pits and particles" means determines the physical magnitude or dimension of the pits and
particles, and the phrase "groups the pits and particles based at least in part on the determination of size" means groups the
pits and particles based at least in part on the determination of physical magnitude or dimension.

1. Determining geographic coordinates corresponding to the property identification data.

The first disputed phrase appears in the 326 patent and is "determining geographic coordinates corresponding to the
property identification data." The parties agree that "geographic coordinates" means "latitude and longitude or other
coordinate set that defines the position of the property on the earth's surface." The dispute concerns the term "determining."
The plaintiff suggests that the term needs no construction. Alternatively, the plaintiff suggests that the term means
"identifying." The defendants contend that the term "determining" means "converting" such that the phase means
"converting" the received property identification data into geographic coordinates. The court rejects the defendants' position.
As the plaintiff points out, in other portions of the defendants' brief, the defendants define "determining" synonymously
with "identifying." The court agrees with the plaintiff's alternate construction and construes the term "determining" to mean
"identifying."

3. Step (B): "Determining"

Defendants claim that "determining," as used in Step (B), means "receiving a total wager amount from the central system
and storing it in memory." (Def. Resp. at 4.) Plaintiff claims that "determining" means "fixing," "deciding upon," and
"set[ting] to a desired amount needed to finance the average prize value . . . without regard to the mathematical exact
combinations or pay tables of any of the linked gaming devices." (Pl. Br. at 21.) Plaintiff uses the terms "fixing," "deciding
upon," and "setting," interchangeably.

Defendants primarily contend that "determining" must include "receiving and storing," because they claim that the fact that
an amount is received and stored is what is special about the patent and Claim 11, and Step (B) should be the appropriate
place for that to happen. (Def. Resp. at 5-7.) Defendants' authority for this proposition comes from the prosecution history
wherein the applicant distinguished Patent '460 from prior art by stating "the function being claimed in Claim 11 for the
central system is the ability to record a total wager amount for a progressive prize." (Def. Br. Appendix, tab. 8 at 141.)
However, the claim being addressed by that particular statement was the prior claim 11 of the application, which later
became Claim 8 in the actual '460 patent, once claims 1-3 were removed. Indeed, Claim 8, step A, does specifically disclose
the recording of the total wager amount. ('460 patent, col 23 at 30-31.) We have not found any reference in the specification
of Claim 11 that indicates that storing is a particular characteristic of Claim 11.

Plaintiffs more persuasively contend that receiving and storing capabilities are device-specific, not invention-specific, and
are addressed in other claims. Some devices will store the total wager amount, while others would not need to, and the
invention is a system for linking all of those different devices. Devices that store would have a free play apparatus, which is
discussed in separate claims, such as Claim 8 (discussed above), Claim 14 ("[t]he method of claim 11 further comprising
providing a free play apparatus . . .") and Claim 16 ("[a] free play apparatus . . . comprising . . . (B) at least one processor,
the processor being adapted to perform at least the following: (a) store information about a progressive prize, including total
wager amount.") The fact that "storing" is specifically mentioned in other claims, but is not mentioned in Claim 11, supports
a finding that "determining" does not encompass the meaning "storing." See Phillips at 1315 ("the presence of a dependent
claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the
independent claim.")
Because we find that the role of "storing" is not disclosed in Claim 11, and it is disclosed in other claims, and because the specification supports a reading of Claim 11 that would not require the disclosure of "storing," we do not construe the meaning of "determining" to include the role of "storing." Therefore, we adopt a version of Plaintiff's proposed construction as follows: "determining" means "setting to a desired amount needed to finance the average prize value." n3

n3 From Plaintiff's three proposed terms, we adopt the one with the simplest and most neutral meaning: setting.

CPI argues that the district court incorrectly construed clause (a) of claims 1 and 4:

(a) determining a condition of the heart from among a plurality of conditions of the heart.

The court held that clause (a) is in the step-plus-function form of § 112 P6. 3 Implementing that holding, the court ruled that clause (a) "is limited to detecting and distinguishing among arrhythmia by analyzing the outputs of rate circuitry and PDF [probability density function] circuitry," the process in the '288 specification. The jury was instructed that unless a combination of rate output and PDF circuitry or the equivalent thereof was used in the St. Jude device, the claim was not infringed.

CPI states that this claim construction is incorrect, that clause (a) is not in § 112 P6 form and is not converted to that form simply because the preamble of the claim states that the invention is "the method comprising the steps of:". See claim 1, ante. CPI states that clause (a) simply recites a step that is part of the claimed method, and that absent the signal "step for" there is a presumption that a step does not invoke § 112 P6. The district court disagreed, stating that if clause (a) were construed as CPI proposes, it would "allow[] CPI to claim all possible methods of detecting heart arrhythmia." Concluding that the patent would thus "sweep[] too broadly," the court ruled that clause (a) covers only the specific procedures in the specification for determining the condition of the heart, and technologic equivalents of those procedures.

CPI is correct that "claiming a step by itself, or even a series of steps, does not implicate § 112 P6," as explained in O.I. Corp. v. Tekmar Co., 115 F.3d 1576, 1582 (Fed. Cir. 1997). Thus clause (a) was inappropriately assigned to § 112 P6. However, removal of clause (a) from § 112 P6 does not automatically convert it into an open-ended step without limits. A claim limitation is always construed in light of the specification, whatever the form of the claim. See, e.g., Kinik Co. v. U.S. International Trade Comm'n, 362 F.3d 1359, 1365 (Fed. Cir. 2004) ("The words of patent claims have the meaning and scope with which they are used in the specification and the prosecution history."); Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1478 (Fed. Cir. 1998) ("The best source for understanding a technical term is the specification from which it arose, informed, as needed, by the prosecution history."); Grain Processing Corp. v. American Maize Products Co., 840 F.2d 902, 908 (Fed. Cir. 1988) ("All claims must be construed in light of the specification and the prosecution history.").

CPI argues that upon the correct claim construction the "determining" step is not limited to any particular procedure, because the specification makes clear that various methods may be used to determine the condition of the heart. The specification, after describing the PDF circuitry, states that "conventional logic circuitry" can be used:
It is also to be noted that conventional logic circuitry can be provided for determining, based on the previously discussed inputs, the existence of various medical conditions, for example, ventricular tachycardia, ventricular fibrillation and supraventricular tachycardia. Such conventional logic circuitry can be provided either in the dedicated cardiac state evaluation circuit 34, or in one of the processors/controllers to be discussed below.

'288 patent, col. 10, lines 19-28 (emphasis added). CPI argues that the invention is not based on how the cardiac condition is determined, but on the treatment that is applied to that condition. CPI states that the rate plus PDF method is simply a preferred embodiment, and that this limitation should not be imported into the claim.

We conclude that the district court erred in applying § 112 P6. Method claims necessarily recite the steps of the method, and the preamble words that "the method comprises the steps of" do not automatically convert each ensuing step into the form of § 112 P6. Nor does the preamble usage "steps of" create a presumption that each ensuing step is in step-plus-function form; to the contrary, the absence of the signal "step for" creates the contrary presumption. The district court's claim construction is modified accordingly; the "determining" step must be construed, as for all claim steps, in light of the specification and the prosecution history. We remand to the district court for that purpose.

GO BACK
1261
B. '288 Claim 1 and 4: "determining a condition of the heart from among a plurality of conditions of the heart"

Claim 1 is incorporated by reference into Claim 4 of the 288 patent. Before the first trial, the court construed the "determining" step as a step-plus-function element that was illuminated by the patent's specification. The specification described the use of a combination of circuitry that measured the heart's rate and that used a technique known as probability density function, or "PDF." Using the step-plus-function approach, the court held before the first trial that the "determining" step was limited to methods using PDF as part of the process. The use of the step-plus-function approach was the reversible error at the heart of the Federal Circuit's remand.

Without using the mistaken step-plus-function mode of interpretation, the "determining" step is straightforward. The court intends to define "determining a condition of the heart from among a plurality of conditions of the heart" from Claim 1 for the jury as follows:

Detecting which one of a number of heart arrhythmias exists, i.e., whether there exists, e.g., tachycardia, fibrillation, or bradycardia, or whether there exists a normal sinus rhythm. This step of "determining" may merely analyze heart rate to determine the condition of the heart.

This construction very nearly reflects the claim construction proposed by CPI. n3

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

n3 The heart's condition should usually be determined as "normal," so the court has revised CPI's proposed construction to account for this happy circumstance.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

CPI's proposed construction is well-supported by the claim language. The "determining" step is the first step of a method for treating arrhythmias, rhythm disorders that typically result from problems with the heart's electrical system. The claim preamble calls for a device "capable of detecting a plurality of arrhythmias." The "determining" step is the only step in the claim that could address that basic requirement for the ICD. The "determining" step itself is not novel -- it merely represents the initial step where one learns whether anything is wrong with the heart's rhythm, and if so what the problem is.

St. Jude argues that CPI's construction equates "determining a condition of the heart" with "detecting an arrhythmia," and that this is contrary to the claim language, specification, and prosecution history of the 288 patent. St. Jude argues that a "condition," as opposed to an "arrhythmia," can be determined only by logically analyzing both rate and PDF inputs.
St. Jude's proposed construction tries to complicate a simple element of the claim. Although the use of different claim terms can create a presumption of different meanings, see CAE Screenplates Inc. v. Heinrich Fiedler GmbH & Co. KG, 224 F.3d 1308, 1317 (Fed. Cir. 2000), this principle does not dictate the outcome here. The ordinary meaning of an "arrhythmia" is an irregular heartbeat. Remand Docket No. 107, CPI Ex. 13 at 7 (Dr. Berger's report: to one of ordinary skill in the art, "the only difference between an arrhythmia and a condition of the heart is that the term condition of the heart' would include a normal condition "). At the time of invention, several methods for detecting arrhythmias were well-known, and prior art had disclosed the use of rate circuitry alone. See Remand Docket No. 107, CPI Ex. 13 at 8-10 (Dr. Berger's report); Remand Docket No. 120, CPI Ex. 15 at 51-55 (Dr. Mihran's testimony that rate detector circuitry can detect conditions of bradycardia, tachycardia, and fibrillation).

The specification also supports CPI's proposed construction. The specification repeatedly refers to an "arrhythmia" as a "heart disorder." See 288 patent, col. 1, ll. 23-28, 38, 53-54, 62-63; col. 4, ll. 8-10; col. 7, ll. 23-33 (describing object of invention to provide device and method capable of electrical heart stimulation "in response to detection of the occurrence of various heart disorders or arrhythmias"). Most important, CPI's proposed construction avoids, and St. Jude's invites, "one of the cardinal sins of patent law" -- reading specific limitations in a specification's disclosed embodiment into the broader claim. See Phillips, 415 F.3d at 1320, 1323. The 288 specification discloses an embodiment that uses both rate and PDF detection circuitry to determine a heart's condition. See 288 patent, col. 9, l. 59 -- col. 10, l. 28. However, apart from the rejected step-plus-function mode of interpretation, there is no indication that this disclosed embodiment was meant to exclude or disclaim devices that use rate circuitry alone. As CPI points out, no particular circuitry is discussed in the patent's abstract, background of the invention, summary of the invention, or objects of the invention.

This case is readily distinguishable from both SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337 (Fed. Cir. 2001), and Wang Laboratories, Inc. v. America Online, Inc., 197 F.3d 1377 (Fed. Cir. 1999), where the court held that the patentees intended to claim only the preferred embodiments disclosed in their respective specifications. In SciMed, the patent specification criticized a dual lumen structure for catheters and stated that a coaxial lumen structure, the only alternative, was "the basic sleeve structure for all embodiments of the present invention contemplated and disclosed herein." 242 F.3d at 1339. Based on this language in the specification, the Federal Circuit held that SciMed had disclaimed dual lumen catheters. Id. at 1343-44. Similarly, in Wang Laboratories, the court held that only the specified protocol was claimed, since the specification would not be understood by a person skilled in the field of the invention as including the other possible embodiment. 197 F.3d at 1382. Although the parties in Wang Laboratories agreed that the term "frame" could theoretically apply to either character-based or bit-mapped display systems, the specification's consistent illustration of "frame" using character-based protocol and the patent's prosecution history indicated that the claim referred only to character-based systems. Id. at 1382-84.

In this case, the 288 patent's claim language, specification, and prosecution history do not disclaim detection methods that are not "rate plus PDF." See, e.g., 288 patent, col. 10, ll. 19-23 (stating that "conventional logic circuitry can be provided for determining, based on the previously discussed inputs, the existence of various medical conditions, for example, ventricular tachycardia, ventricular fibrillation and super-ventricular tachycardia"). Absent specific reasons dictating a narrow claim construction, a particular embodiment in a specification will not limit broader claim language. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 907 (Fed. Cir. 2004).

St. Jude also contends that CPI's proposed construction of Claim 4 would render it invalid, and St. Jude points out that a claim ordinarily should not be construed in a manner that would render it invalid. See Phillips, 415 F.3d at 1327; Carman Indus., Inc. v. Wahl, 724 F.2d 932 (Fed. Cir. 1983). St. Jude argues that CPI's construction places no limit on how a heart condition is determined and therefore poses a host of invalidity problems, such as indefiniteness, failure to meet written description requirements, failure to enable, and anticipation. St. Jude argues that acceptance of CPI's construction for the "determining" step would allow non-ICD devices such as pressure monitors, stethoscopes, and oxygen monitors to fall within the claim.

The claim language and specification strongly support CPI's broader construction of the "determining" step element of Claim 4. Moreover, it is not clear at this point that CPI's construction will lead to invalidity of the claim. The preference for claim constructions supporting validity is essentially a last resort, to be used only when the other tools for interpreting ambiguous claims have been exhausted. See Phillips, 415 F.3d at 1327-28 (noting that the doctrine of construing claims to preserve their validity is of "limited utility" and applies only when claim is ambiguous after applying all other tools of claim
construction); see also Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1356 (Fed. Cir. 1999) (doctrine not applicable where claim is reasonably susceptible of only one meaning). The consequences of the court's adopted construction are best addressed in the context of St. Jude's pending motion for summary judgment of invalidity or at trial.

1262

4. Claim 1: Step (c)

Text:

determining a first position of a second imaging device with respect to the second coordinate system of the operation site;

ZMED'S Proposed Construction:

Determining the position of the second imaging device (e.g., the ultrasound probe) relative to the second coordinate system (the treatment device coordinate system, the second device coordinate system, etc.).

ZMED Opening Brief at 8.

NOMOS's Proposed Construction:

NOMOS agreed at oral argument with ZMED's construction up to the point at which ZMED suggests that the second imaging device would be placed relative to a second coordinate system, "(the treatment device coordinate system, the second device coordinate system, etc.)." Oral Argument at 67.

Construction:

Step (c) means "determining the position of the second imaging device (e.g., the ultrasound probe) relative to the second coordinate system."

Commentary:

The additional detail that ZMED wants, "(the treatment device coordinate system, the second device coordinate system, etc.)," is unnecessary and not within the claim language, and therefore is omitted.

1263

Determining a number of categories which are to be represented in a display and Determining a number of categories which are to be represented in the display

The Court agrees with Sklar that the terms have their plain ordinary meaning and do not require construction. Microsoft argues the terms should be construed to mean "determining the number of categories which contain one or more items. Each of those categories shall be shown in the display with a category label."

Microsoft's proposed construction has two parts. The first part requires "determining the number of categories which contain one or more items." Sklar concedes that all categories have one or more items. Sklar does argue, however, that Microsoft's proposed construction seeks to change the claim language. The '843 patent claim language recites "determining a number of categories which are to be represented in a display" and not as Microsoft argues "which contain one or more items." Instead of "determining [which categories] are to be represented in the display," Microsoft requires an additional step of "determining" how many categories have one or more items and those categories would then be represented in the display. This additional step is not supported by the claim language and
the Court rejects Microsoft's argument.

The second part of Microsoft's proposed construction requires that "each category which is to be represented in a display" actually be shown in the display with a category label. Microsoft argues that the patents-in-suit specifications are consistent with its construction that all category labels, open and unopen, be represented in the display. Microsoft points to Fig. 11 of the '843 patent that shows category labels for an unopened category and for an opened category. Additionally, Microsoft points to the patents-in-suit specifications for support:

To automatically determine which categories to open, a processor, such as the CPU shown in Fig. 5 and described above, determines how much space is available after the display of the category labels, and then opens categories beginning with the smallest category, until there is no space left in the display to open another category.

'843 patent, Col. 10:54-60 (emphasis added). Claim 5, however, of the '843 patent states:

5. A method of presenting a user with selection of items, wherein each item is characterized as being a member of one category selected from a plurality of categories, the method comprising the steps of:

. . .

determining how much of the display area would be left over area, if any, after display of category labels representing items;

. . .
displaying an item label for each item in the at least one open category and other open categories, if any, and a category label for each unopen category.

'843 patent, Col. 12:9-25 (emphasis added). Microsoft's construction attempts to require that which Sklar specifically left out of the claims. The patents-in-suit claim language requires display of category labels for unopen categories that represent items. The claim language specifically does not require the display of category labels for opened categories since all of the items in the opened category are represented by item labels in the display. Therefore, Microsoft's argument is rejected because it seeks to add limitations that are not supported in the claim language of the patents-in-suit.

The words are so common and simple that a lay juror would have no difficulty in understanding them. See Philips, 415 F.3d at 1314. It is difficult to conceive of a more clear way to convey the meaning of these terms. Accordingly, the Court does not construe these terms.

1264

3. "determining a rescue stage from the measured resistance"  

Claim 27 of the '281 Patent discloses a method of monitoring the stage of a rescue procedure of an AED including a step of "determining a rescue stage from the measured resistance." The parties dispute the meaning of this phrase. Philips asserts that the phrase should be construed as "measuring the impedance at the electrodes and comparing the measured impedance to stored values to determine which of the five rescue stages the AED is in." Cardiac Science contends that the word "stage" means "step," and that no further construction is necessary.

The specification teaches that the impedance values indicate the stage of a rescue procedure. ('281 Patent at c. 9, ll: 1-5.) Specifically, the AED compares the impedance values to stored values and then determines the stage of rescue. (Id. at c. 9, ll: 17-46.) Thus, the Court construes "determining a rescue stage from the measured resistance" as "measuring the impedance at the electrodes and comparing the measured impedance to stored impedance values to determine which stage the AED is at during a rescue procedure."
A. "Determining a set of three dimensional coordinates using information identifying a position in said environment and a three dimensional model of at least a portion of said environment"

Claim 1 of the 406 patent claims:

A method of adding a graphic to a video representation of an environment, said method comprising the steps of:

(a) determining a set of three dimensional coordinates using information identifying a position in said environment and a three dimensional model of at least a portion of said environment, wherein said set of three dimensional coordinates corresponds to said position and includes at least one three dimensional coordinate not listed in said information;

(b) converting said set of three dimensional coordinates into a set of two dimensional positions in said video representation; and

(c) enhancing said video representation with said graphic in an area based on said set of two dimensional positions.

Sportvision contends the phrase should be construed as: "A set of three data values that together identify a location are determined based on data about a position, and a model that describes at least a portion of the environment seen in the video." (Sportvision's Memo at 17.)

SportsMEDIA proposes the following construction: "Determining a set of three dimensional coordinates using information identifying a position in said environment and a three dimensional model of at least a portion of said environment." (SportsMEDIA's Memo at 20.)

The 406 patent description calls for the three dimensions to be represented by the letters x, y, and z:

In one embodiment, each data point includes x, y and z values. Any method can be used to obtain these x, y and z values. One example of a suitable method is to use a laser plane for z values and a laser range finder for x and y values, or other surveying devices.

'406 patent, 9:36-43.

This description is also a common convention in geometry.

Accordingly, the Court construes the phrase to mean: "Determining a set of three-dimensional coordinates (x, y, z), using information identifying a position in the environment and using a three-dimensional model (represented in x, y and z coordinates) of at least a portion of the environment."
Pinpoint's citation to claims in the '257 patent with highly particularized mathematical algorithms for finding a subset of data is instructive. Compare Def. Mem. at Ex. 1, Col. 52, Claim 1 ("relating said selected customer profile with the content profiles for the data available from each data source to the customer at a particular time by determining a distance between a customer profile and a content profile in a characteristic space by calculating an agreement scalar for common characteristics, ac, between said selected customer profile, cv, and said content profiles, cp, in accordance with [a] relationship [determined with reference to a specific mathematical equation]") with Def. Mem. at Ex. 1, Col. 55, Claim 43 ("relating said at least one customer profile with the content profiles for the data available from each data source to the customer"). The non-restrictive language of Claim 43 dooms Amazon's proposed construction and counsels a broader construction. The term "match" is construed not with reference to specific mathematic algorithms, but in accord with its general definition of "a suitable pairing of persons or objects." Pl. Opp. Mem. at 23 (quoting Webster Dictionary at 455). The court construes the disputed phrase as "finding the subset of data having content profiles that comprise the most suitable pairings to the customer profile."

1267

5. Determining a total cost of the transaction that includes a price of the product

--- Footnotes ---
n6 This term is also used in Claim 13 of the '020 Patent.

--- End Footnotes ---

DE contends that "determining a total cost of the transaction that includes a price of the product" means "determining a total cost of the transaction for obtaining a selected product at a selected destination that includes a price of the product." Dell asserts that the phrase means "calculating all costs, including the price of the product." As the parties recognized at the Markman hearing, they are generally in agreement on the meaning of this term. See Hearing Tr. vol 2, 119, Nov. 9, 2005.

The court cannot broaden or narrow claims in a way that gives the patentee a different claim than he has set forth. Texas Instruments v. United States ITC, 988 F.2d 1165, 1171 (Fed. Cir. 1993). The court therefore rejects Dell's replacement of the word "determining," with "calculating."

Dell also proposes that all costs must be determined at this step; DE stresses that while the total cost must be determined, all component costs do not have to be determined at this stage. DE recognizes that such a determination would render element (f) of Claim 1, "determining a total cost of the transaction that includes a price of the product," superfluous because element (e), "calculating costs involved in moving such product to said destination," would have involved the determination of some of these costs. The court must presume that all claim terms have some meaning in a claim, and therefore declines to adopt Dell's construction. See Innova/Pure Water, Inc. v. Safari Water Filtration Sys., 381 F.3d 1111, 1119 (Fed. Cir. 2004).

The court agrees with DE's construction, and construes this phrase as "determining the total cost of the transaction borne by the buyer for obtaining a selected product at a selected destination that includes the price of the product."

1268

(1) determining a twist of clothes being washed in a washer

The parties dispute the term "determining a twist of clothes being washed in a washer," which appears in Claims 1, 3, and 4. LG proposes construing the term to mean "determining a bundling [i.e., uneven distribution] of clothes being washed in a washer." (Chart at 1.) Whirlpool proposes instead that the term be construed to mean "deciding whether clothes being washed in a washer are entwined together." (Id.)

In arguing that the term "determining" should be construed as "deciding," Whirlpool refers to the written description, which
states that "[w]hen the correlation coefficient of Y(n) has been determined to be higher than the [] reference value . . . , the clothes is determined as having been twisted . . . ." (474 Patent, col. 9, ll. 19-22.) The Court finds nothing in that description to support Whirlpool's argument that the term "determining" means "deciding," rather than its plain meaning. The Court therefore rejects that aspect of Whirlpool's proposed construction.

With respect to the term "a twist of clothes," however, the Court agrees with Whirlpool that the term should be construed to mean "clothes . . . entwined together." The background section of the patent states that "cloths of the clothes may be damaged when operations in the washing mode and the rinsing mode are continued under a condition that the clothes has been twisted . . . ." (Id., col. 1, ll. 40-43.) "Moreover, there is a problem that the washing degree is degraded at the twisted portion of clothes." (Id., col. 1, ll. 44-46.) The summary section states that "an object of the invention is to provide an apparatus for and a method of determining a twist of clothes being washed in a washer, . . . . so that when the clothes twist signal is a meaningful signal, an operation in a clothes untwisting mode is carried out for minimizing a damage of the clothes . . . ." (Id., col. 1, ll. 49-57.) The written description states that the invention makes it "possible to minimize a damage of clothes and improve the washing degree degraded at the twisted portion of clothes." (Id., col. 9, ll. 32-35.) It is clear, then, that "a twist of clothes" was understood to result in damage to the clothes and degradation of the washing degree at the twisted portion. That limitation comports with Whirlpool's proposed construction, "clothes . . . entwined together." In contrast, LG fails to explain how "bundling [i.e., uneven distribution]" of clothes would result in damage at a bundled, unevenly distributed portion of clothes.

The Court therefore construes the term "determining a twist of clothes being washed in a washer" as "determining whether clothes being washed in a washer are entwined together."

Sub-step (b)(1) of Claim 1 is "determining an initial benefit payment." The parties' disagreement regarding this phrase rests with the difference on whether the first benefit payment should be defined to occur in the post-annuitization phase of the contract. The Defendant argues that it should be. It also narrows the term by submitting that the first payment is based upon pre-existing formulas. The Plaintiff denies a requirement of any pre-existing formulas and defines the term "first benefit payment" as "a first amount of money to be paid under the annuity contract." (Pl. Br. at 25; DE 34.)

For the reasons stated above, the Court declines the Defendant's invitation to import into Claim 1 the concept of pre-existing formulas. As to the parties' second contention, the Court notes that, by definition, the first payment, since it is not a withdrawal, must take place in the distribution phase, also known as payout or post-annuitization phase. The same is true of "subsequent periodic benefit payment."

StorageTek's proposed construction of this element is "selecting a particular network policy from a pre-existing group of such policies." Cisco's proposed construction is "selecting a particular network policy from a pre-programmed group of such policies." The parties agree that in the claimed invention there is a group of network policies from which a particular network policy is selected after a PDU is received and that the policies must exist before a PDU is processed. The dispute is whether the group of policies must be "pre-existing" or "pre-programmed." StorageTek objects to the word "pre-programmed" because use of that word evokes "connotations that are not relevant to the claimed invention." See StorageTek 040 Brief at 10. Cisco responds that StorageTek's construction is inconsistent with the 040 patent which incorporates the word pre-programmed with respect to the network policies and the prosecution history which discusses the network policies as having been "programmed" into the device. See 040 Patent, Col. 2, In. 19-21 ("network policies which have been programmed into the device"); Declaration of Theodore T. Herhold ("Herhold Decl."), Exh. E., 5/8/98 Response at 4 (quoting background of invention portion of specification mentioning "programmed"). 15 Additionally, StorageTek does not
adequately explain to the Court why the term pre-programmed, which is used in the summary of invention part of the specification, is inconsistent with the claim language.

15 Cisco also argues that this construction is consistent with the inventor testimony of Mr. Olson. See Declaration of Steve A. Olson PP 12-15. To the extent that Mr. Hughes' inventor testimony is inconsistent with Cisco's use of the word "pre-programmed," see Hughes Decl. P 20 ("policies can be created by making policy lists, also known as access control lists"), Cisco argues that Mr. Hughes' declaration testimony is inconsistent with his deposition testimony and therefore, should be discounted. See Herhold Decl., Exh. D, Deposition of James Hughes at 51:12-14 ("we did not implement access control lists, we implemented access control policy, which was a program that contained, tests, branches and actions"). While StorageTek argues that Cisco "selectively" cropped the Hughes' deposition testimony, StorageTek does not provide the Court a copy of the earlier deposition testimony relied on by StorageTek to demonstrate why the Court should not find Mr. Hughes' deposition testimony inconsistent with his declaration.

Therefore, the Court finds that "determining an instance of protocol data unit (PDU) network policy from a plurality of policies" should be construed as:

selecting a particular network policy from a pre-programmed group of such policies
Flow argues for the following construction: "Creating movement directives that compensate for lead and taper errors. Adjusting does not require readjusting after the motion control commands have been determined and generated (e.g. after the program is built and sent for execution)." Omax argues that it should be understood to mean: "the motion control commands are changed or altered after having been determined and generated."

The argument here stems from the meaning of the word adjusted. Flow argues that the determining and generating process "adjusts" the instructions so that, when that process is done, they are already "adjusted" to compensate for errors. Omax argues that adjusted means modified, and suggests that after the instructions are determined and generated, they are then adjusted to compensate. Contrary to Omax's argument, both uses of this word constitute "plain meaning": "adjusted adj 1 a: accommodated, altered or revised to suit a particular set of circumstances or requirements b: having achieved a harmonious relationship with the environment or with other individuals." Webster's Third New International Dictionary 27 (1981). Because both approaches are consonant with the word's plain meaning, the Court looks to the specification for guidance. Phillips, 415 F.3d at 1313 ("[T]he person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification.").

The specification supports Flow's approach, which construes "adjusted" as signifying that the motion instructions are already adjusted upon their determination and generation. According to the specification, after the "optimal values for the taper and lead angles at each endpoint of each drawing entity as a function of the speed of the cutting head at that point" are generated, the Dynamic Waterjet Control System ("DWCS") then "builds the final motion program making adjustments to the motion program data structure as necessary for the particular jet controller in use." '452 Patent, col. 8, 11. 2-21. In figure 5 of the '452 patent, the building process occurs in step 507, and afterward instructions are sent to the controller for execution. Thus, there is no adjustment after the determination and generation of the instructions. The Court adopts Flow's proposed construction.

We next address method claim 1 of the '997 patent. It includes a determining step rather than a determination means, but it is not drafted in "step plus function" form. That is because it does not recite a function. See 35 U.S.C. § 112, P 6 (1994). Rather, it recites only the act of determining a last-dialed digit. Therefore, we must simply apply the claim language to the accused devices free from the limiting requirements of section 112, P 6. It is clear from the specification that the determining step determines when a last digit is dialed, as explained above. The accused Dial Jack device and MiniDial version I and II devices perform that step, which is the only limitation arguably in question. Serrano also does not dispute that the accused devices contain the limitations of the asserted dependent claims of the '997 patent. There is thus no genuine issue of material fact concerning whether the accused Dial Jack device and MiniDial version I and II devices are within the scope of any of the asserted claims of the '997 patent.

Determining how much of the display area would be left over area, if any, after display of category labels representing items

The Court agrees with Sklar that the term has its plain ordinary meaning and does not require construction. Microsoft argues the term should be construed to mean "determining the area remaining after display of category labels for all categories containing one or more items."

The primary dispute centers on whether category labels for both open and closed categories must be displayed. Microsoft contends the specification supports its argument:

To automatically determine which categories to open, a processor, such as a CPU shown in Fig. 5 and described above, determines how much space is available after display of the category labels, and then opens categories beginning with the smallest category, until there is no space left in the display to open another category.
'843 patent, Col. 10:54-60 (emphasis added). This statement, however, does not make any clear distinction between open and closed categories when determining the space available after the display of category labels. Microsoft also points to Fig. 11 that displays category labels for an opened category 904a as well as for closed categories 904. As discussed earlier, however, the claim language does not require the display of category labels for opened categories. Sklar specifically left out this requirement from the claim language. Therefore, Microsoft's argument that opened category labels must be used in the determination of how much display area would be left over after the display of opened categories is not supported by the teachings of the specification and contrary to the claim language.

The term is so common and simple that a lay juror would have no difficulty in understanding it. See Philips, 415 F.3d at 1314. It is difficult to conceive of a more clear way to convey the meaning of this term. Accordingly, the Court does not construe this term.

i. Determining if an image element is defective

Based on the joint chart, it appears that the parties' views align regarding the phrase "determining if an image element is defective." IPI construes the term "defective" to mean an element lacking the desired value, such as an image element having an artifact. Sony proposes that the phrase in its entirety should be construed as deciding whether or not an image element is defective. IPI's definition does not account for the term "determining" and Sony fails to define the term "defective." Combining the two definitions, the Court adopts the following construction of this phrase: deciding whether or not an image element lacks the desired value.

12. Determining if the cookie for the current web site visit has expired (First appearing in claim 1 at col. 12, ll. 62-64, and as similarly appearing thereafter in claims 1-31, e.g. "determines if the cookie . . ." appearing in claim 22)

Websidestory contends that the term "determining if the cookie for the current website visit has expired" does not require construction. Joint Claims Construction Chart at 5. Netratings contends that the term should be construed to mean "determining whether a preselected time limit has elapsed between requests for a page at the particular website to distinguish separate visits to the same website." Joint Claims Construction Chart at 5. Netratings further contends that without construction of this term, it will be impossible to determine whether a website visit is "current." Websidestory rejects Netratings' proposed construction as improperly using the specification to limit the scope of the '479 Patent.

The Court has already construed the term "current website visit," and the Court has rejected Netratings' argument that the expiration of a cookie must be tied to the passage of time. Accordingly, in order to construe the term "determining if the cookie for the current website visit has expired," the court need only construe the phrase "determining if the cookie . . . has expired." With respect to this language, however, the Court concludes that the meaning is readily apparent, and no construction is necessary. Phillips, 415 F.3d at 1313; see also Lucent Technologies, 367 F. Supp. 2d at 657-59 (in accordance with their ordinary meanings, "marking" is construed to mean "marking," and "bytes" is construed to mean "bytes").

5. "Determining that an operating characteristic of said method should be scaled from a first level to a second level based on said feedback signal received from said receiver" (Claim 1)

This phrase is the source of four distinct disputes between the parties. For ease of analysis, the Court addresses each component separately.
The first dispute is whether the decision to scale an operating characteristic must be based on only one feedback signal, as Broadcom contends, or whether it can be based on more than one feedback signal, as Agere contends. In the claim text, this dispute concerns the meaning of the phrase "said feedback signal" and its referent, "a feedback signal." Claim 1 is a method claim that recites three steps for "providing communication signals according to operating parameters" using OFDM. ('550 patent, col. 10, ll. 58-60.) The three enumerated steps are introduced in the claim language by the transition word "comprising" and generally consist of: (1) receiving a feedback signal; (2) determining that an operating characteristic should be scaled; and (3) dynamically scaling the operating characteristic. (Id., col. 10, l. 64-col. 11, l. 8.) In method claims, the transition "comprising" is a term of art that indicates to patent practitioners that the claim is "open-ended and allows for additional steps." Invitrogen Corp. v. Biocrest Mfg., L.P., 327 F.3d 1364, 1368 (Fed. Cir. 2003). Thus, when the "comprising" transition is used, steps beyond those recited in the claims may be performed. Id.

In claim 1, the first two steps in the method described consist of "receiving a feedback signal from a receiver" and determining that an operating characteristic should be scaled "based on said feedback signal." ('550 patent, col. 10, ll. 64, 66.) As claim 1 is a comprising claim in which steps beyond those recited may be performed, the system described may receive additional feedback signals before the second step, i.e., the determination to scale, occurs. Notably, however, the claim language states that the second step, i.e., the determination to scale, must be based on "said feedback signal." The singular form of the phrase "said feedback signal" in the second step and its referent, "a feedback signal" implies that although many feedback signals may be received by the receiver, only one feedback signal is the basis for the decision to scale. 9 Abtox, Inc. v. Exitron Corp., 122 F.3d 1019, 1024 (Fed. Cir. 1997) (finding, in context of comprising claim, that "this term itself, 'said chamber,' reinforces the singular nature of the chamber"); see also N. Am. Vaccine, Inc. v. Am. Cyanamid Co., 7 F.3d 1571, 1575-76 (Fed. Cir. 1993) (acknowledging that patent parlance construes "a" to connote "one or more," yet holding that "there is no indication in the patent specification that the inventors here intended it to have other than its normal singular meaning").

9 Agere agreed with this conclusion in its reply brief, stating that, "accordingly, the claim allows many other feedback signals to be used by the receiver. The claim merely demands that one of them be used as a basis for making a determination." (Agere Reply at 14.)

At the Markman hearing, Agere argued that Broadcom's expert, Dr. Cox, admitted in his deposition that the determination to scale could be based on multiple feedback signals. (R. 58 (May 7, 2004).) In support, Agere quoted a portion of Dr. Cox's deposition in which he stated: "It could be more than one feedback signal, and each - well, if there is more than one feedback signal, the transmitter could evaluate more than one feedback signal." (Agere's Post-Markman Br. Ex. 2 (quoting Cox Dep. at 28-29).) The excerpt, however, does not lead the Court to the conclusion Agere suggests. In context, Dr. Cox is referring to Broadcom's proposed construction, which, in relevant part, states that "the transmitter evaluates one feedback signal as it is received from a receiver, and based on that evaluation makes a decision that at least one operating characteristic . . . must be scaled." In other words, the transmitter can evaluate a feedback signal, or even several feedback signals, without making the determination to scale. Thus, Dr. Cox's admission that more than one feedback signal can be evaluated does not necessarily lead to the conclusion that the determination to scale an operating parameter, which, according to the claim language, is "based on said feedback signal," could be based on more than one feedback signal. Rather, as noted previously, the patent contemplates that, while multiple feedback signals may be received, only one feedback signal may be the basis for the decision to scale. Furthermore, Agere's own expert stated in his report that "one of ordinary skill in the art would understand that 'based on said feedback signal' means that the determination of whether the operating characteristic in question should be scaled is based, in part, on the feedback signal." (Goodman Rep. P 13 (emphasis added).) Therefore, according to the claim language, although the transmitter may receive more than one feedback signal, the determination to scale an operating parameter must be based on one feedback signal.

b. "determining that"
The second dispute is whether there must be a scaling event after each evaluation of a feedback signal by the transmitter, as Broadcom contends. Broadcom's argument is based on a comparison of the language used in the "determining" step of claim 1 to that used in the "determining" steps of claims 15 and 21. Claim 1 teaches a transmitter "determining that an operating characteristic . . . should be scaled," whereas the transmitters of claims 15 and 21 "determine[] whether" scaling should occur. (‘550 patent, col. 10, l. 65, col. 12, ll. 11, 63.) According to Broadcom, the phrase "determining that" suggests that an affirmative decision to scale must occur after each feedback signal is received.

The Court rejects Broadcom's position. First, the conclusion that the evaluation of a feedback signal does not necessarily result in a scaling event is a necessary corollary of the Court's determination above that the transmitter may receive multiple feedback signals before the decision to scale occurs. Second, Broadcom's argument is belied by the claim language because the word "determining" itself suggests that, after the evaluation of a feedback signal, the system may either: (1) decide to scale; or (2) decide not to scale. (See Goodman Rep. P 8 (citing Webster's II New College Dictionary definition of "to decide or settle").) Accordingly, the claim does not require that a scaling event occur after each evaluation of a feedback signal.

c. "from a first level to a second level"

The third dispute concerns whether the phrase "from a first level to a second level" should be construed to mean "from a current level to a second level," as Broadcom contends, or should not be construed at all, as Agere argues. The Court agrees with Agere that the plain language of this claim term is clear to both skilled artisans and laypersons alike. As Agere's expert stated, one of ordinary skill in the art "would understand 'first level' and a 'second level' to refer to two different levels, the 'first level' being the level of the operating characteristic before the operating characteristic is scaled and the 'second level' being the level of the operating characteristic after the operating characteristic is scaled." (Id. P 11.)

Despite Dr. Goodman's explanation, which seems eminently logical to the Court, Broadcom asks the Court to construe the phrase "first level" to mean "current level." Broadcom, however, fails to offer any specific support for its construction, merely stating, "if the claimed 'first level' is not the 'current level,' what else could it be?" 10 (Broadcom Resp. at 35.) As there is no clearer way to define this claim term than the language of the claim itself, and as Broadcom has offered no support for its differing construction, the Court finds that the term does not need construction. See, e.g., W.E. Hall Co. v. Atlanta Corrugating, LLC, 370 F.3d 1343, 1350 (Fed. Cir. 2004) (affirming district court determination that term "single piece" was "sufficiently clear to make even resort to the dictionary unnecessary"); Applera Corp. v. Micromass UK Ltd., 186 F. Supp. 2d 487, 508 (D. Del. 2002) ("[Plaintiff] believes such a construction by the court to be unnecessary because 'a rod is a rod.' The court agrees and believes the proper construction of rod to be self-evident."); ASM Am., Inc. v. Genus, Inc., 260 F. Supp. 2d 827, 850 (N.D. Cal. 2002) ("The Court agrees with [plaintiff] that there is no better way to define 'generally circular' than to simply say 'generally circular.' Accordingly, the Court declines to construe the term.").

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

10 In fact, Broadcom's expert, Dr. Cox, does not even address this term in his expert report.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

d. "feedback signal"

The Court construes "feedback signal" as discussed above. See supra Part II.B.1.

e. Conclusion

The following construction is adopted: "Deciding whether an operating characteristic should be scaled from a first level to a second level based on the feedback signal from the receiver."

GO BACK

1278

i. Determining the difference between image elements . . . such surrounding image elements
IPI construes the limitation "determining the difference between image elements . . . such surrounding image elements" to mean calculating the difference between two or more surrounding image elements to determine their similarity. Sony urges the Court to construe the limitation as involving subtracting a value representing at least one of the image elements provided by the providing step, from a value representing at least another of the image elements provided by the providing step, for the purpose of deciding how similar to one another such image elements are. These proposed constructions differ only slightly, as "calculating the difference" can suggest a subtraction function. The Court adopts IPI's proposed construction because it presents a more streamlined definition, and the specification discusses the calculation in terms of "computing pair differences" and "to determine the relative difference." U.S. Patent No. 6,529,637, col. 17, lines 14-18 (emphasis added).

GO BACK

1279

(5) In Claim 1 of the '132 patent, "determining the duration of the color stripe burst" means "determining the duration of the color stripe burst, which may include obtaining an average phase signal from the color burst."

GO BACK

1280

2. "determining positions of the increased intensity portions"

Much of the foregoing explication of the "defining . . . axis" term applies to this claim term as well. Like "defining," "determining" connotes an act; like "defining," "determining" must occur at some location; and like "defining," "determining" is not hitched to a particular physical location, including the Fourier transform plane. The plain language of claim 12 requires only that positions of increased intensity portions be determined in accordance with the mask pattern such that a first- and second-diffracted light passes through a common area of the projection optical system. In this, claim 12's focus is largely spatial, articulating, inter alia, a general structure of planes and portions and patterns. But the claim does not demand that the "determining" occur at any particular location. See, e.g., '041 Patent at 3:52-4:17; id. at 13:55-14:43; see also id. at figs. 2-4. Where no limitations exist in the claim language, and where no limitations are otherwise required to construe a claim properly, the court is reluctant to import claim-text limits. For this reason, the court will not import the "on the Fourier transform plane" language ASML sets forth. Instead, adhering to the plain meaning of the claim term, the court construes "determining the position of the increased intensity portions" to mean "setting or ascertaining the spatial arrangement of increased intensity portions of light."

5. "DETERMINING THE TOTAL DELIVERY TIME . . . TO THE USER"

AOL: "Determining the time between the start and end of receipt by the user."

TWM: No construction required.

In the alternative, "Determining the time between the start of transmission and the end of transmission to the user."

The parties agree that the sole dispute is over the meaning of the word "delivery." The Court must decide if it means "receipt" or "transmission." AOL argues that "delivery" means "receipt"; TWM argues that "delivery" means "transmission." (See D.E. 68, pg. 9).

AOL states that the claim and specification are equivocal and thus, the Court should examine the prosecution history. TWM argues that an examination of the specification impels the Court to side with its definition. As noted above, claims are decided based on the language of the claims and the specification. See, e.g., Vitronics, 90 F.3d at 1582. The reason the Federal Circuit is loath to give deference to prosecution history is because the prosecution history represents an "ongoing negotiation between the PTO and the applicant . . . it often lacks the clarity of the specification and thus is less useful for
claim construction purposes." Phillips, 415 F.3d at 1317.  

Here, the customary definition of "delivery" is the carrying and turning over of goods to a particular recipient or the act of conveying. THE AMERICAN HERITAGE DICTIONARY 378 (2d College ed. 1982). TWM argues it uses the word "delivery" in the same manner, although in the context of computer networking. An inspection of the claim language and the specification reveals that TWM is correct. Specifically, it states: "In the preferred embodiment, the information being delivered is high-quality audio." (D.E. 1, Exh. A, col. 2). The specification later states that users will be "receiving the information being delivered" by the computer network. Id. Substituting the word "receipt" in place of "delivered" in the specification would render the sentences incoherent.  

The Federal Circuit has cautioned that constructions that would exclude coverage of the preferred embodiment are "rarely, if ever, correct." Vitronics, 90 F.3d at 1583. AOL's argument, that delivery means receipt, would exclude the preferred embodiment and thus violate of this rule. 

Because an ordinary skilled person in the computer networking field would understand "delivery" as the carrying and turning over of data, the Court rules that no construction is required on this disputed term.  

1. "Determining when the cruise control is engaged"

With respect to the second element of Claim 1, Detroit Diesel contends that the cruise control must be either engaged or not engaged, that the cruise control is engaged when the on/off switch is closed, and is not engaged when the switch is open or the brake or clutch is depressed. To support the meaning it ascribes to the word "engaged," Detroit Diesel refers the court to the portions of the specification that explain that "when the switch 48 is closed, a signal is passed to the road speed limit and cruise control 44 to engage the cruise control mode of operation," col. 4, lines 29-31, and that "when either the brake pedal 52 or clutch 54 is depressed," the "cruise control mode of operation" is "disengaged." Detroit Diesel also refers the court to Figure 1 of the '597 patent, in which switch (48) is represented as "ON/OFF."  

Caterpillar asserts that the cruise control is engaged when the on/off switch is activated, a vehicle speed is entered, and vehicle speed control is released from the throttle to the engine controller. To support its definition of "engaged," Caterpillar refers the court to the "set" step (50) in the patent's Figure 1, and to the affidavit of Michael Moncelle, the first named inventor of the '597 patent. Mr. Moncelle explains that "it is common and accepted knowledge to one of ordinary skill in the art for engine cruise control systems that an engine cruise control is 'engaged' when it is activated and capable of controlling the engine to maintain a specified vehicle speed," which occurs "only after the cruise control has been activated by turning the feature on, and the vehicle speed has been entered through the set or resume functions." Moncelle Aff., P 4. Caterpillar also cites the affidavit of its expert, James Amend, who explains that "the only interpretation of the word 'engage' in Claim 1 which is consistent with how a cruise control works, the purpose of the invention and the preamble to Claim 1, is that it means: on and set above the minimum, and not disengaged by depressing the brake or clutch." Amend Aff., P 29.  

Although the portion of the specification that states that "when the switch 48 is closed, a signal is passed to the road speed limit and cruise control 44 to engage the cruise control mode of operation," col. 4, lines 29-31, appears to define the cruise control as "engaged" when the switch (48) is "on," reference to the entire specification confirms that the second element of Claim 1 uses "engaged" in its ordinary sense, i.e., "employed." American Heritage Dictionary of the English Language 433 (1981). The cruise control is engaged when it is operating to control the vehicle's speed. This definition is consistent with the patent's preamble, which describes the invention as a "method of operating a vehicle engine (12) equipped with a cruise control (44) which is engageable to control the speed of the vehicle . . . ." It is also consistent with the patent's purpose, described in the specification: "Thus, when the cruise control is engaged, a higher engine output power is available, if needed, so that an operator is less likely to have to downshift in order to provide the torque required to maintain the actual vehicle speed at the desired vehicle speed." The use of "engaged" in this context cannot simply mean that the on/off switch is closed; the purpose of the patent is to make more torque available when the cruise control is actually in use, i.e., controlling vehicle speed, to encourage the use of cruise control and decrease the need to downshift. These purposes would not be served if the higher torque were available simply based on the cruise control on/off switch.
The specification describes the cruise control's operation, see col. 4, lines 20-44, and Figure 1 shows the inputs the cruise control receives. The operation of the cruise control as depicted in the specification, including Figure 1, is consistent with the explanation of Caterpillar's expert James Amend. In his affidavit, Mr. Amend explains that one of ordinary skill in the art would know that a cruise control feature on a manual transmission vehicle could have six operational states: (1) activation switch off; (2) activation switch on; no vehicle speed set; (3) activation switch on and speed set, but the set speed is below a pre-programmed minimum set speed; (4) activation switch on and speed set above minimum, but operator pressed the clutch or the brake; (5) activation switch and speed set above minimum, but operator used throttle to exceed set speed; and (6) activation switch on, speed set above minimum, and operator neither presses brake or clutch, nor exceeds set speed through use of throttle. Amend Aff., P 26; see also Moncelle Aff., P 4. The cruise control is "engaged," i.e. controlling the vehicle speed, only in the final state.

1284

"Determining whether the DNS request transmitted in step (1) is requesting access to a secure web site"

The '135 patent, claim 1 contains the phrase "determining whether the DNS request transmitted in step (1) is requesting access to a secure web site." VirnetX contends that this phrase does not require construction. Alternatively, VirnetX contends that the phrase means "determining whether the DNS request transmitted in step (1) is requesting VPN communication with a secure web site." Microsoft contends that the phrase means "the computer receiving the DNS request checks the request to determine whether access to a secure web site was requested." The parties dispute whether the phrase at issue requires a construction, and if so, what performs the determining step.

No construction is necessary beyond the terms already construed in the phrase "determining whether the DNS request transmitted in step (1) is requesting access to a secure web site." The Court has construed "DNS" and "secure web site." "Determining whether the . . . transmitted in step (1) is requesting access to a" has an ordinary meaning that a jury would understand without construction. Accordingly, the Court does not construe "determining whether the DNS request transmitted in step (1) is requesting access to a secure web site."

However, the parties dispute whether "determining whether the DNS request transmitted in step (1) is requesting access to a secure web site" must be performed by the computer receiving the DNS request. Microsoft argues that it does not make sense for the client computer to generate a DNS request as stated in step 1 and then perform the subsequent "determining" step in step 2. VirnetX argues that nothing in the claim limits which computers perform the "determining" step. VirnetX also argues that there are circumstances where a client computer may have one program that transmits the DNS request to a second program on the same client computer, and the second program performs the "determining" step on the same client computer. Finally, VirnetX argues that the doctrine of claim differentiation between claims 1 and 2 of the '135 patent shows that the "determining" step may be performed by the client computer.

The client computer can perform the "determining" step. Nothing in claim 1 of the '135 patent prevents the client computer
from "determining whether the DNS request transmitted in step (1) is requesting access to a secure web site." See Col. 47:20-32. Also, the doctrine of claim differentiation shows that the client computer may perform the "determining" step. Courts presume a difference in meaning and scope when a patentee uses different phrases in separate claims. Phillips, 415 F.3d at 1314-15. Claim 2 states "The method of claim 1, wherein steps (2) and (3) are performed at a DNS server separate from the client computer." Col. 47:33-35 (emphasis added). Claim 2 states the limitation "separate from the client computer" whereas claim 1 does not. Thus, presumably this limitation is not found in claim 1. This presumption cannot be rebutted because there is no language in claim 1 that limits the "determining" step to computers other than the client computer. Accordingly, "determining whether the DNS request transmitted in step (1) is requesting access to a secure web site" is not limited to being performed by the computer that receives the DNS request.

The instant claim construction dispute concerns the meaning of the term "deterministic function algorithm" as used in claim 2 of the '954 patent. While the parties agree that a "deterministic function algorithm" is a formula or a series of steps such that, for a certain input, there is always the same output, the parties disagree as to whether a deterministic function algorithm, as used in claim 2, necessarily means a hash function that, when applied to a digital document, compresses the document. Plaintiffs assert that, in the '954 patent, "deterministic function algorithm" and "hash" are synonymous; defendant, on the other hand, argues that a hash function is a subset of the universe of deterministic function algorithms, and as a result the terms may not be used interchangeably.

It is settled law that the principal guide to the interpretation of claim language is intrinsic evidence, i.e., the claims, the specification and the so-called "file wrapper." See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83 (Fed. Cir. 1996). If the intrinsic evidence provides a clear meaning for a term, the inquiry is at an end. See id. Typically, extrinsic evidence may only be used in aid of understanding the general technology, not to vary or contradict the terms of the claims. See id. at 1584 n. 6. 5 Claim language will be given its plain meaning unless the inventor, choosing to be his or her own lexicographer, uses terms in a manner other than their ordinary meaning and clearly discloses these special or alternative meanings in the patent specification or file history. id. at 1582; Beachcombers v. Wildwood Creative Prods., Inc., 31 F.3d 1154, 1158 (Fed. Cir. 1994). An important principle in aid of claim construction is the doctrine of claim differentiation, which presumes that there is "a difference in meaning and scope when different words or phrases are used in separate claims." Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987).

Analysis of the intrinsic evidence focuses first on the plain language of the claims. See Vitronics, 90 F.3d at 1582. Here, the plain language is neither dispositive, nor especially helpful because the meaning of "deterministic function algorithm" is technical. In these circumstances, the next step in the claim analysis is to examine the patent specification, which often, as here, provides the answer to the meaning of the claim term. The specification of the '954 patent clearly reveals that the inventors of the '954 patent intended that claim 2 would add to claim 1 the step of condensing or "hashing" the document to be time-stamped. Thus, in discussing the hash-and-sign method claimed in claims 2, 3 and 4, the specification notes that, while claim 1 does not require any condensation of the document prior to its transmission to the outside agency for time-stamping, such a step would be highly desirable both to keep the contents of the document secret and to reduce the digital bandwidth of the transmission. 5 According to the specification, such a step could be achieved through the application of a deterministic function, "which may, for example, be any one of a number of algorithms known in the art as "one way hash functions." This language clearly reveals that the inventors of the '954 patent used deterministic function algorithm and hash
function interchangeably, and that the purpose of the application of the deterministic function algorithm in claim 2 is to condense the document prior to transmission, a step that would be accomplished through the application of a hash function. Indeed, the specification is so clear on this issue that, prior to trial, both parties regarded a deterministic function algorithm to be the same as a hash function. 7

6 The specification states in pertinent part:

To ensure against interception of confidential document information during transmission, and to reduce the digital bandwidth required for transmission of the entire document, the author may optimally convert the digital document string to a unique number having vastly reduced digital size by means of a deterministic function which may, for example, be any one of a number of algorithms known in the art as "oneway [sic] hash functions."

U.S. Pat. No. 34, 954, col. 3, ll. 11-19.

7 Defendant, in its summary judgment brief, stated that claim 2 "simply adds the additional limitation to claim 1 that the transmission from the originator to the outside agent is hashed." The word "hash" never appears in claim 2; only the words "deterministic function algorithm" are used. But, as defendant's brief reflects, it is clear that in the context of the '954 patent, a deterministic function algorithm means a hash function.

Because the specification of the '954 patent makes clear that the inventors used the terms "deterministic function algorithm" and "hash" interchangeably, the inquiry is at an end. This is an instance, in other words, where the inventors plainly manifested their intent to act as the lexicographers of this term as used in their patent. Although extrinsic evidence, such as a technical treatise or dictionary, might reveal that, in the realm of pure mathematics, a hash function is a subset of the universe of deterministic function algorithms, under the rule in Vitronics, such evidence cannot be used to vary the meaning of "deterministic function algorithm" that the inventors of the '954 patent intended to use. See Vitronics 90 F.3d at 1582-83. Thus, the proper interpretation of "deterministic function algorithm" in the context of the '954 patent is that it is synonymous with hashing. This definition "fully comports with the specification and claims and so will preserve the patent's internal coherence." Markman, 517 U.S. at 389.

The principle of claim differentiation confirms this result. In claim 1 of the '954 patent, a representation of the digital document is transmitted to the outside agency to be time-stamped; there is no requirement that the digital form of the document be altered prior to transmission. Claim 2 adds to claim 1 the step of applying a deterministic function algorithm to the digital document prior to transmission. The specification clearly reveals that the goal of this step is to condense, and thereby encrypt, the digital document. Under defendant's proffered broad definition of deterministic function algorithm, however, the function "1 x" would qualify as a deterministic function algorithm. Yet, such a function would not alter the document in any way. If the step disclosed in claim 2 does not by definition alter the digital document, it would not add anything to claim 1, a result inimical to the doctrine of claim differentiation, which presumes that there is "a difference in meaning and scope when different words or phrases are used in separate claims." Tandon Corp., 831 F.2d at 1023. The absence of any difference in the meaning or scope of claims 1 and 2 would make claim 2 superfluous; under the doctrine of claim differentiation, it must be presumed that such a difference exists. Consequently, claim 2 must be interpreted to add to claim 1 the step of altering, or in this case condensing, the digital document.

In conclusion, a deterministic function algorithm as used in claim 2 of the '954 patent is defined as "a formula or series of steps such that for a certain input there is always the same output, and that condenses, or hashes, the digital document." An appropriate order has issued.

1. The Term "Development System"
The dispute between the parties centers on whether the term "development system" should be directed toward an "object-oriented" user interface as opposed to a computer program written using object-oriented source code. The Court is of the opinion that when claim 1 speaks of an object-oriented development system, object-oriented modifies or defines the type of computer program that is invented. Therefore, "development system" refers to a control system project [computer program] consisting of the hardware and software that supports the construction of other software as an end product within a development as opposed to an operating environment. The Court is further of the opinion that "development system," as used in the preamble language, is consistent with the specification and prosecution history. See Catalina Mktg. Int'l, Inc. v. Coolsavings Com., Inc., 289 F.3d 801, 808 (Fed. Cir. 2002).

Development Support Functions

The Court adopts Motorola's proposed construction of the term "development support functions" and construes the term as "functions in support of a development system to debug hardware and/or software of the data processor." The Court finds that Motorola's proposed construction more accurately reflects a person of ordinary skill in the art's understanding. Additionally, the Court rejects ST's proposed construction because the Court does not find that the prosecution history warrants the additional limitations ST proposes.

9. "deviating from the previously computed form line to accommodate one or more terrain features" (Claims 1, 3, 6, 11)

This phrase appears in claims 1, 3, 6, and 11. See Tang Decl., Ex. A at 12:34-49; 12:53-63; 13:6-15; 14:4-14; Ex. D at 2 (amended Claims 1, 3). Once again, the precise wording of each claim's phrase differs, but the parties agree that the phrases all have the same meaning, and that the wording of claims 3 and 6 is representative. Trimble contends that above phrases should be construed to mean "altering the direction of travel provided by steering guidance to avoid obstacle or terrain features." 3 Defendants contend that the phrase should be construed to mean "deviating from a previously computed path across the area to be treated in order to avoid at least one terrain feature."

3 Prior to the claim construction hearing, defendants submitted an administrative request calling the court's attention to the fact that plaintiff's reply brief for the first time changed the word "avoid" in plaintiff's proposed construction to "accommodate." As the court indicated at the hearing, plaintiff's introduction of new arguments and terms on reply, without the filing of a jointly revised claim construction statement, is improper, and plaintiff's alternative unilateral filing of a revised claim construction statement (filed one day prior to the hearing) is rejected. Although the court allowed plaintiff to make their revised arguments at the hearing, the court nonetheless GRANTS defendants' administrative motion to exclude plaintiff's new arguments, and plaintiff is restricted to the proposed construction it set forth in the Joint Claim Construction Statement.

In view of the court's prior constructions, there is very little to be construed here. In accordance with those constructions, "deviating from the previously computed form line" must be construed, as defendants propose, to mean "deviating from a previously computed path across the area to be treated." The only issue is therefore what it means to "accommodate one or more terrain features."

The specification supports defendants' arguments that "accommodate" means "avoid." For in referring to the process of deviating from a prior computed path in order to accommodate obstacles, the specification specifically states in several places that such deviations are undertaken in order to "avoid" or to go "around" obstacles. See, e.g., Tang Decl., Ex. A at 4:39-45 ("Field 32 also includes a number of terrain features or obstacles such as rocks or boulders... During spraying
operations, sprayer rig 30 must avoid these obstacles

As such, the proper construction of "accommodate" is, as defendants argue, "avoid." To that end, and consistently with the other constructions adopted by the court herein, the court construes the term "deviating from the previously computed form line to accommodate one or more terrain features" as: "deviating from a previously computed path across the area to be treated in order to avoid at least one terrain feature."

"First device" and "second device" appear in the '831 patent, Claims 16 and 17. The parties dispute whether these terms require construction. Widevine argues that these terms need no construction and should be given their plain and ordinary meaning: networked computing devices. Verimatrix argues that the claims are means-plus-function claims because "device" is a generic term. Claim 16 in its entirety follows:

A system for managing data securely over a network, comprising: a first device that is operative to perform actions, including:

receiving a packet;

examining a payload portion of the packet for a predefined data type, and if the payload portion includes the predefined data type, selectively encrypting the payload portion and;

communicating the selectively encrypted portions over the network in a packet; and

a second device that is operative to perform actions, including:

receiving the communicated packet,

parsing the received packet into the payload and the non-payload portion, and

decrypting the selectively encrypted payload portion.

Verimatrix points to a number of extrinsic references showing that "device" is used indiscriminately to refer to any type of electronic thing and argues that the surrounding claim language does not identify any structure. The Court agrees. The claim provides no structural context and describes each "device" by the functions that it performs, which means that "one of skill in the art would have no recourse but to turn to the [patent's] specification to derive a structural connotation." Welker Bearing Co. v. PHD, Inc., 550 F.3d 1090, 1096 (Fed. Cir. 2008). Therefore, the Court is of the opinion that "first device" and "second device" are means-plus-function limitations and are therefore governed by 35 U.S.C. § 112(6).

The Court must now identify, if any, "the corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112(6). "For computer-implemented means-plus-function claims where the disclosed structure is a computer programmed to implement an algorithm, 'the disclosed structure is not the general purpose computer, but rather the special purpose computer programmed to perform the disclosed algorithm.'" Finisar Corp. v. DirecTV Group, Inc., 523 F.3d 1323, 1340 (quoting WMS Gaming, Inc. v. Int'l Game Tech., 184 F.3d 1339, 1349 (Fed. Cir. 1999)). Specifically, the corresponding structure to be found in the specification is the algorithm that performs the claimed function. Harris Corp. v. Ericsson, Inc., 417 F.3d 1241, 1253 (Fed. Cir. 2005). The algorithm must provide sufficient structure to allow a person of ordinary skill in the art to program the computer to perform the functions. Id. at 1340-41. It is "important to determine whether one of skill in the art would understand the specification itself to disclose the structure, not simply whether that person would be capable of implementing the structure." See Atmel Corp. v. Info. Storage Devices, Inc., 198 F.3d 1374, 1382 (Fed.Cir.1999). The Federal Circuit "does not impose a lofty standard in its indefiniteness cases." Finisar, 523 F.3d at 1341 (citing Med. Instrumentation & Diagnostics Corp. v. Elekta AB, 344 F.3d 1205, 1214 (Fed. Cir. 2003)).
Notwithstanding the relatively low standard, this Court finds that the '831 patent, Claim 16 lacks supporting structure in the specification for each of the claimed functions. The Court agrees with Verimatrix that the "first device" is the "encryption bridge implemented on a computer system which is located between the multiple servers and clients. ('831 Patent, 6:4-35, 6:41:45; 7:51-60; 7:25-31.)" and that the "second device" is the "decryption shim which is deployed to the client by the encryption bridge, is implemented via pluggable/exchangeable architecture, receives, parses, and decrypts the payload portion of the packet. The decryption shim negotiates and exchanges a key. ('831 Patent, 7:3-5; 9:58-10:56; Fig. 3-330, 340, 360; Fig 5 - 510.)." Defendant's Brief, Ex. 1. However, the Court is unable to find a sufficiently detailed algorithm within the specification to provide the necessary structure for all of the functions claimed in Claim 16. The only algorithms identified by either party are the RSA, DES-X, or Blowfish algorithms for encryption that are discussed in the specification. '175 patent, 8:6-17. These algorithms provide supporting structure for the function of "selectively encrypting the payload portion." Because there are no other algorithms in the specification, the remaining functions in Claims 16 and 17 lack the necessary supporting structure.

In addition to a dearth of briefing on the topic of whether the specification discloses an algorithm for the functions claimed, lacking before the Court is the expert testimony upon which it ordinarily relies when construing means-plus-function terms. While the specification does recite the functions in Claim 16, the specification fails to explain sufficiently how one skilled in the art might perform those functions. See '831 Patent, 8:27-58; 9:58-10:50; Finisar, 523 F.3d at 1340 (failing to find an algorithm where the specification "provides nothing more than a restatement of the function, as recited in the claim") (internal quotations omitted). Independent claim 16 and dependent claim 17 of the '831 Patent are invalid for indefiniteness.

A. Preamble: "A repeater management device for communication networks, the repeater management device controlling repeaters and routing data packets between a receiving port and a destination port, comprising:"

The parties agree that the preamble of Claim 1 should be construed as a claim limitation because it is essential to understand the invention and the claimed elements. "No litmus test defines when a preamble limits the claim scope." Catalina Mktg. Int'l Inc. v. Coolsavings.com Inc., 289 F.3d 801, 808 (Fed. Cir. 2002). "Whether to treat a preamble as a claim limitation is determined on the facts of each case in light of the claim as a whole and the invention described in the patent." Storage Tech. Corp., 329 F.3d 823, 2003 WL 21058359 at *8.

"In general, a preamble limits the invention if it recites essential structure or steps, or if it is 'necessary to give life, meaning, and vitality to the claim.'" 3 Catalina Mktg. Int'l Inc., 289 F.3d at 808 (citation omitted). "Thus, [it must be] determined whether the preamble breathes life and meaning into the claim, and is incorporated by reference because of language appearing later in the claim, making it a limitation of the claim." General Elec. Co. v. Nintendo Co., Ltd., 179 F.3d 1350, 1361 (Fed. Cir. 1999).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

3 "Conversely, a preamble is not limiting 'where a patentee defines a structurally complete invention in the claim body and uses the preamble only to state a purpose or intended use for the invention.'" Catalina Mktg. Int'l Inc., 289 F.3d at 808 (citation omitted).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The words in the preamble, "A repeater management device" recite essential structure by requiring the inclusion of repeater management, bridging support and media access controller functions in a single device. These words in conjunction with the term "comprising" evince that the inventors relied on the preamble phrase to breathe life into the claim. "The word 'comprising' is an open transition phrase," which means that the claim's "scope may cover [a] device[] that employ[s] additional, unrecited elements." AFG Indus., Inc. v. Cardinal IG Co., 239 F.3d 1239, 1244 (Fed. Cir. 2001). Since the preamble to claim 1 is "essential to understand limitations or terms in the claim body," it limits the scope of the claim. Id.

The preamble describes a repeater management device ("RMD") as a single device that controls more than one repeater and routes data packets between a receiving port and a destination port. The patent's "summary of the invention" states "the
The present invention discloses a system which combines the functions of repeater management, ethernet MAC, and network bridging support into a single device. (603 patent at col. 2:31-33.) Intel argues that "device" should be interpreted to mean "a chip or a circuit board." (Level One Proposed Claim Construction P1.) However, no particular physical manifestation is articulated in the claim or the specification; therefore, the term "device" is not limited to these physical manifestations.  

C. "Device"

Claim 3 describes the invention, in pertinent part, as consisting of "a power unit supported on the chassis to supply power to the device and the display screen . . . wherein the device is a computing device." (the '178 patent, claim 3). The Plaintiff seeks to classify the "device" as a computer. The Defendant argues that the term "device" is indefinite in claim 1. The parties agree that the term in claim 3 is dependent upon the term in claim 1. Claim 1 does not describe "the device" in any way.

The Defendant relies on 35 U.S.C. § 112 for the proposition that a patent applicant must draft claims "particularly pointing out and distinctly claiming the subject matter which the applicant regards as his invention." Because claim 1 is indefinite, the Defendant argues, claim 3 must also be indefinite. However, such a cursory dismissal of the term would be counter to the presumption that each claim of a patent is presumed valid independent of other claims. 35 U.S.C. § 282. A claim is presumed valid "even though [the dependent claim is] dependent upon an invalid claim." Id. In fact, only clear and convincing evidence of indefiniteness can overcome this presumption. Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1348 (Fed. Cir. 2005). Even "a difficult issue of claim construction does not ipso facto result in a holding of indefiniteness." Id. at 1347. Thus, "the failure to provide explicit antecedent basis for terms does not always render a claim indefinite." Energizer Holdings, Inc. v. International Trade Com'n, 435 F.3d 1366, 1370 (Fed. Cir. 2006) (quoting The Manual of Patent Examining Procedure § 2173.05 (8th ed. 2004)). Further, a claim will not be invalid for lack of an antecedent basis if the meaning of the claim could reasonably be understood by persons of ordinary skill when read in light of the specification. Energizer Holdings, Inc., 435 F.3d at 1370. "Intrinsic evidence in the form of the patent specification and file history should guide a court toward an acceptable claim construction." Datamize, LLC, 417 F.3d at 1348.

The intrinsic evidence shows that the claim should not fail for indefiniteness. Throughout the patent, it is clear that the device refers to a computer. For instance, the horizontal tray could support "a computer terminal having a display screen." (the '178 patent, Col. 6, lines 2-3). The "horizontal tray [supports] the wireless computer terminal." (the '178 patent, Col. 6, lines 65-67). The specifications describe a workstation with a power unit and battery charger for a "wireless computer terminal." (the '178 patent, Col. 7, lines 20-23). The keyboard within the work station "communicates with the computer terminal through a conventional electrical connection so that the keyboard can be easily connected to the computer terminal whenever the wireless computer terminal is stored within the mobile workstation." (the '178 patent, Col. 7, lines 49-53).

Although indefinite on its face, the weight of intrinsic evidence that the device was meant to be a computer does not even make this "a difficult issue of claim construction." Datamize, LLC, 417 F.3d at 1348. The device should be defined as a computing device.  

F. First Device/Second Device

Visto argues that the term "device" in the context of the '221 patent means "an electronic device for storing workspace data." Seven imports a location limitation and argues that the term "first device" means "an electronic device (e.g. a personal computer) located within a firewall-protected corporate LAN." According to Seven, the term "second device," means "an electronic device capable of storing workspace data located outside a firewall-protected corporate LAN." The court adopts Visto's definition of device, with a slight modification. The term means "an electronic device on which workspace data is stored." "First" and "second" need no construction.
1. "device"

In the "Field of Invention" portion of the '740 patent, "the present invention" is described as "related to a projection exposure apparatus for use to form a pattern of a semiconductor integrated circuit, or liquid crystal device, or the like." See Patent '740 at 1:16-18. Claim 10 repeats this use of "device," discussing a "method of producing a device, comprising . . . using an exposing method recited in claim 8." Id. at 46:3-5. As with any other term, the court must read "device" in accord with its claim- and specification-language context, both of which suggest that "device" means something more particular than the superficially generic "object or item" phrase ASML forwards. The claim language denotes a particular lithography-related "device," viz., the device produced through the lithographic process of transferring a pattern to a workpiece. Specification language, in turn, refers repeatedly to the imaging of a "circuit" "pattern" onto a substrate, typically in reference to various patent figures. See, e.g., 39:41-46 & 42:52-58; figures 29 & 32. Congruent with this intrinsic evidence, the court thus construes "device" to mean "an integrated circuit or similar item."

C. Device Control Circuitry

The term "device control circuitry" appears in Claim 1 of the '192 Patent. Digi contends that "device control circuitry" should be construed as "the mechanism within the device that controls it, for example, by implementing the device's main functionality, or by causing the device to deliver data, take defined actions, or otherwise respond to command signals." Lantronix asserts that this term should be given its plain meaning, "circuitry that controls the device."

The Court agrees with Lantronix's contention that the words "circuitry" and "mechanism" (in Digi's proposed construction) are not synonymous. The claim language and specification do not support such a construction. Moreover, the Court agrees with Lantronix that the meaning of this term is obvious and requires very little construction. Thus, the Court construes "device control circuitry" to mean "circuitry that controls the device."

4. The Term "Device Diagram"

Finally, the Court addresses the parties' dispute concerning the term "device diagram." CSI defines "device diagram" as "a graphical description of a control scheme, created using the device programming means, hence, [it is] a combined representation of the physical description [ ] and the logical definition of the facility." Fisher-Rosemount agrees with this definition with the caveat that both the physical and logical information appear on a single screen.

CSI's expert does not define this term. However, Fisher-Rosemount's expert does. In his opinion the "device diagram" provides a combined representation of the physical description of the facility and the logical definition of the facility, consistent with CSI's description. The specification supports this definition. The result is that a control engineer, using a "device diagram" can understand both the definition of the physical facility, i.e., what equipment is present and how it is connected, as well as the logical definition of control instructions that operate the interconnected equipment. See Specifications; (Col. 15:17-21). The Court, therefore, adopts CSI's proffered definition with the proviso that both the physical and logical information appear on a single screen.
The issue regarding this term is whether the court should construe the term in such a way as to allow the "device driver" to be a component of an application program. The defendants' proposed construction would define the term as "a software component." In this situation, the patent specification makes a distinction between a "device driver" and other types of interfaces.

The use of a device driver as the interface is a feature of the invention. . . . Many other interfaces with the circuit 100 are possible. For example, the interface may be incorporated into an application program, a program intermediate between operating system programs and applications, such as Windows TM, a program placed in a bios 1620 on a memory board 1600 (FIG. 16), wired into firmware, or designed in any other way that computer peripherals may be interfaced with. Interfaces other than a device driver may also be used. '242 Patent, col. 24, ll. 17-33 (emphasis added).

In other passages, however, the specification also suggests that the device driver may be a component of an operating system.

As can be seen from the above, the applications program 1222 communicates with the RNG module 1102 via the device driver. The device driver software 1200 is preferably part of the operating system of the computer and is typically stored on the hard disk 1165. '242 Patent, col. 22, ll. 63-67.

During the claim construction hearing, Quantum stipulated to the defendants' construction so long as the court replaced "permits a computer system" with "provides a standard interface." The court agrees with Quantum's argument regarding the distinction between a device driver and other interfaces, but concludes that its proposed stipulated construction fails to clarify the claim language in light of the previous construction of the interface terms. Additionally, the court agrees with the defendants that nothing in the intrinsic record restricts a "device driver" from being incorporated into an application program.

As such, the court defines "device driver" as "software that permits a computer system to communicate with a device."

1297

D. "a device for capturing the symbol, identifying the object from the symbol information"

Defendants present an email dated June 27, 2007, in which counsel for Cognex agrees to the following construction of this limitation: "a device that captures symbol image and identifies an object upon which the symbol is affixed, attached, etched, and/or engraved from the information contained within the symbol." Cognex now seeks to append the following phrase to the agreed-upon construction: ", regardless of whether or not the device can do this at substantially any orientation of capture."

The Court declines to adopt Cognex's proposed amendment. The language of the agreed construction is derived from the language of the '524 Patent claims. See, e.g., '524 Patent, claim 1 ("a device for capturing the symbol, identifying the object from the symbol information"). The Court finds no justification in the language of the claims or the specification for the addition of the orientation-related language proposed by Cognex. The Court construes this disputed term as "a device that captures symbol image and identifies an object upon which the symbol is affixed, attached, etched, and/or engraved from the information contained within the symbol."

1298

2. The Term "Device Object"

Next, the parties dispute the definition and limitation of the term "device object." CSI defines "device objects" as a
"software construct comprising the set of data associated with a "device" and the procedures used to manipulate that data." Fisher-Rosemount defines "device" as a physical or logical entity used in a facility. It defines "object" as a set of data encapsulated by a set of procedures that provides the only access to an allowable operation on that data. CSI contends that Fisher-Rosemount's definition fails because neither the claim language nor the specification supports the limitation that the "object" provides the sole access to a set of data.

The specification teaches that a "device object" contains device symbols or physical representations, logical instructions and configuration information pertaining to each device. "Each device may be of its own unique type." Therefore, all device characteristics are encapsulated within the device. Viewing Figure 14, the Court concludes that a "device object" encapsulates device logic, device tag definitions, device diagram symbols and graphic screen symbols and dynamics. Hence, the encapsulation is the improvement, but it is also the limitation, providing the only access to the data set. Moreover, there is no indication in any claim or the specification that the term "device" has more than one meaning.

The district court first construed the term "device-specific style" during a Markman proceeding. During that proceeding, MicroStrategy argued that the term meant "one or more parameters that designate the format in which a particular type of output device receives service outputs." After a careful review of the claim language and relevant statements in the specification and file wrapper, the district court largely adopted MicroStrategy's proposed definition. Thus, the district court construed "device-specific style" to mean "the format in which a particular type of output device receives and displays service output, consisting of values of a plurality of parameters." MicroStrategy, Inc. v. Business Objects, S.A., Civil Action No. 2:01cv826, slip op. at 27 (E.D. Va. Mar. 18, 2004) (Claim Construction Order).

The district court construed the remaining claim language on summary judgment. Patent Judgment, 331 F. Supp. 2d at 439. Based on the claim language, the district court "concluded . . . that the system or method [must] function on a device-by-device basis." Id. at 440. The district court's interpretation focused on two aspects common to the three independent claims: "(1) each user device is associated with a device-specific style, and (2) output is created for each user device according to the style specified for the user output device." Id. (emphasis in original). Thus, the district court concluded that the claim language requires association of output devices with a device-specific style on an individual, device-by-device basis. Id. In other words, the invention requires a particular format and presentation for one device, e.g. mobile phone data, that could differ from the format for a second device, e.g., electronic mail data. The district court summarized its conclusion as follows:

The patent covers methods and systems that retain associations between individual devices and device styles . . . because only in that manner does the patent cover systems that handle multiple device types or customization of subscription features on a subscriber-by-subscriber or device-by-device basis . . . While it is not necessary that the devices always be different, the system or method described in the claims is structured to facilitate the transmission of the same output to multiple device types.

Id. at 442-43.

This court recently restated: "It is a 'bedrock principle' of patent law that 'the claims of a patent define the invention to which the patentee is entitled the right to exclude.'" Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc) (quoting Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1115 (Fed. Cir. 2004)). "The inquiry into how a person of ordinary skill in the art understands a claim term provides an objective baseline from which to begin claim interpretation." Id. "Importantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Id.

All three of the '050 patent's independent claims recite the term "device-specific style." As previously noted, the district court construed this term as part of its Markman proceedings to mean "the format in which a particular type of output device receives and displays service output, consisting of values for a plurality of parameters." Claim Construction Order, slip op. at 27. This construction accurately reflects the claim language and the context supplied by the specification. See '050 patent, col. 4, ll. 49-63.
While accepting the district court's Markman construction, the parties dispute its meaning. MicroStrategy argues that this Markman construction and the context of the invention do not require support for more than one type of output device. In particular, MicroStrategy notes that the specification contemplates a system with "one or more" output devices. See id., col. 5, ll. 4-6. Thus, MicroStrategy reads the claim and the district court's Markman construction to permit a system with support for just one type of user device.

To the contrary, as noted in the district court's summary judgment order, all three independent claims require that each user output device subscribed to a service be associated with a device-specific style. See id., col. 17, ll. 58-62; col. 18, l. 65-col. 19, l. 2; col. 20, ll. 21-25. The term "associated" implies that the system creates a link between user output devices and corresponding "styles." In other words, the system must identify and track in some manner the "style" in which a particular user output device receives and displays output. This claim language further requires a direct link between each user output device, individually, and a corresponding "device-specific" style.

In addition, the claims require a device-specific formatted output according to a style specified for each device. See id., col. 17, l. 66-col. 18, l. 10; col. 19, ll. 6-11; col. 20, ll. 30-35. As noted by the district court, the words "specified" and "each" reaffirm that these claims require individual, device-by-device association. Moreover, the ultimate creation of a "device-specific" format requires at least two different device-specific styles. Otherwise, the references in the claims to individualized, device-by-device association of styles with user output devices and corresponding creation of a device-specific formatted output would be meaningless.

The specification supports this construction as well. The specification reads:

> According to one embodiment of the present invention, a system for automatically generating output from an on-line analytical processing system based on scheduled services specified by subscribers of the system is provided. The system processes scheduled services in an on-line analytical processing system with each service comprising at least one query to be performed by the on-line analytical processing system. The system then automatically forwards output from the services to one or more subscriber output devices specified for that service. Users may define new services, including the schedule of the services and the type, such as alert services or scheduled services, and may also subscribe to the services provided by the system. . . . The output devices the system may forward output to may comprise electronic mailbox, facsimile, printer, mobile phone, telephone, pager, PDA or web pages.

Id., col. 4, l. 64-col. 5, l. 22 (emphases added).

While this paragraph does state the system may ultimately forward output to only "one" output device, it does not address at all a minimum capacity to support a number of output formats (e.g., only one). Instead, this paragraph is open to an interpretation requiring support for multiple types of subscriber output devices, see id., col. 5, ll. 19-22, even though, in practice, all the subscribers may receive their subscription via only one format (e.g., e-mail or another suitable for mat). Therefore, this paragraph does not conflict with a claim construction requiring support for multiple device types or an association of styles with devices on an individual, device-by-device basis. The district court read the specification correctly in its well-reasoned decision. See Patent Judgment, 331 F. Supp. 2d at 443 (commenting that, while the system must be structured to support multiple device types, in operation, it is not necessary for the output devices to be different). In sum, based on the claim language in proper context and the specification that supplies much of that context, the district court correctly interpreted the claims.
The Court is of the opinion that the specification reveals "device symbols" as equipment or control functions. Hence, it is a physical representation that also conveys logical information, thereby requiring connection points in order that a control engineer may make functional connections. "Device symbols" are shown as part of the device diagram — [a graphical representation of a control scheme]; therefore, it makes sense that "device symbols" have functional connection points, otherwise, there is no functionality in the facility.

This conclusion is supported by Figure 33, which teaches that "when a user clicks on [a] connection point and holds down, the connection drawing is started." And, the same function "completes the connection from the tank to the pump . . . [and] . . . from the switch to the tank." As well, physical representations are device symbols that represent physical information.

The Court, therefore, rejects CSI's combined definition of "device" and "symbol" because its definition does not require that "device symbols" have specific connection points. These connection points are not cosmetic but "facilitate the interrelation of device symbols in a device diagram." In the Court's opinion, a person of ordinary skill in the art would read the claim to include specific connection. See Cook Biotech, Inc. v. Acell, Inc., 460 F.3d 1365, 1373 (Fed. Cir. 2006).

B. The Meaning of "Diagnose" -- "diagnose an operation"/ "diagnostic operation"

The second overarching claim construction issue concerns the meaning of the term "diagnose." In particular, the parties dispute the meanings of the claim terms "diagnose an operation" and "diagnostic operation" which appear in claims 57 and 58 of the '554 Patent. Ricoh proposes that the terms mean "to display or process state data received from the office machine system in order to identify or characterize the operational state of the office machine system." (Chart at 7). Pitney asserts that the terms mean "to analyze the cause or nature of errors in software or hardware." (Id.). In light of these constructions, the disputed issue is whether diagnosing requires an error.

Ricoh's construction is primarily based on the specification and Figure 5 of the patent. Additionally, Ricoh also relies on statements made by the patentee during prosecution whereby he distinguished his invention from the Patel prior art. The patentee stated that the prior art did "not have reference to a system which controls and diagnoses an office device in the context of not only identifying the device and its mechanical state of operation, but also of providing information with regard to the dynamic state of the device itself." ('779 Patent Prosecution History, Oct. 23, 1992 Amendment at 8).

In response, Pitney argues that Figure 5 of the patent merely shows codes, and does not illustrate the use of an "intelligent diagnostics" as Ricoh claims. Additionally, Pitney asserts that Ricoh's reliance on the patentee's statements during prosecution is misplaced since it does not define the term "diagnose an operation." Rather, Pitney contends that its construction should be adopted based on the plain language of the claim and the ordinary meaning of the word "diagnose."

Based on a review of the intrinsic evidence, the Court concludes that the construction for these terms do not require the presence of an error in software or hardware. The relevant portion of the claim language reads:

"A diagnostic processor, connected to a second end of said communication line, which processes said state data received from said office machine system to diagnose an operation of the office machine system and to communicate interactively with the office machine system . . . ."

'554 Patent, Claim 57 (emphases added). Based on the plain language, it appears that the diagnostic processor processes state data after it receives it from the office machine system. There is no mention in the claim language requiring the presence of an error before a diagnostic operation takes place. Further, as Ricoh correctly notes, state data includes static state data which does not change during the life of the device. Thus, the diagnostic operation proceeds even after processing static state data which need not involve errors in software or hardware. Accordingly, the Court does not find a basis in the claim language for importing the limitation Pitney seeks to adopt, and therefore adopts Ricoh's construction.

Consequently, "diagnose an operation" and "diagnostic operation" mean "to display or process state data received from the
office machine system in order to identify or characterize the operational state of the office machine system."

Claim 13 of the 720 patent depends from independent claim 12. Both claims are reproduced below, with the pertinent claim terms emphasized:

12 A water control system for bathing, comprising:

an open container for holding water for bathing;

a heater element for heating said water;

a temperature sensor for monitoring the temperature of the water in said container;

a control panel positioned adjacent said container for controlling the temperature of said water;

a microprocessor electrically coupled to said control panel, said microprocessor programmable by a user via said control panel to control the operation of said heater element, said microprocessor also being capable of diagnosing failures in said water control system and providing an output signal to the control panel indicative of a source of the failures.

13 A system as in claim 12, wherein said microprocessor comprises an 8-bit CMOS device.

In its opinion accompanying the order granting the preliminary injunction, the district court construed the phrase "diagnosing failures in said water control system" to mean "displaying error codes when there is a failure in the water control system." The district court also construed the phrase "indicative of a source of the failures" to require that "the system be capable of displaying multiple error codes dependent on the source of the failures, such as, for example, heater not heating, pump not operating, lack of water flow, or a microcomputer failure."

As this appeal arises from the grant of a preliminary injunction, we recognize that the district court's claim construction may evolve with greater understanding of the dispute. Although we agree generally with the district court's claim construction, we suggest the following clarifications subject, of course, to the district court's plenary consideration during subsequent proceedings.

First, it would seem that the phrase "diagnosing failures" connotes the process of detecting the causes or symptoms of failures in the water control system. Second, the phrase "indicative of a source" connotes the ability to indicate where in the water control system the failures might be occurring. The minor differences between our claim construction and the district court's, however, are not sufficient to convince us that the district court abused its discretion in granting a preliminary injunction. In particular, we agree with the aspect of the district court's claim construction that is most relevant to this appeal, i.e., the court's determination that the plural form of the word "failures" requires that the microprocessor be capable of diagnosing and indicating a source of more than one failure in the system.

2. "diagnostic processor"

The next disputed term in this category appears in Claims 57 and 58 of the '554 Patent. Ricoh contends that "diagnostic processor" should be construed as:

An intelligent device for communicating with and diagnosing the operation of the office machine system. A diagnostic processor is not part of the office machine system. It includes a microprocessor and a communication capability for communicating with the modular office machine system that itself includes intelligent modules that can interact with the
diagnostic processor. The intelligent modules of the office machine system and the diagnostic processor each make use of intelligent communication protocols. These intelligent protocols allow the diagnostic processor to communicate with a variety of models and products.

(Chart at 3). Pitney offers the following construction:

The diagnostic processor is part of the Remote Diagnostic Station, which is remotely located from the office machine system. It communicates interactively with the office machine system, via a communication line, to process data and then diagnose the office machine system. The diagnostic processor is not a passive system or a data collection site.

(Id.). Based on these constructions, the parties agree that the "diagnostic processor" is a device that communicates with the "office machine system," but is not part of the "office machine system." This much is clear from the plain language of the claim. In particular, Claim 57 recites:

A system, comprising:

an office machine system communicating with a first end of a communication line . . .; and

a diagnostic processor, connected to a second end of said communication line, which processes said state data received from said office machine system to diagnose an operation of the office machine system and to communicate interactively with the office machine system

wherein:

said diagnostic processor includes means for sending a command from the diagnostic processor to the office machine system over the communication line which initiates a diagnostic operation in the office machine system; and

data is transmitted from the office machine system to the diagnostic processor over the communication line after the diagnostic operation is initiated.

'554 Patent, Claim 57 (emphases added). Thus, the claim language reveals that two separate elements, i.e., the office machine system and the diagnostic processor, comprise the claimed system.

The Court further finds that a number of limitations contained in Pitney's proposed construction find support directly in the claim language and will therefore adopt them. This includes the limitation that the "diagnostic processor" interactively communicates with the "office machine system" via a communication line to which it is connected. Id. The claim further specifies that the "diagnostic processor" receives and processes state data from the "office machine system," which is then used to diagnose an operation of the "office machine system." n4 Id. Additional support is also found in the written description to include these limitations. Specifically, the written description provides that "Diagnostic Process 302 is an intelligent process which can communicate interactively with the Copier Engine 10 based upon the responses it receives and data accumulated in the Data Base 303." '554 Patent, col. 3, ll. 33-36. Consequently, the Court will include these limitations in its construction.

n4 The parties agree that "state data" means "any one of static state data, semi-static state data, and dynamic state data." (Tr. of Markman Hr'g at 49:4-11).

Turning to the remainder of Pitney's proposed construction, the Court will now determine whether the "diagnostic processor" is remotely located from the office machine system. Pitney argues that it is, relying on Figures 1 and 2 of the patent, the patent's Abstract, and the prosecution history. As it contended with regard to the previous claim term, Ricoh argues that there is no basis to import the additional limitation that the diagnostic processor is remotely located from the office machine system.
Based on the intrinsic evidence, the Court concludes that Pitney again has the stronger argument. The intrinsic evidence supports the conclusion that the patentee intended the diagnostic processor to be remotely located from the office machine system. Notably, during prosecution the patentee represented to the PTO that "the limitations recited in Claim 64 reciting that the diagnostic processor is located in a diagnostic station which is remote from said office machine system is supported by Figures 1 and 2." ([554 Patent Prosecution History, Sept. 13, 1995 Amendment at 24] (emphasis added). Figures 1 and 2 depict the Diagnostic Process 302 as part of the Remote Diagnostic Station 30 which is remotely located from the Copier Engine 10. [554 Patent, Figs. 1 & 2. The patent's Abstract also reflects this construction. See id., Abstract ("a remote diagnostics station can provide remote diagnostics of the target device.") (emphases added).

Other aspects of the prosecution history provide additional support for this construction. During prosecution, the Examiner rejected Application Claim 64 on grounds of obviousness-type double patenting in light of Claim 29 of the '779 Patent. The Examiner explained that although Claim 29 itself did not indicate that the diagnostic processor is remotely located from the office device, the claim in combination with the specification would yield an "obvious variation of the patented claim." ([554 Patent Prosecution History, Jan. 4, 1996 Examiner's Action at 6). In particular, the Examiner stated that it would have been obvious "to locate the diagnostic processor in a remote location as shown in Figs. 1 and 2 of the patent," implicitly stating that the Application Claim 64 of the '554 Patent application requires a remote location. (Id. at 7). To overcome the double patenting rejection, the patentee filed a terminal disclaimer. ([554 Patent Prosecution History, Feb. 1, 1996 Response at 13). Although the patentee noted that he did not agree with the rejection, he did not argue that the Examiner was incorrect in concluding that the claim requires a remote diagnostic processor. As such, this part of the prosecution history provides additional support for the conclusion that the diagnostic processor is located in a remote location.

At another point during prosecution of the patent, the Examiner rejected original claims 43 and 47 because the term "remote terminal" lacked proper antecedent basis. The patentee amended the claim by replacing the term "remote terminal" with "diagnostic processor." The Court finds this to be yet another indication in the intrinsic evidence that the patentee intended that the "diagnostic processor" be remotely located from the office machine system. ([554 Patent Prosecution History, Apr. 24, 1995 Prelim. Amendment at 11-12; July 26, 1995 Examiner's Action at 2; Sept. 13, 1995 Amendment at 5-7, 23). In light of these conclusions, the Court will include this limitation in its construction.

Lastly, Pitney further seeks to include the limitation that "the diagnostic processor is not a passive system or a data collection site." (Chart at 3). Pitney argues that the patentee disclaimed this type of diagnostic processor during prosecution of the '779 Patent in an effort to overcome a rejection based on the Weinberger reference. The prosecution history reveals that the patentee described the invention of the Weinberger reference as a "passive system which gathers specific information regarding the devices associated with a remote terminal." ([779 Patent Prosecution History, May 4, 1993 Amendment at 3). Thus, Pitney argues that Ricoh cannot now attempt to reclaim this subject matter. In response, Ricoh asserts that patentee's statements regarding the Weinberger reference were not characterizations of the invention "that uses words of manifest exclusion or restriction representing a clear disavowal of claim scope that is required in order [to] give rise to a prosecution disclaimer." (Ricoh Reply at 12 n.5).

It is well-settled that "the prosecution history may not be used to infer the intentional narrowing of a claim absent the applicant's clear disavowal of claim coverage." SuperGuide Corp. v. DirecTV Enters., Inc., 358 F.3d 870, 875 (Fed. Cir. 2004) (citations and quotations omitted). "To be given effect, such a disclaimer must be made with reasonable clarity and deliberateness." Id. In this instance, the Court agrees with Ricoh that the patentee did not clearly and deliberately disclaim the claim scope at issue. The patentee distinguished its invention over the Weinberger reference by stating that the reference only used one-way communication between the data top to the translator. n5 Moreover, the patentee argued that the Weinberger reference did not "show exchanges of data between the office device and operation terminal." Id. The patentee further stated that his invention "includes office equipment that store static, dynamic and control information and communicates the data to a remote location which includes an operation terminal that processes the information." Id. The Court finds, however, that the patentee's arguments did not clearly disavow claim scope with respect to the diagnostic processor, as it fails to specifically reference this term. Rather, the patentee's arguments were focused on the operation terminal. Thus, the Court concludes that importing this limitation is unwarranted in light of the prosecution history.

--- Footnotes ---

N5 The data top was described as the device "which transmits signals applied to the display on control panel 12 to the
With regard to Ricoh's proposed construction, the Court again finds that Ricoh's construction fails to accurately define the "diagnostic processor." Rather, it provides a general description of one aspect of the invention. The Court finds Pitney's construction, except for the last limitation, to be a more appropriate interpretation of this specific term because it is clearly supported by the intrinsic evidence. Consequently, the Court will adopt Pitney's construction in part. Accordingly, the "diagnostic processor" is part of the Remote Diagnostic Station, which is remotely located from the office machine system and communicates interactively with the office machine system, via a communication line, to process data and then diagnose the office machine system.

1304

F. "dial-up network server"

The term "dial-up network server" is found in claim 1: "a dial-up network server that receives user IDs from users' computers" and "wherein the dial-up network server communicates a first user ID for one of the users' computers and a temporarily assigned network address for the first user ID to the authentication accounting server." "Dial-up network server" is described in the following passage from the specification:

The PC [ ] first connects to the dial-up network server[]. The connection is typically created using a computer modem, however a local area network (LAN) or other communications link can be employed. The dial-up network server[] is used to establish a communications link with the user's PC[] using a standard communications protocol.

('118 patent, 3:57-63). Linksmart's proposed construction is "a server that is used to establish a temporary link to a network." Thedefendants contend that this term means "a server on the network that receives a connection via a modem, or establishes a connection via a modem, where the modem dials a phone number over a telephone line."

The defendants argue that the commonly understood meaning of "dial-up" requires the use of a modem to establish a dial-up connection over a telephone line. The defendants also note that the box labeled "Modem Array & Built-in dialup networking software" in Figure 2 of the '014 application corresponds to the "Dial-up Networking Server" in Figure 2 of the '118 patent. In response, Linksmart points to the language of the specification, quoted above, which explains that the connection to the dial-up network server "is typically created using a computer modem, however a local area network (LAN) or other communications link can be employed." ('118 patent, 3:58-60) (emphasis added). The court must 'adopt a definition that is different from the ordinary meaning [of a claim term] when 'the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in either the specification or prosecution history.'" Edwards Lifesciences LLC v. Cook Inc., 582 F.3d 1322, 1329 (Fed. Cir. 2009)(quoting CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366-67 (Fed. Cir. 2002)). Here, the specification clearly teaches that connections to the dial-up networking server are not limited to the use of a modem, but may also include other types of connections. Because the patentee defined "dial-up networking server" in a manner that differs from its ordinary meaning, this term is not limited to dial-up or modem connections. Therefore the court construes "dial-up network server" to mean "a server that is used to establish a communications link with the user's PC."

1305

9. "Dialing"

"Calling"

Cygnus advocates a broad construction of "dialing" and "calling," while defendants seek a narrow interpretation. Specifically, defendants wish to limit dialing or calling to the use of DTMF tones (which the defendants describe as "touch
IGC is the assignee of U.S. Patent No. 5,361,765 ("the '765 patent"). At issue in the present case are independent claims 1 and 5. With respect to claim 1, IGC argues that the district court erred when it construed the claim limitation "at least one diametric conductor" to refer to a segment connecting two sides of a coil through its center. According to IGC, the limitation "diametric conductor" encompasses any structure that divides a coil into two loops and thereby enables electric current to flow around the coil in opposite directions. Appellant asserts that the district court imprecisely focused on the definition of "diametric" in the sense of "diameter of a circle" rather than acknowledging that the word could also denote "diametrically opposed." In IGC's view, the district court's construction imprecisely imported limitations from the preferred embodiment and the prosecution history into the claim and erroneously led the court to conclude that USAI's devices do not literally infringe the '765 patent. Additionally, Appellant argues that the district court improperly held that the doctrine of equivalents requires the presence of each literal claim element in the accused device.

We agree with USAI that the district court properly granted summary judgment that USAI's devices do not infringe the '765 patent. Further, we agree that the district court construed claim 1 correctly. In construing patent claims, we look first to the intrinsic evidence of record - the claims, the specification, and, if in evidence, the prosecution history. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Claim 1, in relevant part, is directed to a "second coil having at least one diametric conductor to divide the second coil into a pair of loops . . . ." The claim is therefore limited to devices that have one or more diametric conductors. The plain language of the claim suggests that such a conductor is a single segment dividing a coil into two loops at its center. As claim 1 states, the diametric conductor exists "to divide the second coil into a pair of loops . . . ." '765 patent, col. 9, ll. 33-34. On appeal, IGC attempts to alter the meaning of this plain language by arguing that the term "at least one diametric conductor" includes anything that bisects a coil into two loops in order to allow for counter-cyclic current flow. The claim language, however, is not directed to current flow, and IGC's argument is without merit.

As the district court correctly found, the specification also supports the construction of "diametric conductor" as a segment that bifurcates a coil at its center. IGC-Medical at 10. The Summary of the Invention states that "a second loop, opposed substantially symmetrically to the first loop about the imaging volume, has a diametric conductor to divide it into a pair of coils." '765 patent, col. 3, ll. 36-39 (emphasis added). Figures 3, 5, and 7 of the patent disclose coils with precisely this configuration: all three figures show two loops, one of which is divided by a straight line running through the middle. Finally, the Detailed Description of the Preferred Embodiment describes the diametric conductor as a "simple straight segment" between the segments of the loop coil. Id. at col. 9, l. 6. On appeal, IGC argues that this analysis imprecisely limits claim 1 to its preferred embodiment. Although "references to a preferred embodiment, such as those often present in a specification, are not claim limitations," Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865, 9 USPQ2d 1289, 1299 (Fed. Cir. 1988), this court has repeatedly held that a claim must be read in light of the specification. Slimfold Mfg. Co. v. Kinkead Indus., Inc., 810 F.2d 1113, 1116, 1 USPQ2d 1563, 1566 (Fed. Cir. 1987) ("Claims are not interpreted in a vacuum, but are part of and are read in light of the specification."). We therefore conclude that claim 1 should be interpreted to cover only coil pairs where the second coil is bisected by at least one segment running through its center.

If ambiguity remains after consideration of the intrinsic evidence, "extrinsic evidence may also be considered, if needed to assist in determining the meaning or scope of technical terms in the claims." Pall Corp. v. Micron Separations, Inc., 66 F.3d
1211, 1216, 36 USPQ2d 1225, 1228 (Fed. Cir. 1995). In the instant case, we view the intrinsic evidence regarding diametric conductors as unambiguous and consequently need not discuss the extrinsic evidence.

**1307**

6) "Dielectric"

The parties agree that the term "dielectric" should be construed according to its ordinary meaning. Though the parties submit different constructions, Advanced contends that the submitted meanings are synonymous. The Court construes "dielectric" according to its ordinary meaning to mean "electrically insulating."

7) "Dielectric Spacer"

The term "dielectric spacer" appears in the '296 and '628 patent. MKS contends that "dielectric spacer" should be construed to mean "an insulating material inserted between two components to keep them electrically apart." (D.I. 53 at 1.) Advanced contends that "dielectric spacer" should be construed to mean "any component or device that holds two parts at a distance from each other." (D.I. 56 at 8.) The parties primarily dispute the physical properties of a dielectric spacer. While the terms "dielectric" and "spacer" are individually capable of ordinary and common construction, "dielectric spacer" is not a term of common or ordinary usage. After reviewing the patent claims, specification, and prosecution history, the Court construes "dielectric spacer" to mean "an insulating material or device that keeps components electrically apart."

**1308**

2. "[D]ielectric pair separator" 3 "Pair separator that serves as a dielectric medium." This construction is consistent with the claim language of the '095 patent. ('095 patent at claims 1, 10, 14-17, 27, 31; '537 patent at claim 19) For example, claim 24 discloses "a dielectric pair separator consisting of a dielectric layer and a conductive layer" while other claims disclose a dielectric pair separator "consisting of" only a dielectric layer. Conversely claims 27 and 31 of the '095 patent simply recite a "dielectric pair separator." This construction is also consistent with the claim language of the '537 patent. Claim 19 recites a "dielectric separator that consists of nonconductive, dielectric materials" including a "foamed polymer." The language "consists of" serves to narrow this term to require purely nonconductive materials. Neither the '095 patent nor the '537 patent support plaintiffs' narrow understanding of this limitation to mean a "non-conductive separator." Accordingly, the claims of both patents demonstrate that the patentee understood this limitation broadly and narrowed it when necessary with further limiting language. See Phillips, 415 F.3d at 1314.

3 '095and '537 patents.
"Different Codes" - Claims 1 and 5

The district court also addressed the "different codes" element of claims 1 and 5, and found these elements literally present in the Intellicode. In particular, the district court construed "different codes" to mean "factory-defined codes stored within the radio transmitters which uniquely identify each different transmitter and are not selectable or modifiable by the user of the garage door opener ("GDO") system." The district court's interpretation of this term is consistent with the claim language and finds support in the written description. The claim language requires association of each code with a different transmitter. The written description notes that each code uniquely identifies a transmitter. The specification adds that the codes are set in a factory and remain unchangeable by the user "to eliminate the requirements for code selection switches in the transmitters." '364 patent, col. 1, ll. 53-54.

The claim language does not supply any further constraints on the meaning of "codes." See Vitronics, 90 F.3d at 1582. Claims 1 and 5 do not require an identical code in the transmitter and the receiver. The language of both claims recite "that the code of said first transmitter will be stored in said memory means." Properly construed, this language requires the memory to retain the code it associates with the "first transmitter." The claims, however, do not require that the memory store the exact sequence of coded bits transmitted from the transmitter as its identifying signal. This reading of the claim language finds support in the written description, which explains that a code is associated with a transmitter. It does not describe any particular format, encryption, or alteration in transmitted and stored codes. The district court thus avoided interpreting "codes" so narrowly that any simple reformatting or addition of a single bit at the end of the code before storage would avoid the literal scope of claims 1 and 5.

In the Intellicode system, the unique, fixed, factory-programmed string of binary numbers in the transmitter do not match exactly the bits stored in the microprocessor's memory. Rather the Intellicode encrypts the transmitter code for transmission creating a different string of bits, the so-called "hopping code." The Intellicode microprocessor in "program" mode stores a secret key (yet another string of bits), and thereafter in "operate" mode uses the secret key to verify authorized (i.e. previously learned) transmitters. These features of the Intellicode, as explained above, however, do not avoid literal infringement of the "different codes" element. Thus, this court affirms the district court's construction of the "different codes" element and its finding that this element is literally present in the Intellicode.

"Each of a Different Color"

Finally, Defendants contend that the claim term "each of a different color" — which appears in each of the independent asserted claims — is indefinite because it is not clear what constitutes a "different color" for purposes of that limitation. For example, according to Defendants, it is not clear whether different shades of a particular color (e.g., magenta and light magenta) would be considered sufficiently different. Plaintiff responds that the different colors are the six claimed colors. According to Plaintiff, "each of a different color" should be construed as requiring at least four colors to be different.

The Court concludes that the phrase "each of a different color" is not indefinite. Rather, it means that each colored material in a particular color printing system must be of a different color. The claim term "color" in that phrase refers to the six claimed colors plus black and white. See '018 patent, abstract (describing the claim invention as "[a] color printing system * * * wherein these colors are selected from (1) an orange-red; (2) a violet-red; (3) a violet-blue; (4) a green-blue; (5) a green-yellow; and (6) an orange-yellow; as well as white and black"). Both magenta and light magenta are violet-reds, and therefore are not "different colors" for purposes of the asserted claims.
Types Of Computer Architectures

1. The '459 patent, claim 16: "plurality of different data formats for different types of computer apparatus"

Claim 16 of the '459 patent, in relevant part, describes a camera that stores images in a "plurality of different data formats for different types of computer apparatus." (D.I. 486, Ex. 4.) The parties dispute whether the reference in this element to "different data formats" is limited to formats relating to different computer architectures (e.g. formats for IBM or Apple computers) or can also include formats relating to different computer software (e.g. formats for GIFF or PICT software). The parties' dispute as to this element of claim 16 of the '459 patent is representative of their dispute over similarly worded phrases in the '219, '010, and '899 patents.

Fuji and Canon (collectively "Defendants") contend that "data formats" should be construed to mean formats that are different because they correspond to different types of computer architectures. Defendants contend that the M59 patent only provides for a camera with compatibility between different types of computer architectures and does not provide for a camera with compatibility between different types of software. Defendants contend that this issue is distinct from the issues considered by the Court in Sony.

Conversely, St. Clair contends that the Court resolved the meaning of the disputed phrase in Sony when it construed the key terms comprising the phrase, and St. Clair contends that there is no reason to reverse the Court's prior decision. St. Clair contends that the '459 patent discloses a camera compatible with different types of computer software, in addition to a camera compatible with different types of computer architecture.

After reviewing the parties' arguments in light of the claim language and specification of the '459 patent, the Court agrees with the construction advanced by St. Clair. In Sony, the Court issued a claim construction for both of the key terms in the phrase "a plurality of different data formats for different types of computer apparatus." Specifically, the Court defined the term "data format" to mean "the arrangement of digital data in a file" and the term "computer apparatus" to mean "a computer and any operating system or application software loaded on the computer." Sony, 2002 U.S. Dist. LEXIS 17871, *4, Civ. Act. No. 01-557-JJF, order at P 1. The Court concludes that these definitions are correct and should be applied to the construction of the phrase in dispute, so that the different formats referred to in this claim element may correspond to different architectures or different software.

Defendants contend that the use of the phrase "different types of" in the context of "different types of computer apparatus" limits the phrase to different types of computers. The Court is not persuaded by Defendants' argument. Neither the plain language of claim 16 nor the specification of the '459 patent support a construction as narrow as Defendants propose. Defendants' proposed construction ignores the plain language of the disputed element by excising the word "apparatus" from the phrase. The plain language of the disputed phrase refers to "different types of computer apparatus" and not just different types of computers, and the phrase "computer apparatus" includes different application software loaded on the computers, as well as different computers and operating systems. Thus, the Court's construction is supported by the plain language of the claim.

In addition, the Court's claim construction is supported by the specification of the '459 patent. The specification of the '459 patent explains that the patent is directed to the incorporation of digital image files into different software applications. As the Background of the Invention explains:

"The digital diskette is removable from the electronic camera for direct insertion into a PC which contains the previously loaded corresponding decompression algorithm whereby the digital image is in a format compatible for immediate use with word processing, desk top publishing, data base, and multi-media applications."

'459 patent, col. 1, 11. 19-25 (emphasis added). Describing the problem addressed by the '459 patent and distinguishing the claimed invention from the prior art, the specification further explains that "with the current state of the art, it is expensive and time consuming to convert the analog image equivalent to a digital format for direct utilization with PC software applications." (D.I. 986, col. 1, 11. 57-60 (emphasis added).) The objective of the patent to provide compatibility with different types of software is also confirmed in the Summary of the Invention, which explains that "it is a further object of this invention to provide an improved electronic still camera that provides digital image files for immediate and direct incorporation into popular word processing, desktop publishing, and other software programs on PCs." (D.I. 986, col. 2,
A. Whether the patents require one-to-one correspondence of file format with computer hardware architecture?

(Construction of category (1) claim terms: "plurality of different data formats for different types of computer apparatus" and variations thereof)

The parties' first dispute centers on whether the patents-in-suit require what has been referred to as a "one-to-one correspondence" between file formats and computer hardware architecture. St. Clair contends that the claim terms are not limited to such a one-to-one correspondence. Therefore, St. Clair proposes that the disputed claim term "plurality of different data formats for different types of computer apparatus" be construed as:

a plurality of different data formats for different types of computer apparatus where: (1) a 'data format' is the arrangement of digital data in a file including image, audio, text or other data and includes, at least, MPEG, JPEG, GIF, TIFF, PICT, BMP, JFIF, DCF, TXT, DOC, WPD and WAV, and (2) a 'computer apparatus' is a computer and any operating system or application software loaded on the computer.

Defendants, on the other hand, insist that the patents require the one-to-one correspondence. Accordingly, they propose that "plurality of different data formats for different types of computer apparatus" be construed as "two or more different arrangements of digital data in a file, wherein each different arrangement is in one-to-one correspondence with a particular type of computer architecture (e.g., IBM PC/Clone or Apple Macintosh)." (D.I. 259 at 7)

On this dispute I agree with St. Clair. Having reviewed the claims, the specification, the prosecution history (including that generated during the re-examinations), and the extrinsic evidence of record, I conclude that the patents-in-suit are not limited to the one-to-one correspondence Defendants propose.

As an initial matter, Defendants are correct that Judge Farnan's two prior claim construction rulings are not dispositive. Among the Defendants contesting claim construction here are parties who were not parties to the prior actions and who are not barred by collateral estoppel or res judicata from pursuing their proposed constructions here. See Novartis Pharms. Corp. v. Abbott Labs., 375 F.3d 1328, 1333 (Fed. Cir. 2006). 3 Also, Defendants here have a non-frivolous argument that the intrinsic evidence has expanded -- due to reexamination proceedings with respect to four of the patents-in-suit -- and that the applicable legal framework may have changed as well (since both the Sony Construction and the Canon Construction pre-date Phillips). Hence, I have undertaken my own analysis and have reached my own conclusions. Having conducted my own review, I find that I agree with Judge Farnan's prior conclusion and, like him, I reject Defendants' proposed limitation of a one-to-one correspondence.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

3 I make no ruling at this time as to whether any party before the Court in the current actions who was also a party in a prior action is bound by a claim construction order entered in a prior case.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

Importantly, there is no reference in the asserted claims to a "one-to-one correspondence" between a file format and a particular type of computer architecture. Indeed, as St. Clair emphasizes, the claims "don't mention IBM, don't mention Macintosh, don't mention architecture." Tr. at 67. Hence, there is no indication in the claims themselves that the claims require a one-to-one correspondence.

Nor does the specification mention a "one-to-one correspondence." To the contrary, the specification demonstrates that the inventors understood that while certain relationships were predominant between particular file formats and particular computer architectures, these predominant relationships were not the only relationships the claimed invention could accommodate. 4 The specification states:

The compressed digital frame is then formatted into either an IBM PC/Clone (such as GIFF) or Apple Macintosh (such as PICT II) image file format depending on the setting selected by the operator for a user switch 17 . . . .

'010 patent, col. 4 lines 61-65 (emphasis added). In writing that an IBM PC user, for instance, would want data files in a format "such as GIFF," the inventors recognized that while an IBM PC user might likely want data files in a GIFF format, she might also want them in a format other than GIFF.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

4 Defendants observe that in connection with claim construction in the Canon litigation, St. Clair stated: "in the experience of most consumers of digital photography in 1990 . . . IBM equal[ed] GIF and Apple equal[ed] PICT." (D.I. 282 at Defs. Ex. E at 8) This marketplace reality is neither disputed nor relevant. The issue is not what a consumer thought in 1990; rather, it is how one having ordinary skill in the art would have read the asserted claims of the Roberts Patents at that time.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -
Similarly, the specification states:

It should be noted that a large number of image formats for PCs exist. PICT and GIF are the most common for the Apple and IBM PC's and are therefore the preferred formats for the present invention although other formats can be easily incorporated into the design by changing the software format routines. These software image formats are commercially available from many sources most notably Apple computers for PICT and IBM for GIF.

'459 patent, col. 11 lines 36-44 (emphasis added)

As St. Clair explains, the Roberts Patents are addressed to resolving multiple problems in the prior art: one involving software and one involving hardware:

The inventors identified two distinct shortcomings in the prior art. First, the inability of digital cameras to allow users a choice of multiple image files for immediate use in various computer applications. Second, hardware incompatibilities such as different storage or memory formats between IBM and Apple computers. The inventors sought and obtained different claims which separately address each short-coming.

(D.I. 172 at 15) "[T]he asserted claims address the first shortcoming, i.e., the failure of prior art cameras[. . .] to allow users the ability to select in the camera between at least two of many common image file formats such as JPEG, GIF, TIFF, PICT, MPEG, BMP, and JFIF which are designed for use by any number of computer programs." Id. Other -- unasserted -- claims relate to the second issue: hardware incompatibility. 5 In this way, the specification again supports St. Clair: software and hardware problems are addressed separately by separate claims of the Roberts Patents; nowhere is the software problem addressed by requiring a one-to-one correspondence between a file format and a type of computer architecture. There is no requirement that the asserted claims accomplish all of the objectives of the patents-in-suit. See Phillips, 415 F.3d at 1327 ("We have held that the fact that a patent asserts that an invention achieves several objectives does not require that each of the claims be construed as limited to structures that are capable of achieving all of the objectives.") (internal quotation marks and citations omitted).

5 See, e.g., D.I. 172 at 20 (citing '222 patent, claims 1-12, ensuring diskette in camera is compatible with "memory format" used with particular hardware brand); '459 patent, claims 7 and 11; '219 patent, claims 7, 11, 14, and 15; '757 patent, claim 10 (all foregoing being dependent claims focusing on selection of particular memory, data storage, or hardware formats)).

On this point, too, I agree with Judge Farnan. In the Canon Construction, Judge Farnan wrote:

. . . The specification of the '459 patent explains that the patent is directed to the incorporation of digital image files into different software applications. As the Background of the Invention explains:

The digital diskette is removable from the electronic camera for direct insertion into a PC which contains the previously loaded corresponding decompression algorithm whereby the digital image is in a format compatible for immediate use with word processing, desk top publishing, data base, and multi-media applications.

'459 patent, col. 1, 11. 19-25 (emphasis added). Describing the problem addressed by the '459 patent and distinguishing the claimed invention from the prior art, the specification further explains that "with the current state of the art, it is expensive and time consuming to convert the analog image equivalent to a digital format for direct utilization with PC software applications." '459 patent, col. 1, 11. 57-60 (emphasis added). The objective of the patent to provide compatibility with different types of software is also confirmed in the Summary of the Invention, which explains that "[t]he purpose of the invention is to provide an improved electronic still camera with a digital image file for immediate and direct incorporation into popular word processing, desktop publishing, and other software programs on PCs." '459 patent, col. 2, 11. 15-19. The specification goes on to discuss the selection of software formats in the patented camera, further demonstrating that the patent is not limited to the computer architecture problem. '459 patent, col. 4, 1. 68-col. 5, 1. 9; col. 11, ll. 32-49.
Defendants point to Figure 6 of the specification, which depicts switch 17 as enabling the user to choose between "IBM" and "Apple" formats, as purported support for their construction. (D.I. 259 at 16) (citing '459 patent, JCCC Ex. A at STCLR000006) However, Figure 6 is a preferred embodiment. See '459 patent, col. 3 lines 23-24 ("FIG. 6 is an example of the control panel logic in accordance with one aspect of the present invention."); id. col. 3 lines 62-63 & col. 6 lines 42-54 (stating, in "DESCRIPTION OF THE PREFERRED EMBODIMENT," "The user must then select the desired PC format (IBM PC/Clone or Apple Macintosh, etc.) via switch 17 (FIG. 6) on the control panel 2."). It would be improper to import this feature of the preferred embodiment into the claim. See Liebel-Flarsheim, 358 F.3d at 906.

Defendants also find support for their proposed construction in the prosecution history, most particularly in the reexaminations of four of the Roberts Patents that occurred subsequent to Judge Farnan's issuance of the Sony Construction and the Canon Construction. In the course of these reexaminations, various PTO Examiners stated or suggested that they disagreed with this Court's construction of the "plurality of data formats" terms. 6 The PTO allowed the claims to emerge from reexamination without amendment based, at least in part, on the PTO's interpretation of the claims as being limited to a one-to-one correspondence.

--- Footnotes ---

6 The '459 and '219 patents proceeded through reexamination at approximately the same time as one another. Tr. at 89. In allowing the reexamined claims to stand, the PTO noted in its "Statement of Reasons for Patentability and/or Confirmation:"

Roberts et al. explicitly state that switch 17 on the control logic panel of figure 6 is provided for allowing a user to select between image file formats (PICT II, GIFF, etc.) for formatting a compressed digital image into a selected file format, wherein the image file formats provided for selection (PICT II or GIFF) are in one-to-one correspondence with a particular type of computer system (Apple Macintosh or IBM PC, respectively). . . . In other words, Roberts et al. DO NOT provide selecting between various sub-species on the same computer species . . . . Roberts et al. disclose and precisely claim selecting an image file format (PICT II, GIFF, etc.) from a plurality of image file formats for formatting a digital image into the selected image file format, wherein each of the image file formats provided for selection (PICT II or GIFF) are in one-to-one correspondence with a particular type of computer system (Apple Macintosh or IBM PC).

JCCC,Defs. Ex. 6 at PP 3, 6.

The '010 and '899 patents proceeded on essentially the same schedule as one another. See Tr. at 89, 115. They emerged from reexamination without amendment -- but only after the PTO expressly distinguished its claim construction from that previously adopted by this Court. See JCCC Defs. Ex. 30 at 2-3 ("[I]n light of the disclosure a very different interpretation that[that] adopted by the court must be made. . . . [I]n light of the specification, the claim limitation 'formatting the digital image signal in one of a plurality of computer image formats' is interpreted to mean formatting the image signal as one of an IBM PC/Clone, Apple Macintosh, or other PC Format.") (emphasis added). At no point did the patentees indicate agreement with the PTO's construction.

--- End Footnotes ---

I agree with Defendants that the reexamination history needs to be considered in connection with construing the claims. See, e.g., Tr. at 111 ("[W]e're not suggesting that you are bound [by what] happened in the re-exam. But we are suggesting that it's an important part of the intrinsic record."). I do not, however, agree with the conclusion Defendants would have this Court draw from that history.

Statements by patentees and Examiners are part of a patent's prosecution history, which is intrinsic evidence a court should consider in construing patent claims. See SRAM Corp. v. AD-II Eng'g, Inc., 465 F.3d 1351, 1359 (Fed. Cir. 2006); Salazar v. Procter & Gamble Co., 414 F.3d 1342, 1345 (Fed. Cir. 2005). This is as true of statements made during a reexamination as it is of statements made during the initial prosecution. See Laitram Corp. v. NEC Corp., 952 F.2d 1357, 1361 (Fed. Cir. 1999). This is one reason courts sometimes stay patent litigation pending the resolution of a simultaneous reexamination. See, e.g., Procter & Gamble Co. v. Kraft Foods Global, Inc., 549 F.3d 842, 848 (Fed. Cir. 2008). Also consistent with this
conclusion is the Federal Circuit's guidance to district courts (at least in the context of preliminary injunction motions) to "monitor the proceedings before the PTO to ascertain whether its construction of any of the claims has been impacted by further action at the PTO or any subsequent proceedings." Kraft, 549 F.3d at 848.

There are important differences, however, between the legal standard applicable to claim construction before the PTO and claim construction before an Article III Court. A PTO Examiner construing claims is required apply the broadest reasonable construction consistent with the specification. See In re Morris, 127 F.3d 1048, 1054 (Fed. Cir. 1997); see also In re American Academy of Science Tech Center, 367 F.3d 1359, 1364 (Fed. Cir. 2004) ("The broadest reasonable construction rule applies to reexamination as well as initial examinations.") (internal quotation marks omitted). Courts do not apply this "broadest reasonable construction" rule. Also, before the PTO, any ambiguity or excessive breadth in a patent claim may be corrected by amending the claim. See Burlington Indus. Inc. v. Quigg, 822 F.2d 1581, 1583 (Fed. Cir. 1987). This is not a possible outcome of judicial claim construction.

That the PTO is required by law to apply the broadest reasonable construction does not mean, however, that the PTO's claim construction is, per se, the broadest reasonable construction. The PTO -- like a court -- may make mistakes. See SRAM, 465 F.3d at 1351, 1359 (Fed. Cir. 2006) (finding that PTO "paradoxically" failed to give disputed claim term its broadest reasonable construction and construed claim in an improperly narrow manner).

Hence, once claim construction is before a court, the court is obligated to construe claims de novo as a matter of law, without according any deference to the PTO's construction. See SRAM, 465 F.3d at 1359 (noting de novo standard of judicial review and rejecting construction adopted by district court and by PTO Examiner -- after three reexaminations); see also Salazar, 414 F.3d at 1343, 1347-48 ("[T]he examiner's unilateral remarks did not alter the scope of the claim. An examiner's statements cannot amend a claim."); Inverness Med. Switzerland v. Princeton Biomeditech Corp., 309 F.3d 1365, 1372-73 (Fed. Cir. 2002) (rejecting contention that statement in examiner's Reasons for Allowance governed construction of disputed claim term). 7

Footnotes

7 Of course, a district court can -- and must -- adopt the same construction as the PTO when the court concludes for itself that the PTO's construction is correct. See, e.g., Biogen, Inc. v. Berlex Labs., Inc., 318 F.3d 1132, 1140 (Fed. Cir. 2003) (affirming district court's construction, which itself was consistent with PTO Examiner's view that scope of disputed term had been limited during prosecution, as advocated by alleged infringer).

Having reviewed the extensive prosecution history here, including especially the history generated during the reexaminations, I conclude that the "plurality of data formats" terms should be construed in a manner so as to not require the one-to-one correspondence proposed by Defendants. 8 I have considered the portions of the specification on which the PTO relied in reaching its contrary conclusion and continue to believe, as this Court has previously ruled, that the patent does not require a one-to-one correspondence. 9 Although the PTO appears to have found such a limitation in construing the disputed claims under the "broadest reasonable construction" standard, I accord the PTO's views on claim construction no deference. 9 I do not find support in the claims or the specification for the one-to-one correspondence limitation and I am not persuaded by the reexamination history that I am wrong.

Footnotes

8 See JCCCDefs. Ex. 30 at 2 &Defs. Ex. 27 at 2 ("Examiner believes the confusion of the interpretation of the claim language arises out of the apparent disclosure that a user is selecting between two different image file types, such as between GIFF or PICT II. However, upon further inspection of the disclosure this is not found to be the case. Examiner notes that the disclosure goes on to teach that the user selects 'the desired PC format (IBM PC/Clone or Apple Macintosh, etc.) via switch 17 (Fig. 6) on the control panel 2.' (column 6, lines 42-25) As such, a user is selecting between the PC format by using switch 17, not the image file type."); JCCCDefs. Ex. 30 at 3 &Defs. Ex. 27 at 3 ("In looking at the disclosure on the whole a user is given an option for selecting between PC formats by using switch 17, wherein a particular image file type is assigned to each of the PC formats. . . . There is no disclosure in the Roberts et al. patents to suggest that once the user selects that the image is to be output as an IBM PC/Clone, for example, that the user is further given the
option of selecting between various image file formats such as GIFF, TIFF, BMP, JFIF, etc.

9 Defendants observe that given the evident disagreement between the PTO and this Court as to the proper construction of the disputed claim terms, if this Court adheres to its construction there is a risk that, at trial, Plaintiffs will obtain a greater-than-appropriate benefit from the presumption of patent validity. See D.I. 258 at 11 n.9 (citing Applied Materials, Inc. v. Advanced Semiconductor Materials Am., Inc., 98 F.3d 1563, 1569 (Fed. Cir. 1996)). That is, on Defendants' reading of the prosecution history, it is plain that the PTO does not view the patents-in-suit as validly extending beyond a one-to-one correspondence; without a one-to-one correspondence limitation, the PTO would find these patents invalid. It seems to me that this risk is inherent in the legal relationship between the PTO and district courts: while the PTO has sole authority to grant patent rights in the first instance, once the PTO does so a district court asked to construe claim terms is required to determine, de novo, as a matter of law, the scope of the patent protection granted by the PTO (in accord with how one having ordinary skill in the art would read the claims in light of the intrinsic evidence). In any event, Defendants' concern is not one that affects claim construction. It may be necessary, however, to consider this issue in connection with jury instructions.

Accordingly, I recommend that the Court construe the disputed "plurality of data formats" claim terms in the manner proposed by St. Clair, and reject the one-to-one correspondence limitation proposed by Defendants. 10

10 The specific constructions are set out in full at the end of this Report and Recommendation. See infra Part IV. 1.

F. Different Distinct and Independent Games

<table>
<thead>

<td>Two or more games that have different rules and random factors. regard to the status of the other. Each game must operate with unique rules of play and unique random factors from the other. For example, the games cannot share a random number generator or ball blower.</td>
<td>Two very dissimilar games able to reach a winning stage independently, without</td>
</tr>
</tbody>
</table>

Defendants argue the claim term "different distinct and independent games" does not permit playing two games of the same type because during prosecution the patentee continually narrowed the term in response to the PTO's rejections based on prior art. Defendants argue the patentee narrowed the claim in three ways: (1) by listing the types of different distinct and independent games; (2) by differentiating a single bingo game as using a different random number generator; and (3) by describing the different distinct and independent games as "very dissimilar."

FortuNet argues this Court previously interpreted the claim to mean if the two games have a difference in rules and random factors they are unique. FortuNet asserts the two games can be of the same type, such as concurrently playing two bingo
games, particularly because the specification uses the example of two concurrent bingo games. FortuNet denies the patentee narrowed or abandoned this meaning during prosecution.

In the Stuart litigation, this Court interpreted "different distinct and independent games" as follows:

If the games have a difference in the rules of play and random factors, they are unique. Both the rules of play and random factors must contain a difference, a game with different rules of play and nonunique random factors would not be covered by the language of the claim.

(Pls.' App. to Markman Claim Construction Br., Ex. H at 35.) The Court concludes this remains the proper construction of this claim limitation. With respect to playing two of the same type of game, the specification itself states that the patent contemplates the player playing two different bingo games at the same time. (JA0011, Col. 5 at 37-43.)

Although during patent prosecution the patentee refined this term to overcome the patent examiner's rejection of the claim, a review of this history does not suggest the patentee abandoned the simultaneous play of two games of the same type. The initial patent application disclosed the limitation of playing two games simultaneously. (JA0022.) The patent examiner rejected this language, stating prior art taught the simultaneous play of two games over a network. (JA0036.) In response, the patentee added the words "distinct and independent" to describe the games. (JA0044.) The examiner again rejected the claims, explaining that "distinct and independent games" was covered by a prior Itkis patent which allows a player to play two separate bingo cards. (JA0048; JA0050-51; JA0082.) The examiner stated that the "games are distinct because they are on two different cards. They are independent in that matches occur on each card independent of the other card." (Id.) The examiner noted that because the application did not define the word "games," the claim language was broad enough to include two bingo cards within the same overall bingo game. (JA0050-51.) The patentee again amended the claim by adding "different" to the distinct and independent games, as well as including additional new language regarding the unique rules of play and unique random factors and listing the types of games. (JA0054.) The PTO thereafter approved the application. (JA0085.)

Viewing this prosecution history, the patentee did not surrender playing two bingo games at the same time, so long as those bingo games had unique rules of play and unique random factors. The patentee listed the types of games to overcome the patent examiner's interpretation that two bingo cards within a single bingo game could constitute "games" under the patent because the patent did not define "games." The patentee defined "games" to include bingo, poker, etc., to show that "games" did not include two bingo cards within the same bingo game.

This determination is consistent with this Court's ruling in the Stuart litigation in which the Court found the defendant's device which permitted simultaneous play of two different distinct and independent bingo games infringed claim 1 of the '787 patent. The Stuart litigation involved the play of regular bingo along with a game called bonanza bingo. The Court found the defendant's device infringed the '787 patent because it permitted the play of both regular and bonanza bingo at the same time. (Defs.' App., Ex. 3.) Although both games were bingo games, regular bingo and bonanza bingo had different rules and different random factors, thus making them different distinct and independent under claim 1. (Id.)

Defendants also argue that even if claim 1 includes the simultaneous play of two bingo games, to be different distinct and independent games, the two bingo games cannot use the same blower or random number generator. Defendants argue that the patent cannot cover two bingo games using the same blower or random number generator because during prosecution, the patentee specifically noted that a single bingo game would not use the same blower or number generator as another bingo game:

A single (bingo) game is defined as a unique game distinct and independent from another bingo game or any other (non-bingo) game by a number of factors including but not limited to a single random number generator ("ball blower") and a single prize ("pot") to be shared by all the winners. The fact that a player may possess more than one bingo card does not convert a single game into a plurality of distinct and independent games. Similarly, the fact that two or more players simultaneously play the same (bingo) game does not convert this game into a plurality of distinct and independent bingo games.

The difference between a single bingo game and a single poker game is even more obvious than the difference between two bingo games being played at different times and/or in different places (assuming independent prizes and independent
random number generator processes for the bingo games).

(JA0045.)

The claim language does not support Defendants' position. Nothing in claim 1 indicates two bingo games must use different random number generators to be different distinct and independent. The specification does not make this distinction either. This Court rejected Defendants' position in the Stuart litigation where the Court found infringement even though the regular bingo game and the bonanza bingo game used the same blower. (Defs.' App., Ex. 3 at 14.) The Court noted that although the games shared the same blower for selecting numbers, bonanza bingo had a different random factor because players could swap out their bingo cards during the bonanza bingo game, which they could not do during the regular bingo game. This created a unique random factor between the games, thus satisfying the patent language. Consequently, the bingo games need not have a separate bingo ball blower or random number generator so long as they have another difference in random factors and rules of play.

The prosecution history does not alter this conclusion. The patentee noted that a single bingo game is distinct from another by a number of factors "including but not limited to" a single random number generator and prize pot. (JA0045.) Reviewing this comment in the context of the prosecution, the patentee was attempting to distinguish a bingo game from the individual bingo cards being played within that game. It is not evident that the patentee was attempting to identify different random number generators as the only way to differentiate one bingo game from another bingo game. The Court will not impose a limitation which is not expressed by the claim language and is contrary to the specification based on an isolated comment in the ongoing negotiation between the patentee and the PTO. This is particularly appropriate when the statement is viewed contextually. It is unclear whether the patentee intended to narrow the scope of his claimed invention or was attempting to explain to the examiner the difference between two bingo games as opposed to the difference between a bingo game and a bingo card. Furthermore, in a subsequent amendment the patentee added the language requiring the two games to have unique random factors and unique rules. (JA0054.) The patentee thereby clarified through specific claim language what distinguishes two different distinct and independent games.

Finally, Defendants argue that during prosecution, the patentee surrendered the play of two bingo games because he stated the two different games must be "very dissimilar," and then listed the type of games, such as bingo, poker, keno, etc. Defendants thus argue to be "very dissimilar," the games must be of a completely different type. However, two bingo games could be "very dissimilar" if they had different rules of play and random factors.

The Court therefore holds that "different distinct and independent games" means "the games are unique if they have a difference in the rules of play and random factors. Both the rules of play and random factors must contain a difference. A game with different rules of play and nonunique random factors would not be covered by the claim language. The two games can be of the same type and can use the same ball blower or random number generator so long as some other difference in the rules of play and random factors exists."

---

1. "A first predetermined wavelength" and "a second predetermined wavelength different from said first predetermined wavelength".

There is no dispute between the parties that "a first predetermined wavelength" refers to an optical communication signal and that "a second predetermined wavelength" refers to an optical service signal. The crux of the matter is how different is "different". Ciena argues that the two wavelengths must be "substantially different". Pirelli refutes this contention by saying "different" means "sufficiently different" so that an optical coupler can properly separate the two wavelengths. There is also no dispute that neither prosecution history nor extrinsic evidence shed any light on how this specific language should be construed.

(a) The Claim Language

As dictated by the foregoing claim construction principles, the Court starts with the language of the claim itself. In both claim 1 and claim 7 of the '459 Patent, the claim, in relevant part, reads: "An optical communication signal transmitter for
transmitting optical communication signals of a first predetermined wavelength; . . . a second predetermined wavelength different from said first predetermined wavelength . . ." Col.7, lines 57-59 and Col.8, lines 19-21 (claim 1); Col.9, lines 1-3 and 29-31 (claim 7) (emphasis added).

Pirelli's position is that the term "different" is clear and unambiguous from the claim. Pirelli construes "different" as "any two optical wavelengths sufficiently different so that they can be separated from one another." See D.I. 79, at 10. In particular, Pirelli points out that the word "different" is not further characterized anywhere else in the claim and there is no basis in the claim language itself for the limitation supplied by the word "substantially".

(b) The Specification

Ciena relies on the language of the specification for the argument that the two wavelengths must be "substantially different". Specifically, Ciena cites the following language:

In order for such couplers to operate correctly, with a complete separation between the extracted signals and the unaltered signal and with a reduced attenuation of the signals themselves, they must operate between wavelengths that are substantially different whereas optical communications are accomplished in a fairly narrow range of wavelengths where the transmission characteristics of the fiber are better.

Col.1, line 68 through Col.2, line 8 (emphasis added). This "substantially different" language is found again in the specification, see Col.2, lines 25-30, and in another section where the two wavelengths are selected to be "appreciably different" from one another. See Col.4, lines 57-60. Ciena concludes that this limitation found in the specification language precludes the use of closely spaced wavelengths for the service and communication signals.

In rebuttal, Pirelli points to another section of the specification which states that, "a different wavelength . . . may be adopted for the service signals . . . as long as it is sufficiently far from the range of transmission signal wavelengths as to allow the making of the corresponding optical couplers." Col.7, lines 30-38. Further, Pirelli advances two other arguments. First, it is impermissible to read limitations from the specifications into the clear language of the claims, especially where a claim term does not say it must have a particular definition. Second, Pirelli asserts that under the rule of claim differentiation, independent claims 1 and 7 should not include the limitations sought to be read into them because those limitations already appear in dependent claims 4 and 5.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

5 Claim 4 of the '459 Patent reads:

An optical fiber transmission system as set forth in claim 1 wherein said second wavelength is selected to be substantially equal to a wavelength at which the attenuation in the sections of optical fiber line is less than the attenuation at adjacent wavelengths.

Col. 8, lines 51-55.

Claim 5 of the '459 Patent reads:

An optical fiber transmission system as set forth in claim 1 wherein said first determined wavelength is in the range from about 1500 nm to about 1600 nm, said second predetermined wavelength is in the range from about 1200 nm to about 1400 nm and said service signals have a rate substantially less than 300 kilobits per second.

Col. 8, lines 56-62.

(c) Claim Construction

As discussed above, when the meaning of words in a claim are in dispute, the specification can provide relevant information
about the scope and meaning of the claim. See Electro Medical Systems v. Cooper Life Sciences, Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994). For the most part, however, "claims are not to be interpreted by adding limitations appearing only in the specification." Id. This is so because "no matter how great the temptations of fairness or policy making, courts do not rework claims. They only interpret them." See Intervet Am. v. Kee-Vet Lab., 887 F.2d 1050, 1053 (Fed. Cir.1989). Ciena suggests the language in the specification that, "[the two wavelengths] must operate between wavelengths that are substantially different . . . " Col.2, lines 2-5 (emphasis added), should be read into the meaning of the claim. See Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988) ("Where specification does not require limitation, that limitation should not be read from specification into claims of patent.").

The Court is unpersuaded. Even if, arguendo, the "substantially different" language could be read into the claim, there is no guidance in the claim itself how "substantially" should be defined. Ciena suggests that the Court might define the communication signal as being in the third window of the silica gel attenuation curve and the service signal as being in the second window of the curve. The Court declines this invitation for three reasons. First, "although the specifications may well indicate that certain embodiments are preferred, particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments." Electro Medical, 34 F.3d at 1054. While Ciena's attenuation curve suggestion is found in the preferred embodiment, see Col. 4, line 61 through Col. 5, line 10, it is does not mean the preferred embodiment should be used to limit the broad language of the claim. See CVI/Beta Ventures, 112 F.3d at 1158 ("As a general matter, the claims of a patent are not limited by preferred embodiments").

In addition, the Court is counseled by the rule of claim differentiation. Under this "fixed, long and well established" rule, a limitation cannot be read into a claim that already appears in another claim. See D.M.I., Inc. v. Deere & Co., 755 F.2d 1570, 1574 (Fed. Cir.1985). Ciena's suggestion to define "substantially different" by reference to the various windows of the silica gel fiber attenuation curve is found almost verbatim in dependent claim 5. "Where some claims are broad and others narrow, claim limitations cannot be read into the broad . . . " Deere & Co. v. Int'l Harvester Co., 658 F.2d 1137, 1141 (7th Cir.), cert. denied, 454 U.S. 969, 70 L. Ed. 2d 386, 102 S. Ct. 514 (1981). Therefore, the word "different" in independent claim 1 and 7 of the '459 Patent cannot be limited by reference to language found in dependent claim 5.

Third, Ciena's last ditch argument that "different" should mean "substantially different" is based on the proposition that optical couplers were available when the patent issued that allowed separation of signals not substantially apart and yet, Pirelli's specification language only refers to optical couplers that work with signals "substantially different". Therefore, by negative inference, Ciena asserts Pirelli cannot now claim that its invention was intended to work with optical couplers that can differentiate wavelengths not "substantially different". Pirelli contends that a patent should be read based on the current technology, not on what was in existence at the time of the invention of the patent.

The Federal Circuit recently declared in Eastman Kodak: "As a general rule, the construing court interprets words in a claim as one of skill in the art at the time of the invention would understand them." Eastman Kodak, 114 F.3d at 1555 (emphasis added); Markman v. Westview Instruments, Inc., 52 F.3d 967, 986 (Fed. Cir. 1995) (en banc), aff'd 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996) ("The focus in construing disputed terms in claim language is not the subjective intent of the parties . . . rather the focus is on the objective test of what one of ordinary skill in the art at the time of the invention would have understood the term to mean."); see also SRI International v. Matsushita Electric Corp. of America, 775 F.2d 1107, 1122 (Fed. Cir. 1985) ("It is not necessary to embrace in the claims . . . all possible forms in which the claimed principle may be reduced to practice.").

At the time of the '459 Patent invention, it is Ciena's assertion, and it is unrefuted by Pirelli, that optical couplers existed that could separate wavelengths of almost any difference. Therefore, "one of skill in the art at the time of the invention" would understand these claims in the '459 Patent to include optical couplers that could separate wavelengths that did not have to be "substantially different". Thus, by Ciena's own admission, Pirelli is entitled to claim as part of its invention optical couplers that are able to differentiate wavelengths that are not "substantially different".

The Court therefore construes the word "different" in the claim language "the second predetermined wavelength different from said first predetermined wavelength" (emphasis added), to mean any difference in wavelength that allows for signal separation by optical couplers that existed at the time of the invention. 6 This definition in effect adopts the "sufficiently far" specification language that Pirelli has espoused, but does so in terms intelligible to a jury.
6 It is appropriate to define a claim in terms of some other element or structure. See, e.g., In re Benson, 57 C.C.P.A. 797, 418 F.2d 1251, 1254 (C.C.P.A. 1969); Autogiro Co. of America v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 403-04 (Ct. Cl. 1967). Both decisions of the former U.S. Court of Customs and Patent Appeals and the U.S. Court of Claims are binding precedent in matters of patent law. See UMC Electronics Co. v. United States, 816 F.2d 647, 652 n.6 (Fed. Cir. 1987).

B. "different light signals"

The plaintiff proposes "light signals produced according to different timing patterns." Defendants propose "two or more light emissions that convey information and are not identical." The main issue is whether "different" means different timing patterns or "not identical."

The plaintiff argues that light signals with different timing patterns are clearly different from each other, and that the specifications refer to different light signals in terms of timing patterns, e.g., flashing, strobing, alternating, etc. See '865 patent, 19:21-25, '269 patent, 4:37-41.

Defendants argue that the patents-in-suit distinguish signals based on color, intensity, and position. Defendants also contend that the plaintiff's construction would not classify a wide range of light signals (e.g., amber warning lights on utility vehicles, red and/or blue warning lights on police vehicles, etc.) as "different light signals."

In reply, the plaintiff points to claim 15 of the '865 patent describing the ability to selectively illuminate LEDs on different sides as a way to create different light signals, and claim 3 (and other claims) of the '269 patent disclosing the independent control of LEDs on two exterior surfaces. The plaintiff argues that if "position" made light signals different, then there would be no need to independently control LEDs on each side or surface in order to create different light signals. Second, the plaintiff argues that "color" does not create "different light signals" because "color" is an attribute of "light signal," but does not define "light signal." The plaintiff further argues that, in the prosecution history, the examiner did not cite the combination of prior art with different color LEDs as reciting "at least two different light signals."

The plaintiff's proposed construction is too narrow. Nothing in the specification limits "different light signals" only to "light signals" with different timing patterns. Accordingly, "different light signals" means "two or more light signals that are not identical." The Court incorporates by reference its definition of "light signal."

E. "different types of visually distinct warning light signals"

The plaintiff proposes "different kinds or categories of visually distinguishable warning light signals." Defendants propose "different categories of visually distinguishable warning light signals, each having attributes establishing it as an exclusive group (e.g., steady-on, flashing, oscillating, rotating, character, or symbols)." The main dispute centers around Defendants' further limitation of "exclusive."

The plaintiff argues that the ordinary meaning of "type" should be used because nothing in the specification or prosecution history indicates a deviation from the dictionary definition or the need to include the word "exclusive." The plaintiff further argues that the defendants' parenthetical list is unnecessary because a lay person would understand that a "kind" or "category" of signals would have some common attributes.

Defendants argue that the phrase is indefinite because the claims, specification, and prosecution history do not provide a standard or objective means for one of ordinary skill in the art to determine whether or not a product infringed. In addition,
Defendants argue that claim scope was limited during prosecution. Defendants contend that the patentee abandoned previous claim language from "a plurality of visually distinctive warning light signals" and narrowed the claims to "more than two different types of visually distinct warning light signals" produced either "simultaneously" or "in at least one combination." See Dec. 13, 2001 Amendment, at 1-4; June 13, 2002 Amendment, at 1-5; Feb. 19, 2004 Amendment, at 2-4; Feb. 20, 2004 Amendment, at 2-7; Dec. 6, 2004 Amendment, at 2-4. In addition, throughout the prosecution, the patentee referred to "constant on," "flashing," and "sequencing" as "single and exclusive types of light signals." See Feb. 19, 2004 Amendment, at 9; Feb. 20, 2004 Amendment, at 6; Dec. 6, 2004 Amendment, at 6. Defendants, therefore, contend that a "simple flash" is a different type of light signal from a "triple flash" because they are both "flashing" light signals.

In reply, the plaintiff argues that whether a "single flash" is a different type of signal from a "triple flash" is a question for the jury to decide.

The Court disagrees with Defendants' attempt to limit the phrase to "exclusive" groups. There is nothing in the claims or specification to suggest such a limitation. The Court also disagrees with Defendants' indefiniteness argument because one of ordinary skill in the art would understand that different types of a "visually distinct warning light signal" refers to different categories or kinds of warning light signals. Accordingly, the Court adopts the plaintiff's proposed construction, and "different types of visually distinct warning light signals" means "different kinds or categories of visually distinguishable warning light signals."

D. "different warning light signals"

The plaintiff proposes "warning light signals produced according to different timing patterns." Defendants propose "two or more light emissions that convey warning information and are not identical." The parties make the same arguments as above for the construction of "different light signals" and "light signals."

For essentially the same reasons as discussed in Section B, the Court concludes that "different warning light signals" means "two or more warning light signals that are not identical." The Court incorporates by reference its definition of "warning light signals."

(2) Claim Construction of the '934 Patent. One part of the '818 device, namely, the "real image projecting system" built around the "beam splitter," is covered by the '934 Patent. Claim One of the '934 Patent states:

1. In a real image projecting system including a concave mirror for reflecting a virtual image of an object and an aperture through which is projected a real image of the object into space, a beam splitter interposed the mirror and the aperture comprising:

   a planar expanse having a front surface facing the aperture and rear surface facing the mirror, the plane of said expanse being oriented at an angle to an axis defined between the mirror and the aperture;

   said expanse having differential light transmissivity in either direction along the axis characterized by relatively high transmissivity of light incident thereon from the mirror and relatively low transmissivity of light incident thereon from the aperture, thereby reducing reflected external object image visibility that would clutter the view of such a projected real image.

'934 Patent Specifications, Col. 6, Lines 24-38. The key dispute here centers on the meaning of "differential light transmissivity." OPD argues that this term should be interpreted as referring to a special effect achieved by use of the beam splitter to enable more light to pass through it from the mirror than from the aperture. DMA argues, by contrast, that "differential light transmissivity" describes an effect produced by the functioning of the image-projecting system as a whole.
rather than a special property of the beam splitter alone. According to DMA, the image-projecting system described by the '934 Patent simply exploits the fact that light passing through the beam splitter twice--first on its way from the aperture to the mirror and then back from the mirror to the aperture--will be more attenuated than light only passing through once, thus decreasing the visual clutter around the projected image. In other words, OPD says that the '934 Patent describes a system in which the beam splitter causes the differential in light transmissivity, whereas DMA says it describes a system that takes advantage of a naturally occurring differential in light transmissivity.

In the broader perspective of this litigation, it is hard to see the practical significance of this somewhat semantic debate. If OPD's interpretation is correct, then its own products do not infringe the '934 Patent since they do not include a beam splitter that causes this special effect. But if DMA's interpretation is correct, the ultimate result is likely the same, for the '934 Patent very likely then suffers from the same defect of "obviousness" that invalidates the '818 Patent, see infra.

Given the subsequent stipulations of the parties, however, the only issue the Court has been called upon to determine regarding the '934 Patent is the issue of claim construction. And as to that issue, it is clear that, whatever DMA may have meant to say about the beam splitter, what is actually described by the '934 Patent is a beam splitter that causes the differential in light transmissivity. Thus, the plain language of Claim One states that it is the "expanse" of the beam splitter, rather than the entire image-projecting system, which has the characteristic of "differential light transmissivity." So, too, the "Background of the Invention," Col. 1, Lines 13-22, describes the beam splitter as having "unique directionally differential transmissive properties." Likewise, the "Summary of the Invention" recites that it is the principal object of the invention to provide, in an image projecting system including an image projecting concave mirror and an aperture, an improved piano-beam splitter by the use of which the virtual images of objects external to the system's enclosure do not superimpose on the real image projected through the aperture into a space external to the enclosure.

Col. 1, Lines 25-31 (emphasis added). The clear focus of the '934 Patent is thus on the specific "improvement" of the beam splitter, rather than on some known property of light that the system exploits, and this "improvement" is the beam splitter's "differential light transmissivity."

1 Similarly, subordinate claims Two through Six repeatedly use the term "expanse" to refer to the beam splitter, rather than the overall system.

Conversely, there is no mention in the patent specifications of the relatively greater attenuation of light from external objects reflected off the mirror within the enclosure. In fact, the specifications claim that the beam splitter's relative absorption and reflectivity vis-a-vis this external light can be increased to such an extent that "most light entering [the] aperture . . . fails to reach the concave mirror." Col. 6, Lines 4-7.

Accordingly, the Court interprets the term "differential light transmissivity" in the '934 Patent to mean the claimed ability of the beam splitter to "reflect[] light entering the aperture and striking the outer surface of the beam splitter, while transmitting therethrough light that is projected from the concave mirror toward the aperture." Col. 2, Lines 2-5. While, as DMA now asserts, its beam splitter does not actually do this, OPD had a right to rely on the language of the '934 Patent in developing what it therefore could reasonably believe was a product that did not infringe that patent.
(b) differentially thermally growing an oxide to serve as an implant mask having controlled thickness on both the top and sides of the gate electrode whereby a relatively thicker layer of oxide is developed on the top and sides of the gate electrode and a relatively thinner layer of oxide is developed on the intended source and drain regions of the substrate; then

(c) anisotropically etching said oxide;

(d) implanting a source/drain region in the substrate such that said implant mask shields an underlying portion of the substrate from implantation to result in a gap between a side edge of the gate electrode and a side edge of the implanted region; and then

(e) heat driving the implanted source/drain region until its side edge is substantially aligned with the previously separated side edge of the gate electrode, whereby the source/drain edge is aligned with the gate electrode edge and there is substantially zero overlap.

The parties do not dispute any additional language in dependent claims 2 and 3.

During this litigation, the parties have presented the following issues of claim construction with respect to claim 1 of the '943 patent:

1) Must the gate electrode be doped prior to differentially thermally growing an oxide layer over the gate electrode?

2) How much oxide must be grown on the top and sides of the gate electrode versus on the substrate for the oxide to be "differentially" grown as required by step (b)?

3) What is the meaning of the word "gap" in step (d)?

4) What are the meanings of the phrases "substantially aligned" and "substantially zero overlap" in step (e)?

Prior to the hearing on June 10 and 11, 1996, both parties submitted briefs, expert reports, and documentary evidence outlining their positions with respect to these disputed issues. In its May 28, 1996 Opinion, the court decided the first issue in the affirmative. In other words, the court construed claim 1 to require doping the gate electrode prior to differentially thermally growing an oxide layer over the gate electrode.

At the conclusion of the claim construction hearing on June 10 and 11, 1996, the court announced its resolution of the remaining claim construction issues. The court construed the phrases "differentially thermally growing," "relatively thicker," and "relatively thinner" to require three elements:

1) the grown oxide must be thick enough on top of the gate electrode to serve as a mask for the implant of step (d);

2) the grown oxide must be thick enough on the side of the gate electrode to block the implant of step (d), thereby making a "gap;" and

3) the top oxide thickness must be in a proportion of at least 1.77 to 1 to the substrate oxide thickness.

*   *   *

1. To what extent must the oxide growth of step (b) be "differential"?

At the conclusion of the claim construction hearing on June 10 and 11, 1996, the court set out three requirements that are implied by the following phrases in step (b) of claim 1: "differentially thermally growing," "relatively thicker," and "relatively thinner." In its answering brief in opposition to Intel's motion for summary judgment, TENA raises arguments against each of these requirements. The court will first explain its basis for a particular construction of the claim language. It will then address TENA's arguments in opposition to that construction.
a. "The grown oxide must be thick enough on top of the gate electrode to serve as a mask for the implant of step (d)"

The plain language of claim 1 and the prosecution history support the requirement that the grown oxide must be thick enough on top of the gate electrode to serve as a mask for the implant of step (d). Step (b) of claim 1 specifically recites "growing an oxide to serve as an implant mask having controlled thickness on both the top and sides of the gate electrode." Step (d) of claim 1 defines the term "implant mask" as a device that "shields an underlying portion of the substrate from implantation" of the source and drain regions. Thus, the claim language states that a grown oxide mask alone must be sufficient to block implantation. Furthermore, the prosecuting attorney, Edward Manzo, added in his First Proposed Amendment after Final Rejection the limitation that the mask must consist of a grown oxide, rather than a deposited oxide or other deposited material.

TENA merely seeks to clarify this part of the court's construction in light of an alleged ambiguity. TENA believes that this construction might imply that the oxide layer must remain on top of the gate during the implant of step (d). Intel has never asserted this contention. In fact, Dr. Chung specifically testified at the claim construction hearing that the oxide layer may be removed after it is grown. Moreover, requiring the oxide layer to remain on top of the gate would be inconsistent with the anisotropic etching step in claim 1, which suggests that the oxide layer may be removed, and dependent claim 4, which explicitly requires the oxide layer to remain on top of the gate. Thus, to the extent the court's construction has caused any ambiguity, the construction is not meant to imply that the oxide layer must remain on top of the gate during implantation.

b. "The grown oxide must be thick enough on the side of the gate electrode to block the implant of step (d), thereby making a 'gap'"

The requirement that the grown oxide must be thick enough on the side of the gate electrode to block the implant of step (d), thereby making a "gap" is also straightforward. According to step (d) of claim 1, the oxide mask "shields an underlying portion of the substrate from implantation to result in a gap between a side edge of the gate electrode and a side edge of the implanted region." Likewise, the specification, at column 3, lines 42-44, states that the oxide on the sides of the gate electrode must be thick enough to act as the implant mask of step (d) "to shield underlying portions of the substrate from implantation." Thus, the oxide mask on the sides of the gate electrode must be thick enough by itself to block implantation of the source and drain regions.

TENA argues that "if this construction means that the grown oxide alone must be thick enough to block the implant of step (d) thereby making a gap, it is erroneous for the reasons earlier discussed." TENA does not explicitly state the "earlier reasons" to which it is referring. It appears that TENA is arguing the following. The three requirements set out in the court's construction of the phrases "differentially thermally growing," "relatively thicker," and "relatively thinner" are interdependent. If the first requirement is that the oxide on the top of the gate electrode must remain on the top during the implant of step (d), that requirement is erroneous. Therefore, the requirement that the oxide mask on the sides of the gate electrode must be thick enough alone to block implantation is erroneous.

TENA's argument is inapposite for two reasons. First, as set out above, the court has never construed claim 1 to require that the oxide mask remain on the top of the gate electrode during the implant of step (d). Second, the three requirements set out by the court are not interdependent in the way that TENA seeks to imply. Separate evidence from the claims, specification, and prosecution history supports each requirement independently. In finding each requirement, the court does not rely on a separate finding with respect to claim construction. For example, in finding that the oxide alone must be thick enough on the sides to block the implant of step (d), the court does not rely on its finding that the oxide on the top of the gate electrode must be thick enough to serve as an implant mask, or even its finding that doping the gate electrode must precede differential growth. These separate findings are consistent, but they do not interlock such that all fail if one is incorrect.

c. "The top oxide thickness must be in a proportion of at least 1.77 to 1 to the substrate oxide thickness"

The limitation that the top oxide thickness must be in a proportion of at least 1.77 to 1 to the substrate oxide thickness derives entirely from the prosecution history. As initially filed, claim 1 did not contain any reference to differential thermal growth. In subsequent amendments, however, Manzo added a differential growth limitation to dependent claims 2 and 3. The examiner nevertheless issued a final rejection of all of the claims as obvious in light of the combination of the Cohen and Steinmaier patents. Referring to the process of the Steinmaier patent, the examiner stated, among other things, that "the
thermally grown oxide is inherently thicker on the top and sides of the polysilicon gate than on the silicon substrate."

In his First Proposed Amendment After Final Rejection, Manzo amended claim 1 to state in relevant part:

....

(b) differentially thermally growing an implant mask of oxide of a controlled thickness on both the sides and on the top of the gate electrode including controlling ambient conditions to promote a high rate of oxidation on the top and sides of the doped polysilicon gate compared to the silicon substrate, whereby a relatively thicker layer of oxide is developed on the top and sides of the gate and a relatively thinner layer of oxide is developed on the intended source and drain regions of the substrate; then . . . . (emphasis added to show amendments to claim)

Manzo observed, citing the Kamins article, that the inherent differential growth observable in Steinmaier would result in only a 7% to 9% differential. Manzo emphasized that the differential growth of the '943 patent contemplated, in its preferred embodiment, a differential of 300%. See also First Proposed Amendment at 14 ("Clearly the application inherently supports the use in the claims of 'a high differential' because a ratio of 3 to 1 is certainly high compared to 1.07 to 1.").

In his subsequent File Wrapper Continuing Application, Manzo continued to distinguish the differential growth of the Steinmaier patent. Manzo stated:

Further, the oxidation in a dry atmosphere at 950 [degrees] C for a mere 50 minutes would not lead to an appreciably different thickness because, as Table I of Kamins establishes, the differential will be a factor of only 1.77, and that is when 375 minutes of dry oxidation occurs. . . . Thus, the offset which would result from the process specified in Steinmaier, even if the ordinarily skilled artisan inadvertently practiced the method with doped poly, would be quite small.

Thus, Manzo thought that a differential of "only 1.77" would result in an offset that is "quite small" compared the offset obtained by the differential growth required to practice the inventions of the '943 patent.

After the submission of the First Proposed Amendment and the File Wrapper Continuing Application, the examiner interviewed Manzo to discuss claim 1 in light of the Cohen and Steinmaier patents. The examiner stated the following in his "Examiner Interview Summary Record" ("EISR"): "Mr. Manzo to submit preliminary amendment to place case in condition for allowance. Anisotropic etching limitation to be added to claim[ ] 1 . . . ."

Manzo subsequently submitted a Voluntary Amendment in which he added an anisotropic etching step to claim 1 and removed the following language from that claim: "controlling ambient conditions to promote a high rate of oxidation on the top and sides of the doped polysilicon gate compared to the silicon substrate." Manzo left in the requirement that the oxide be "differentially thermally grown," however. In addition, he left in the requirement that the oxide on the top and sides of the gate electrode be "relatively thicker" than the oxide on the substrate, which is to be "relatively thinner." Therefore, it appears that differential growth is still important to claim 1 of the '943 patent and that a minimum differential of 77% is still required.

TENA makes three arguments in opposition to this limitation. First, TENA asserts that by removing the "ambient conditions" language, Manzo removed the limitation in claim 1 requiring a "high rate" of oxidation. Thus, TENA argues that the court's construction impermissibly resurrects that removed limitation. TENA is correct that Manzo removed the "high rate" limitation from claim 1. The court's construction requiring a 1.77 differential does not resurrect this limitation, however.

TENA fails to acknowledge that the "high differential" of claims 6, 10, and 15 is most likely the 300% differential identified in the specification, at column 3, lines 26-33, and in the First Proposed Amendment. Thus, while claim 1 may no longer require a 3 to 1 ratio, the removal of the "ambient conditions" language does not suggest what ratio is required. Moreover, Manzo did not remove all of the limitations directed to differential growth added in the First Proposed Amendment. Thus, TENA's argument only establishes that the differential required by claim 1 is less than 300%. A 77% differential is substantially smaller than the "high differential" of 300%. Therefore, the court is not resurrecting a limitation that was specifically removed from the claims. Rather, it is construing the claims consistently with Manzo's representations to the examiner.
TENA's second argument is that Manzo was not speaking about the oxide on the top of the gate electrode when he referred to the 1.77 differential. Instead, he was arguing that the 1.77 differential was an advantage for the side oxide in order to create a sufficient gap between the edges of the source and drain regions and the edges of the gate electrode. TENA's argument appears correct but irrelevant. The patent does not teach, and none of the experts have explained, how one skilled in the art of making MOS transistors could achieve differential growth as between the top and sides of the gate electrode, which are made of the same material. Testimony at the hearing established that during the heating stage the oxide on the top of the gate electrode should grow at approximately the same rate as the oxide on the sides of the gate electrode. Therefore, a limitation that the oxide on the sides of the gate electrode must be 77% bigger than the oxide over the substrate as a practical matter is a limitation that the oxide on the top of the gate electrode must be 77% bigger as well.

TENA's third argument is that Manzo made a mistake in interpreting the Steinmaier patent in light of the Kamins article. Citing In re Eskild, 55 C.C.P.A. 807, 387 F.2d 987, 989 (C.C.P.A. 1968), TENA argues that the true content of Steinmaier and Kamins "must necessarily result from an inquiry made from the objective standpoint of...one of ordinary skill in the art." Manzo's statement does not appear to be properly characterized as a mistake, however. Rather, it appears that Manzo was defining the differential growth required to practice the patent by speaking in hypothetical terms about Steinmaier in light of Kamins. For example, the Steinmaier process involves oxidation of an undoped gate electrode in a dry atmosphere at 950 [degrees] C for 50 minutes. Manzo's hypothetical, based on the Kamins article, involved dry oxidation of a doped gate electrode for 375 minutes. Manzo obviously was aware that the Kamins article did not accurately reflect the process taught by Steinmaier ("Thus, the offset which would result from the process specified in Steinmaier, even if the ordinarily skilled artisan inadvertently practiced the method with doped poly, would be quite small." (emphasis added)). Manzo clearly had in mind that even if Steinmaier resulted in 77% differential growth, such differential growth would not create a sufficient "gap" in order to practice the inventions of the '943 patent.

1. "apparatus arranged for differently encoding a plurality of data signals"

The first disputed term of the '604 Patent is found in Claims 1 to 14 and 22. Claim 1, a representative claim, provides:

1. A data transmission system using multicarrier modulation, comprising:

   FECC (forward error correction code) coding and codeword interleaving [24] apparatus arranged for differently encoding a plurality of data signals to provide a plurality of encoded data signals with different delays through the coding and interleaving apparatus, the coding and interleaving apparatus comprises a plurality of data paths providing the encoded data signals with different delays, and a switch for switching different data signals to different data paths; and a modulator arranged to modulate bits of the encoded data signals onto multiple carriers of the transmission system, different numbers of bits in each transmission

   system symbol period being allocated to different carriers.

'604 Patent, col. 11, ll. 6-20 (emphasis added). Plaintiff offered the following proposed construction in the Chart: "the apparatus implementing the encoding is actually arranged to carry out at least two types of encoding that are not the same." (Chart at 7). Defendants argue that the term must be construed as an "apparatus having the capability of encoding more than one data signal using encoding that is not the same." Id. Thus, the dispute centers around the construction of the phrase "arranged for." 18

18 The parties agreed that there is no dispute concerning "a plurality of data signals." The phrase should be construed to mean "more than one" data signal. (Tr. at 114:7-20).

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -
- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -
Plaintiff asserts that the term must be construed as "actually arranged." According to Plaintiff, "actually" is required to modify "arranged" to signify the "degree" of arrangement required by the claim. (Tr. at 116:10). Plaintiff states that the specification explains that hardware and software must be arranged in a particular manner in order to carry out particular functions. (Pl.'s Opening Br. at 31). It states: "The various units in the transceivers 10 and 12 can be implemented in various ways, using arrangements of hardware and/or software." '604 Patent, col. 8, ll. 35-37. Plaintiff asserts that Defendants' construction, which incorporates the phrase "capable of," is without meaning. (Tr. at 116:13).

Defendants argue that the ordinary meaning for the term "arranged" should be adopted. Defendants offer two definitions from dictionaries that were published before the date the patent issued. First, "arrange" can mean "to put in the correct, proper or suitable order," or "to make ready; prepare or plan." WEBSTER'S NEW WORLD DICTIONARY 76 (1991). Second, "arrange" can mean "to put into a proper order or into a correct or suitable sequence, relationship, or adjustment." MERRIAM WEBSTER'S COLLEGIATE DICTIONARY 64 (1993).

The Court concludes that the ordinary meaning of the term "arranged" should be adopted. There is no evidence in the specification that the patentees chose to define the term in a different way. Interestingly, the Court finds that Plaintiff's reasoning more closely reflects the ordinary meaning than Defendants' proposed construction. Plaintiff's assertion that the apparatus must be arranged in a proper or suitable order to perform the particular functions comports with the plain meaning of "arranged." Defendants have not demonstrated that "capable of" is synonymous with "arranged." Thus, the Court adopts the ordinary meaning "to put into a proper or suitable order," but for the sake of simplicity, will use a simpler term that adequately reflects this definition. The Court concludes that the term "configured" serves this purpose, and will use it in its construction.

Accordingly, the Court concludes that disputed term [24] "apparatus arranged for differently encoding a plurality of data signals" means "the apparatus implementing the encoding is configured in such a way that it encodes more than one data signal by using at least two types of encoding that are not the same."

The parties disputed six terms used in the claims of the '843 patent. The Court has construed those terms as follows:

a) "Waveguiding structure" is used interchangeably with "waveguide" and is defined as: "A structure formed by a waveguiding film and a substrate and containing a diffraction grating";

b) "Waveguide film" means: "A film which, in combination with a sample having a lower index of refraction and a substrate can guide light along a path";

c) "Diffraction grating" means: "Any arrangement in the waveguiding structure that imposes a periodic variation of amplitude and/or phase on an incident wave";

d) "Wavelength" means: "A wavelength of light at which the optical sensor, including the waveguiding structure, waveguiding film, and diffraction grating, detects chemical, biochemical or biological substances in the sample";

e) "Effective index" means: "A number that relates the propagation velocity of light guided in a waveguide to the speed of light in a vacuum";

f) "Measuring the effective index and effective index change" means: "determining the effective index" and "determining the effective index change."

(D.I. 156).
Diffractive Follow-on Track

The parties dispute whether the "diffractive follow-on track" includes any portion of the disc's area that does not lie physically within the disc's grooves. The area in between the grooves is known as the "lands of the disc." Philips argues that the track is simply the groove itself, while Defendants argue that it is the groove and a portion of the lands on each side of the groove, which they refer to as "track pitch." See Tr. at 17 ("It is impossible to read the width of the groove as also encompassing the lands on either side of the groove. . ."); at 46 ("It is the defendants' position that this diffractive follow-on track includes not only the groove, but also includes the land adjacent to the groove."). Defendants' argument is again one of functionality. They assert that an insufficient amount of light will be diffracted if the track does not include a portion of the land on each side of the groove. See id. at 46 ("Our argument on this issue, your Honor, if that if you don't take these lands into account, because the lands directly adjacent to the groove are what provide this diffractive pattern with sufficient intensity so that they will be able to read, if you don't have that, it will not work.").

The claims are clear that the "diffractive follow-on track" is a groove that exists to guide the radiation beam as it writes information on the disc. See Claim 1 of '209:

... said record carrier body having a radiation-sensitive layer on which the information to be recorded is written with the write beam and a continuous, generally circular, diffractive follow-on track extending about the center of said disc-shaped record carrier body for guiding the write beam during recording of the information, said follow-on track being configured to diffract radiation incident thereon when scanned with a spot of radiation of a predetermined size and having a width which is smaller than the dimension of the spot in the width direction.

Claim 11 of '493 states:

... the information to be recorded is written with the write beam and a diffractive follow-on track in the form of an elongated groove formed in said record carrier body for guiding the write beam during recording of the information, said groove being configured to diffract radiation incident thereon when scanned with a spot of radiation of a predetermined size and having a width which is smaller than the dimension of the spot in the width dimension.

Defendants' argument that the "track" includes a portion of the lands is inconsistent with the language of the patent, which explains that the track is a groove. What is a groove? The Oxford English Dictionary, Second Edition 1989 defines a groove as:

1. A mining shaft; a mine, pit;
2. A channel or hollow, cut by artificial means, in metal, wood, etc.; e.g. the spiral rifling of a gun, one of the air-passages leading from the wind-chest to the pipes of an organ, etc.;
3. A channel or furrow of natural formation.

As noted in the above definition, a groove is synonymous with a furrow. A furrow is defined as:

1. A narrow trench made in the earth with a plough, esp. for the reception of seed;
2. In extended sense: A trench, drain;
3. A quantity (of land) having the length or breadth of a furrow;
4. Anything resembling a furrow; a. generally, e.g. a rut or track, a groove, indentation, or depression narrow in proportion to its length.

A furrow or groove, cannot exist without the existence of sidewalls as well as a floor. The sides are formed by portions of the adjoining "lands." A groove by its very definition is comprised of only a floor and sidewalls extending up from the floor of the groove to the "ground level" on each side of the groove. It would defy all customary usages of the word "groove" to include land outside of the indentation itself as being part of the groove.
The patent specifications also support the view that the "track" does not include any part of the surrounding "lands." '209 1:55-61 states:

The record carrier body according to the invention is characterized in that the follow-on track is a flat track, and that follow-on track influences the direction of a radiation beam in the same way as, but the radiation distribution over the beam section in a different way, than the rest of the surface of the record carrier body on which the information is to be written.

The patent differentiates clearly the groove itself from the area between the grooves. It also makes clear that the track's radiation distribution differs from its surrounding "lands." See also '209 17-22

For example, the reflection coefficient or the absorption coefficient of the follow-on track may differ from its surrounding, so that the intensity of a beam which emerges from the record carrier body differs according to whether the beam has or has not interacted with the track.

Defendants' assertion that the "diffractive follow-on track" must include a portion of the adjoining lands due to functional necessity to achieve a sufficient level of diffraction does not find support in either the claim language itself or in the patent specifications. The Court is bound by the plain language of the patent. The patent differentiates between the track, which is a groove, and the area surrounding the track, known as the land. The patent teaches that diffraction occurs when the radiation beam strikes the narrower groove. Accordingly, the Court interprets "diffractive follow-on track" as meaning "the groove in between the lands on a optical storage disc, which is narrower than a spot of radiation."

3. Digest (claims 1-2, 6-8) / network protocol processing information (claims 1 and 8)

Plaintiff's Construction:

. digest: A predefined portion of a message which is generated by a receiving processor and transmitted to a transmitting processor instead of the entire data link layer and which contains preselected network protocol processing information for the particular message, obtained via sequential byte processing of the message at the time of the reception of the message, which is necessary to permit the transmitting processor to process each byte of the data packet in sequence.

. network protocol processing information: All network protocol information that is necessary for the completion of the processing tasks to be performed by the processor of the transmitting processor.

Defendant's Construction:

. digest: Collected information relating to network protocol processing of a particular message.

. network protocol processing information: Information utilized when employing a particular network protocol for message transmit processing.

I will consider these two terms together because they are so closely related. As discussed further below, the central dispute for both of these terms is whether the digest must contain all of the information necessary to perform certain tasks.

Plaintiff's proposed construction of the term "digest" is its most massive. It contains so many clauses and limitations that even plaintiff does not try to justify some parts of it. Although many patent lawyers might be reluctant to admit it, Occam's Razor applies no less in the context of claim construction than it does to any other walk of life. It is clear that plaintiff has struggled with this term; originally it proposed an even longer construction with now abandoned limitations such as "compliant with all IEEE 802 standards" and "the digest is not sent to the management processor." With such a bloated and fluid construction, a skeptical judge might think that plaintiff's proposal is not a genuine effort to explain an ambiguous term, but merely an attempt to define the term around its own products.
Defendant's proposed construction of "digest" suffers from the opposite problem: it says nothing at all. Claim 1 itself says that the digest "contain[s] network protocol processing information for message transmit processing." The only real change in defendant's construction is to unjustifiably broaden the contents of the digest to include not just "network protocol processing information" but also information "relating to" network protocol processing. But that is not what the claim says. Although defendant points to parts of the specification and prosecution history that use the "relating to" language, these references cannot expand the scope of the claims. United States v. Adams, 383 U.S. 39, 48-49, 86 S. Ct. 708, 15 L. Ed. 2d 572, 174 Ct. Cl. 1293(1966) ("the claims of a patent limit the invention, and specifications cannot be utilized to expand the patent monopoly").

The question remains whether any part of plaintiff's construction is appropriate for adoption. Plaintiff devoted much of its argument to the proposition that the digest must contain all the necessary information so that certain tasks may be performed. I say "certain" tasks because the precise nature of these tasks changed throughout plaintiff's briefs and at the hearing. In the context of its "digest" construction, plaintiff says that digest must include all "network protocol processing information . . . necessary to permit the transmitting processor to process each byte of the data packet in sequence." But as plaintiff points out, that alleged limitation comes from one embodiment in the specification, '181 pat., col. 11, lns. 31-33. It is not part of the invention as a whole.

Plaintiff changes the type of information the digest must contain in the context of its construction for "network protocol processing information" to information that is "necessary for the completion of the processing tasks to be performed by the processor of the transmitting processor." In support of its argument, plaintiff cites a passage that appears in both the abstract and the summary of the invention: "The information placed into the digest is information that is necessary for the completion of the processing tasks to be performed by the processor of the transmitting line card." '181 pat., abstract; col. 4, lns. 62-65. But this passage says only that the information in the digest is necessary for completing the processing tasks; it does not say that the digest contains all the necessary information for completing those tasks. In other words, plaintiff's argument is that the information in the digest must be sufficient to perform the task but the cited passage supports only the proposition that the information in the digest is necessary to perform the task.

Plaintiff suggested another alternative, not included in its construction, that the digest must include all the information needed to "permit it [the invention] to process and transmit the message." Pkt's Br., dkt. # 31, at 28. See also Cl. Const. Tr., dkt. # 48, at 100 ("[T]he digest has to contain all of the information necessary to allow the transmitting processor to forward the message.") Plaintiff argues that this construction is necessary because (1) one of the steps of the invention is to forward the message; (2) without the information necessary to forward the message, the invention fails; (3) if the invention fails, it is not patentable.

Plaintiff's argument fails on its third premise. It is true, as the case plaintiff cites says, that an invention is not patentable if it is not "operative," In re Lemuel Wooddy, 331 F.2d 636, 639, 51 C.C.P.A. 1317, 1964 Dec. Comm'r Pat. 617 (CCPA 1964), but there is a significant and obvious difference between a device that does not work as intended in all instances and a device that never works at all. The specification makes it clear that "in most instances" there is sufficient information to allow the transmitting processor to route the message. '181 pat., col. 5, lns. 7-10. Because the patent does not require perfection, I cannot read such a limitation into the claims.

Plaintiff repeats the same arguments in the context of its construction for "operating to perform the first preselected processing of a message received by the message receiving process." I conclude that the parties have failed to show that any of these three terms would benefit from judicial construction.

1325
1. The term "digital assistant module" in claim 34 is construed as "a small portable computing device;"

1326
A. "Digital Audio Signal"
This term appears in each of the patents, beginning with the '573 patent in Claim 1, which begins "A method for transmitting a desired digital audio signal stored on a first memory . . ." (Docket # 69, Exhibit J at 6) (italics added). Plaintiff maintains that this term should be construed to mean "a sound wave converted to binary form." (Docket # 69 at 11). Defendants assert that the term's proper construction should be thus:

A representation of audio in binary form intended to produce an audible sound. It can be recorded sound, a sound effect, or instructions for producing a sound, and need not be a complete song. (Docket # 65 at 15). The essence of the dispute in this instance is whether or not the term "digital audio signal" includes MIDI instructions or computer software programs as opposed to simply digital representations of audible sounds.

MIDI is a means of creating musical sounds by instructing a computer to play a synthesizer to produce a specified tone. By contrast, Pulse Code Modulation, or PCM, is a means of converting a sound wave into binary form so that the same sound wave (or one so close to the original so as to be indistinguishable by the human ear) may be produced when the binary language is interpreted by a computer and sent through a digital/analog converter to a speaker.

Sightsound asserts that the phrase "digital audio music" does not include MIDI representations. Resort to contemporaneous dictionary definitions for those skilled in the art supports this conclusion. The IEEE 6 Standard Dictionary of Electrical and Electronics Terms in 1988 defined "audio" in the context of data transmission as "pertaining to frequencies corresponding to a normally audible sound wave - roughly 15Hz-20Hz." (Docket # 69, Exhibit A). "Digital" is defined as "pertaining to data in the form of digits." (Id., Exhibit B). "Signal," again as employed in the context of data transmission, is "(a) a visual, audible or other indication used to convey information; (b) the intelligence, message or effect to be conveyed over a communication system; (c) a signal wave; the physical embodiment of a message." (Id., Exhibit C).

6 The Institute of Electrical and Electronic Engineers, which is part of an American National Standard (ANSI).

Defendants argue that the phrase "sound wave," which is part of Sightsound's proposed definition of "digital audio signal," is nowhere to be found in the specification. While this is true, "sound wave" is part of the IEEE definition of "audio," and is a source to which one skilled in the art would refer in construing the claim terms. Indeed, Sightsound persuasively argues that, relying upon contemporaneous trade definitions, the term "digital audio signal" refers to "a normally audible sound wave" which has been represented as "data in the form of digits" for purposes of sending or conveying it.

Resort to the specification for purposes of determining if a different meaning was intended by the patentee does nothing to change the meaning of the phrase. The specification of all three patents provides several clues concerning the meaning of "digital audio signal." A review of the specification in some detail at this point will serve to provide needed background for this term, as well as for the other terms which remained to be construed.

First, in rather graceless language in common to the species, the specification contains a description of the field of the invention:

The present invention is related to a method for the electronic sales and distribution of digital audio or video signals, and more particularly, to a method which a user may purchase and receive digital audio or video signal from any location which the user has access to a telecommunication line. (Docket # 70, Tab 51, '573 Patent at col. 1, lines 9-14). What follows is a description of the then-existing "medium" or "hardware units" of music, which include records, tapes and compact discs (Id., lines 17-68). Throughout this discussion, the disadvantages inherent in the use of "hardware units" for storing, selling and playing back music are discussed. Then, the advent of digitizing sound is discussed:

QUALITY: Until the recent invention of Digital Audio Music, as used on Compact Discs, distortion free transfer from the
hardware units to the stereo system was virtually impossible. Digital Audio Music is simply music converted into a very basic computer language known as binary. A series of commands known as zeros and ones encode the music for future playback. Use of laser retrieval of the binary commands results in distortion free transfer of the music from the compact disc to the stereo system . . . .

(Id., lines 50-59). With respect to copyright protection of musical pieces, the specification indicates that, "if music exists on hardware units, it can be copied." (Id., col. 2 lines 8-9).

Thus, the objectives of the invention are listed as providing a new "methodology/system" to: (1) "electronically sell and distribute Digital Electronic Music"; (2) "electronically storing and retrieving Digital Audio Music"; (3) electronically sorting, cuing and selecting Digital Audio Music; and (4) preventing "unauthorized electronic copying" of Digital Audio Music. (Id., lines 10-23).

The specification goes on to explain that Digital Audio Music, in the disclosed invention, is stored on only one piece of "hardware," that being a hard disk (Id., lines 31-34). This eliminates the former types of "hardware" identified in the specification, namely "records, tapes, or compact discs." (Id., line 34). The reader is further informed that, "inasmuch as Digital Audio Music is software and this invention electronically transfers and stores such music, electronic sales and distribution of the music can take place via telephone lines onto a hard disk." (Id., lines 63-67). A more concise description of the invention is then provided:

The present invention is a method for transmitting a desired digital video or audio signal stored on a first memory of a first party to a second memory of a second party. The method comprises the steps of transferring money via a telecommunications line to the first party from the second party. Additionally, the method comprises the step of then connecting electronically via a telecommunications line the first memory with the second memory such that the desired digital signal can pass there between. Next, there is the step of transmitting desired digital signal from the first memory with a transmitter in control and in possession of the first party to a receiver having the second memory at a location determined by the second party. The receiver is in possession and in control of the second party. There is also the step of then storing the digital signal in the second memory.

(Id., col. 3, lines 3-19). This description is repeated after the preferred embodiment is set forth (Id., col. 5 lines 29-45).

Again, it is helpful to focus the court's inquiry on the crux of the dispute between the parties. Defendants assert that any means of directing a computer to make sound through use of binary code is acceptable as a "digital audio signal" for purposes of the invention. This is so, defendants argue, because the specification identifies "digital audio music" as "music converted into a very basic computer language known as binary" and because the specification refers to Digital Audio Music as "software." (Docket # 65 at 16). MIDI is a form of computer "software" in that it consists of instructions, stored in binary form, which will produce sound when interpreted by the computer. "Instructions" to produce sound are, in defendants' view, part of the claimed invention.

Sightsound responds that software programs, such as MIDI, are not properly within the scope of the term "digital audio signal." The manner in which the terms "hardware" and "software" are used in the specification are, Sightsound argues, the most important indicia of the meaning of those terms. The specification consistently refers to any physical storage medium for sound, whether in binary form or not, as "hardware." Such storage units including records, tapes, compact discs and even the hard drive of a computer. The specification explains that the key advantage to storing music as digital signals is that the digital signal is "software," i.e., it can be transferred to a purchaser without also transferring along with the signal some type of "hardware" unit on which the signal is stored.

There are repeated references in the specification to "music" and "songs." Likewise, the patentee refers to storing music on other media, such as records and tapes, which do not normally contain computer instructions. These references from the specification lead the court to conclude that Sightsound's definition is the preferred one in this case, and that "digital audio signal" does not include all types of computer software or, more specifically, MIDI. 7 Rather, it includes only digital representations of sound waves.
7 This conclusion has been reached without reference to extrinsic evidence, with the exception of dictionary references. Further, evidence presented by defendants addressed to the ability of the technology available to the normal consumer in 1988 to handle the transfer of PCM songs is not, at this stage, relevant.

The court understands that, in order to play these digital representations of sound waves, a computer must have instructions for converting the binary into analog form. Hence, as Dr. Moorer pointed out, compact discs include, along with a digital representation of sound waves, instructions concerning how those digital representations are to be interpreted. This, however, does not alter the nature of what is being represented: a recorded sound as opposed to an instruction to a computer to play an instrument which, in turn, will produce a sound.

The specification does not, therefore, support the construction proffered by defendants that "digital audio signal" includes "software programs." The specification does not refer to such programs, and clearly uses "software" in a sense different from what is commonly understood when used to refer to "software programs." 8 Further, the specification focuses upon the common practice of selling musical recordings, and does not mention storing or transferring instructions for playing music.

The parties dispute the meaning of "digital audio tape," as used in claim 1 of the '371 patent. NICE contends that Witness seeks to read in limitations not supported by the claim language or specification, and that the specification does not support the contention that the tape must be "magnetic" or "designed" for storage. Witness contends that NICE's construction improperly reads out the term "audio," and that one skilled in the art in 1993 (when the '371 patent was filed) would have understood DAT to mean a magnetic medium designed for audio (citing Dictionary of Multimedia, 52 (1997)(DAT "records and plays back digital audio on magnetic tape cassettes that are smaller than common audio cassettes.")). NICE responds that a person of ordinary skill would have understood DAT as being capable of non-audio storage, as evinced by the contemporaneously-filed '005 patent-in-suit (col. 3:65), which stores computer "time-data" on a DAT.

Considering the only intrinsic evidence cited, the language of the disputed term, and the extrinsic evidence cited by both parties, the Court concludes that digital audio tape means "magnetic tape designed for storage of audio in digital form." NICE has not persuaded the Court that the claim or specification support a reading of "digital audio tape" that gives no meaning to "audio," a term included in the disputed phrase. Further, the Court accords more probative value to a technical dictionary definition than to a contemporaneously-filed patent, finding that the former is more representative of the understandings of a person of ordinary skill in the art than the latter.
"digital camera electronics"

Claims 3, 10, 17, 24, and 29 of the ’869 patent contain the term "digital camera electronics." Defendants argue that the term in claim 10 (the only one of these claims asserted against Defendants) is indefinite because it is not defined in the specification. While Defendants are correct that the term "digital camera electronics" is not used in the specification and only appears in the summary of the invention and the claims themselves, the term "digital camera components" appears multiple times throughout the specification. For instance, the specification recites examples of "digital camera components including a light sensitive chip and one or more outputs (such as video output outputs or a USB port) for outputting the digital images to a TV, a computer, or a storage device." ’868 patents at 6:50-55. The specification further explains that "[a] digital camera can also include a removable or permanent flash memory card to hold images. In one example, an 8 Mbyte flash memory is provided to hold up to 116 images." Id. at 54-57; see also ’868 patents at 9:52-58; 7:52-57.

Defendants do not argue that one skilled in the art would lack understanding of the specification's term "digital camera components." Rather, they argue that the doctrine of claim differentiation requires that the term be defined differently than "digital camera electronics" used in the claims. Defendants' argument misunderstands and misapplies the law of claim differentiation.

Claim differentiation creates a presumption that each claim in a patent has a different scope and is "not a hard and fast rule of construction." Comark Commc'ns, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998). Furthermore, as the Federal Circuit has explained, "claim differentiation refers to the presumption that an independent claim should not be construed as requiring a limitation added by a dependent claim. Thus, the claim differentiation tool works best in the relationship between independent and dependent claims." Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380-81 (Fed. Cir. 2006). Because the term "digital camera components" is not used in the claim language, but rather the specification, the doctrine of claim differentiation does not apply.

Instead, it is clear from the specification's use of the term "digital camera components" that the term is synonymous with the claim term "digital camera electronics." In fact, the specification's detailed explanation of "digital camera components" is highly relevant in understanding the definition of "digital camera electronics." See Phillips, 415 F.3d at 1314-15 ("[T]he specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term."). Though the term "component" used in the specification is different from the term "electronics" in the claims, it is exceedingly clear from the context of those terms that their meanings are synonymous. See Nystrom v. TREX Co., 424 F.3d 1136, 1143-46 (Fed. Cir. 2005) ("Different terms or phrases in separate claims may be construed to cover the same subject matter where the written description and prosecution history indicate that such a reading of the terms or phrases is proper."). Thus the term "digital camera electronics" is not ambiguous or unexplained in the specification because it simply refers to "digital camera components" which are thoroughly explained and referenced in the patent's specification. Accordingly, Defendants' motion for summary judgment is denied with regard to claim 10 of the ’868 patents.

--- Footnotes ---

1 Defendants also argue that claim 17 of the ’387 patent and claim 10 of the ’868 patents are invalid for lack of an adequate written description or for lack of enablement. However Defendants' briefing on these issues simply incorporates their indefiniteness arguments under different headings. Since neither of these claims are indefinite, Defendants' arguments regarding written description and enablement are similarly rejected.

--- End Footnotes ---
"Digital data file" appears in each disputed patent claim (536 Patent: 1,6; 709 Patent: 1,17). The defendants contend that "digital data file" means "a self-contained electronic representation of information, i.e., a document, graphic, or database record, created by a user or copied by a user from another source, which has a unique file name by which it can be accessed by a user" (Doc. 62 at 10). The plaintiff argues that one of ordinary skill in the art would understand "digital data file" to mean merely "an aggregate of digital data" (Doc. 60 at 18).

The plaintiff's interpretation of "digital data file" presumably encompasses the digest or digital fingerprint that results from a hashed file, which digest is next transmitted to a third party for time-stamping in a conventional DTS. However, this construction contradicts the use of "digital data file" in the patents' claims, which repeatedly depict "digital data file" and "digest" as distinct. For example, the disputed claims of the 709 Patent describe "hashing said digital data file to produce a digest" (709 Patent: 1, 17). If a "digital data file" is a digest (as urged by the plaintiff), the phrase "hashing said digital data file to produce a digest" becomes unintelligible. Also, the disputed claims of the 536 patent distinguish a "saved file" from a digest (536 Patent: 1,6). Likewise, as the defendants persuasively argue (Doc. 70 at 11), the plaintiff's proposed construction ("an aggregate of digital data") impermissibly renders the word "file" superfluous within the phrase "digital data file," which phrase preposterously becomes, under the plaintiff's definition, a "file file." See Primos, Inc. v. Hunter's Spec., Inc., 451 F.3d 841, 847-48 (Fed. Cir. 2006).

Further, both patents repeatedly distinguish the patented invention over prior art on the basis that a conventional DTS time-stamps the digest of a digital file but not the file itself (Patent 536 at 12:4-8; Patent 709 at 11:60-64). Highlighting the advantages of his invention over a conventional DTS, the patentee discloses a means to avoid "counterfeiting" problems by time-stamping the actual digital data file as opposed to time-stamping merely the digest that results from the hashed file (Patent 536 at 12:52-64; Patent 709 at 12:40-52). The patentee also observes that time-stamping a digest, as opposed to time-stamping a file, certifies the date the DTS received the digest but not the date the actual document was accessed, created, modified, or transmitted (536 Patent at 12:4-9; 709 Patent at 11:60-64). Having disclaimed in the specifications the time-stamping of a digest, the patentee's claims may not be read to construe "digital data file" to encompass a digest.

Finally, the patents' prosecution history reveals that a "digital data file" is either created by a user or copied by a user from another source. The Examiner's Amendment, distinguishing prior art, explains that the applicant's time-stamp confirms the time at which "said file" is "accessed, created, modified, received, or transmitted by the user" (Doc. 99). This language confirms that time-stamping a digest reveals when the file associated with the digest existed but not when the file was accessed, created, modified, or transmitted by the user. This written description further distinguishes time-stamping a "digital data file" from the conventional DTS practice of merely time-stamping a digest.

Nothing in the patents' language or history supports equating a "digital data file" to a mere "aggregate of digital data." The patents' consistent use of "digital data file" and "digest" as distinct terms (536 Patent: 1,6; 709 Patent: 1, 17), the patents' express disavowal of the time-stamping of digests as an important aspect of the invention (536 Patent at 12:4-9; 709 Patent at 11:60-64), and the patents' prosecution history decisively disfavor the broad construction urged by the plaintiff. Accordingly, "digital data file" means "a collection of digital data stored as a self-contained unit, either created by a user or copied by a user from another source, and containing a unique file name by which it can be accessed by a user."
the dependent claims comprise different "communication networks," the patent uses the term "digital data network" to mean something other than a telephone network. (Id.) With respect to claim 1, the defendants contend that the applicants argued patentability to the patent examiner by stating that claim 34 is limited to a "digital data network," whereas claim 1 recites a broader "communication network." According to the defendants, if the court accepted PHT’s construction then the "digital data network" of claim 34 would be superfluous -- that is, the "digital data network" would be the same as the "communication network" recited in claims 1 and 22. (04-821 D.I. 42, at 12-13.)

--- Footnotes ---

9 Claim 46 reads:

A personal health tracking system according to claim 43 wherein the communication network comprises a public telephone network and the portable unit comprises a modem that is directly connectable to the telephone network.

Claim 47 reads:

A personal health tracking system according to claim 43 wherein the communication network comprises a digital data network and the portable unit is connectable directly to the data network a local data network access connection.

--- End Footnotes ---

The defendants further contend that their proposed construction is supported by the specification because the specification "expressly distinguishes between a telephone network and the 'alternative,' a data network." (Id. at 12.) The defendants reason that if a data network, as used in the '985 patent, included a telephone network, "there would be no need for the applicants to describe the use of a 'combination of a telephone network and a data network,'" as is recited in the specification.

PHT asserts that its construction is correct because the patent describes transmitting information from the health tracker to a central database using various types of networks. (D.I. 39, at 18.) In addition, PHT asserts that a telephone network "can be a data network," providing two examples: (1) telephone communications carried over computer networks utilizing a voice over Internet protocol ("VoIP") system, or system that converts standard telephone audio into digital data so it can be sent over a computer network; and (2) digital information transmitted over traditional telephone lines using digital subscriber line ("DSL") technology. (Id.) According to PHT, "so long as the network is capable of transmitting digital data, the network is a digital data network, even if... [it] is also capable of transmitting telephone communications." (Id.)

PHT asserts that although "digital data network" and "telephone network" may have different meanings in claims 46 and 47, it does not follow that the terms are mutually exclusive. (D.I. 45, at 7.) PHT further asserts that "although telephone networks typically utilize digital data networks, not all digital data networks are telephone networks." (Id.) Lastly, PHT points to claim 39, which depends from claim 34, and is directed to "[a] personal health tracking system... wherein the connection device comprises a modem that is connectable directly to a public telephone network." (Col. 31, 11. 46-48.) PHT maintains that because claim 39 is encompassed by claim 34, the "digital data network" recited in claim 34 cannot exclude the "public telephone network" of claim 39. (D.I. 45, at 7.)

The court is persuaded by PHT's argument that, as used in the '985 patent, the term "digital data network" does not exclude a telephone network. The plain meaning of the term "digital data network" is "a network that transmits digital data." As PHT correctly asserts, a telephone network is a network that transmits digital data, for example, through a VoIP system or DSL technology. Thus, the plain and ordinary meaning of "digital data network" includes a telephone network. In addition, while the terms "digital data network" and "telephone network" in claims 46 and 47 have a different meaning, the court agrees with PHT that none of the language recited in those claims suggests that the terms are mutually exclusive.

The specification does not rebut the presumption that the plain and ordinary meaning of "digital data network" applies. The patent applicants have not acted as their own lexicographers, as they have not clearly set forth a definition of "digital data network" in the specification or prosecution history. See CCS Fitness, 288 F.3d at 1366; Johnson Worldwide, 175 F.3d at 990. The specification does provide that the preferred embodiment uses "some combination of a telephone network and a data network." (Col. 5, 11. 23-24.) As previously discussed, the defendants contend that the description of the preferred

- 1748 -
embodiment "expressly" distinguishes a telephone network from a digital network in the specification. The court does not agree. The language cited by the defendants to support their contention may be limiting. However, it is improper to read a limitation from the specification into the claim, especially when, as here, the specification does not expressly or implicitly limit the scope of the invention to a digital data network that excludes a telephone network. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 904, 908 (Fed. Cir. 2004). for example, the specification states that "those skilled in the art will recognize that there is a variety of means to transfer data from site to site." (Col. 5, ll. 29-31.) This statement certainly contemplates the use of a telephone network that transmits digital data.

Lastly, the prosecution history does not support the conclusion that the patentees distinguished the term "digital data network" from the prior art on the basis that a telephone network was excluded, disclaimed a telephone network, or described an embodiment that excluded a telephone network as important to the invention. As previously stated, the defendants contend that the difference between claim 1 and claim 34 that the applicants referred to is that claim 1 is directed to a broad "communication network," while claim 34 is limited to a "digital data network." Again, the court disagrees and concludes that the applicants distinguished claim 34 from claim 1 by adding a limitation to what the "data transmission device" could do. In other words, when describing the amendments to claim 1, the applicants stated that the claim was amended "to specify that the handheld device includes a data transmission device that is capable of connecting directly to a communication network," thereby broadly defining "data transmission device." When distinguishing claim 1 from claim 34, however, the applicants told the patent examiner that claim 34 is "similar to claim 1, but is limited to a data transmission device that transmits data to a remote data storage location via a digital data network," thereby limiting the properties of the "data transmission device." (See D.I. 42 Ex. C, at 13.) Thus, the statements that the applicants made during prosecution do not support a construction of "digital data network" different from its plain and ordinary meaning. The court, therefore, construes "digital data network" to mean "a network that transmits digital data." 10

--- Footnotes ---

10 The court will construe the term "digital data network" in claim 37 consistently with its construction of "digital data network" in claim 34. Thus, for the reasons stated above, the court construes the term "digital data network" in claim 37 to mean "a network that transmits digital data."

--- End Footnotes ---

A. Applicability of 35 U.S.C. § 112, P 6

PMC argues that the Commission erred in construing the "digital detector" limitation as a means-plus-function limitation under 35 U.S.C. § 112, P 6. In support, PMC contends that the term "digital detector" recites sufficiently definite structure to prevent the application of § 112, P 6 under our case law. PMC also points out that our case law makes clear that § 112, P 6 should not be invoked merely because this structure takes its name in accordance with its function. Finally, PMC argues that the lack of the term "means" in this limitation invokes a presumption that § 112, P 6 does not apply. The Commission responds that the evidence of record makes it clear that one of ordinary skill in the electrical arts would not have understood the term "digital detector" to connote a definite structure, and therefore that this limitation is defined entirely by the functional language that follows the language "digital detector for ..." Accordingly, they contend that § 112, P 6 is applicable to this limitation.

Section § 112, P 6 provides that

an element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof; and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

35 U.S.C. § 112, P 6 (1994) (emphasis added). Thus, § 112, P 6 operates to restrict claim limitations drafted in such functional language to those structures, materials, or acts disclosed in the specification (and their equivalents) that perform the claimed function.

- 1749 -
We have had several recent opportunities to assess whether certain claim language has invoked § 112, P 6. In Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 39 U.S.P.Q.2D (BNA) 1783 (Fed. Cir. 1996), we were presented with the claim language "detent mechanism defining conjoint rotation of said shafts." In deciding that § 112, P 6 was not invoked, we stated

The fact that a particular mechanism--here "detent mechanism"--is defined in functional terms is not sufficient to convert a claim element containing that term into a "means for performing a specified function" within the meaning of [§ 112, P6]. Many devices take their names from the functions they perform. The examples are innumerable, such as "filter," "brake," "clamp," "screwdriver," or "lock." . . .

"Detent" (or its equivalent "detent mechanism") is just such a term. Dictionary definitions make clear that the noun "detent" denotes a type of device with a generally understood meaning in the mechanical arts, even though the definitions are expressed in functional terms. It is true that "detent" does not call to mind a single well-defined structure, but the same could be said of other commonplace structural terms such as "clamp" or "container." What is important is not simply that a "detent" or "detent mechanism" is defined in terms of what it does, but that the term, as the name for structure, has a reasonably well understood meaning in the art.

Greenberg, 91 F.3d at 1583, 39 U.S.P.Q.2D (BNA) at 1786 (citations omitted). We also made clear that use of the term "means" is central to the analysis: "the use of the term 'means' has come to be so closely associated with 'means-plus-function' claiming that it is fair to say that the use of the term 'means' (particularly as used in the phrase 'means for') generally invokes [§ 112, P 6] and that the use of a different formulation generally does not." Id. at 1584, 39 U.S.P.Q.2D (BNA) at 1787.

Subsequent cases have clarified that use of the word "means" creates a presumption that § 112, P 6 applies, see York Prods., Inc. v. Central Tractor, 99 F.3d 1568, 1574, 40 U.S.P.Q.2D (BNA) 1619, 1623 (Fed. Cir. 1996) ("In determining whether to apply the statutory procedures of [§ 112, P 6], the use of the word 'means' triggers a presumption that the inventor used this term advisedly to invoke the statutory mandates for means-plus-function clauses."); 9 and that the failure to use the word "means" creates a presumption that § 112, P 6 does not apply, see Mas-Hamilton, 156 F.3d at 1213, 48 U.S.P.Q.2D (BNA) at 1016. These presumptions can be rebutted if the evidence intrinsic to the patent and any relevant extrinsic evidence so warrant. 10 See, e.g., Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531, 41 U.S.P.Q.2D (BNA) 1001, 1006 (Fed. Cir. 1996) (noting that whether § 112, P 6 is invoked involves an analysis of the "patent and the prosecution history," and consulting a dictionary definition of "perforation" to understand if one of skill in the art would understand this term to connote structure). In deciding whether either presumption has been rebutted, the focus remains on whether the claim as properly construed recites sufficiently definite structure to avoid the ambit of § 112, P 6. See Sage Prods. v. Devon Indus., Inc., 126 F.3d 1420, 1427-28, 44 U.S.P.Q.2D (BNA) 1103, 1109 (Fed. Cir. 1997) ("Where a claim recites a function, but then goes on to elaborate sufficient structure, material, or acts within the claim itself to perform entirely the recited function, the claim is not in means-plus-function format" even if the claim uses the term "means").

9 See also Unidynamics Corp. v. Automatic Prods. Int'l, Ltd., 157 F.3d 1311, 1319, 48 U.S.P.Q.2D (BNA) 1099, 1104 (Fed. Cir. 1998) (holding that the claim language "spring means tending to keep the door closed" invokes § 112, P 6: "the recitation of 'spring,' which is structural language, [does not take] the limitation out of the ambit of the construction dictate of § 112, P 6."); Serrano v. Telular Corp., 111 F.3d 1578, 1582, 42 U.S.P.Q.2D (BNA) 1538, 1541 (Fed. Cir. 1997) (holding that the claim language "determination means . . . for determining" invokes § 112, P 6); Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1536, 19 U.S.P.Q.2D (BNA) 1367, 1369 (Fed. Cir. 1991) (holding that the claim language "means for joining said pluralities [of link ends] to one another so that the axes of [certain holes are arranged in certain configurations]" invokes § 112, P 6: "The recitation of some structure in a means-plus-function element does not preclude the applicability of [§ 112, P 6 when it] merely serves to further specify the function of the means. The recited structure tells only what the means-for-joining does, not what it is structurally.") (emphasis in original).

10 See, e.g., Mas-Hamilton, 156 F.3d at 1214, 48 U.S.P.Q.2D (BNA) at 1017 (holding that the claim language "lever moving element for moving the lever" invokes § 112, P 6: "even though the catch phrase ['means for'] is not used, the limitation's language does not provide any structure. The limitation is drafted as a function to be performed rather than
1. The Whereby Clause

GO BACK

- 1751 -
A. Whether the Whereby Clause is a Claim Limitation

DTL argues that the language, "whereby said acoustic signal is converted to a digital signal, transmitted to said remote receiver in digital form, and utilized by said digital system located at said remote location such that said digital system at said remote location receives a highly faithful digital representation of said acoustic signal" should not be construed as part of the function because it adds nothing substantive to the claim limitation. Cingular's position is that the whereby clause is meaningful and limiting.

Where the words following "whereby" simply state a result, they are not considered to be part of the function, or even a claim limitation because it adds nothing to the patentability or substance of the claim. Lockheed Martin Corp. v. Space Sys./Coral Inc., 324 F.3d 1308, 1319 (Fed. Cir. 2003); In re Krodel, 223 F.2d 285, 42 C.C.P.A. 993, 1955 Dec. Comm'r Pat. 305 (Cust. & Pat.App. 1955). On the other hand, a whereby clause limits a claim when it recites a capability that was "an integral part of the invention" based on the specification and prosecution history. See Hoffr v. Microsoft Corp., 405 F.3d 1326, 1330 (Fed. Cir. 2005)(per curium). The terms of a whereby clause must be regarded as an essential feature of the invention if it is used to distinguish the invention over the prior art during prosecution of the patent. Eltech Sys. v. PPG Indus. Inc., 710 F.Supp. 622, 633 (W.D.La. 1988), aff'd 903 F.2d 805 (Fed. Cir. 1990).

It is clear from the prosecution history that the terms of the whereby clause was used to overcome the prior art, namely U.S. Patent No. 4,370,523 ("the Bader patent"). In particular, the applicants repeatedly argued that the fidelity of transmission was a critical feature distinguishing their invention over that of Bader:

The fidelity of Bader's conversion is inherently very poor, in contrast to the nearly perfect transmission of applicant's invention. Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-00089 P 8 [Doc. # 60, Attachment #4, p. 81 of 175].

The Bader reference alone or modified as suggested is incapable of fulfilling the essential objective of high quality, high resolution conversion accurately representing the incoming sounds. In contrast to Bader, Applicant's claimed invention is capable of 90 - 120 dB of dynamic rage, .1 dB frequency response to 20kHz, and distortion better than .005%. Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-00095 P 22 [Doc. # 60, Attachment # 4, p. 87 of 175].

Bader, even with the suggested modifications, produces a low quality conversion, with poor fidelity, bad frequency response and little dynamic range . . . Applicant's claimed invention produces the new and unexpected result of a self-contained, hand-held microphone with high quality professional audio reproduction. Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-000105 P 42 [Doc. # 60, Attachment # 4, p. 97 of 175].

The language in the specification is consistent with the statements in the prosecution history that the listed features in the whereby clause are required, rather than a hoped-for result of the invention or a laudatory phrase. When describing the prior art, the specification states: "The fidelity of analog transmission is restricted by interference, such as noise, . . . etc. The limited dynamic range (60-70dB) and high (up to 3%) harmonic distortion of the analog recording and reproduction process has hitherto masked the transmission effects." '799 patent, col. 1, ll. 44-50. The specification proclaims that one object of the invention is to "provide[] for the most accurate possible reproduction of the transducer output." '799 patent, col. 2, ll. 60-62. To achieve that objective, the patent states: "Virtually any form of varying energy could be transduced and transmitted over any distance with real life fidelity of up to 96-140 dB of dynamic range, and with virtually no distortion, using the present invention." '799 patent, col. 3, ll. 29-33 (emphasis added). The whereby clause in Claim 18 does not merely state a result, but rather, delimits how accurate the reproduction of the input must be.

DTL points to the examiner's statement that "there is no claim limitations [sic] addressing fidelity or frequency response" in support of its argument that the whereby clause only states the result of the prior limitations. 3 Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-000118 P 7 [Doc. # 60, Attachment # 4, p. 110 of 175]. It is the applicants' statements that matter when construing the scope of an invention, not whether the examiner accepted or rejected them. See Lifesream Diagnostics, Inc. v. Polymer Tech. Sys., Inc., 109 Fed. Appx. 411, 414 (Fed. Cir. 2004)(stating that the "public notice function of a patent and its prosecution history requires that a patentee be held to what he declares during the prosecution of his patent.")
3 The court notes that in Claim 15, the claim states, not in a whereby clause, that "said transmission will be performed in a highly faithful manner." '799 patent, Col. 14, ll. 67-68.

In fact, the patent examiner held an interview with the applicants to discuss Claim 1, which also has a whereby clause that its system is able to transmit the input "faithfully." At the interview, the examiner reiterated that Claim 1 "did not have specific language showing a functional conclusion of accurate reproduction." Exhibit A of PI's Opening Claim Construction Brief, DTL-000128 P 3 [Doc. # 60, Attachment # 4, p. 120 of 175]. In response, the applicant "argued that the word 'faithfully' in the conclusion of the claim . . . implies sufficient frequency response and good fidelity for accurate reproduction of the input." Exhibit A of PI's Opening Claim Construction Brief, DTL-000129 P 18 [Doc. # 60, Attachment # 4, p. 121 of 175]. At the hearing, DTL admitted that "[t]here is not a distinction between 'highly faithful' and 'faithful.'" Trans. at p. 32. Because the applicants consistently argued during the prosecution of their patent application that the invention required an accurate reproduction of the analog signal, the court finds that when the patent containing the whereby clause ultimately issued, the terms of the whereby clause are interpreted as a limitation on the scope of the patent that was granted.

B. Whether the Term "Highly Faithful Digital Representation" is Indefinite

Cingular asserts that the term is indefinite and, hence, invalid under 35 U.S.C. § 112 P 2. To invalidate a patent for indefiniteness, the Federal Circuit has stated that the evidence must be shown by "clear and convincing evidence." Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1348 (Fed. Cir. 2005). In determining whether the claim at issue "particularly point[s] out and distinctly claim[s] the subject matter which the applicant regards as his invention," the claim should be construed in light of the specification as interpreted consistent with the level of the ordinary skill in the art practiced in the invention. See Eibel Process Col. v. Minnesota & Ontario Paper Co., 261 U.S. 45, 65-66, 43 S. Ct. 322, 67 L. Ed. 523, 1923 Dec. Comm'r Pat. 623 (1923). That some claim language may not be precise, however, does not automatically render a claim invalid. Seattle Box Co. Inc. v. Industrial Crating & Packing, Inc., 731 F.2d 818, 826 (Fed. Cir. 1984).

Looking to the specification of the '799 patent, the phrase "highly faithful digital representation" is given defining limits first, by describing the object of the invention: "It is therefore an object of the present invention to provide better audio reproduction with increased dynamic range, and reduced distortion and noise." '799 patent, col. 2, ll. 50-53. The reproduction is "virtually perfect, and there is no effect of any interference or noise in the transmission process." '799 patent, col. 6, ll. 55-60. Given the problem addressed by the invention and the specification language describing the '799 patent's solution to the problem, the phrase "highly faithful digital representation" is sufficiently defined to those skilled in the art to avoid invalidity.

c. Construction of the Whereby Clause

The parties focus on three terms within the whereby clause, "said remote receiver," "digital form," and "highly faithful digital representation." Of the three terms, the parties agreed on the definitions of "said remote receiver" and "digital form" if the court considers the whereby clause to be a limitation. Therefore, only "highly faithful digital representation" requires discussion.

The specification states that DTL argues that "highly faithful digital representation" should be construed as "a digital signal that is an accurate representation of the original analog signal." This is a generic definition that fails to differentiate "highly faithful" requirement in Claim 18 from "faithful" in Claim 1. '799 patent, col. 2, ll. 60-62. The applicants had argued that the word "faithfully" implies "accurate reproduction" of the input. By stating that the whereby clause requirement of a "faithful" transmission in Claim 1 imposed an "accurate" reproduction, a "highly faithful" transmission must, a fortiori, impose at least greater fidelity and frequency response requirements.

Cingular proposes "highly faithful digital representation" requires "representation with at least: a) 90 dB dynamic range, b) 0.1 dB frequency response to 20 kHz, and c) distortion better than 0.005%." There are several fallacies in Cingular's formulation. One is that it focuses upon the application of the invention, which is beyond the control of the inventors, rather
than the structure of the invention itself. The specification teaches that if an A/D converter with 20 bit resolution is used, the
dynamic range of signals can be greater than 118dB. '799 patent, col. 9, ll. 25-27. If a low cost, low power integrated
circuit converter is used, the performance would be lessened by noise and distortion of 5-10dB. '799 patent, col. 9, ll. 41-45.
The specifications detail a preferred embodiment using a 16 bit A/D converter to provide a theoretical 144 dB (24 bit)
dynamic range. '799 patent, col. 10, ll. 25-27.

Cingular analyses the prosecution history in isolation from the specification and claim language. It is perhaps true that the
applicants' claimed invention is "capable of 90-120 dB of dynamic range, .1 dB frequency response to 20kHz, and distortion
better than .005%," but that is not required by the claim language. (emphasis added). The applicants may merely have been
indicating that the Bader patent could not achieve such reproduction, unlike the present invention. Exhibit A of Pl.'s
Opening Claim Construction Brief, DTL-00995 P 22 [Doc. # 60, Attachment # 4, p. 87 of 175]. Neither the language of the
claim nor the specification requires, or even hints, that such a narrow definition must be adopted for this claim term.

The specification states that patent creates a reproduction that "is virtually perfect, and there is no effect of any interference
or noise in the transmission process. '799 patent, col. 6, ll. 57-60. Accordingly, the court defines the terms as follows:

"Said remote receiver" means: a receiver.

"Digital form" means: a format that represents data by numerical digits or discrete units.

"Highly faithful digital representation. . ." means: the representation that is virtually perfect, with no effect of any
interference or noise in the transmission process.

Verizon alleges that "digital input means" means "a panel of push buttons on the remote terminal for inputting digital
signals." Katz alleges that "digital input means" means "a telephone keypad or computer keyboard."

Despite use of the words "means" and the presumption it entails, both parties appear to believe that "digital input means"
connotes sufficient structure to avoid application of 35 U.S.C. § 112, P 6. The Court agrees as "digital input means" in the
context of the surrounding claim language and in light of the 285 patent specification, appears to connote sufficient
structure. Accordingly, the term "digital input means" means "a panel of push buttons or keypad on the remote terminal for
inputting digital signals." As used in the claims, "digital input means" is described as being part of a "conventional
telephone instrument," which appears to exclude a computer keyboard as asserted by Katz. See also 285 patent, Col. 2:14-
17 ("e.g. conventional telephone instruments including voice communication means, and digital input means in the form of
alphanumeric buttons for providing data"); Col. 4:4-9 ("the exemplary telephone terminal T1 includes a handpiece 10
(microphone and earphone) and a panel 12 provided with a rectangular array of push buttons 14 in a conventional
configuration. Of course, the handpiece 10 accommodates analog signals while the panel 12 is a digital apparatus.").

2. "digital logger"

NICE's Construction Witness's Construction
A device, system or software for recording, in digital form, audio data representing multiple concurrent telephone calls.
A device, system or software for recording audio in digital form.
The parties dispute the meaning of "digital logger," as used in claims 1, 16, and 21 of the '920 patent. NICE contends that the claim language itself supports its proposal that a logger can record from multiple input sources, citing claims 1 and 16 ("A method for accessing information in at least one digital logger storing data associated with input from a plurality of input channels,..."). Witness contends that the claim language demonstrates that multiple input sources can be recorded by the logger, but does support the proposal that "at least one digital logger" must record more than one call concurrently.

The Court construes "digital logger" to mean "a device, system or software for recording audio in digital form." The claim language states that a digital logger can record from a variety of input types, but makes no mention of whether those recordings are done concurrently. Further, NICE cites no other intrinsic or extrinsic evidence to support its proposed construction.

1335

3. Digital Sample: Echometer's proffered construction of digital sample is a digital representation of the instantaneous value of an electrical signal, while Lufkin's position is that a digital sample is derived from the return signal, which contains the rate of collar reflections as the most important information of the signal. As discussed previously, a return signal does not necessarily contain the rate of collar reflections. Without this important distinction between the two constructions, the Court finds the parties definitions in harmony with each other and the '399 Patent specification. '399 Patent, at 23 (col. 2, 1. 57-59) ("the return signal is digitized to produce a set of digital samples representing the return signal."). Thus, a digital sample is a digital representation of the instantaneous value of the return signal.

GO BACK

1336

3. "[D]igital signal processing means."

DTL contends that this limitation is not a means-plus-function limitation under § 112, P 6 and should be construed as "a digital signal processor." Cingular states that if the court does not consider the limitation to be a means-plus-function limitation, the term should be construed as "a digital signal processing microcomputer with a word length of at least 16 bits."

DTL's counsel admitted at the hearing that the means-plus-function presumption is harder to rebut for this term that the previous term involving an A/D converter. DTL argues that the gerund form of the word "processing," namely a digital signal "processor," recites sufficient structure to overcome the means-plus-function presumption. Neither the verb "processing" nor the gerund "processor" recites sufficient structure, material, or acts to overcome the presumption despite DTL's plea that all digital signal processors would modify sequences of groups of digital bits. The word "said" refers to groups of digital bits that are converted from an A/D converter and represent values of analog electrical output signals. See '799 patent, col. 15, l. 25-28; Eastman Chem. Co. v. BASF Aktiengesellschaft, 47 Fed. Appx. 566, 570, 573-574 (Fed. Cir. 2002)(explaining construction of "said" based on prior antecedents.) Because claim 18 does not recite limited and definable structure, the court will construe this language as a means-plus-function limitation.

DTL argues that should the court consider it a means-plus-function limitation, the function is "modifying the sequence of groups of digital bits." Cingular contends that the function is "modifying the sequence of groups of digital bits output from the analog-to-digital converter means." The parties substantially agree on the function. DTL agrees that the sequence of digital bits are outputs from the analog-to-digital converter means, but believes that such language is surplusage. Trans. at p. 132. Cingular agrees that the digital signal processing means need not receive the sequence of digital bits directly from the analog-to-digital converter means. Despite its concession, Cingular's construction may mislead a juror into thinking that elements between the analog-to-digital converter means and the digital signal processing means cannot exist. For the purposes of clarifying both parties' construction for the jury, the court finds that the function is "modifying the sequence of groups of digital bits that are received, directly or indirectly, from the analog-to-digital converter means."
Having identified the function of the means, the court now turns to the specification to define the structure corresponding to this claimed function. Although the specifications mention the generic term "digital signal processor" numerous times, the specification clearly sets forth the structure for performing the claimed function:

This system shown in Fig. 3 will digitally process the transduced signal, prior to its transmission as digital data. This is done by placing a digital processing integrated circuit, such as the Motorola DSP56001, inside of the transducer housing. '799 patent, col. 8, ll. 33-38.

However, DTL, noting the number of occasions where the generic term "digital signal processor" is used, argues that the corresponding structure is "a digital signal processor programmed to modify or digitally process the bits representing the acoustic signal, and equivalents thereof." DTL points to '799 patent, col. 9, ll. 8-22, which references a generic digital signal processor. The general digital signal processor, however, identifies no specific structure for performing the claimed function; it only describes a generic class of structures and cannot be included. Moreover, this construction ignores the clear language of the specification set forth above.

DTL argues that the patent teaches that the digital signal processor may be in the form of an integrated circuit, citing the court to '799 patent, col. 12, ll. 3-10. However, this portion of the specifications merely summarizes that the invention may include within the transducer housing a digital signal processor, in the form of an integrated circuit, to process the signal. It does not, as DTL argues, suggest that an integrated circuit is but one form of a digital signal processor which may be used.

It should be stressed that the court is not limiting the structure to the structure of a preferred embodiment. This is not an instance where the patent teaches that a general "digital signal processor" may be used and an integrated circuit is utilized in the preferred embodiment. In that case, the court would read the claim element to embrace distinct and alternative structures disclosed in the specifications for performing the recited function. Again, the specifications clearly state that a digital signal processing integrated circuit, such as the Motorola DSP56001 is placed inside the transducer housing to perform the recited function.

Turning to the competing proposal, Cingular argues that the corresponding structure is "a digital signal processing microcomputer with word lengths of 24 bits or more such as the Motorola DSP 56001, or a substantially equivalent structure in existence as of September 1991." Cingular points only to a preferred embodiment in '799 patent, col. 9, ll. 30-32. There is no evidence that the digital signal processing microcomputer must be a 24-bit processor to perform the recited function. In fact, Cingular acknowledges that some 16-bit digital signal processors can perform the claimed function. Def.'s Responsive Claim Construction Brief, p. 23 n. 26 [Doc. # 63]. Accordingly, the court rejects Cingular's assertion that the corresponding structure must be a microcomputer "with word lengths of 24 bits or more." The court concludes that the structure associated with this means-plus-function term is "a digital signal processing integrated circuit, such as the Motorola DSP56001, or equivalents thereof."
Papst is correct that the "digital signal processor" in Claim Five cannot be any kind of microprocessor. Claim Five is a dependent claim. Thus, it includes the limitations of Claim One, but also adds something new, rendering it more narrow than Claim One. See 35 U.S.C. § 112; Tr. 3:38. Claim One is broad. It recites that interface device includes a "processor." '399 Patent, col. 12:48. The specification expressly notes that while a preferred embodiment would include a digital signal processor, it could include any type of processor: "In a preferred embodiment of the present invention, the digital signal processor 13, which need not necessarily be implemented as a digital signal processor but may be any other kind of microprocessor . . . ." '399 Patent, col. 6:48-51 (emphasis added); see also id., col. 9:18-19 ("[T]he DSP can be any DSP"). Because "processor" in Claim One means any kind of processor, the term "processor" in Claim Five must be more limited. See 35 U.S.C. § 112 ("[A] claim in dependent form shall . . . specify a further limitation of the subject matter claimed."). To interpret Claim Five as coextensive with Claim One would render Claim Five meaningless. Such a construction is disfavored. See Cytologix, 424 F.3d at 1173. The Court adopts, with some modification, Papst's proposed construction: a "digital signal processor" as specified in Claim Five of the '399 Patent means a "processor optimized to perform repetitive computations used in digital signal processing such as multiply-accumulates."

The parties' dispute with respect to term one is a dispute as to whether the '672 patent applies only to video signals or also to other types of signals (including, significantly, still images). Plaintiff argues that term one should be construed as: "A sequence of data to be runlength encoded, having multiple values and a predetermined length." Defendants argue that this term should be construed as: "A digital signal or processed signal is a set of data representing frames of a video." As Defendants argue, in the context of the "typical[]" utilization of the ordered redundancy coding system, the specification of the '672 patent clarifies that "processed signals" include only video signals: "The processed signals are in the form of a plurality of multivalued digital numbers, X(k), typically one number X(k), for each frame." '672 Patent col.3 11.49-56 (emphasis added). Plaintiff argues that the foregoing definition must include a typographical error because there are necessarily many numbers in a block and many blocks in a frame. Tr. 117:3-10. However, because the specification makes clear that "X(k)" represents a series of values, n3 the foregoing description of "processed signals" is consistent with Plaintiff's view that there are many numbers in a block. Accordingly, as explained in the specification, "processed signals" typically are comprised of plural frames, thus indicating that processed signals are video signals.

n3 "In general, a K-valued digital number, X(k), is formed by a series of K values, x(k), as follows: X(k) = x(1), x(2), x(3), . . . x(K), . . ., x(K) where 1=k=K." '672 Patent col.12 11.38-43.

Plaintiff contends that its construction of "processed signals" and "digital signals" is supported by the doctrine of claim differentiation. This doctrine "refers to the presumption that an independent claim should not be construed as requiring a limitation added by a dependent claim." Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380 (Fed. Cir. 2006); see also Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir., 2004) ("the presence of a dependent claim that adds a particular limitation raises a presumption that the limitation in question is not found in the independent claim."). While claim 19 is limited to "input signals represent[ing] images . . . presented in sequential frames," claim 6, which addresses "processed signals" and upon which claim nineteen is dependent, does not include such a restriction. '672 Patent col.24 11.13-16; col.25 11.52-65. Plaintiff argues that this necessarily means that claim six does not include a requirement that the signals be video signals. However, "that the claims are presumed to differ in scope does not mean that every limitation must be distinguished from its counterpart in another claim, but only that at least one limitation must differ." Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368 (Fed. Cir. 2000). As Defendants point out, because claim 19 adds limitations that are not in claim 6-the steps of forming the mean-square difference and error and selecting a mode-
the doctrine of claim differentiation does not compel the Court to read out the restriction that the processed signals in claim 6 are video signals.

Although the specification does not provide a similar explanation of "digital signals," the parties initially agreed "that the Court should construe the terms 'processed signals' and 'digital signals' identically for the purposes of the claims at issue." n4 Defendants and Declaratory Judgment Plaintiffs' Responsive Markman Brief, p. 7 n.3. Because "processed signals" are a subset of "digital signals," the Court was hesitant to apply the above explanation of "processed signals" also to "digital signals." Accordingly, the Court requested and received supplemental briefing addressing the question of whether "digital signals" and "processed signals" should be given the same construction and, if so, why.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
n4 Plaintiff's expert, Dr. Sheila Hemami, indicated that both "digital signals" and "processed signals" have a special meaning: "The terms 'digital signals' and 'processed signals' normally have a very broad meaning, but those terms are given a special and more particular meaning in the specification of the '672 Patent and as they are used [in] the claims." Declaration of Tibor L. Nagy ("Nagy Decl."), Ex. 2, p. 18. During oral argument, Plaintiff's counsel indicated that this was an "error" and that Dr. Hemami and Plaintiff's counsel "both regret having opened this can of worms [that Plaintiff conceded that the term 'processed signals' is not being used in the patent in accordance with how those ordinarily skilled in the art would commonly understand it] by suggesting that there is some special meaning to 'digital processed signals.'" Tr. 109:4-20. While the Court finds it somewhat instructive that Dr. Hemami wrote that "digital signals" and "processed signals" have a special and particular meaning in the '672 patent, the Court's construction of these terms does not turn on her statement.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Plaintiff argues in its supplemental brief that, if the Court gives the above construction to "processed signals," n5 "digital signals" should not be similarly limited. Plaintiff emphasizes that "processed signals" are a subset of "digital signals," pointing out that "digital signals" are equivalent to "input signals" n6 and "input signals" are processed to form "processed signals." n7 Plaintiff argues also that the "processing" referred to in claims 1 and 38 is different than the "processing" in claim 6. However, assuming arguingo that "digital signals" are not video signals, Plaintiff does not provide any explanation for how the processing of "digital signals" to create "processed signals" converts non-video signals into video signals. As Defendants argue, if "processed signals" are video signals, and processing does not convert non-video signals into video signals, the input signals or "digital signals" must also be video signals. In light of Plaintiff's initial concession that the terms should be construed identically, and in the absence of a persuasive argument as to how processing "digital signals" would convert non-video signals into video signals, the Court concludes that, if "processed signals" are video signals, "digital signals" must be given the same restriction.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
n5 Plaintiff disputes that "processed signals" should be limited to video signals in its supplemental brief. Plaintiff's Second Supplemental Brief, p. 1.

n6 "Digital signals to be processed are input on lines 5 to the transmitter 2. The input signals on lines 5 are processed in one of a number of different modes so as to efficiently compress the data input signals to form processed signals for transmission to a receiver." '672 Patent col.4 11.33-37.

n7 Claim 6 describes "[a] method for processing input signals to reduce the amount of data utilized to represent the input signals, the steps comprising, processing the input signals to form processed signals where the processed signals are digital numbers having first values, second values, and other values." '672 Patent col.24 11.10-16; see also id.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Considering that the above explanation of "processed signals" is given in the context of a "typical[]" system, it does not on its own persuade the Court that "processed signals" and "digital signals" must be construed as video signals. However, this clear explanation of "processed signals," combined with numerous other indications that the patent applies exclusively to video signals, most logically supports such a construction. As noted above, where "the specification makes clear at various
points that the claimed invention is narrower than the claim language might imply, it is entirely permissible and proper to limit the claim." Alloc, 342 F.3d at 1370.

The abstract of the '672 patent indicates that the patent is limited to video data: "The present invention specifically relates to methods and apparatus useful in video compression systems." '672 Patent, abstract; Hill-Rom Co., Inc. v. Kinetic Concepts, Inc., 209 F.3d 1337, 1341 (Fed. Cir. 2000) ("We have frequently looked to the abstract to determine the scope of the invention, [citations], and we are aware of no legal principle that would require us to disregard that potentially helpful source of intrinsic evidence as to the meaning of claims."). The location of a statement within the specification "can signal the likelihood that the statement will support a limiting definition of a claim term." C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004). Specifically, "]statements that describe the invention as a whole [which are more likely to be found in certain sections of the specification], rather than statements that describe only preferred embodiments, are more likely to support a limiting definition of a claim term." Id. Although "certain sections of the specification are more likely to contain statements that support a limiting definition of a claim term than other sections," the Court must determine the significance of language in the specification "on a case-by-case basis." Id. Because the abstract of the '672 patent states that it is "useful in video compression systems," this language in itself does not necessarily limit the patent to video data. However, the language is another significant factor supporting the Court's conclusion that the patent applies specifically to video signals.

Another such factor is the explanation in the specification that the '672 patent was designed to solve a problem specific to video data. "In construing claims, the problem the inventor was attempting to solve, as discerned from the specification and the prosecution history, is a relevant consideration." CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1160 (Fed. Cir. 1997). The patent specification describes the need that the '672 patent was designed to meet:

> If the communications link is an earth satellite, an unprocessed video signal typically occupies nearly the entire bandwidth of the satellite, with very few channels, if any, left over for other uses. A T1 communication channel is typical and has only a 1.5 megabit per second bandwidth. A practical yet effective way to reduce the bandwidth of digitalized television signals is needed so that fewer channels are required for transmission over a communications path and so that the quality of transmitted signals is maintained even when reduced bandwidth transmission is employed.

'672 Patent col.1 11.34-44 (emphasis added).

Plaintiff argues that video data is referred to in the specification as an example of how the ordered redundancy coding system may be applied. n8 However, Plaintiff does not identify any examples in the patent that do not involve video data. Plaintiff's argument that the specified application of the patent to the "intraframe mode" demonstrates that the patent was intended to be applied to still images is not persuasive. The specification explains that "[t]he decision as to which mode to select is made based upon an analysis of the frame-to-frame differences (motion) between the current input signals and the previous input signals." '672 Patent, col.3 11.61-64. While the specification describes a "single image frame" in intraframe coding, it does so in the broader context of describing video:

-------- Footnotes --------

n8 See, e.g., "The present invention specifically relates to methods and apparatus useful in video compression systems," '672 Patent, col.1 ll.19-20; "The ordered redundancy coding of the present invention is typically utilized in a system that processes input signals, such as spatial domain image signals occurring in successive frames, to form processed signals for each frame," id. col. 3 11.49-53.

-------- End Footnotes --------

The U.S. Pat. No. 4,302,775 patents reduces redundancy by employing intraframe coding techniques utilizing intraframe comparisons of cosine transform coefficients. While the patent provides significant improvement over other techniques, there is a need for even greater compression.

In addition to intraframe coding techniques, interframe coding techniques have been used to reduce the rate required for video transmission as described, for example, in the above-identified application. Typically, each video frame is held in memory at both the transmitter and the receiver and only frame-to-frame changes are transmitted over the communication link. In contrast to intraframe coding schemes in which the quality of coded images is dependent upon the amount of detail
in each single image frame, the quality of the coded image in interframe coding is dependent upon the differences from frame to frame. Frame-to-frame differences are often referred to as "motion."

'672 Patent, col.2 11.12-31 (emphasis added). Nor is Plaintiff's argument that Defendants' proposed construction excludes intraframe coding persuasive, as intraframe coding is a type of video coding.

Considered together, the explanation that "processed signals" typically are comprised of plural frames, the language of the abstract, the purpose of the invention, and the absence of any example expressly identified as applying to still images all point to the conclusion that the '672 patent applies exclusively to video data. Defendants note that Plaintiff's conduct over the past two decades n9 is persuasive extrinsic evidence that the '672 patent applies exclusively to video data. This line of argument is unnecessary to support the Court's conclusion that "digital signals" and "processed signals" are video signals and is in the outer bounds of the type of extrinsic evidence that a Court should consider in construing patent claims. Accordingly, while evidence that Plaintiff may have delayed asserting that the use of JPEGs infringes the '672 patent would be highly relevant to a defense of laches at a later stage of litigation, the Court need not and does not rely on this argument in construing term one.

--- Footnotes ---

n9 For example, Defendants argue that even though Plaintiff was aware of the work being done by JPEG standard-setting committee and itself voted to approve the JPEG standard, it neither disclosed the '672 patent to the committee nor sought to license it. See Scarsi Decl., Ex. 2, pp. 202-204; Ex. 3, pp.153-56; Ex. 15. In contrast, Plaintiff was involved in the MPEG committee and disclosed the '672 patent to that committee. See, e.g., Scarsi Decl., Exs. 12 and 13.

--- End Footnotes ---

For the reasons stated above, the Court adopts Defendants' proposed construction of term one.

1339

4. Digital Words

A digital word is a digital value for representing the grey scale or color of a portion of the non-digital signal.

1340

1. "digitally-encoded messages"

The phrase appears in claims 13 and 21 (and parent claims) of the '414 patent, and claims 1, 2, 15 and 19 of the '399 patent. Claim 15 of the '399 patent is representative (the disputed term is in boldface):

15. A method for automatically distributing digitally-encoded messages that are input to an automatic message distribution system that includes a resource load containing a plurality of resources, comprising the steps of:

(a) storing each of said digitally-encoded messages in one or more distributed message queues;

(b) storing resource information concerning said resources in a resource information table that enables the automatic message distribution system to determine which of said resources is available to a digitally-encoded message stored in said one or more distributed message queues;

(c) storing a set of routing rules in a distribution routing table that control distribution of said digitally-encoded message to the resources; and
(d) automatically routing a digitally-encoded message stored in said one or more distributed message queues.

[a] The Parties' Proposed Constructions

The parties propose the following constructions:

<table>
<thead>
<tr>
<th>eBay</th>
<th>IDT</th>
</tr>
</thead>
<tbody>
<tr>
<td>The content of a communication from a sender that has been converted into digital form, not simply an identification of the type of information to be communicated.</td>
<td>Digitally-encoded information from a message sender to one or more message receivers.</td>
</tr>
</tbody>
</table>

*2*See Doc. No. 99 at 62 (JCCC Exhibit 1 at 60).

Net2Phone urges that the specification of the '414 and '399 patents defines the term, and thus that is the definition that should control, citing Phillips, 415 F.3d at 1316. (Doc. No. 83 at 11). Specifically, Net2Phone contends that the specification of the patents use "message" and "digitally-encoded message" interchangeably and expressly defines "message" as:

As used herein the term "message" includes any digitally-encoded information that can be transmitted by a sender to a receiver.

'414 patent, col. 4, lines 24-27. Net2Phone urges that eBay's proposed construction improperly imports a "content of a communication" limitation. (Doc. No. 83 at 12).

eBay urges that its proposed construction "follows directly from how the 'invention' is repeatedly characterized and distinguished over prior art systems in the intrinsic record." (Doc. No. 87 at 19). eBay contends that the patents "expressly distinguish prior art systems from the 'present invention' on the ground that prior art systems were only able to base routing decisions on the 'type of information that will be discussed,' whereas the 'AMD system of the present invention' receives and stores 'digitally-encoded messages,' and thus can base routing decisions on 'message content information.' "Id. (citing '399 patent, col. 1, lines 54-65, col. 2, lines 55-56, col. 3, lines 9-12; Open Port's Provisions Appl. at 1, 2, 4.) eBay also points to the Summary of the Invention explaining "'[t]he AMD of the present invention processes information that is received in message format rather than as a telephone call, and therefore can base routing decisions on message content.'" (Doc. No. 87 at 19) (emphasis by eBay), (citing '399 patent, col. 2, lines 51-56, and col. 3, lines 9-12) ("Because the messages are stored, the present invention can extract content information from the messages for routing purposes that is not available to conventional AMD or ACD systems.").(emphasis by eBay).

eBay argues that "[i]n characterizing the 'present invention' as a content-based message routing system and distinguishing the prior art on this basis, Open Port excluded from the scope of a 'digitally-encoded message' the mere identification of the 'type of information' to be communicated." (Doc. No. 87 at 20) (citing Curtiss-Wright Flow Corp. v. Velan, Inc., 438 F.3d 1374, 1378-80 (Fed. Cir. 2006), and Honeywell Int'l, Inc. v. ITT Indus., 452 F.3d 1312, 1318-19 (Fed. Cir. 2006)).

eBay also argues that its proposed construction "makes clear that a 'digitally-encoded message' refers to the content of a communication that has been converted into digital form. This follows from both the description of the invention in the intrinsic record as well as the plain meaning of the term 'digitally-encoded' itself," pointing to the IEEE Standard Dictionary of Electrical and Electronics Terms (6th ed. 1996) at 168, defining "encoded data" as "[d]ata that has been converted from one form of representation to another, using a set of rules." (Doc. No. 87 at 21) (emphasis added). eBay urges that "'[d]igitally-encoded' data, then, is data that has been converted into digital form so that it can be read and manipulated by a computer." Id. (citing '399 patent, col. 2, lines 37-48).

In response to Net2Phone's proposed construction, eBay says that the specification does not define "digitally-encoded message," but even if so, "it cannot trump how the Summary of the Invention repeated characterizes the invention and distinguishes the invention over the prior art." (Doc. No. 87 at 21-22). eBay also urges that the sentence Net2Phone relies is taken out of the overall context of the specification, which "runs afoul of the fundamental principal that the claims of a patent may not be construed broader than how the patentee characterized the 'present invention' in the intrinsic record."
Net2Phone responds that eBay's proposed construction "suggests that messages are digitally-encoded after receipt into a distribution system." Net2Phone urges that according to the '414 and '399 patents, messages are "digitally-encoded" when they are transmitted from a message sender to a receiver. (Doc. No. 92 at 5).

Net2Phone also says that "information" in its proposed construction refers to the many types of information that are part of a message, for example, "the identity of the sender, the type of information to be communicated, mail headers, addresses, priority of the messages, amount of time the message have been in the system, and any other information sent by the message sender, such as the actual substantive content of the communication." (Doc. No. 92 at 6). Limiting the "digitally-encoded message" to "content of a communication," Net2Phone argues, ignores the other information that the patents disclose is in the message.

With respect to distinguishing the prior art, Net2Phone argues that "when the Patents distinguished the prior art ACD systems, they were not limiting the scope of a digitally-encoded message to the actual substantive content of the communication, as eBay asserts. Rather, the Patents made clear that, unlike the prior art ACD systems, the invention can also use the actual substantive content of the communication to distribute a message, which was unavailable in the old ACD system." Id.

In its sur-reply, eBay reiterates that the patents "repeatedly distinguish the prior art Automatic Call Distribution ('ACD') systems on the ground that they were only able to base routing decisions on the 'type of information' to be communicated, whereas the 'AMD system of the present invention' receives and stores 'digitally-encoded messages,' and thus can base routing decisions on the actual 'message content' itself." (Doc. No. 95 at 4-5) (citing '399 patent, col. 1, lines 54-65, col. 2, lines 55-56, col. 3, lines 9-12; provisional app. at 1, 2, 4).

eBay further characterizes Net2Phone's argument that "the Patents made clear that, unlike the prior art ACD systems, the invention can also use the actual substantive content of the communication to distribute a message, which was unavailable in the old ACD system," (emphasis by eBay) as a "critical admission" and "exactly right." eBay urges that "[w]hat Net2Phone overlooks, however, is that the message distribution system can do so only because a 'digitally-encoded message' contains the 'actual substantive content of the communication.'" (Doc. No. 95 at 5).

eBay further disputes that it's proposed construction limits a digitally-encoded message to the "content of a communication." eBay argues that under its proposed construction a "digitally-encoded message" must contain the "actual substantive content of a communication," but it may also contain other information such as e-mail headers etc. Id. at 6.

eBay also disputes Net2Phone's contention that messages are "digitally-encoded" before receipt by the distribution system. eBay contends that facsimile messages are transmitted in analog form, and then digitally encoded after they are received into the distribution system, citing the '399 patent, col. 2, lines 37-48: "The message can assume one of a number of manipulatable forms. For example, in the case of facsimile (fax) data, messages can be stored in one of the TIFF, PCX or DCX formats." Id. at 6-7.

b) Discussion

Beginning as always with the terms of the claim, and using claim 15 of the '399 patent as representative:

15. A method for automatically distributing digitally-encoded messages that are input to an automatic message distribution system that includes a resource load containing a plurality of resources, comprising the steps of:

(a) storing each of said digitally-encoded messages in one or more distributed message queues;

(b) storing resource information concerning said resources in a resource information table that enables the automatic message distribution system to determine which of said resources is available to a digitally-encoded message stored in said one or more distributed message queues;

(c) storing a set of routing rules in a distribution routing table that control distribution of said digitally-encoded message
to the resources; and

(d) automatically routing a digitally-encoded message stored in said one or more distributed message queues.
[paragraphing added by the parties]

eBay points to nothing in the claim language, other than the term itself, that requires that "digitally-encoded messages" include the "content of a communication from a sender." eBay further does not rely on any arguments made during prosecution. eBay relies exclusively on statements made in the "Background" and "Summary of the Invention" portions of the specifications of the patents-in-suit. And Curtiss-Wright and Honeywell.

In Curtiss-Wright, the patent-in-suit was drawn to a coke drum de-heading system. One of the claim limitations called for "an adjustable dynamic, live loaded seat coupled to said main body." The district court, in construing "adjustable," (1) began with the ordinary meaning of "adjustable": "capable of making a change to something or capable of being changed," (2) determined that a narrower construction of "adjustable" would be inconsistent with other claims, and (3) explained that any construction of the term "adjustable" that requires the presence of an adjustment mechanism disclosed in the patent-in-suit would impermissibly narrow the claim to the preferred embodiment. The district court accordingly construed "adjustable" as, inter alia, "not limited by any time, place, manner, or means of adjustment." The Federal Circuit reversed commenting that the district court's construction "places too much emphasis on the ordinary meaning of "adjustable" without adequate grounding of that term within the context of the specification . . ." and misapplied the doctrine/guideline of claim differentiation. 438 F.3d at 1378.

The Federal Circuit explained that "the specification of the [patent-in-suit] consistently, and without exception, describes adjustment that occurs during operation of the de-header system," and that the district court's construction "which includes a structure that requires dismantling of the valve to perform the adjustment, finds no support in the overall context of the . . . specification." The Federal Circuit further commented that "the district court's construction of 'adjustable' renders that limitation nearly meaningless. This court finds it difficult, if not impossible, to imagine any mechanical device that is not 'adjustable,' under the ordinary meaning of that term adopted by the district court." Id. at 1379.

In Honeywell, the patent-in-suit disclosed a fuel filter that was specially made for use with electronic fuel injection systems, i.e., it addressed an "arcing" problem. Although the specification disclosed a fuel filter, the asserted claim was drawn to a "fuel injection system component." The accused products were "quick connects" used to join various components of a fuel injection system together. The district court construed "fuel injection system component" to mean "a fuel filter" finding that the written description of the patent-in-suit limited the "fuel injection system component" to a fuel filter. On appeal, the Federal Circuit affirmed commenting: "Here, the written description uses language that leads us to the conclusion that a fuel filter is the only 'fuel injection system component' that the claims cover, and that a fuel filter was not merely discussed as a preferred embodiment. On at least four occasions, the written description refers to the fuel filter as 'this invention' or 'the present invention' . . . ." 452 F.3d at 1318. See also, Netcraft Corp. v. eBay, Inc., 549 F.3d 1394, 1398 (Fed. Cir. 2008)("We agree with Netcraft that use of the phrase 'the present invention' does not 'automatically' limit the meaning of claim terms in all circumstances, and that such language must be read in the context of the entire specification and prosecution history. . . . For the reasons below, however, we agree with the district court that the common specification's repeated use of the phrase 'the present invention' describes the invention as a whole, . . ."). Cf., Rambus Inc. v. Infineon Techs. AG, 318 F.3d 1081, 1094 (Fed. Cir. 2003)("While clear language characterizing 'the present invention' may limit the ordinary meaning of claim terms, . . . such language must be read in context of the entire specification and the prosecution history.").

Turning then to the specification, the first portion of the specification that eBay relies on, '399 patent, col. 1, lines 52-67, appears in the "Background" portion of the specification, and explains in context:

A second conventional message processing system is used in telephone call distribution systems. FIG. 2 is a schematic diagram of an automated call distribution (ACD) system 200 for distributing telephone calls received by the ACD system 200. In the ACD system 200, the only information that is known about the telephone call at the time the telephone call is answered is the type of information that will be discussed during the call (e.g., the caller dials a number for customer service for a particular product line), the identification of the caller (e.g., the caller's telephony system identifier), or both. Such systems are limited because the information content of a telephone call is unknown at the time of call receipt by the ACD system 200. Thus, such content cannot be used in the routing process. As a result, information based on the content of the message, the telephone call, cannot be used to determine the ultimate receiver of the call.
In short, in the prior art ACD system illustrated in Fig. 2:

GET DRAWING SHEET 2 OF 7

because these were telephone calls, when the call was answered there was as yet no information about the actual content of the telephone call -- the only information known was (1) the general type of information -- discerned from the caller having called customer service for a particular product, (2) an identification of the caller, e.g., the caller's telephone identifier, or (3) both. Without knowing the content of the telephone call, content could clearly not be used to further route the call.

The second portion of the specification that eBay relies on, '399 patent, col. 2, lines 55-56, appears under the heading "Summary of the Invention," and explains that "[m]essage content information is not available to conventional ACD systems as described above." Before turning to putting that statement in context, though, it is useful to review the actual disclosure of the '414 and '399 patents.

Under the heading "Background of the Invention," the patents explain that:

Generally, a message distribution system distributes information in the form of one or more messages from a message sender to a message receiver. The message sender combines data representing the information content of the messages into a form that can be transmitted to the message receiver. A variety of communication media exist over which messages can be transmitted, including telephone, wireless communication systems and computer networks. There are several conventional message distribution systems currently in use for delivering messages from a message sender to a message receiver.

'399 patent, col. 1, lines 19-30 (emphasis added).

The first of the "conventional message distribution systems" described in the "Background" is an automated message routing (AMR) system, illustrated in Fig. 1. The patents explain that this is a point-to-point message distribution system, i.e., messages are distributed by establishing a direct path between a message sender and a message receiver:

GET DRAWING SHEET 2 OF 7

In that prior art AMR system 100, the patents explain, "a message sender 1s sends a message to a message receiver 1r along a direct path 101. The message receiver 1r is located at logical address 102. Both the message recipient 1r and the route through which the AMR system 100 delivers the message are predetermined by the respective addresses of the message sender 1s and the message receiver 1r. Common forms of addresses for the message sender 1s and the message receiver 1r include a dialed telephone number and an identified mailbox address." '399 patent, col. 1, lines 37-46.

The patents further explain, however, that the AMR system is limited "because it does not select the route over which to transmit a message. Rather, the particular route is determined solely by the respective addresses of the message sender and the message receiver." Id. at lines 47-51.

A second of the "conventional message distribution systems" described in the "Background" is an automated call distribution (ACD) system 200 illustrated in Fig. 2 above. As noted above, that system is limited to telephone calls, and thus the content of the call is not known when the call is answered.

A third of the "conventional message distribution systems" described in the "Background" is an automated message distribution (AMD) system illustrated in Fig. 3 below. The patents explain that "[c]onventional AMD systems place inbound messages in one or more general-purpose mail-boxes that correspond to known pieces of information, and "[i]n an AMD system, the only information known prior to receipt of the message is similar to that of the ACD system described above, i.e., type of information to be discussed and caller identification data." '399 patent, col. 2, lines 1-8.

However, the patents explain, "because the information is in a message format, rather than a telephone call, the rules for message distribution in an AMD system can differ substantially from those for distributing calls in an ACD system. For example, conventional content processing mechanisms, including mail header parsers, addressing parsers, and optical mark recognition (OMR) and optical character recognition (OCR), can add further information to the routing decision." '399
The patents explain that "AMD system 300 has a mailbox subsystem 302, a content processing subsystem 304 and a message distributor subsystem 306. The mailbox subsystem 304 receives a message from a message sender 1s-6s. The message is received in message format and stored in the mailbox subsystem 302. The content processing subsystem 304 then derives information from a message stored in the mailbox subsystem 302. This information can be passed to the message distributor subsystem 306 to help distribute the message to an appropriate message receiver 1r-4r." '399 patent, col. 2, lines 17-28 (emphasis added).

According to the patents, therefore, deriving content information from received messages, using "conventional content processing mechanisms," and then using that information to appropriately route the messages to the proper recipient, was known in "conventional" AMD systems. "However," the patents explain, "the information stored in conventional mailbox-based AMD systems is not sufficient to determine optimal routing of the mailbox messages to an appropriate message receiver. This is because no information regarding the priority of the message, the amount of time the message has been in the mailbox subsystem 302, nor the status of the mailbox subsystem 302 potential recipients is monitored in the conventional mailbox system." '399 patent, col. 2, lines 27-34 (emphasis added).

The discussion in the patents then turns to the "Summary of the Invention."

Returning to the second portion of the specification that eBay relies on, '399 patent, col. 2, lines 55-56, that portion once again explains that "[m]essage content information is not available to conventional ACD systems as described above." That is true because, as discussed above, ACD systems were call processing systems and content of a telephone call is not known at the time a telephone is answered. However, the invention disclosed in the '414 and '399 patents is not an ACD system, but rather an AMD system -- i.e., a message distribution system of the variety illustrated in Fig. 3. In those AMD systems, according to the foregoing description, content information was known, and such content information could be used to route the messages to the proper recipients.

Putting the portion of the specification that eBay relies on in context, this portion of the specification first explains:

The present invention is an AMD system that is optimized for distributing digitally-encoded messages (DEMs) received from a number of sources through a computer network and initially stored in one or more distributed message queues (DMQs). The DEMs can be received from a database, over a LAN or WAN or other communication media. Using the present invention, message distribution is optimized according to a set of configurable distribution rules. The message can assume one of a number of manipulatable forms. For example, in the case of facsimile (fax) data, messages can be stored in one of the TIFF, PCX or DCX formats.

'399 patent, col. 2, lines 37-48. Given the foregoing discussion of Fig. 3, it seems clear that "digitally-encoded messages (DEMs)" necessarily include "content information."

The patents go on to explain that:

Unlike conventional AMD systems described above, neither the message receiver's identity nor the route by which the message should be distributed is predetermined.

'399 patent, col. 2, lines 49-52. The reason, of course, is that the invention of the patents-in-suit adds further routing features to the conventional AMD, for example the use of a "distribution rule table (DRT)" that may be used to distribute messages on information other than content.

Nevertheless, the patents further explain in the portion (emphasized) that eBay relies on:

- 1765 -
The AMD of the present invention processes information that is received in message format rather than as a telephone call, and therefore can base routing decisions on message content. Message content information is not available to conventional ACD systems as described above.

'399 patent, col. 2, lines 51-56 (emphasis added).

eBay points to the above emphasized portion as distinguishing the "present invention" from the "prior art." That is not what the patents are saying at this juncture. It is true that message content was not available on conventional prior art ACD (telephone call) systems, but message content information was available on "conventional AMD system 300" of Fig. 3. Nevertheless, as already noted, it seems clear that "digitally-encoded messages (DEMs)" necessarily include "content information," and that is reinforced by the disclosure preceding that which eBay relies on, i.e., "[t]he AMD of the present invention processes information that is received in message format rather than as a telephone call, and therefore can base routing decisions on message content."

On the other hand, it is also clear that routing may be based on other factors. For example, the patents explain that:

The present invention uses a distribution rule table (DRT) in which a set of configurable distribution rules are stored. The distribution rules determine various information regarding the AMD system. Using this information, the message distributor of the present AMD system can route received messages to appropriate message recipients in an optional manner. For example, it may be desirable to evenly distribute messages to available message recipients. In this case, the distribution rules in the table would be chosen such to effectuate even distribution of messages to message recipients.

The DRT operates in conjunction with a resource information table (RIT). The RIT maintains information corresponding to the availability of resources that are able to process DEMs that are stored in the DMQs. Thus, the present invention uses the DRT in conjunction with the RIT to optimally route incoming DEMs that are initially stored in the DMQs to resources that are able to process the DEMs.

'399 patent, col. 2, line 57-col. 3, line 7.

The third portion of the specification that eBay relies on, col. 3, lines 9-12, explains that "[b]ecause the messages are stored, the present invention can extract content information from the messages for routing purposes that is not available to conventional AMD or ACD systems." Although it is not entirely clear what "content" information vis-a-vis a conventional AMD system this portion of the specification is referring to, nonetheless it is clear that the invention is capable of using content information for routing purposes.

As for IDT's contention that the specification "defines" "digitally-encoded messages," the entire paragraph reads:

The present invention provides a mechanism whereby an operator can optimize the distribution of transmitted messages to appropriate receivers in an AMD system. Preferably, the messages are digitally-encoded messages (DEMs). As used herein the term "message" includes any digitally-encoded information that can be transmitted by a sender to a receiver.

'414 patent, col. 4, lines 21-27. It is true that defines "message" and indirectly "digitally-encoded messages." However, it is also clear that is in the context of an AMD system. As discussed above, the patents explain that in an AMD system, "because the information is in a message format, rather than a telephone call, the rules for message distribution in an AMD system can differ substantially from those for distributing calls in an ACD system. For example, conventional content processing mechanisms, including mail header parsers, addressing parsers, and optical mark recognition (OMR) and optical character recognition (OCR), can add further information to the routing decision." '399 patent, col. 2, lines 8-15.

Accordingly, IDT's proposed construction, "[d]igitally-encoded information from a message sender to one or more message receivers," must be rejected. The patents use "digitally-encoded message" in a more limited manner.

With respect to eBay's proposed construction, "[t]he content of a communication from a sender that has been converted into digital form, not simply an identification of the type of information to be communicated," the exclusion "not simply an identification of the type of information to be communicated" -- which could be garnered in ACD systems, as the patents point out, from the number called -- "the caller dials a number for customer service for a particular product line" -- is
understood. However, the precise scope of what eBay intends by the "content of a communication," which eBay sometimes refers to as "the actual substantive content of the communication," (Doc No. 95 at 5), is less clear.

Once again, the patents in connection with AMD systems explain that "conventional content processing mechanisms, including mail header parsers, addressing parsers, and optical mark recognition (OMR) and optical character recognition (OCR), can add further information to the routing decision." In context, the patents appear to include "mail header parsers, addressing parsers" etc. within the scope of "content information" that is available in an AMD system, and which is not available in an ACD system. Yet, eBay's arguments would seem to exclude the same from "content information." See (Doc. No. 95 at 6) ("While a 'digitally-encoded message' must contain the actual substantive content of a communication, it may also contain other information, such as mail headers, addresses, and the like.") In light of eBay's arguments, the Court must likewise reject eBay's proposed construction.

Rather, the Court believes that one of ordinary skill in the art, having reviewed the claims and specification of the '414 and '399 patents, would understand "digitally-encoded message" to mean "digitally-encoded information from a message sender to one or more message receivers that includes message content information, for example mail header parsers, addressing parsers, and the like, which may be used in making routing decisions, rather than simply an identification of the type of information (analogous to a caller dialing a number for customer service for a particular product line.)"

c) Conclusion

In view the foregoing, the Court concludes that:

"In the context of the '414 and '399 patents, "digitally-encoded message" means "digitally-encoded information from a message sender to one or more message receivers that includes message content information, for example substantive content, mail header parsers, addressing parsers, marks, and the like, which may be used in making routing decisions, rather than simply an identification of the type of information, analogous to a caller dialing a number for customer service for a particular product line.""

B. Claim 29

Claim 29 is dependent on claim 22 and reads as follows:

A portable personal health tracker according to claim 22 further comprising a tactile input device on which the subject may write and the subject's writing is detected, said tactile input device generating a digitized representation of the detected writing.

The parties dispute the meaning of "digitized representation of the detected writing." The defendants contend that this term should be limited to a subject's handwriting, and proposes that the term be construed as "digital data that represents the subject's handwriting." (D.I. 41, at 30-31.) According to the defendants, the specification supports their construction because it differentiates between any input on a touch-sensitive screen by a pen and handwriting. Additionally, the specification "makes clear that 'writing' refers not to any record of tactile input by a subject, but instead specifically to the subject's handwriting." (Id. at 32.)

Conversely, PHT requests the court to adopt a broad construction of the term. PHT proposes that the term means "a digital record of a pattern created on a tactile input device of the health tracker." (D.I. 39, at 14.) PHT asserts that the defendants' proposed limitation is not justified by the specification or the prosecution history. The court agrees. However, the court also concludes that PHT's proposed construction is too broad.

The patent specification describes the writing as follows:

Shown in FIG. 20A is a message screen of the subjective data logger in which a space is provided where the patient may write a message to a person who reviews his or her database records, such as a reviewing physician. In the preferred
embodiment, the message is transmitted as bit-mapped data, such that... when displayed by the recipient, it appears in the handwriting of the patient. Although software is available which could be used to convert the message into characters, the handwriting itself may be of use to a reviewing physician in assessing the patient's medical condition and in establishing the authenticity of the record.

(Col. 26, 11. 44-55.) As previously discussed, there is a "heavy presumption" that a claim term carries its ordinary and customary meaning. CCS Fitness, 288 F.3d at 1366. Here, the ordinary meaning of the term "writing" is broad: "letters or characters formed on a surface that serve as visible signs of ideas, words or symbols." Webster's Third New International Dictionary 2641 (1993). While accused infringers may rebut the "heavy presumption" to limit a claim term, they "cannot do so simply by pointing to the preferred embodiment." CCS Fitness, 288 F.3d at 1366. Moreover, "where a specification does not require a limitation, that limitation should not be read from the specification into the claims." Intel Corp. v. United States Int'l Trade Comm'n, 946 F.2d 821, 836 (Fed Cir. 1991) (citation omitted). In addition, "just as the preferred embodiment itself does not limit claim terms, . . . mere inferences drawn from the description of an embodiment of the invention cannot serve to limit claim terms." Johnson Worldwide, 175 F.3d at 992.

Here, the defendants merely point to the preferred embodiment and state that nothing in the claim suggests that it covers anything but handwriting. However, neither the claim nor the specification require that the term "writing" be limited to "handwriting." Indeed, the specification explains that software is available that can convert the message into characters. (Col. 26, 11. 51-52.) Thus, the patent postulates that a "digitized representation of the detected writing" can include more than just a subject's handwriting. Accordingly, the court will construe the phrase "digitized representation of the detected writing" as having its plain and ordinary meaning -- specifically "digital data that represents the subject's writing." 6

6 The phrase "digitized representation of the subject's writing" in claim 30 should be construed consistently with the term "digitized representation of the detected writing" in claim 29. See Southwall Techs., 54 F.3d at 1579. Thus, for the reasons stated above, the court construes the term "digitized representation of the subject's writing" to mean "digital data the represents the subject's writing."

GO BACK

1342

9. "digitizer"

The parties dispute the construction of the term, "digitizer." The term at issue appears in Claim 5 of the '025 Patent as follows:

5. A system of tracking real estate and real estate related demographic information using a computer network system comprising:

   a media unit, said media unit having:

       a multimedia computer;

       a digitizer, said digitizer receiving information from outside said network system and within said multimedia computer;

       i/o means, . . . .

   (Herbst Decl. P 5, Ex. 3 at col. 15, ll. 57-66.)

Plaintiffs' proposed construction of the term is "a device that converts information in analog form to digital form." Defendants' proposed construction of the term is "hardware device for converting analog audio, video, text, photograph and
graphics to a digital format." Thus, the parties agree that the claimed "digitizer" functions to convert information from analog format to digital format. However, the parties disagree as to whether the claimed function should be limited to converting only particular types of analog data into digital data.

Here, the Court finds that Defendants' proposed construction is improper for two primary reasons. First, by limiting the claimed function to "analog audio, video, text, photograph and graphics," the proposed construction improperly imports limitations from the specification. (Herbst Decl. P 5, Ex. 3 at col. 7, ll. 39-45); See, e.g., Phillips, 415 F.3d at 1323. Second, by restricting the claim in such a manner, the proposed construction also improperly limits the claimed function to the preferred embodiment. (See Herbst Decl. P 5, Ex. 3 at col. 7, ll. 39-45); See Northern Telecom Ltd., 215 F.3d at 1292; see also Kemco, 208 F.3d at 1362.

For this reason, and after having considered the intrinsic evidence before the Court, the Court construes "digitizer" as "a device that converts information in analog form to digital form."

E. "Digitizing"

Multi-Tech finally argues that the district court improperly construed the term "digitizing," found in claim 7 of the '627 patent, as necessarily being performed by the codec circuit that is disclosed in the specification's preferred embodiment. Microsoft responds that the court did not interpret the term "digitizing" as necessarily being performed by the codec circuit. Thus, there is no dispute regarding this term, and we affirm the district court's construction of the term "digitizing" as meaning simply "converting analog signals into digital signals."

3. Digitizing

Digitizing is the process of creating a digital representation of a non-digital signal by converting, or encoding, the non-digital signal into digital words.
3. "Direct inward dial telephone number"

The court previously determined that, in the contexts of the patents-in-suit, "direct inward dial number" means "the last four or five numbers dialed by a subscriber which are passed to the system over a trunk line capable of carrying a direct inward dial number." Order (dkt. # 263 2) at 21. Although Cygnus has repeatedly objected to the court's construction of "direct inward dial number," Cygnus's contentions in support of revising that construction are unpersuasive. In summary, the court's previous construction was based on several factors. First, the specification of each patent contains an identical definition of "direct inward dial number":

Accordingly, the present invention advantageously utilizes the Direct Inward Dial (DID) numbers. Under LEC [local exchange company] tariffs it is possible to lease a block, or group, of telephone numbers. The size of the groups may vary between LECs, but a group of one hundred numbers is often a typical group. When these numbers are sequential, they are commonly referred to as blocks, but groups of random numbers are also used.

For purposes of this invention, sequential numbering is not required. The customer leasing the numbers from an exchange does not have to lease a corresponding terminating circuit for each number in the group in order to place a call to each number. Instead, the customer leases local facilities in quantities the customer feels are adequate to handle traffic from the leased numbers. When a caller dials one of the numbers in the group, the central office of the terminating LEC (the LEC that assigned the numbers) will complete the call over any of the leased local facilities that are available and also pass the last four, sometimes five, numbers that the called party dialed. The numbers that are passed are called the Direct Inward Dial, or DID, numbers.

'964 patent at 5:63-6:16; '027 patent at 5:66-6:18 (emphasis added). Second, telecom dictionaries dating from 1990 to 2000 describe "direct inward dialing" as a feature of certain phone systems that allowed the phones of a company to be connected so that they could call each other by dialing sequences of fewer than seven digits. Dkt. # 263 at 20. These definitions are consistent with the quoted language of the patent specifications and the inventor apparently contemplated leasing blocks of numbers analogous to a block of numbers used by a large office. Third, during prosecution of both applications, the examiner rejected the claiming of identifying a subscriber via giving him an "assigned number" for calling the service. Id. at 25. In response, the patentee limited the claims to identification using DID numbers, which the PTO allowed, so the plaintiff is now estopped from attempting to expand the claims of the patents to identifying a subscriber via assigned numbers other than DID numbers. Id.

--- Footnotes ---
2 Except where otherwise noted, all docket numbers in this order are those of the master docket for MDL 1423.
--- End Footnotes ---

Cygnus now contends that a DID number cannot be four or five digits because one cannot complete a phone call by dialing less than seven digits. However, Cygnus overlooks the specification of the patents-in-suit, which explain that while a subscriber dials a seven or ten digit phone number sufficient to complete a call, the local exchange carrier passes along only "the last four, sometimes five, numbers that the called party dialed," which is enough to determine which number in the rented block of numbers a subscriber called. Cygnus also argues that if a provider rents telephone numbers in different area codes, blocks of non-sequential telephone numbers, or block of more than telephone 100,000 numbers, four or five digits may not provide enough information to reliably distinguish all the rented numbers. Although Cygnus has pointed out potential problems with practicing the invention on a large scale, this does not overcome the definition of "direct inward dial number" provided by the inventor. Although Cygnus identifies Call Interactive (a company with which Cygnus contracted) planned to have more than 10,000 subscribers, which would have required consideration of at least five digits to distinguish subscribers. Call Interactive's method of operation is not disclosed in the specifications of the patents-in-suit and is not relevant to the construction of the claims.

In its previous order, the court ruled that claims covering all methods of identifying a subscriber based just on the number he dialed had been surrendered during prosecution, and that Cygnus was estopped from expanding the claims beyond using
any method other than a direct inward dial number to identify a subscriber. Cygnus has not explained why the court's ruling that it is limited by its narrowing argument made during prosecution is incorrect.

The court reaffirms its prior order; "direct inward dial telephone number" means "the last four or five numbers dialed by a subscriber which are passed to the system over a trunk line capable of carrying a direct inward dial number."

### 1347

3. "direct sequence spread spectrum codes"

<table>
<thead>
<tr>
<th>Wi-LAN's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;codes over which information bits are spread&quot;</td>
<td>&quot;pseudo random noise sequences over which information bits are spread&quot;</td>
</tr>
</tbody>
</table>

The parties' constructions are in agreement with respect to the phrase "over which information bits are spread." Thus, the dispute turns on whether the term "direct sequence spread spectrum codes" should be construed as "codes …" as Wi-LAN proposes or "pseudo random noise sequences …" as the Defendants propose.

The Court finds that the specification and the claims provide for various kinds of "codes." Certain claims, such as independent claims 17, 23, and 33, require "more than one and up to M direct sequence spread spectrum codes." On the other hand, claims 1, 4, and 12 just require "more than one and up to M codes." Thus, some claims require the more limited "direct sequence spread codes" while others merely require the broader "codes." The Court finds this difference in the claim language is controlling in this instance. Further, the Court finds that the applicant made the decision to claim these "different" codes in the claims during the reissue application. For example, during the prosecution of the reissue application, the applicants amended the phrase "spreading of each ith data symbol over a separate code symbol" in claim 4 to the phrase "spreading of each data symbol over a separate code selected from a set of more than one and up to M codes, …" In contrast, during the prosecution of the reissue application, the applicants amended the phrase "invertible randomized spreading of each set of N data symbols over N code symbols" in claim 17 to the phrase "invertible randomized spreading of each set of N data symbols over more than one and up to M direct sequence spread spectrum codes." See also reissue amendments in claim 12 as compared to claim 21. Thus, the Court finds that the applicants made a choice to claim "M codes" in some claims and to claim "M direct sequence spread spectrum codes" in other claims. The Court cannot ignore this different terminology in the claims.

The specification confirms this different use of terminology. The specification states that in a direct sequence spread spectrum (DSSS) system it is customary to use noise-like codes called pseudo random noise (PN) sequences. '802 patent, 1:27-30. In the descriptions of Figures 1 and 2 the spreading code is described as the "ith code." '802 patent, 2:36-45. The specification states that the computing means shown in Figure 1 includes "a source 16 of N direct sequence spread spectrum code symbols." '802 patent, 4:8-9. In the descriptions of Figures 13, 14, 17, and 18, the code is described as the "DSSS code." '802 patent, 3:29-37; 3:47-54. Referencing Figures 13, 14, 17, and 18, the specification uses the term PN code in relation to the referenced DSSS codes. The specification also states that "[i]n this patent, we introduce new codes, which we refer to as 'MC' codes," and then generally describes some advantages of using the "MC codes." '802 patent, 2:15-33. Figure 3 "is a schematic showing of the ith MC code c(i)." '802 patent, 2:54-55. The specification further states that Figure 3 "illustartes the code generator of the MC codes." '802 patent, 2:29-34. Figures 4 and 5 describe an alternate transmitter and receiver "using MC codes generated in Figure 3." '802 patent, 2:58-67. The specification further confirms that the transmitter and receiver illustrated in Figures 4 and 5 use the "MC codes" generated using the code generator in Figure 3. '802 patent, 4:35-46. Thus, the Court finds that the specification and the claims provide for various kinds of "codes."

Defendants have provided ample evidence in the form of dictionary definitions, treatises, and expert opinion that the term "direct sequence spread spectrum code" had a well-known meaning at the time the application leading to the '802 patent was filed. The Court finds that one of ordinary skill in the art would consider that the codes used in a DSSS system would have noise-like properties or would be a pseudo-random code sequence. Further, as part of its intrinsic record the '802 patent cites an authoritative text, the Proakis reference, that explains that pseudo-random or pseudo-noise sequences are basic elements of spread spectrum systems. '802 patent, 1:22-32. Still further, inventor Fattouche wrote an article that confirmed that "[a]ll spread spectrum techniques use a repeating pseudo-random sequence to spread the spectrum of the data signal to be
transmitted" and that the data signal is multiplied by a "pseudo-random code sequence." In light of the substantial evidence that one of ordinary skill in the art would view the term "direct sequence spread spectrum code" to be a pseudo random code or noise sequence, and when there is nothing in the specification that clearly indicates that the term direct sequence spread spectrum code should have a different meaning, the Court rejects Wi-LAN's arguments that "direct sequence spread spectrum codes" should not be pseudo-random. The Court finds that the specification's use of the term "MC codes" does not change the well-known definition of DSSS codes, particularly when the specification and claims refer to different types of codes.

The specification provides that "DSSS is a communication scheme in which information bits are spread over code bits (generally called chips)." '802 patent, 1:25-27. Both parties agree that the codes are those "over which information bits are spread." Thus, the Court construes the term "direct sequence spread spectrum codes" as "pseudo random codes over which information bits are spread."

7. Direction of at least one of said . . . thoroughfares

The next phrase in dispute in the fourth subpart of claim 1 is: "direction of at least one of said one or more thoroughfares corresponding to said current vehicle location." The dispute is over the meaning of "direction." Defendant contends that plaintiff originally agreed to define the term "direction" as "the compass heading," but that after the claims construction hearing plaintiff indicated that it did not agree to this construction. Exh. 7 at 4 n.1. Now plaintiff contends that the term "direction" requires no construction. Defendant argues that plaintiff "has waived any right to challenge this construction ["the compass heading"] by agreeing to the construction and not briefing it timely." Id. I am not persuaded by defendant's argument. Both parties' pre-hearing submissions were pretty much useless because they failed to inform the court precisely which terms were in dispute. It appeared that the parties had not met to discuss claims construction; their briefs contained only speculation as to the other party's positions, based on prior correspondence exchanged. At the claims construction hearing I ordered the parties to prepare and submit a joint list of disputed terms. That list (submitted as eight exhibits, one for each patent in dispute), dkt. # 61, is presently before the court and is the basis for this opinion. The list includes multiple disputed terms that were not presented to the court in the parties' original pre-hearing briefs. I am considering all of the terms and arguments presented in dkt. # 61, including plaintiff's position that the term "direction" requires no construction. I agree with plaintiff that the term "direction" is clear and requires no judicial construction.

3. Directly

As stated above, the multi-room controller discussed in claim 1 controls "a plurality of individual light controls, each light control adapted to control directly lighting within an associated room of partitionable space..." (emphasis added). Genlyte proposes that the Court construe "directly" to mean "independently of a central controller," where "central controller" means "a single hub from which all commands exclusively come." Lutron argues that no construction is necessary.

Genlyte and Lutron agree that "directly" refers to the ability of an individual light control to control the light intensity in the room where the individual control is located without the need of the multi-room controller. Both parties acknowledge the patent history of the '731 patent, which states that "applicants' apparatus has many individual controllers that each acts independently to directly control its own lighting until linked via the multi-room controller." See September 25, 1987 Amendment (emphasis in original).

Citing the dictionary definition of "directly," which reads "without divergence from the source," Lutron argues that "no construction of the term is needed, as the meaning of the word 'directly' in the claims is no different from the commonly understood meaning of the word." Genlyte argues that "if 'directly' merely had its 'commonly understood meaning,' then the reason for adding the limitations 'directly' and 'indirectly' to the claims and the arguments that the applicants made to the U.S. PTO in connection with adding those limitations to the claims would be rendered meaningless."
Ultimately, both parties agree that "directly" means "independent of a central controller," an important distinction which distinguished the '731 patent from the prior art of U.S. Patent Number 4,489,385, also known as the "Miller" patent. This distinction is part of the intrinsic evidence, and shows the special meaning which the applicants intended to use through the word "directly." Therefore, "directly" is construed to mean "independently of a central controller."

3. "directly"

The parties dispute the ordinary meaning of the word "directly." Claim 1 of the '602 patent states in pertinent part: "means . . . for applying the V[pp] supply voltage level directly to the word line through the source-drain circuit of an FET." '620 patent, claim 1 (emphasis added). Defendants argue that "directly" means that the FET must apply the voltage to the word line without any intervening circuitry. MOSAID argues that "directly" does not exclude intervening circuitry as long as the voltage level does not change between the FET and the word line.

The Court begins its analysis by looking to the language of the claims. The claim language is clear on its face that a voltage level is applied directly through a FET to the word line. Based on that clear language, the word "directly" and its context demonstrate that there simply is no room for intervening circuitry. MOSAID's construction would not only read the word "directly" out of the claim, but the words "to" and "through" as well. As a result, the ordinary meaning of "directly" is "without intervening circuitry."

The dictionary definitions submitted by the parties support that ordinary meaning of the claim term. The definition of "directly" is "in a direct way or line; straight . . . without a person or thing coming between; immediately." Webster's New World Dict. 399 (2d ed. 1980). Two other dictionary definitions of "directly" were also provided by the parties:

1a: without any intervening space or time: next in order:
SQUARELY, EXACTLY

2c: without divergence from the source of the original

Webster's Third New Int'l Dict. 641 (1986). Defendants contend that all three of the definitions support an ordinary meaning of "a direct line . . . without anything or anyone intervening." MOSAID does not address the first two definitions. Instead, MOSAID asserts that the ordinary meaning of "directly" is definition 2c above - "without divergence from the source of the original."

The Court agrees with Defendants and finds that the ordinary meaning does not allow for any intervening circuitry. Even if the Court adopted definition 2c above as the ordinary meaning, it still would not change the plain meaning of the claim. "Without divergence from the source of the original" connotes a straight line between two points without branching off on a different course. MOSAID's interpretation of that definition would effectively require this Court to rewrite the term "directly" as "without changing the voltage level." Although the patentee could have acted as her own lexicographer, she did not. It is not the Court's obligation to rewrite the claims to reflect what the patentee may have been able to claim, but to ascertain the ordinary meaning of the claim language she did in fact use.

The intrinsic evidence does not alter the ordinary meaning of "directly." During prosecution of the '602 patent application, the patentee added the word "directly" to distinguish the Lines invention from a prior art reference that included a capacitor between the pass transistor and the word line. The patentee explained the purpose of adding the word "directly" by stating:

In order to distinguish even more clearly, applicant has added the word "directly" in line 14 of claim 1, thus specifying even more clearly that the voltage supply level is applied "directly" to the word line through the source drain circuit of an FET.
The applicant claims in claim 7, and in all of the other claims, an invention which provides a word line voltage that does not include a capacitor type bootstrap circuit and applies that voltage directly from a power supply. Appl. No. 07/680,746, 2/13/92 Response to PTO Action at pp. 11, 15.

MOSAID claims that those remarks were an attempt to distinguish a prior art reference that used circuitry to boost the supply voltage before it was applied to the word line. Thus, according to MOSAID, the word "directly" was added to emphasize that the voltage level being applied to the word line remains unchanged from the voltage level leaving the FET.

MOSAID's position is unconvincing. Those remarks were made to distinguish the Lines invention from a reference that had a circuit between the pass transistor and the word line. The patentee clarified that the word "directly" was added to demonstrate that there was no intervening circuitry, such as a capacitor, between the pass transistor and the word line. This is evident from another remark made by the patentee earlier in that same response:

Contrast this with applicant's invention as shown in Figure 1. The voltage to be applied to the word line is received from a power supply at a desired voltage \( V_{pp} \) directly through transistor 14A. The word line is switched between ground and \( V_{pp} \) by means of transistors 13A and 14A. There is no slow-charging bootstrap circuit required. There is no capacitor connected to the word line which must be charged to provide the word line voltage in a bootstrap circuit, and as shown in both Figures 2 and 3 of Tran. Appl. No. 07/680,746, 2/13/92 Response to PTO Action at p. 10 (emphasis added, underline in original).

Accordingly, "directly" means "without any intervening circuitry."

B. Directly

The term "directly" appears in Claim 1 of the '192 Patent. Digi maintains that "directly" should be defined as "providing the only link between the device control circuitry and the client machine, requiring no intermediate devices or application-specific processing. In other words, allowing the client machine to interface with the device control circuitry of the device without any additional intermediating device or entity." Lantronix, on the other hand, contends that "directly interfacing" should be construed as "the module can interface the device's control circuitry to a computer network without the need of additional hardware components."

The term "directly" was added to the preamble of Claim 1 during the prosecution of the '192 Patent along with the following explanation:

Claim 1 is amended, without prejudice and without adding new matter, to more specifically point out the scope of the invention of the present application. "Directly" has been added to the preamble to more specifically point out the fact that the module directly interfaces (without intermediate devices) the device control circuitry of a device and a client machine.

(Reply to Office Action at 7.) In addition, in an attempt to distinguish prior art, the Reply to Office Action stated:

In the present application the single module is the only link between a remote device and the Internet. In addition, the module of the present application is also the only and direct interface between device control circuitry of a device and a client machine with its own programming interface through an API.

(Id. at 6 (emphasis in original).)

The specification states:

Because this single chip is the only link between the remote device and the Internet, it provides an extremely simple and inexpensive solution to remote monitoring and control. The simplicity of this direct interface has the additionally important benefit that the number of possible points of failure between the device and the network is minimized. Prior art solutions, in contrast, typically have multiple intermediary devices, such as gateway servers in combination with device hardware.
Moreover, the specification states:

the architecture of the present invention links the remote device/equipment 34 to the high performance network 32 without any expensive intermediary server machine.

(Id. at c. 5, 11: 1-4.)

The Court agrees that this language supports a definition of "directly" to mean that the module provides the only link between the device control circuitry and the client machine without the need of additional intermediate devices. Consistent with the Court's discussion of Digi's proposed construction of the term "autonomous," the Court finds no support for Digi's assertion that the module requires no application-specific processing. As a result, the Court construes the term "directly" as "the module interfaces or links the device control circuitry of a device to a client machine without the need of intermediate devices."

B. "directly"

The differences between the parties' proposed claim interpretations are as follows:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Emergis's Construction</th>
<th>Cable One's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;directly&quot;</td>
<td>the customer communicates payment instructions to the invoicer without reliance upon a third party acting provider independently from the invoicer</td>
<td>the customer communicates payment instructions to the invoicer without reliance upon or through a third party service provider</td>
</tr>
</tbody>
</table>

The parties dispute the term "directly," a term that appears initially in Claim 1 and throughout the other claims. Emergis contends that the term includes an invoicer's use of a third party service provider, like Crescent Systems, because such third party does not act "independently" from the invoicer. Conversely, Cable One argues that the term precludes any third party from assisting the invoicer or the customer where the customer communicates payment instructions to the invoicer. In support of their construction, the parties point the Court to the claim language, the specification, and the prosecution history. As explained below, because these three sources support Cable One's proposed construction, the Court construes "directly" as "the customer communicates payment instructions to the invoicer without reliance upon or through a third party service provider."

Claim Language

Claim 1 describes the automated billing system as "providing remote customer review of automated billing from an invoicer, wherein the customer payment instructions are sent from the customer directly to the invoicer." Cable One argues that the plain and ordinary meaning of "directly" supports its construction. "Directly" is defined in the dictionary as "without the intervention of a medium or agent; immediately; by a direct process or mode." n47 Cable One argues that the patent inventor used "directly," meaning that the invoicer uses the automated billing system without the intervention of a medium or agent.

--- Footnotes ---

n47 OXFORD ENGLISH DICTIONARY ONLINE, Def. no. 5 (2d ed. 1989).

--- End Footnotes ---
Emergis's proposed construction ignores the claim language and its plain meaning. Further, Emergis's proposed construction uses language that cannot be found anywhere in the claim, specification, or prosecution history. Among the intrinsic evidence, the language, "third parties acting independently from the invoicer," cannot be found. "'[T]he words of a claim are generally given their ordinary and accustomed meaning, unless it appears from the specification or the file history that they were used differently by the inventor." n48 As shown below, the specification and the prosecution history, do not support an alternative meaning to the term, "directly." Thus, the Court will construe "directly" as it is ordinarily defined, and as Cable One suggests. Because the claim language uses the term, "directly," and does not specifically exclude "third parties acting independently from the invoicer," the Court finds that the claim language supports Cable One's proposed construction.

--- Footnotes ---

Specification

Emergis contends that Cable One's definition conflicts with the inventor's preferred embodiment, and that this preferred embodiment is supported by the specification. At the hearing, Emergis described the history of EIPP technology leading up to Mr. Neely's invention of the '362 patent. Mr. Neely ("the inventor") developed the '362 patent in light of prior art, known as the Electronic Consolidator Model. Under this system, a third party service provider presents an invoice to a customer on behalf of a business. The customer then directs payment from an account to the third party service provider. Emergis contends that businesses did not like this system because it allows a third party to insert itself into the relationship between the business and the customer. This Electronic Consolidator Model is disclosed in the specification as Figure 1:

In the '362 patent, the inventor disclosed United States Patent Number 5,465,206, invented by James J. Hilt ("the Hilt reference," n49 as an early example of a consolidator model. In the system described by the Hilt reference, participating customers can pay bills to participating invoicers via an existing payment network, such as a bank. The payment network coordinates the exchange of data and information between banks or other service providers acting on behalf of each participating customer and invoicer. Under this system, an invoicer sends the customer a bill that specifies payment amounts, due dates, account number, or other invoicer reference numbers. Afterwards, customers initiate payment transactions to their banks or other service providers identifying the invoicers to whom payment should be sent, payment account information, payment amounts, and payment dates for each bill to be paid. Unlike the system disclosed in the '362 patent, customers do not transmit their payment instructions to invoicers or other entities acting specifically on behalf of invoicers. Hilt described his invention as: "Customers and billers participate in the bill pay system, but they need not deal with the many consumers or billers directly. Instead, they need only deal with their bank, or other participating financial institution." n50

n50 (Doc. 61, Ex. 2 at 12:47-50.)

--- End Footnotes ---

[SEE FIGURE 1 IN ORIGINAL]

In the language of the specification, the inventor contrasted his invention with these consolidator models. The inventor explained the need for his system because systems using third party service providers to receive and transmit payment instructions between invoicers and customers added "a great deal of complexity and no small amount of expense to the process." n51 The inventor stated: "Thus, there exists a need for a simple, straight forward system and method of automated electronic invoicing and payment that directly involves the invoicer and the customer while, at the same time, does not
require a third party service provider. . ." n52 The inventor referred to the system as described in Figure 1 as "cumbersome and time/labor intensive." n53

n51 (1:31-32.)
n52 (1:53-57) (emphasis added).
n53 (4:18-19.)

The inventor also distinguished his invention from another patented invention issued to Anderson ("Anderson patent"). n54 In the Anderson patent, n55 the inventor stated that his invention could be used by third party bill payment services to collect payment from customers on behalf of product and service providers. n56 Cable One contends that since the '362 patent inventor distinguished his invention from the Anderson patent, the '362 patent does not include a claim to a system where a third party service provider acts on behalf of an invoicer to collect payment from customers.

n54 (1:32-38.)
n55 (Doc. 62, Ex. C.)
n56 (Id. at 4:53-65.)

With the disclaimers of the Hilt reference and the Anderson patent, the inventor of the '362 patent created an EIPP system that allowed invoicers to deal directly with customers. His system is shown in Figure 2:

[SEE FIGURE 2 IN ORIGINAL]

While this system in the '362 patent omits the use of a third party service provider, Emergis contends that the language of the specification shows that the inventor allowed for outsourcing of certain functions of this system. The specification reads: "[A]n invoicer may choose to outsource webserver hosting or webserver and remittance processing to an outside company on behalf of the invoicer." n57 Thus, Emergis argues that when an invoicer outsources the EIPP services, payment transactions are processed by and through a vendor of the invoicer, who was selected by that invoicer rather than the customer, and who stands in the shoes of the invoicer for purposes of the EIPP transactions. Emergis argues that when this transaction occurs, the customer is interacting "directly" with the invoicer. Cable One refutes this argument by claiming that Emergis is reading this part of the specification out of context, and this text refers to outsourcing the information-technology function of hosting a webserver, not any arrangement where the customer transmits payment instructions to third party service providers. The language of the specification does not refer to the outsourcing of payment instructions. If the language did refer to such a system, a third party would be introduced, and the system in the '362 patent would function much like the consolidator systems that the inventor of the '362 patent disclaimed. Thus, the Court agrees that while the specification allows for the outsourcing of certain functions of the EIPP system, the specification does not envision the outsourcing of the receipt of payment instructions.

n57 (8:31-35.)
As another example, Emergis notes that the specification reads: "In another embodiment, the electronic consumer authorization interface is a digital computer with the billing data and the payment request instructions presented by e-mail to the customer with an email reply for relaying customer payment instructions to the invoice presentation electronics." n58 Emergis argues that Cable One's construction would exclude this EIPP system from the invention when a third party email service provider is involved. However, the specification does not refer to the outsourcing of the email function as it would occur in the above-mentioned embodiment. The specification only speaks to outsourcing webserver hosting or webserver and remittance processing. Thus, this portion of the specification does not support Emergis's construction.

n58 (6:8-13.)

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

Finally, Emergis also claims that its construction of "directly" is the preferred embodiment of the claim in that it includes a third party vended system. The inventor of the '362 patent was the founder and president of InvoiceLink, a third party provider of vended EIPP services to various invoicers in several industries. Thus, Emergis argues that the inventor's use of the patent was the preferred embodiment of the claim. However, such evidence is extrinsic evidence, and the Court may not rely on this evidence to contradict the meaning of claims discernible from the intrinsic evidence. n59 Emergis argues that claim interpretation that causes the preferred embodiment to fall outside of the patent claim is "rarely, if ever, correct and would require highly persuasive evidentiary support, which is wholly absent in this case." n60 However, the Court can distinguish Vitronics from this case. In Vitronics, the court refused to accept the proposed claim construction when it would exclude the only embodiment in the claim. n61 In this case, the '362 patent discloses other embodiments, such as a system in which the invoicer operates the EIPP system on its own. Thus, unlike Vitronics, an exclusion of this embodiment would still allow coverage of other embodiments. Thus, the Court finds that the specification history supports Cable One's proposed construction for the term, "directly."

Prosecution History

In the original application for the '362 patent, the inventor's claims did not include the term, "directly." The inventor added this term after his first application was rejected by the Examiner as unpatentable over the Hilt reference. In response to the First Office Action, rejecting the inventor's patent application, the inventor interviewed with the patent examiner on January 25, 1999. During this meeting, the parties agreed that the pending claims should be amended "to reflect that customer is directly communicating the invoice related matter with the invoicer." n62 On February 12, 1999, the inventor filed an amendment, incorporating this agreement. Each of the independent claims of the application was amended to require that customer payment instructions be transmitted "directly" to its invoicer. n63 In this amendment, the inventor explained:

Consistent with the above interview, the independent claims have been amended to recite that the customer directly communicates the invoice related matter to the invoicer. As discussed during the interview, unlike the prior art of record, the present invention eliminates the problems associated with using a third party service provider. n64

The above language supports Cable One's proposed construction in that the inventor, by adding the term, "directly," disclaimed all third party systems, not just third party service providers acting on behalf of customers.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
In the Second Office Action, the Examiner again rejected all of claims as being obvious over the Hilt reference, finding that the inventor's amendment and accompanying arguments were "not persuasive." n65 Referring to the Hilt reference, the Examiner found that it would have been obvious to one of ordinary skill in the art to modify the disclosed invention of Hilt to provide for direct communication from customers to invoicers, because such direct communications would be preferred by customers, would be more convenient and faster, and would eliminate the need for intervention by third parties. n66

In response to the Final Office Action, the inventor again amended his application and distinguished the claimed inventions from the Hilt reference. Discussing the addition of the term, "directly," the inventor reminded the Examiner that the claims require direct communication of invoice-related matter to the invoicer, and for that reason, "unlike the [consolidation model of the Hilt reference], the present invention eliminates the problems associated with using a third party service provider." n67

In an Advisory Action, the Examiner acknowledged that the inventor had previously argued that the present invention required direct communication from a customer to an invoicer, but that he had failed to submit appropriate amendments regarding that limitation. n68 Without such limitation, the Examiner would not allow the claims. Afterwards, the applicant submitted supplemental amendments to all independent claims to include the "directly" language in the claims. n69 Based on these amendments, the Examiner issued a Notice of Allowability for all pending claims, and the '362 patent was issued on March 28, 2000.

Emergis contends that these amendments and arguments were made solely for the purposes of more clearly distinguishing the prior art--a system in which a customer might initiate payment transactions to several invoicers via a customer-selected third-party service provider such as the customer's bank. Emergis contrasts the system in the '362 patent because it requires that customers communicate "directly" with the invoicer for purposes of receiving and reviewing invoice information,
for initiating appropriate payment transactions. Emergis contends that the ‘362 patent does not preclude an invoicer's use of a third-party vendor to operate an EIPP system on behalf of that invoicer. In fact, Emergis argues that the patent specifically contemplates that this is the preferred way to practice the invention. Thus, Emergis argues, to the extent the relationship between the invoicer and its third-party EIPP vendor is more or less transparent to the customers of the invoicer, such a facility clearly falls within the scope of the claims.

However, the prosecution history fails to support Emergis's arguments. There is nothing in the prosecution history that states when a third-party EIPP vendor is transparent to the customer, such a system falls within the scope of the claim. The inventor inserted the term, "directly," in order to gain patent approval by the Examiner. Throughout the prosecution history, there is no clarification by the inventor that the term, "directly," should be construed as "without reliance upon a third party acting independently from the invoicer." Instead, when the inventor added the term, "directly," the Examiner approved this amendment and provided the following statement for his reasons: "[t]he prior art does not teach or suggest: . . . transmitting said instruction directly to the invoicer. . . ." n70 After the Examiner made this statement, the inventor made no further amendments nor did he seek to clarify the Examiner's statement to ensure that invoicers acting "without reliance upon a third party acting independently from the invoicer" were included within the scope of the claim. n71 Because the prosecution history shows that the claims were approved with the understanding that no third parties were involved in this process, Cable One's proposed construction of "directly" is the more appropriate construction.

n70 (Doc. 62, Ex. 1 at 4.)

n71 See Chef America, Inc. v. Lamb-Weston, Inc., 358 F.3d 1371, 1375 (Fed. Cir. 2004) (declining to "rewrite unambiguous patent claim language" when "[t]he patentee made no attempt to have such an error corrected, either by obtaining a certificate of correction from the Patent and Trademark Office pursuant to 35 U.S.C. § 255, or by action of the district court.") (citation omitted).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The Court notes Emergis's argument that its construction of "directly" is more appropriate because it is the same definition used by Cable One in its automated billing system. Emergis points the Court to Cable One's website, which tells customers: "Your payment goes directly from your bank to Cable One." Although Crescent Systems is involved in this process, Emergis argues that even Cable One uses the term, "directly" to describe this EIPP system. However, this evidence is extrinsic evidence that the Court may not rely on "to contradict the meaning of claims discernible from thoughtful examination of the claims, the written description, and the prosecution history--the intrinsic evidence." n72 Because the intrinsic evidence supports Cable One's proposed construction, the Court will not look to such extrinsic evidence to contradict the meaning of this term.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Disclaimer of Subject Matter

Emergis also contends that by including the "directly" language, the inventor never disclaimed the use of a third-party vendor by an invoicer to maintain an EIPP system on behalf of the invoicer. ""[W]here the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender."" n73 But Emergis contends that it did not unequivocally disclaim the use of a third-party vendor. However, there is nothing the prosecution history to support this limited disclaimer with the addition of the term, "directly." The inventor could have made a statement during the prosecution that the "directly" amendments were meant only to exclude "third party service providers acting independently from the invoicer," rather than any third party vendor. But no such statement was made. The Federal Circuit has found that:
it frequently happens that patentees surrender more through amendment than may have been absolutely necessary to avoid particular prior art. In such cases, we have held the patentees to the scope of what they ultimately claim, and we have not allowed them to assert that claims should be interpreted as if they had surrendered only what they had to. n74

n73 Liquid Dynamics Corp. v. Vaughan Co., 355 F.3d 1361, 1368 (Fed. Cir. 2004) (quoting Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003)).

n74 Norian Corp. v. Stryker Corp., 432 F.3d 1356, 1362 (Fed. Cir. 2005).

In this case, the inventor amended the claims to include the term, "directly," and thereby disclaimed the use of third parties in this invention. Because the inventor did not clarify that the term, "directly," should be construed as Emergis suggests, there is no support in the prosecution history for such a construction. The Court finds that Cable One's proposed construction is supported by the prosecution history, as well as the claim language and the specification. Therefore, the Court will construe the term, "directly," as "the customer communicates payment instructions to the invoicer without reliance upon or through a third party service provider."
In light of the prosecution history as a whole, it would be inappropriate to construe the term "directly" in the way proposed by Defendants. Furthermore, although the drawing in the '121 patent does not show any circuitry between the two memory components (see '121 patent), I will not limit the meaning of the term "directly" based on the embodiment depicted in a single block diagram. See, e.g., Beckson Marine, Inc. v. NFM, Inc., 292 F.3d 718, 724 (Fed. Cir. 2002) (holding that, in light of other language in the written description, the figures depicting a single preferred embodiment will not be construed as limiting the claim terms). The statements made by the applicant during prosecution indicate that "directly" was intended to mean the transfer of data without intervening size reduction or, by logical extension, other similar processing. (D.I. 346 at 17.) Therefore, I will construe the term "directly" to mean "the transfer of data without intervening processing."

3. "directly accessing" (claims 1 and 6)

The plaintiff asks the court to construe this term to mean "communicating with the flash memory storage module using USB or IEEE 1394 bus protocol without a communication protocol conversion" while the defendant proposes to define the term to mean "accessing the physical addresses of the flash memory without a format conversion." The parties' central dispute regarding this term is whether it requires a format conversion.

"Directly accessing" is not defined in the specification. The parties rely on the prosecution history concerning United States Patent No. 6,199,122 (the "Kobayashi Patent") to support their arguments.

The Kobayashi Patent discloses a connection between the USB port and a memory card operating via the ATA standard. Kobayashi required an ATA controller for communicating with the memory card and required a conversion controller for translating between the USB and the ATA formats. The patent examiner cited the Kobayashi Patent in a January 2003 office action. The '672 applicants argued to the examiner that the '672 patent directly accessed the memory module from the USB port without the standard/protocol conversion that the Kobayashi Patent required. See April 2003 Amendment; September 2003 Amendment; October 2003 Amendment. "Direct access" was addressed with the examiner within the framework of a conversion from USB-ATA standard/protocol conversion. In fact, the prosecution history passages cited by the defendant make this point clear:

One of the functions of the external storage device [in Kobayashi] is as a conversion device for providing a conversion operation between the data format of a computer interface (USB) and that of a removable storage card (ATA). . . That means, a data conversion step and a connector based on ATA standards are necessary for accessing data in the removable storage card [of Kobayashi].

In the present invention . . . [t]he data or information access operation to the flash memory storage module of the external storage device is implemented directly based on the USB or IEEE 1394 standards, i.e., the conversion step contain [sic] in Kobayashi's patent is not necessary for accessing data in the flash memory storage module of the external storage device claimed in claim 34.

Moreover, no directly accessing data in the flash memory is disclosed in Kobayashi. In Kobayashi, any data access must go through USB/ATA data conversion. . . while the claimed invention provides that users can directly access data in the flash memory from host computer without any data format conversion since the data exchange channel [is] based on one standard either USB or IEEE 1394. . .[T]hus, upon plugging in, the flash memory can be directly accessed from the host computer."

September 2003 Amendment

The '672 applicants further distinguished their application from the Kobayashi Patent using the following language:
[Kobayashi] is used for converting a command of USB specification sent from a USB interface of the computer into a command of ATA specification

April 2003 Amendment

[In Kobayashi there is a conversion operation between the data format of a computer interface (USB) and that of a removable storage card (ATA) . . . converting a command of USB specifications]

September 2003 Amendment

In Kobayashi, any data access must go through USB/ATA data conversion while the claimed invention provides that users can directly access data in the flash memory from host computer without any data format conversion since the data exchange channel [is] based on one standard either USB or IEEE 1394

October 2003 Amendment

The defendant correctly notes that the patentee chose to use the words "without any data format conversion" in the prosecution history. But that statement must be placed in context and viewed in light of all relevant portions of the intrinsic record. Another passage from the September 2003 Amendment provides guidance:

The data or information access operation to the flash memory module of the external storage device is implemented directly based on the USB or IEEE 1394 standards, i.e., the data conversion step contained in Kobayashi's patent is not necessary for accessing data in the flash memory storage module of the external storage device claimed in claim 34.

September 2003 Amendment

The prosecution history shows that the '672 applicants waived/disclaimed the conversion from the ATA protocol to the USB or IEEE 1394 Protocol to overcome the Kobayashi Patent.

The specification also supports the plaintiff's construction. At col. 4, ll. 27-30, in describing the preferred embodiment, the specification states that the storage method includes firmware that resides in the flash memory external device and directly controls the access of flash memory. See also col. 3, ll. 26-35. A user could not practice the claimed method on the preferred embodiment using the defendant's proposed construction because some format conversion must occur to access the flash memory storage device by implementing and processing the requests issued by users as claim 1 requires.

The court defines "directly accessing" to mean "communicating with the flash memory storage module using USB or IEEE1394 bus protocol without a communication protocol conversion such as a USB to ATA conversion."

(i) "directly connected"

The parties also contest the construction of "directly connected." Premier asserts that "directly connected" means "joined by a single wire without deviation." (Def. Opp. Mot. Prelim. Injun. at 11.) Advanced contends that Premier's reading of that term is too narrow. As discussed, there is a hierarchy to the evidence to be considered in claim construction: the claim language first, then the patent specification and finally the file history. Vitronics, 90 F.3d at 1582-85. Based upon the claim's language, the specification and the prosecution history, the court construes the term "directly connected" to mean connected by non-switched connections not involving a local area network or wide area network.

The plain language of the claim supports this understanding of "directly connected." The relevant portion of element (c) reads: "preview station means, said preview station interface means separate from and directly connected to said data control means and said at least two preview stations by non-switched connections not involving a local area network or wide area network." (Helget Aff., Ex. A, Col. 8, Ins. 25-31.) The patent language itself therefore defines the term "directly
connected" to mean connected "by non-switched connections not involving a local area network or wide area network."

The specification also supports that definition of "directly connected." The specification language emphasizes that the term is used to distinguish the claim from an implementation which would use a preview station microcontroller to process the video data. The specification provides: "The video display 80 does not transfer data or information through the preview station microcontroller 26 but rather is directly connected to a video display interface means 82 through a high gauge wire 83 having RC connectors at either end." (Helget Aff., Ex. A, Col. 5, Ln. 65- Col 6 Ln 2.) The specification does not state that "directly connected" means only connected by a single wire, as Premier asserts. Such an understanding would erroneously read the limitations of a particular embodiment into the claim language. Instead, the specification provides that "the present invention may be embodied in other specific forms without departing from the spirit of the essential attributes thereof…." (Helget Aff., Ex. A, Col. 8, Lns. 6-12.)

Moreover, the prosecution history supports the court's construction of "directly connected" and undermines Premier's construction. During prosecution, Advanced argued that "direct connections do not involve switching software and hardware like a local area network." (Tolliver Decl., Ex. K at 3.) Although "directly connected" was added during prosecution, the words were added to distinguish this patent from a prior art that showed a LAN between the display device and the server. (Tolliver Decl., Ex. I at 10, 12; K at 2-5.) The words were not added to narrow claim 1 to a single wire implementation.

1356

12. Directly Connected

A connection that runs from the driver IC directly, without any intervening connections, to the center memory chip in the chip clusters on the memory module.

1357

C. "For directly controlling a recording device"

We next turn to the phrase "for directly controlling a recording device." In construing this phrase, the district court reasoned that the purpose of the present invention was to provide a commercially viable system by use of a "small nonvolatile memory" to turn on or control the recording device. SuperGuide Corp., 169 F. Supp. 2d at 525. The district court therefore construed this phrase as meaning that "the event timer sequences [stored in the nonvolatile memory of an event timer] are used to turn on or control the recording device; however, only the [sic] those sequences are so used and stored." Id. at 529-30.

According to Gemstar, the disputed phrase means that the "event timer information sequences stored in an event timer are used to provide the information and generate the signals that are necessary to control a recording device." Thus, Gemstar maintains that the court's construction, as modified by its summary judgment ruling, erroneously interpreted the instant phrase as excluding electronic signals generated by the "event timer information sequences" to control the recording device, including infrared signals. Gemstar also contends that the asserted claim does not require that recording be "directly controlled" from non-volatile memory.

Agreeing with the district court's construction, Thomson argues that "directly controlling" means that the event timer information sequences, not the program schedule information, control the recording device. Thomson further contends that the event timer information sequences control recording completely independent from the program schedule information after the "event timer" is loaded. Accepting that there is no generally accepted meaning in the art for the phrase "directly controlling," Thomson maintains that the specification and prosecution history show that the '357 patentee used "directly controlling" to mean that only event timer information sequences are used to control the recording device. In addition, Thomson asserts that Gemstar agreed before the district court that "no additional schedule information from the stored television program schedule information beyond that loaded into the event timer is used to control the recording device."
Lastly, in response to Gemstar's argument, Thomson asserts that nothing in the court's construction excludes the use of infrared activation signals in the process of "directly controlling"; it only excludes the use of program guide information to control recording.

The phrase "directly controlling" does not have an accepted meaning in the art and we therefore look to the specification for the necessary guidance in interpreting this phrase. The asserted claim requires that recording be "directly controlled" from the nonvolatile event timer memory rather than the schedule listings contained in volatile memory. Indeed, this is the purpose of the '357 patent. The specification teaches that the claimed system does not control the recording device directly from the schedule information. '357 patent, col. 3, ll. 39-41. Rather, this information is used to load an event timer with "event timer information." Id. at col. 3, ll. 41-43. "The event timer then controls the [recording device]." Id. at col. 3, l. 43.

In order to maintain unattended control of recording by the VCR after a power interruption, only the event timer need be made of nonvolatile memory. See Id. at col. 3, ll. 58-60. The specification further explains that because the event timer only requires time and channel information for a limited number of events, the nonvolatile memory can be small and thus not prohibitively expensive. Id. at col. 3, ll. 60-65.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

18 We note that Thomson agrees that the disputed phrase does not exclude the use of activation signals, such as infrared signals, to control recording. Thomson does argue that this construction was not a basis for the court's non-infringement finding. Because we are remanding this case for further proceedings, we do not find it necessary to resolve this factual dispute.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

In addition, although the event timer must control the recording device, the claim does not exclude the event timer from referring back to or accessing the schedule information before recording occurs. The patent emphasizes that the "VCR event timer information exists independent of the information in the TV schedule listings." Id. at col. 6, ll. 18-20 (emphasis added). Thus, the ability to record the designated program is not lost if the TV schedule listings are lost or discarded. Id. at col. 6, ll. 8-18. Further, if the TV schedule listings are updated, the event timer information sequences are not automatically updated and may not reflect the updated schedule listings. Id. at col. 6, ll. 13-17. The patent does not, however, exclude the event timer from referring back to or accessing the stored schedule information before controlling the recording device, e.g., to update the event timer information sequences. The claim only requires that the VCR control information exist independently of the program listing information and that at the time of recording "the event timer . . . controls the [recording device]." Id. at col. 3, l. 43.

Nothing in the prosecution history dissuades us from this construction. Thomson notes that the '357 patentee distinguished Kinghorn during prosecution because it did not describe television schedule listings which are free of information for directly controlling a recording device. This distinction only confirms that in the claimed invention the VCR control information exists independently from the program listing information.

Accordingly, we adopt Gemstar's definition of "for directly controlling a recording device" as meaning that the "event timer information sequences stored in an event timer are used to provide the information and generate the signals that are necessary to control a recording device." The district court's construction is modified to the extent discussed above.

XIV. "directly correlating" -- '638 patent claim 37

Lexar's proposed constr: Toshiba's proposed construction: Pretec's proposed construction:
without any a logical address assigned to a linking, in one
intermediate single block containing superseded data map, without any
mapping or must be directly associated with the intermediate
Calculation physical address of the block containing the corresponding
calculation
updated data in one map, without any intermediate mapping or calculation, where the map is not uniquely addressable by the logical address.

Lexar first suggests that this term need not be construed. In the alternative, Lexar proposes the simple construction "without any intermediate mapping or calculation." Pretec, citing the '638 prosecution history, proposes a similar construction but with two additional limitations: first, to include the word "linking" and second, that the linking occur "in one map." The Court addresses "linking" first. Lexar's proposed construction does not provide an explanation of the word "correlating" (presumably because it finds the term needs no additional construction). To substitute Lexar's proposed construction into claim 37 would make it incomprehensible. "Linking" should therefore be included in the construction of "directly correlating."

With respect to Pretec's proposed "in one map" limitation, Lexar argues that the Examiner said nothing in the Office Action (wherein "directly" was added to claim 37 reciting the step of "correlating a logical address assigned to a block of superseded data to a physical address of a corresponding block of updated data") that would require direct correlation to occur in one map. The Court agrees. The amendment to claim 37, adding "directly," distinguished the prior art of Ban and Wells because that prior art required an intermediate mapping step. Adding "directly" satisfied the Examiner that the intermediate mapping step was unnecessary in the patentee's invention and thereby distinguished from the prior art. The Examiner explained that "[w]ith directly correlating, no intermediate address mapping or table walking is required . . . which contrasts with the teachings of Ban and Wells et al." ('638 file history, paper 12 at 3-4.) Neither the Examiner nor the patentee suggested that the direct correlation occur in one map and that that feature is what sets the patentee's invention apart from prior art. The mere fact that there is no intermediate step is what makes this patented invention different. The Court rejects Pretec's proposed "in one map" limitation.

Toshiba proposes a complex 47-word construction for "directly correlating." Pretec does not address Toshiba's construction at all and Lexar only addresses it in its Opening Brief. There, Lexar disagrees with Toshiba's construction but only on the grounds that the construction is too long and includes restrictions and requirements that are not present in the claim. Toshiba contends that its construction is the proper because the specification and prosecution history in an unrelated patent, the '313 patent, distinguished the '638 patent by explaining that the '638 "includes a programmable map" and "does not disclose a correlation map that is addressable by logical block addresses." Toshiba's reliance here on a wholly unrelated patent and its file history is misplaced and the Court finds that the '313 patent does not limit the construction of this term. The '638 patent claim language and its own prosecution history explain adequately that the proper construction of "directly correlating" here is as follows: linking without any intermediate mapping or calculation.

5) "Directly Coupled"

MKS contends that the term "directly coupled" in method claim 31 means "coupled via a relatively simple pathway versus a complex pathway; without undue complication of the circuit, in a non-circuituous pathway." (D.I. 103 at 33). Advanced Energy contends that the term means "connection with no circuitry or components between the switches and the primary winding." (D.I. 110 at 25).

In construing the term "directly coupled" the Court has reviewed the specification and the prosecution history. (See D.I. 111, A9 col. 2 ln. 21-67, A10 col. 3-4, A11 col. 5 ln. 1-21). Based upon a review of these sources, the Court concludes that the specification contains neither a definition of the term, nor a suggestion that the term should be assigned a meaning other than its ordinary and accustomed meaning. Accordingly, the Court construes the ordinary and accustomed meaning of "directly coupled" to be a connection with no circuitry or components between the switches and the primary winding.
C. Claim 11: "directly from the body-worn tracking device to remote associated notification devices"

While Claim 1 describes what the invention is, Claim 11 describes what the invention does. In simple terms, the purpose of the monitoring device is to send information regarding the location of the offender wearing the device to the intended recipients, such as law enforcement and victims. The two terms of the most concern are "directly" and "remote associated notification devices."

STOP argues that Claim 11 should be construed to mean that a signal gets sent from the tracking device to the intended recipient without first going through the central database. STOP's proposed construction would also exclude the central database as a remote associated notification device. This construction, however, is inconsistent with the context of the patent as a whole.

Consideration of the prior art is especially important in construing Claim 11. As discussed in detail above, prior tracking devices were two piece designs; a body worn piece and a tracking piece either based in the home or carried by the offender. The body worn piece sent a signal to the tracking piece, which then sent a signal to the remote associated notification devices either going through the central database or without going through the central database.

The change from the prior art to the '080 patent is the combination of the earlier two piece devices into a one piece all body-worn device. The pathway of the signal has only changed in that the signal in the '080 patent is sent from the body-worn device to remote associated devices, including the central database, without going through a second carried tracking piece. In this context, it becomes clear that "directly" means without passing through a second piece carried by the offender.

The next question is whether the central database is a "remote associated notification device." Claim 7 of the '080 patent enumerates the group of remote associated devices. This group includes "victim devices, central database, supervisory agency, and law enforcement." '080 patent, column 9, lines 48-49. STOP argues that the central database is not a remote associated notification device because the "patent carefully avoids calling the central data base a 'notification device.'" (Dkt. 44, at p. 17)

STOP's argument is hyper-technical. In addition to the list of remote associated devices given in Claim 7, the specification also includes the central database among the list of notification devices. The specification claims the "body-worn tracking devices transmits rule violations…to the supervising agency's notification device 132,150, the law enforcement agency's notification device 132, 164, the central database system 132, 128, 148, 152, and the victim's notification device." '080 Patent at column 8, lines 17-25. This statement is the same as saying that notifications of rule violations are sent to the listed devices. The patent clearly intended for these devices to receive the notices of rule violations, which, in plain English, makes all of these devices, including the central database, notification devices. Therefore, Claim 11 is construed to mean sending signals directly from the starting point of the body-worn tracking device in a pathway with a destination of remote associated notification devices, which includes the central database.

5. Directly manipulate

Several of the disputed terms relate to the manipulation of data on the client. The term "directly manipulate" appears in the '542 patent. Seven argues that the term means "causing tasks to occur, such as querying, adding, or removing data, by commands sent to the client." Visto argues that the term means "to control without any intervening agency or step."

The specification provides guidance. The patent refers to "Remote Database APIs" and states:

These calls are used to directly manipulate the client database during a connection. When invoking Remote Database APIs from services, corresponding events will be passed back to the services that generated the call.
'542 patent, col. 8, ll. 59-62.

Seven points to this passage, as well as other portions of the specification, to argue that the proper construction of “directly manipulate” is the use of software calls or commands to perform certain actions on the client database. The court agrees with this view and holds that Visto's proposed definition does not account for the meaning of the term read in light of the specification. Accordingly, the court defines the term "directly manipulate" to mean "causing tasks to occur, such as querying, adding, or removing data, by commands sent to the client."

6. Directly manipulate the associated client database

For similar reasons as those expressed with respect to the previous term, the court construes "directly manipulate the associated client database" to mean "causing tasks to occur on a client database, such as querying, adding, or removing data from that client database, by commands sent to the client."

After holding a Markman hearing, the Court issued its Memorandum Opinion and Order on Claim Construction in which it construed six terms integral to the determination of this case and the instant motions. (doc. 270) The claims were construed as follows:

(1) "connected and connectable" -- These terms mean "directly joined to one another within the same unitary piece of equipment without any intervening equipment."

(2) "unified structure" -- Although not a claim term, the Court defines the term "unified structure" to mean "a consolidated structure with all components directly connected to one another."

(3) "bypass" -- "Bypass" means "a structure and path by which data channels completely go around and in no respect go through the TST switch."

(4) "control store" -- "A 'control store' is included within a single unified DRTST switching unit that includes a memory, processor, and operating software that determines (1) which data circulating on the network loop is to be selected and diverted to the TST switch of a given switching node; (2) how that data passes through the TST switch; (3) which data is output from the TST switch back onto the network loop; and (4) which data is to bypass the TST switch of that node."

(5) "means for measuring" -- The Court finds that this term is not capable of construction.

(6) "direction of the timing adjustment interval" -- This term means "[t]he timing adjustment control command signal is fed in a reverse direction from the data signal; that is, from a downstream digital switching unit to an upstream digital switching unit, in a direction opposite the data flow."

(Mem. Op. and Order on Claim Constr. at 30-31)

2. "Directory"

The word "Directory" is used throughout the Claims of the '531 Patent. For example, Claim One recites:
A method for entering new information on a recordable CDROM operatively connected [to] an operating system of a computer system having an updatable memory comprising:

a) opening a directory in an updatable memory, said directory being identifiable with a directory on a CDROM, said directory in the updatable memory constituting a working directory,

b) storing the data on the CDROM and updating the working directory to reflect the data on the CDROM,

c) upon completion of the data entry, copying the working directory from the updatable memory to the track on the CDROM containing the last entered data, writing a track information map, and closing the track where the data is entered, such that an operating system accessing data stored on the CDROM is routed by the working directory directly to the latest revision of such data on the CDROM, any previous versions of said data which are still present on the CDROM being transparent to the operating system.

Each party's proposed claim construction of "Directory" is as follows:

<table>
<thead>
<tr>
<th>Optima's Proposed Claim</th>
<th>Roxio's Proposed Claim</th>
</tr>
</thead>
<tbody>
<tr>
<td>Construction</td>
<td>Construction</td>
</tr>
<tr>
<td>&quot;Directory&quot;</td>
<td>A set of records containing the locations of and other information about files and other directories.</td>
</tr>
</tbody>
</table>

Roxio's proposed construction of "Directory" is derived from the "Definitions" section of the '531 Patent, which states the following:

The Recording Technique ends each track with two special data structures; a directory and a track info map. The directory on any given track occupies one or more packets and contains the cumulative location of all files and operating system information for the disc up to and including the track on which it resides.

('531 Patent, col. 3, ll. 16-21).

Optima, however, argues that this language should be ignored because the term "Directory" is well understood and "has been used for decades." (Pl.'s Opening Markman Brief, p. 11.) Rather, Optima contends, the term should be given its ordinary meaning. (Id. at p. 12.)

The Court rejects Optima's proposed construction because it finds that Optima acted as its own lexicographer when it included a definition of "Directory" in the '531 Patent. 3 The Court believes that the inclusion of the quoted language above, particularly in a section of the '531 Patent labeled "Definitions," is sufficient to provide notice of the term's intended meaning to an individual of skill in the art. 4 See In Re Paulsen, 30 F.3d at 1480. At the hearing for the instant motion, however, Optima urged the Court to consider the following language, which immediately precedes the "Definitions" section:

"The new recording technique embodying features of the invention . . . uses existing recordable CD elements in a unique way. These elements are defined in detail in various standards documentation addressing recordable CD, the primary standard referred to by the industry as the Orange Book. The definitions of several elements are summarized below and the method of using these elements in the invention are set forth.

('531 Patent, col. 2, ll. 49-57) (emphasis added.) Optima contends that this language disclaims any definition found in the next section of the patent.
Roxio's Markman Brief, p. 2. This proposed analysis is unsupported by case law, which clearly indicates that the ordinary meaning of a term will be modified if the patentee acts as its own lexicographer. Nystrom v. Trex Co., Inc., 374 F.3d 1105, 1111 (Fed. Cir. 2004) ("The ordinary and customary definition will be overcome if the patentee has acted as his or her own lexicographer in explicitly setting forth a definition of a claim term distinct from its ordinary meaning . . . ."); K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1363 (Fed. Cir. 1999).

4 This conclusion is bolstered further by noting that the word "definition" itself is defined as "The act or process of stating a precise meaning or significance; formulation of a meaning." AMERICAN HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE (4th ed) (emphasis added.)

The Court rejects Optima's argument. It may be true that some of the terms found in the "Definitions" section of the '531 Patent are defined in detail elsewhere; however, the very reason that inventors are permitted to act as lexicographers in the patent context is because the public may not be familiar with particular technical terms used, or there may not be a singular meaning for the concept that is claimed. Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998). Therefore, the Court finds, notwithstanding the precedent language that Optima acted as a lexicographer by including the "Definitions" section of the IN so doing, Optima provided notice to the public of the meaning of terms contained therein and clarified any ambiguities in definitions that may be found elsewhere.

The Court also rejects Roxio's proposed construction as inconsistent with the definition of "Directory" provided in the '531 Patent. The Court agrees with Optima that Roxio's proposed construction is too narrow because it is limited to tracking only files on the CD and does not include files that may be subsequently written onto the CD from a working directory, as described in Claims 1, 2, 5, and 6. (Pl.'s Opening Markman Brief, p. 12.)

Therefore, the Court rejects both parties' proposed constructions and finds that, since Optima acted as its own lexicographer, the language included in the '531 Patent and quoted above controls. See Voice Techs. Group v. VMC Sys., 164 F.3d 605, 613-14 (Fed. Cir. 1999) ("When the meaning of a term as used in a patent is clear, that is the meaning that must be applied in the construction of the claim . . . .").

5 The Court notes that the parties stipulated to the Court's construction of the terms "track," "directory," and "session" at the hearing for the instant motion. Pursuant to Local Rule 7-1, this stipulation is binding. C.D.Cal. L.R. 7-1 ("Stipulations will be recognized as binding . . . when made in open court . . . ."). Optima, however, now urges the Court to revisit these constructions. (Optima's Supplemental Brief, pp. 3-6.) Even if the Court disregards the stipulation, which it does not, the result is the same because the Court finds that Optima acted as a lexicographer with respect to these terms.

"When enabled," "to enable" and "disable"

For "when enabled" and "to enable," Plaintiff proposes "when activated" and "to activate," respectively. Defendants suggest "when power is supplied, i.e., when the device is turned on." On the flip side, Plaintiff argues that "disable" should be defined as "to deactivate." Defendants submit that the construction of "disable" should be "to switch off power, i.e., to turn off."

Claim 3 uses the terms "enabled," "to enable" and "disabled," but the specification includes no special definition of these terms. Plaintiff argues first that no definition is needed, and that the "plain and ordinary" meaning of the terms should suffice. As with so many patents involving electronic devices, "plain and ordinary" is not so easy to discern.

Defendants correctly argue that these terms are used in the specification in connection with a power management feature of...
the invention. At times, the described devices (the location signal generating device and the telemetry transmitter) use no power, i.e. they are turned off. When a signal is received, power is turned on, and they are able to operated. In other words, according to Defendants, the claim merely describes devices similar to a common electric lamp. When the switch is in the "on" position, the light bulb is illuminated. When in the "off" position, the bulb is dark.

LunarEye asserts that the claim language should not be so limited. LunarEye would interpret the claim to also describe devices which continuously receive power, although they might be in a "low" power condition, so that power consumption is minimized. This would be similar to the "hibernation" state observed in some computers and cell phones, which have a blank screen when not used for a certain period of time, although they are still using some power.

Defendants argue that because the specification and prosecution history do not disclose any embodiment that does not involve power being turned off and on, the claim must be so defined. See Wang Laboratories, Inc. v. America Online, Inc., 197 F.3d 1377 (Fed. Cir. 1999). Plaintiff naturally reminds the court that limitations may not be imported into the claim from the specification. See Teleflex, Inc., 299 F.3d 1313, 1327-28 (Fed. Cir. 2002)

But review of contradictory axioms is not analysis. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F3d 898, 904 (Fed. Cir. 2004). The court must determine if there is either a limitation in the claim language itself, or a clear intent to limit the claim expressed in the specification or prosecution history.

The claim simply refers to devices being "enabled" and "an enable controller" configured "to disable" devices. This could mean, as Defendants argue, that the devices have all power supply turned off. But anyone who owns a computer or a cell phone, let alone someone skilled in the art, would be aware that such devices can be in a "hibernation" or "sleep" mode, in which they receive a small amount of power.

The question then becomes whether the applicant expressed a clear intent to limit the claim scope. According to the specification, the invention's operational sequence may begin "[u]pon receipt of a page or the occurrence of another triggering action . . . ." Col. 1, L. 63-64. This does not indicate whether the device is already using some low level of power. The "method may include applying power to a GPS receiver and a cellular transmitter upon receipt of the page, and disconnecting power from the GPS receiver and the cellular telemetry transmitter upon transmission of the location of the object." Col. 2, L. 39-43. "Disconnecting power" implies that all power is shut off. But, this is just a description of one variation of the invention.

A flow chart of the power management system is provided by Figure 3 of the patent. The verbal description of the flow chart states that the "[t]he controller wakes up the GPS receiver . . . .," which then "wakes up" the cellular network transmitter. Col. 6, L. 26-28. The prosecution history contains a communication from the Patent Examiner with the following references:

"a controller 25 (enable controller) configured to wake-up (enable) the LDS . . . ."

"to put back to sleep (disable) the LDS receiver/processor . . . ."

See Independent Witness' Brief, Ex. 2, [Doc. # 84-3] p. 7. There seems to be little dispute that "enable," as used by the inventor, and as understood by the Examiner, is synonymous with "wake up." Similarly, "disable" can be used interchangeably with "put to sleep."

Together, these references indicate that "to enable" and "when enabled" (or "waking up") requires the application of power. Conversely, "to disable" (or "put to sleep"), involves the removal or reduction of power.

The question still remains: Does the claim describe only a device which receives no power until it is "enabled?" In an Office Action (Date Mailed: 07/12/01) the Examiner compared Claim 26 of Allen's application, (which later became the Claim 3 now in dispute) with language in an earlier, related, patent, U.S. Patent No. 5,777,580 (Janky) Col. 11, L. 26-40. As a basis for rejecting Claim 26 of Allen's application, the Examiner states that "Janky et. al. clearly show and disclose a vehicle location system (triggerable location-reporting apparatus)" with the same features disclosed in Allen's Claim 26. See Independent Witness Brief, DX 2 [Doc. # 84-3] p. 7 of 15.
The Examiner noted that Janky already taught an enable controller configured to "wake-up (enable)" the LDS system receiver/processor (location signal generating device) and the telemetry transmitter when it receives a trigger signal, and, inherently, to "put back to sleep (disable)" the location signal generating device and the telemetry transmitter. See DX 2, [Doc. # 84-3] p. 7 of 15. (Emphasis added)

--- Footnotes ---

n2 In Janky, an LDS is a "Location Determination System" such as GPS, GLONASS, Loran or an inertial navigation system that receives LDS signals from two or more sources. See Janky, Abstract.

--- End Footnotes ---

On the next page of the Office Action, the Examiner stated: "Janky et. al. further disclose that the GPS processor is in a 'sleeper' mode (power is not applied) until the system receives a page (column 11 lines 35-40)." (Emphasis added). Nothing in the record indicates that Allen ever tried to contradict or correct the Examiner's obvious understanding that "disable" meant "put back to sleep" and "sleeper mode" meant "power is not applied." On the other hand, whether or not power was being turned off, or merely reduced, was not the focus of the interchange between the Examiner and Allen.

The "Response To Final Office Action" states that "the enable controller in Janky does not necessarily disable the location-signal generating device and the telemetry transmitter after the telemetry transmitter transmits the location signal, as required by claim 26 [now claim 3 in the patent before the court], and Janky does not inherently include this limitation." (Emphasis in the original) [IW's Brief, EX. 4, Doc. # 84-4, p. 10 of 18]. The Response explained to the Examiner that Claim 26 [now claim3] can be distinguished from Janky because the system in Janky "may leave the system enabled" until it is "unenabled" sic by a person performing an action such as removing power, rather than by the enabler itself. In other words, Allen distinguished his patent by asserting that the controller would accomplish a task performed by a person. But there was no clear statement that the task could not be a reduction of power.

The argument that "sleep" or "sleeper mode" means "no power" could be supported by the specification's description of the power management flow chart, Figure 3.

The controller then goes back to sleep. 72 With this power management approach, significant power is being used only when position information is being transmitted over the cellular network. The rest of the time the only drain on system power is the page receiver, which has a very low power requirement . . .

Col. 6, L. 33-38. (Emphasis added). If the "only drain" is the page receiver, then the GPS and the transmitter must be using no power at all. This conclusion is supported by the following at Col. 5, L. 62-64: "When the page receiver 34 receives a page over antenna 44 that is addressed to the page receiver 34, the page receiver 34 transmits a "power-on" signal 46 to the controller 36." (Emphasis added).

The foregoing are the strongest arguments for defining "enabled" as meaning that power is supplied or "tuned on." But none is a "clear disclaimer" of other possibilities. There is no statement that the GPS the (location signal generating device) or the telemetry transmitter could not be, or would not be in a low power state. The single statement by the patent examiner about a GPS processor in a "sleeper mode (power is not applied)" referred specifically to Janky and how much power was being applied or removed was not the focus of debate. The court can not merely assume or infer a "clear disclaimer."

The claim language is broad enough to encompass an enable controller which turns the devices completely on and off, or a system in which in which at least some power is continuously applied to the devices. While only one embodiment (the preferred embodiment) is described in the specification, there is no clear statement disclaiming other embodiments or limiting the devices. The court therefore defines these terms as follows:

"Enabled" means "fully operational and performing its function."

"To enable" means "to place into a condition which is fully operational and performing its function."

"To disable" means "to place into a condition which is not fully operational and performing its function."
1. "disable request signal"

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposal</th>
<th>Defendants' Proposal</th>
<th>Claims 5, 8</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;disable request signal&quot;</td>
<td>a signal to initiate entry into a</td>
<td>a signal that requests the system to</td>
<td></td>
</tr>
<tr>
<td></td>
<td>shut-down mode</td>
<td>stop the output clock signal and that</td>
<td></td>
</tr>
<tr>
<td></td>
<td></td>
<td>starts the predetermined length of time</td>
<td></td>
</tr>
</tbody>
</table>

Saxon argues that the "disable request signal" corresponds with signal 48 of Figure 1. PL.'S BR. at 5. Defendants argue that the language of claim 5 requires that the "disable request signal" correspond with signal 48 and the SDENTR signal of Figure 1. DEF.'S BR. at 2. They point out that claim 1 describes two separate signals: a "shut-down entry request signal" which corresponds with signal 48, and a "disable activation signal" which corresponds with the SDENTR signal. Claim 5, on the other hand, only recites one signal by name—a "disable request signal." Defendants argue that because this is the only signal identified in claim 5, it must perform both of the functions of the signals identified in claim 1.

Regardless of the merits of Defendants' interpretation of claim 1, Defendants' interpretation of claim 5 is not supported by the plain language of the claim. Claim 5 recites the step of "stopping said at least one output clock signal . . . after receiving said disable request signal" wherein this signal is processed only if it satisfies a predetermined protocol requirement. In other words, claim 5 recites the steps of (1) receiving a disable request signal, (2) verifying it, and (3) stopping the output clock signal only after the disable request signal has been received and verified and a predetermined length of time has elapsed. 2 There is no requirement that the disable request signal must start the predetermined length of time. In fact, Defendants' interpretation would exclude the figure 1 embodiment, which shows a separate signal initiating the predetermined length of time after signal 48 is verified, from the scope of this claim. See Globetrotter Software, Inc., 362 F.3d at 1381 ("A claim interpretation that excludes a preferred embodiment from the scope of the claim is rarely, if ever correct."). Thus, the Court rejects Defendants' proposed construction to the extent that it requires the disable request signal to start the predetermined length of time.

--- Footnotes ---

2 At the hearing, Defendants argued that, because claim 5 requires that the predetermined length of time begin "after" the disable request signal is received, the predetermined length of time must begin immediately after the disable request signal is received. Defendants further argued that this requirement is equivalent to the requirement that the disable request signal initiate the predetermined length of time. However, Defendants offer no support for the idea that the word "after" means "immediately after" or "in response to."

--- End Footnotes ---

Having resolved the parties' claim scope dispute, the Court must determine how best to construe this term for a lay jury. Defendants argue that Saxon's proposed construction contains two needlessly ambiguous terms: "shut-down mode," and "initiate entry into." Although the term "shutdown mode" does not appear in the language of claim 5, it is adequately described throughout the '689 Patent. The title of this patent is "Clock Generator Capable of Shut-Down Mode and Clock Generation Method." Furthermore, the patent specification consistently describes "shutdown mode" as a power saving mode in which "the clock generator does not generate any clock signals." '689 Pat. at 3:11-15. Therefore, the Court finds that the term "shutdown mode" is not ambiguous. The term "initiate," on the other hand, is more problematic. The patent specification uses this term in a number of different contexts. See '689 Pat. at 7:59-64, 8:49-52.
The Court finds that the proper construction of this term is "a signal requesting the system enter into shut-down mode."

1. disabling

In the only office action sent by the Patent and Trademark Office ("PTO"), the patent examiner suggested changing the term "disenabling" to "disabling." He did not provide a reason for the change. Nonetheless, the patentees complied with this request. Neither the language of the claims nor the patent specification provide a definition for the term disabling. Instead, the term is used in phrases to describe the status of the second microphone while the first microphone is activated. [See e.g., claims 1 (d)&(e), 8(a)&(b), 9, 13(b), 19(d)&(f) and 26(d)]. In the description accompanying the claims, the patent provides:

At any point in time where there is an attempt by the party in the interior environment to transmit, that party will immediately assume transmit control over the line and the party in the exterior environment will only be in a receive mode. (501 patent, col. 3:46-50).

* * *

During each monitor of the phone line, the external microphone is temporarily disabled so that any signal on the line cannot be the result of external noise or someone talking on the external microphone. (501 patent, col. 4:7-10).

Plaintiff relies on Webster's II New College Dictionary to construct its definition. Plaintiff defines disabling as "to suppress, to make incapable or ineffective; synonymous with the word weaken." (Plaintiff's Supplemental Reply, at 1). Plaintiff further asserts that any written responses during the course of the patent prosecution which define disabling are irrelevant. (Plaintiff's Supplemental Reply, at 3 n.2).

--- Footnotes ---

4 Although defendants do not rely on a dictionary, they contend that disabling "is such that transmission cannot occur from the second (exterior) microphone when audible sounds are generated at the other microphone (see, for example, claims 1, 13, and 19), and occurs whenever audible sound is to be transmitted by the [interior] location (e.g., Claims 8 and 16)." (Defendants' Supplemental Reply at 3). This definition while more detailed is consistent with the Court's understanding of the claim term "disabling."

--- End Footnotes ---

The patentees' attorney's comments, in this instance however, were made to overcome prior art objections. As a result, the prosecution history is highly relevant to defining the term disabling. For example, in describing how plaintiff's device operates differently from U.S. Patent No. 3,588,360 (the "Knox patent"), patentees' counsel wrote in response to the Office Action, dated October 2, 1985:

In accordance with the present invention, one of the microphones is literally de-activated and that is the microphone in the noisy area for the purposes of monitoring the telephone line. This clearly does not exist in the case of the Knox patent.

Defendants' Exh. C at 152. Thus, the patent attorney represented to the patent examiner that disabling with respect to plaintiff's device meant the external microphone is "literally de-activated."

In response to the Patent Examiner's objection raised by U.S. Patent No. 4,513,177 (the "Nashino patent"), the patent attorney stated:

Of primary importance is the fact that Nashino et al does not cut off a microphone or a speaker at any time. In other words, the microphone and the speaker are always on. However, Nashino et al merely attenuate for the background noise and for the noise from the speaker which might otherwise be coupled into the microphone.
Defendants' Exh. C at 154 (emphasis added). Here, the patent attorney explained that the patentees' device disables or "cuts off" the external microphone unlike the Nashino device which does not "cut off" a microphone at any time.

The patentees' counsel concluded his response to the Office Action by stating that:

Applicant has amended the claims to insure that they patently define over the references of record. Claim 1 has been amended to recite the monitor means for monitoring the telephone line to determine if audible sounds are being generated at the first microphone or at the second microphone while temporarily disabling one of the microphones. The references of record do not even remotely suggest the disabling of any one of the microphones to determine if audible sounds are being carried over the telephone line. In addition, Claim 1 calls for the control means which is responsive to the monitor means for disabling one of the microphones such that transmission cannot occur through that microphone.

Defendants' Exh. C at 155 (emphasis added). Again, the patent attorney made clear distinctions between the prior art cited by the patent examiner and the claimed invention which disables "one of the microphones such that transmission cannot occur through that microphone." Id. Thus, the prosecuting attorney's aforementioned statements clearly define disabling as literally de-activated or cut off in order to secure allowance of the patent.

While plaintiff may wish to retract the representations made by the patentees' attorney or explain the subjective intent behind making the statements, assertions made during the patent prosecution can be used to define or limit a claim term. Standard Oil Co. v. American Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985); see also, Southwall Technologies Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution."); Ekchian v. Home Depot, Inc., 104 F.3d 1299, 1304 (Fed. Cir. 1997) (holding that a court may use statements made in an Information Disclosure Statement to interpret the scope of the claims of a patent); Spectrum Int'l, Inc. v. Sterlize Corp., 164 F.3d 1372, 49 U.S.P.Q.2D (BNA) 1065, 1998 WL 854715 *5 (Fed. Cir. December 9, 1998) (noting rule that "explicit statements made by a patent applicant during prosecution to distinguish a claimed invention over prior art may serve to narrow the scope of a claim"). Moreover, the standard for reviewing the subject matter surrendered during prosecution is objective and depends upon what a competitor reading the prosecution history would reasonably conclude was given up by the applicant. Insituform Technologies, Inc. v. Cat Contracting, Inc., 99 F.3d 1098, 1107-08 (Fed. Cir. 1996). The subjective intent of what the patentee intended to convey during prosecution is not relevant to the Court's inquiry. Id. 99 F.3d at 1107.

Plaintiff also contends, in effect, that the patent attorney's statements were unnecessary because the prior art was distinguishable for other reasons than by limiting the scope of disabling. However, the public record is clear and cannot be disregarded by the Court. Plaintiff cannot urge the Court to ignore statements made by the prosecuting attorney simply because the plaintiff realizes in hindsight that these statements were unnecessary or a mistake. Spectrum Int'l, 164 F.3d 1372, 1998 U.S. App. LEXIS 30992, 1998 WL 854715 at *5 (noting that the public has a right to depend on definitive statements made during prosecution); see generally, Vitronics, 90 F.3d at 1583 (competitors must be able to rely on the public record to determine the scope of a patent).

In sum, the file history reflects that the patent examiner suggested the change of dissembling to disabling and rejected claims as anticipated by the Knox, Nashino and Warman patents. To overcome these objections, the patent attorney distinguished the Knox patent by asserting that one microphone is literally de-activated. He distinguished the Warman patent by noting that only one person could obtain transmit control. Finally, the patent attorney distinguished the Nashino patent by emphasizing that it merely attenuates for background noise rather than cutting off a microphone or speaker at any time.

Accordingly, the Court concludes that disabling as used in the 501 patent means: to de-activate, or cut-off, not mere attenuation. This definition applies to all the claims of the 501 patent.

1368

I. Claim Construction

The first step in an infringement analysis is the proper construction of the asserted claims. The claims at issue include means
plus function limitations. The dispute is not whether the accused devices contain structure equivalent to the claimed means but whether the accused devices perform the function recited in the means plus function limitations. In its February 1999, claim construction order, the district court construed the term "disabling" that is found in the disputed claims. Claim 1, for example, recites "control means responsive to said monitor means for . . . disabling said second microphone such that transmission cannot occur through said second microphone when audible sounds are generated at said first microphone . . . ." '501 patent, col. 10, ll. 15-20. The claims define the first microphone as being at a "generally quiet location," i.e., the tenant's apartment, and the second microphone as being at a location "which may have relatively substantial background noise," i.e., the visitor location. After discussing the language of the claims themselves, the specification, and the prosecution history, the district court held that "disabling as used in the '501 patent means: to de-activate, or cut-off, not mere attenuation." DoorKing I, slip op. at 10. DoorKing asserts that the district court erred in its claim construction, and that "disabling should be construed to have its ordinary dictionary meaning."

Citing one dictionary meaning, DoorKing urges that "disabling" should be construed to mean "to suppress, to make incapable or ineffective," and that the term is synonymous with the word "weaken." For example, Webster's Dictionary defines disable: "to make incapable or ineffective" and lists "weaken" as a synonym for "disable." Webster's New International Dictionary 642 (3d ed. 1968). Standard dictionary definitions indicate ordinary meaning. See, e.g., MSM Investments Co. v. Carolwood Corp., 259 F.3d 1335, 2001 WL 893890, at *4 n.1 (Fed. Cir. 2001). Of course, it is appropriate to look to the dictionary to help determine the ordinary meaning of "disable."

However, Sentex urges that the specification and prosecution require a narrower interpretation of "disabling." Of course, claim language must be interpreted in light of the specification and prosecution history. Biovail Corp. Int'l v. Andrx Pharms., Inc., 239 F.3d 1297, 1301, 57 U.S.P.Q.2d (BNA) 1813, 1816 (Fed. Cir. 2001). Sentex first directs our attention to the specification. The specification states that: "During each monitor of the phone line, the external microphone is temporarily disabled so that any signal on the line cannot be the result of external noise or someone talking on the external microphone." '501 patent, col. 4, ll. 6-10. Sentex urges that this portion of the specification requires a narrower interpretation.

Sentex also argues that the prosecution history requires the term "disabling" to mean that one of the microphones must be literally de-activated or cut-off. During prosecution of the patent, several claims, including the later allowed claim 1, were rejected as being anticipated by three separate prior art references: United States Patent No. 3,588,360 to Knox, U.S. Patent No. 4,467,143 to Warman, and U.S. Patent No. 4,513,177 to Nishino. In response to the rejection, DoorKing amended its claims, added new ones, and made several statements about the prior art. In distinguishing the invention from Knox, DoorKing stated: "In accordance with the present invention, one of the microphones is literally de-activated and that is the microphone in the noisy area for purposes of monitoring the telephone line. This clearly does not exist in the case of the Knox patent." With respect to Warman, DoorKing stated, in part, that: "In distinction, the system of the present invention is obviously quite different in that only one person can obtain transmit control." With respect to Nishino, DoorKing stated that:

Of primary importance is the fact that Nishino et al. does not cut off a microphone or a speaker at any time. In other words, the microphone and the speaker are always on. . . . The references of record do not even remotely suggest the disabling of any one of the microphones to determine if audible sounds are being carried over the telephone line. In addition, Claim 1 calls for the control means which is responsive to the monitor means for disabling one of the microphones such that transmission cannot occur through that microphone.

Like the district court, we find that the prosecution history at least requires a narrower interpretation of the claim language than indicated by the dictionary definition. The proper interpretation is that "disabling" means "to make incapable or ineffective," but not "to weaken." The prosecution history is not consistent with a broad interpretation of disabling that includes merely weakening the signal from the visitor microphone. We construe "disabling" as requiring that the visitor microphone be rendered incapable of: (a) transmitting a signal that is audible at the tenant location; and (b) preventing the tenant microphone from controlling the system. This construction is similar to but not identical to the district court's construction.
coherently caching I/O devices available for shared access on a network comprising . . . disabling cache operations upon finding that a new computer joined the network; and enabling caching operations at each computer after each computer has connections in place with the cache software of every other computer on the network." (‘136 Patent, at 26:17-22) (emphasis added). The parties agree that "enabling caching operations" is the opposite of "disabling cache operations" and that the two terms should be construed together. (Instrument No. 69, at 28; Instrument No. 77, at 15). There is also no dispute that "cache operations" and "caching operations" are the same. (Id.).

The parties also appear to agree that the term "disable" means "prohibit," and the term "enable" means "permit." (Instrument No. 69, at 29; Instrument No. 77, at 15). In order to assist the Court, both parties refer to the IEEE DICTIONARY definition of "disable" and "enable." (Id.). The IEEE DICTIONARY defines "disable" as "[a] command or condition that prohibits some specific event from proceeding." IEEE DICTIONARY at 299. (emphasis added). As a corollary, the IEEE DICTIONARY defines "enable" as "[a] command or condition that permits some specific event to occur [or] to proceed." (Instrument No. 69, at 29) (emphasis added). In this case the specific event is "cache operations" or "caching operations." The parties have agreed that the term "cache" means "a portion of system main memory (e.g., RAM) used for temporary storage of data." (Instrument No. 69, at 9-10). The parties have further agreed that the term "caching" means "storing in cache." (Id.). The parties dispute whether the term "caching" is the same as "cache operations," or whether "caching" is just one of several different "cache operations." The parties further dispute whether the duration of the prohibited or permitted cache operations should be reflected in the construction of the terms "disabling cache operations" and "enabling caching operations."

With regard to the duration of prohibited or permitted cache operations, Claim 1 of the ’136 Patent implies that the disabling of cache operations is only temporary, because cache operations are only disabled "upon finding that a new computer joined the network." (’136 Patent, at 26:18-19). "After each computer has connections in place with the cache software of every other computer on the network," cache operations are enabled again. (Id. at 26:20-22). The specifications of the ’136 Patent further confirm the temporary nature of disabling cache operations, and explain that "the 'disable' flag is used to indicate that the remote computer connections are inconsistent, which will temporarily disable caching operations until the remote computer connections are completely formed in a consistent state." (Id. at 7:10-11; 8:52-53) (emphasis added).

Superspeed argues that "while the '136 claim 1 does not explicitly require 'temporarily disabling' it does explicitly contemplate that the disabled operations will be subsequently enabled." (Instrument No. 69, at 29). Thus, Superspeed argues that the term "disabling cache operations" means "temporarily prohibiting (i.e., suspending) cache operations," and "enabling caching operations" is "continuing or resuming those caching operations." (Id.). Although the terms "suspending" and "resuming" may constitute a convenient short-form to reflect the temporary nature of prohibiting or permitting cache operations, the Court finds that it is unnecessary to use these specific terms in the construction. Because the specifications specifically provide for operations to be "temporarily disabled," the Court finds that the term "temporarily prohibiting" cache operations is a preferable construction. Because the specifications do not specifically state that "enabling caching operations" is temporary in nature, the Court finds that the term "permitting" caching operations is a preferable construction. However, the Court must also determine what specific cache operations are temporarily prohibited or permitted.

Superspeed contends that the specifications and flow chart figures of the ’136 Patent indicate that "if cache operations are disabled . . . data cannot be read from the cache nor placed into the cache from the disk." (Instrument No. 69, at 31). Specifically, the specifications provide:

Referring to FIG. 5C, the "read data" (440) program flow will now be described. . . . The program checks whether the cache status flag 'disable' is set (452), if so, the program exits. . . . The cache status flag 'disable' indicates that some Open VMS system in the VMScluster . . . does not have the cache driver . . . of the invention loaded. This normally would indicate that some Open VMS system is currently joining the VMScluster . . . and has not yet successfully loaded the cache software of the invention. . . . [T]he cache status flag 'disable' indicates an inconsistent view of the cache for the invention across the VMScluster and VAXcluster, preventing active cache operations (and possible subsequent corruption) of the data contained in a disk I/O device."

(‘ 136 Patent, at 17:46-18:9) (emphasis added). Figure 5C of the ’136 Patent further indicates that the "read data" program flow checks whether the cache status flag "disable" is set. (Id. at FIG. 5C).

The specifications do not specifically define the term "active cache operations." However, the parties appear to agree that
the active cache operations that are disabled include: the reading of data from the cache, and the storing of data into the cache. Superspeed admits that "placing data into the cache for rapid access and then accessing it from the processor" are operations that are prohibited while caching operations are disabled. (Instrument No. 69, at 31). Oracle agrees that the "plain meaning of 'cache operations' exceeds just storing data in a cache and includes reading data from a cache (a prerequisite to using the cached data), and writing data to the cache." (Instrument No. 77, at 16). According to the demonstrative exhibit that Oracle presented in oral argument, Oracle uses the term "writing data" from the disk to cache synonymously with "caching" or "storing data" in cache. (DX 1, at 60). Accordingly, the parties agree that disabling cache operations prohibits reading data from the cache, and storing data in a cache.

However, disabling cache operations does not prohibit all cache operations. Superspeed argues that even while caching operations are disabled, some operations on the cache may still be undertaken. Specifically, Superspeed contends that "the software continues to check the free memory and can release cache if the memory used in the cache is needed elsewhere." (Instrument No. 69, at 30). This allows the program to modify the size of the cache for small, medium, or large cache data buckets. (Instrument No. 69, Exh C, at 8:61-65). Superspeed further contends that the system can "unload" or clear cache data in the system when cache operations are "disabled." (Instrument No. 69, at 30; Exh C, at 17:31-36, FIG. 5B). Finally, Superspeed contends that the software can invalidate cache data when writing to an I/O device. (Id.; Exh C, at 17:40-45, 21:58-22:27, FIG. 5K). Oracle does not dispute that the program can modify the size of cache, clear the cache, and invalidate cache data while caching operations are disabled. (Instrument No. 77, at 20). This interpretation appears to be consistent with the specifications and flow chart figures described in the '136 Patent.

Because "disabling cache operations" does not prohibit the use of all cache operations, a construction that the term "disabling cache operations" means "prohibiting use of data in the cache" would be too broad. However, a construction of the term "disabling cache operations" to mean "suspending caching" does not indicate that reading data from the cache is also prohibited, and would thus be too narrow. Taking into consideration the duration of prohibited cache operations and the specific cache operations that are prohibited by "disabling cache operations," the Court finds that the term "disabling cache operations" means "temporarily prohibiting the storing and reading of data on the cache," and that the term "enabling caching operations" means "permitting the storing and reading of data on the cache."
A "disabling device that disables . . . after loading" is a device that disables the assembly machine, after loading of the machine has been completed, if any compartment is removed from a location, and that enables said machine once all emptied locations have been filled with corresponding components.

(Docket Entry No. 40, p. 23). Plaintiffs propose the following construction of the term "disabling device that disables . . . at the beginning of a loading operation" found in claim 19:

A "disabling device that disables . . . at the beginning . . . " is a device that disables the assembly machine at the beginning of a loading operation, and that enables said machine after all compartments are placed in corresponding locations.

(Docket Entry No. 40, p. 26). Universal contends that the claim terms for "disabling devices" are in means-plus-function format; plaintiffs dispute that section 112, P 6 applies.

The word "means" does not appear in the "disabling device" claims, giving rise to the presumption that those claims are not in means-plus-function format. Universal can rebut this presumption by showing that "disabling device" fails to recite sufficiently definite structure or recites a function without reciting sufficiently definite structure to perform the function. Apex, 325 F.3d 1364, 2003 WL at *5. [T]his presumption can collapse when a limitation lacking the term 'means' nonetheless relies on functional terms rather than structure or material to describe performance of a claimed function." Id. (citing Micro Chemical, 194 F.3d at 1257).

Unlike the term "indicator," which is defined in technical dictionaries, the term "disabling device" is not defined in standard or technical dictionaries in a way that connotes sufficient structure to avoid the application of section 112, P 6. This court has found no definition of the term "disabling device" after searching technical dictionaries of the electronic and mechanical arts. Standard dictionaries define the term "device" as "a piece of equipment or a mechanism designed to serve a special purpose or perform a special function." WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY (1983). This definition reveals that the term "device" is generic and does not connote structure to one skilled in the relevant art. See Personalized Media, 161 F.3d at 704 (stating that the term "detector" is "not a generic structural term such as . . . 'device').

The Federal Circuit has held that similar generic terms lack sufficient structure to avoid means-plus-function status. See Mas-Hamilton, 156 F.3d at 1214 (stating that the term "lever moving element" was a generic term that could apply to any device that caused a lever to move, if section 112, P 6 was not applied). The Federal Circuit has found such seemingly generic terms as "reciprocating member" and "detent mechanism" sufficiently connotative of structure to avoid application of section 112, P 6. In such cases, the court found that the dictionary definitions of the terms and the surrounding claim language connoted sufficient structure. See CCS Fitness, 288 F.3d at 1369-70 (construing the claim term "reciprocating member," the court found that the definition of the term "member" as "a structural unit such as a . . . beam or tie, or a combination of these" and as a "distinct part of a whole" and the presence of additional structural language in the claim avoided the ambit of section 112, P 6); Greenberg, 91 F.3d at 1583 (finding that an English dictionary definition of "detent" as "a mechanism that temporarily keeps one part in a certain position relative to that of another, and can be released by applying force to one of the parts" and a technical dictionary definition of "detent" as a "catch or checking device, the removal of which allows machinery to work such as the detent which regulates the striking of a clock" provided sufficient structure to avoid application of section 112, P 6 to the term "detent"). There are no such dictionary definitions connoting structure for the term "device" or "disabling device." Claims 7 and 20 do not contain additional structure, necessary to avoid application of section 112, P 6. If section 112, P 6 does not apply, the claimed "disabling devices" would cover any device that disables.

Claims 6, 7, 19, and 20 do not recite structure that would prevent the application of section 112, P 6. Id. This court finds that section 112, P 6 applies to the claim terms "disabling device that disables . . . after loading" and "disabling device that disables . . . at the beginning of a loading operation," limiting those terms to the structures disclosed in the specification and their equivalents.

Under section 112, P 6, this court must identify the claimed function of the "disabling devices" and the structure that is described to perform the claimed functions. Micro Chemical, 194 F.3d at 1258. The written description clearly identifies the claimed function for the disabling device: it "operates to prevent the operation of the assembly machine until all components
or compartments have been loaded in their proper location. The device acts to disable the assembly machine prior to loading, and to enable the machine after it is determined that all compartments have been loaded into their proper locations." ('943 Patent, claim 6, claim 19, col. 6, 1.26-1.34). The disabling device also disables the assembly machine if a compartment is removed from its proper location and enables the assembly machine once all compartments are returned to their proper location. (Id. at claim 7, claim 20, col. 8, 1.54-1.64).

After identifying the function of the means-plus-function element, a court looks to the written description to identify the structure corresponding to that function. Micro Chemical, 194 F.3d 1250, 1258. A means-plus-function claim encompasses all structure in the specification corresponding to that element and equivalent structures. Id. A court must not incorporate structure from the written description beyond that necessary to perform the claimed function and must not adopt a function different from that explicitly recited in the claim. Id.

The written description states that "in one embodiment, the disabling device comprises a relay." ('943 Patent, col. 6, 1.35-1.36). The written description also states that "Nil the three element embodiment, the relay is responsive to each applicable element . . . individually. . . . In the four element embodiment, the relay is responsive to the information processor. Since the information processor is responsive to all elements, the relay can respond to any applicable situation in the process." (Id. at col. 6, 1.35-1.42).

Universal contends that the claimed disabling device of claim 19 must include a computer programmed to disable the assembly machine at the beginning of the compartment loading by turning off this relay and turning the relay back on after all the components are loaded. 7 Universal also contends that the disabling devices of claims 7 and 20 must include a computer programmed to: (1) disable the assembly machine after loading if a compartment is removed from a location; and (2) enable the assembly machine after all the locations are filled with corresponding compartments by turning on the relay. (Docket Entry No. 46, p. 58). Universal points to the fact that the written description of the '943 Patent links the relay and a computer programmed to enable and disable the assembly machine in accordance with the algorithm presented in Figures 8B and 8C. The written description states that "[i]f at block 832 [of the algorithm in Figure 8B], it is determined that all necessary compartments are present then control moves forward to 'turn on the relay sensor' block 833 [of the algorithm in Figure 8C]. Here, the computer [element 202 in Fig. 2] sends a signal through I/O card 204, to a relay which enables the assembly machine." ('943 Patent, col. 16, 1.39-1.44). If a necessary compartment is missing, "the computer 202 [in Fig. 2] prompts the relay to disable the assembly machine 101 [in Figure 2]." (Id. at col. 17,1.19-1.21).

7 Universal has not challenged the use of the term "disabling device" in claim 6, and plaintiffs have not alleged that defendants infringed claim 6. Claim 6 and claim 19 are virtually identical, except that claim 6 depends on claim 1, the three-element embodiment of the invention, and claim 19 depends on claim 13, the four-element embodiment of the invention. The disabling devices of both claims 6 and 19 disable the assembly machine until all compartments are in their proper location. (Id. at claim 7, claim 20, col. 8, 1.54-1.64). The disabling device also disables the assembly machine if a compartment is removed from its proper location and enables the assembly machine once all compartments are returned to their proper location. (Id. at claim 7, claim 20, col. 8, 1.54-1.64).

The fact that the relay is controlled by the computer in the embodiment recited in the written description does not, however, mean that the disabling device of claims 6, 7, 19, and 20 must contain a computer. The written description shows that the computer is an embodiment of the information processor of the four-element version of the invention, separate from the relay. The block diagram of the invention in Figure 2 is a preferred embodiment of the invention. ('943 Patent, col. 7, 1.34-1.36). The computer, element 202 in Figure 2, is an embodiment of the information processor of the four-element embodiment. ('943 Patent, col. 5, 1.19-1.25). As analyzed earlier in this Memorandum and Opinion, the claimed information processor is not limited to a computer. The relay is connected to the computer through the I/O card (element 204 in Figure 2). The computer -- the information processor of the preferred embodiment -- sends an enabling signal through the I/O card to the relay after all the compartments are loaded. (Id. at col. 8, 1.48-1.50). Importantly, the information processor, which in the preferred embodiment is the computer and not the relay, determines whether the compartments are properly loaded. (Id. at col. 8, 1.22-1.33). The information processor, in this case the computer, and not the relay, determines if a compartment is missing. (Id. at col. 8, 1.55-1.64).

- 1800 -
Based on the written description, the relay of the four-element embodiment does not contain a computer or other information processing structure. Rather, the relay responds to commands from the information processor, which determines whether all components are properly loaded and the assembly machine should be enabled. In the three-element embodiment, the functions of the information processor are distributed between the compartment identifier and the location indicator. The relay comprising the disabling device is responsive to the "applicable elements." Which elements are "applicable" depends on the distribution of the function of the information processor between the location indicator and component identifier. (943 Patent, col. 6, 1.8-1.10; col. 6, 1.36-1.38). This court construes the claim term "disabling device" in claims 19 and 20 (which depend on claim 13, the four-element version of the invention) as a relay, or equivalent structure, connected to the information processor and the assembly machine, which disables or enables the assembly machine in response to commands from the information processor. This court construes the term "disabling device" in claims 6 and 7 (which depends on claim 1, the three-element version of the invention) as a relay, or equivalent structure, connected to the location indicator, the component identifier, and the assembly machine, which disables or enables the assembly machine in response to commands from either or both the location indicator and component identifier, depending upon the distribution of the functions of the information processor between the location indicator and the component identifier.

Mediatek argues "disabling said EFM decoder" should be construed as "stopping the flow of EFM decoded audio data." Matsushita argues "disabling said EFM decoder" should be construed as "deactivating the EFM decoder."

The Court finds, for the reasons stated by Mediatek, that "disabling said EFM decoder" is properly construed as "stopping the flow of EFM decoded audio data."
invention to a switch that completely interrupts the flow of electrical current between the network and the telephone jack. MediaCom argues that the ordinary meaning of the terms used indicate a switch that shunts the telephone from the network's electrical current to the local current source that is part of the call rating device. Rates counters that the telephone can and must remain electrically connected to the network at all times during the call in order for the telephone to work properly, noting that a claim construction that has the effect of excluding the preferred embodiment in the specification from coverage by the claims is "rarely, if ever, correct." Vitronics, 90 F.3d at 1583. Rates urges a construction that is limited to the disabling of signaling between the telephone and the network, while the telephone remains electrically connected.

The Court looks to the specification, and particularly to the wiring diagram at Fig. 2, to guide the resolution of this disagreement. See Vitronics, 90 F.3d at 1582 (stating that the specification "is the single best guide to the meaning of a disputed term"). The diagram is found as Appendix A to this opinion. The Court has already ruled that no special definition appears in the specification to indicate that the words "switch" or "disconnect" are to be given any other than their ordinary meanings. See MediaCom, 4 F. Supp. 2d at 27; see generally Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388 (Fed. Cir. 1992). The Court has further ruled that the "switch means" element is not a means-plus-function claim element governed by the sixth paragraph of 35 U.S.C. § 112. See MediaCom, 4 F. Supp. 2d at 27; see generally Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996).

There are two switch elements represented on the diagram as being operatively connected to the first, or telephone jack. One switch means is represented as No. 36 on the diagram, a "2 From C" switch. In the written specification, the switch is referred to as a "2 Form C" switch. See Col. 3, 1. 52. The Court concludes that the specification identifies a "2 Form C" switch. "Form C", in the parlance of electrical circuitry, refers to a "single pole, double throw" switch. Single pole indicates that only one wire from the element being switched is connected to the switch. Double throw means that the element may be switched to either of two different connections. This type of switch is distinguishable from a switch which has only on or off states, as opposed to two alternative on states. The 2 in "2 Form C" switch means that there are two switches in the configuration labeled No. 36 in Fig. 2, each having one wire that may be switched and two possible connections that may be made. This interpretation of "2 Form C" is consistent with the explanation offered by Rates' expert, Stephen Burns, Ph.D., see Declaration of Stephen K. Burns, Ph.D. at P 12, and has not been the subject of dispute in this action. See also Charles J. Baer & John R. Ottoway, Electrical and Electronic Drawing, (5th ed. 1986) 86 Fig. 3-9. 2

--- Footnotes ---

2 It is important to note that the "switch means" element of the claim is not at issue here, and it is not limited to the "2 Form C" variety of switch identified in the specification. See MediaCom, 4 F. Supp. 2d at 27 ("switch means" is not a means-plus-function claim). It is useful, however, to identify the particular switch identified in the specification, because the Court may thereby gain insight into the operation of the invention and its preferred embodiment.

--- End Footnotes ---

With the understanding that the 2 Form C configuration controls one pair of wires from the element to be switched and two pairs of wires each representing one possible connection, the Court returns to the diagram at Fig. 2. The switch configuration is connected to seven different wires. One pair leads to the network, or central office (25). One pair leads to the telephone (24). A third pair leads to the local central office (CO) current source (38). The remaining wire leads to an array consisting of the micro-processing unit (50), the RAM chip (52), the EPROM chip (54), and the real time clock (56). Specifically, the wire is connected to the input/output (I/O) bus (66). See Fig. 2. 3

--- Footnotes ---

3 The seventh wire represents a relay. A relay is an "automatic electromagnetic or electromechanical device that responds to a small current or voltage change by activating switches or other devices in an electric circuit." See American Heritage Dictionary Second College Edition; see also Electrical and Electronic Drawing 84. Such a current or voltage change is produced by the micro-processor when the phone is off-hook, but there is no ring detected, that is, when the user lifts the handset not in response to a ring signal but because he wishes to place a call. See Fig. 3; Col. 5, 11. 16-25. The relay is the mechanism by which the device, in effect, tells the switch to operate.

--- End Footnotes ---
According to the specification, the function of the switch (36) is to disconnect the telephone from the network and connect it to the device. See Col. 3, Lns. 52-54. Logically, it follows that the pair of wires leading to the telephone jack (24) may be connected by the switch to either the pair of wires leading to the network jack (25) or to the pair of wires leading to the local CO current source (38). The switch thus connects the telephone pair either to the network or to the local CO current source, but not to both.

The specification indicates that the switch (36) is connected to a "local CO (central office) current source (38) which generates a current corresponding to the current supplied by the . . . network." Col. 3, 11. 54-55. The local CO current source in turn is connected to a "power supply" (76). Col. 4, Lns. 22-24. Current is thereby supplied to the telephone when it is disconnected from the pair of wires leading to the network. In addition, the switch (36) connects to the DTMF tone detect (88), which "detects the tones generated from the first phone." Col.4, 11. 41-43. When the user dials a series of digits, the electrical impulses thus pass from the telephone jack (24), through the switch (36), and on to the DTMF tone detect (88), so that the device can identify the telephone number and determine which carrier access code to dial. See Col.5, 11. 16-18, 28-31.

The second switch is represented by the gate-like configuration in the line current detect (40). See Electrical and Electronic Drawing 86 Fig. 3-9. According to the specification, the device "connects to the central office (phone network)." Col. 5, 11. 19-20. This connection is made by means of two additional components: "A combination polarity guard (42) and Direct Access Arrangement (44) (DAA) interfaces and allows communication to the network." Col. 3, 11.64-66. The connection is made when the line current detect (40) senses that the telephone is off-hook, but the ring detect (74) does not sense a ring signal indicating an incoming call.

It is evident from the diagrams and written specification that when a user lifts the telephone handset, two things occur. The switch (36) breaks the circuit that had existed between the telephone and the network, and establishes a new circuit between the telephone and the device. The device itself, however, establishes a new connection with the network, by means of the second switch at the line current detect (40). In broad terms, the device becomes interposed between the telephone and the network by operation of the two switches. Only the switch that disconnects the telephone from the network, however, is claimed.

Rates chooses to characterize this operation as the disabling of the signaling function. While this may be an accurate description of the end result, it is insufficiently complete and precise to allow the finder of fact to evaluate Rates' infringement claim. Yet it is clear that MediaCom's suggestion that there must be a complete interruption of electrical current between the network and the telephone overstates the claim. When one connection is broken, another is established, and it is not possible to establish on the basis of the diagram or the claim language whether or not the telephone remains connected to the network through some other path.

Thus, the term "disconnecting" is not susceptible to either party's proffered construction. Rather, the term "disconnecting" in the context of this patent refers to the interruption of the electrical circuit between the telephone and the network. In the preferred embodiment, the disconnecting is accompanied by the establishment of other circuits; one between the telephone and the device, and another between the device and the network. Those aspects of the preferred embodiment, however, are not claimed as part of the invention. An accused device may, but need not, contain a mechanism for establishing an alternate connection. The Court therefore construes the "disconnecting" element of Claim 1 of the '085 patent to require the interruption -- the breaking or opening -- of the electrical circuit between the telephone jack and the network.
an application. and providing the information in a specified format.

The parties have three main disputes: whether the language proposed by Sun -- "for discovering information about devices on a fabric network" -- should be included in the term's construction; whether the term "discovery interface" requires a direct connection to a fabric driver as proposed by NetApp; and whether the term should refer to an "application" as proposed by NetApp or a "specified format" as proposed by Sun. 6

6 The parties originally disputed whether the interface is "software" or a "software module." At the hearing, however, the parties agreed that the interface was "one or more software modules."

Regarding the first issue, Sun argues that the patent specification consistently describes discovery interfaces as providing the ability to discover information about the devices on a fabric network. For example, the summary of the invention section notes that device centric and transport centric discovery interfaces 7 "may provide an interface to the fabric driver to obtain information about the devices in the fabric network" and are "configured to provide" such an interface. '951 patent at 2:5-7, 21-24. See also id. at 6:50-52 (device centric discovery interface "may allow a user . . . to discover information about fabric devices . . ."); 6:65-68 (interface to fabric driver may include transport centric discovery interface "to provide fabric device discovery information"). While the specification describes this function of a discovery interface, this language is duplicative of the language already present in the claims. For example, claim 1 provides for "a device centric discovery interface configured to provide an interface to the fabric driver to obtain information about the devices in the fabric network." Id. at 14:25-28. Claim 6 also describes the discovery interface as one that obtains "information about the devices in the fabric network." Id. at 15:12-14. Claims 3 and 9 are dependant on claim 1. Therefore, while Sun argues that NetApp's construction is flawed due to its silence on this point, Sun's proposed description is redundant of language already present in the claims.

7 These two types of discovery interfaces differ in the format of the information sent and received through the interfaces. NetApp Op. Brief at 19, Sun Opp. Brief at 20.

As to whether the term requires a direct connection, the claim language does not indicate that such a connection is required. Claims 1 and 6 call for a "discovery interface configured to provide an interface to the fabric driver," which indicates that the fabric driver is the object to which the discovery interface is connected. While one may infer that this is a direct connection, the claim language by no means requires such an inference.

Turning to the specification, NetApp argues that the only examples in the specification show interfaces that are connected directly to the fabric driver and receive information directly from the fabric driver. In Figure 5, interface 503 contains discovery interfaces 520 and 522, as well as interfaces 524 and 526. In that figure, interface 503 is connected to fabric driver 504, and the figure depicts these connections with two arrows, one going from interface 503 to the fabric driver, and one going from the fabric driver to the interface. There is also an additional arrow pointing to the interface from the fabric driver labeled "events." The figure also shows a connection between interface 503 and administrative application 502, depicted by two arrows pointing from interface to application and vice versa. The written description describes interface 503 as providing "an interface between the administration application 502 and the fabric driver 504." '951 patent at 6:37-39.

NetApp's expert Professor Long maintains that a person of ordinary skill in the art would understand from this statement that the discovery interface is connected directly to the fabric driver and receives information directly from the fabric driver. Long Decl. P 89. However, Sun's expert explains that one of ordinary skill in the art would conclude that the arrows in the software architecture diagram in Figure 5 indicate a connection, but not necessarily a direct connection between the connected components. Declaration of Dr. Martin Kaliski PP 35-36. In other words, while the components are conceptually connected and there is some mechanism by which the two components may communicate, the components need not be
directly connected. In fact, at the Markman hearing, Professor Long himself conceded that the arrows in Figure 5 show that information flows in both ways, but do not necessarily reveal a direct connection; rather, the arrows are ambiguous in this respect.

The Court concludes that the specification does not require a direct connection. The arrows in Figure 5 portray a general conceptual connection. In addition, only interface 503 -- not the discovery interfaces contained in the subset of interfaces inside of it -- is shown as connected to the fabric driver in Figure 5. Moreover, the arrows between the fabric driver and the interface are labeled events, indicating that the arrows show what is being communicated rather than the physical means by which the communication is accomplished. Finally, the description of Figure 5 states that the discovery interface "may" provide or return information, revealing that this figure is just one embodiment of the invention. See, e.g., '951 patent at 6:46-65 ("discovery interface may return device centric discovery information", "discovery interface . . . may provide . . . discovery information"). See also Liebel-Flarsheim Co., 358 F.3d at 906 (noting that even if the specification describes a single embodiment, the claims of the patent are not to be read restrictively absent clear intention to limit claim scope).

Sun also points out that the specification provides an example of an interface that does not provide such a direct connection: "the host system may include a fabric driver configured to interface the system to the fabric network through the host adapter ports." '951 patent at 2:2-11. While this portion of the specification discusses interfacing more generally as opposed to the "discovery interface" at issue, it indicates that the term "interface" need not involve a direct connection, because in the example given, the fabric driver is interfaced to the system, but is connected indirectly through host adapter ports. Since NetApp argues that the plain meaning of the term "interface" implies a direct connection as discussed below, this portion of the specification significantly weakens NetApp's position.

Sun also relies on the fact that the specification uses the term interface in the context of a "user interface," but these portions of the specification do not discuss whether such an interface is direct. '951 patent at 9:42-44, 10:1-3, 12:27-31. Sun's expert Dr. Kaliski notes that a user interface provides an interface between a user and an application, but connects that user to the application indirectly via intermediate components, such as a keyboard or mouse. Kaliski Decl. P 30. This argument, while marginally helpful to Sun, is somewhat attenuated since the specification is discussing a different type of interface and does not focus on whether such an interface is directly connecting two things.

In looking at the claim language and specification as a whole, Sun is correct that the interface is not specifically described or defined as requiring a direct connection. See Kaliski Decl. P 25. The specification simply requires that information about devices on fabric networks be discoverable, and indirect discovery is not explicitly ruled out. Id. The patent, therefore, does not support NetApp's argument for importing the term "directly" into this claim phrase.

The parties also argue over the significance of a statement by the applicant made during patent prosecution:

In the current Office Action dated November 12, 2004, the Examiner states "it is clear that in the species of Fig. 4, the Fabric Driver (504) communicates directly with the Administration Application (502) whereas in the species of Fig. 5, the Fabric Driver (504) communicates with the Administration Application (502) via a dedicated interface (503)." However, the Applicant's specification does not state that the Fabric Driver (504) shown in Fig. 4 can only communicate directly with the Administration Application (502). The phrases "communicates directly" and "dedicated interface" used by the Examiner are not found in the Applicant's specification.

Williamson Decl., Ex. A (February 17, 2005 petition at 2-3) (emphasis in original). This portion of the prosecution history is a side detour that is not particularly helpful, because it involves Figure 4, which does not show the discovery interface, not Figure 5. NetApp points out that the patent examiner determined that the systems shown in Figures 4 and 5 were patentably distinct species, and therefore mutually exclusive. Weber Decl., Ex. 2 (August 3, 2004 Office Action at 2). The Examiner then directed the applicant to choose one of the two species for prosecution. The Examiner explained in the next office action that he made this determination because Figure 4 showed a direct communication between Fabric Driver 504 and Administrative Application 502, while Figure 5 showed communication through Interface 503. Weber Decl., Ex. 3 (November 12, 2004 Office Action at 2).

NetApp argues that applying the Examiner's reasoning to Figure 5, the Fabric Driver 504 must be directly connected to Interface 503, which includes the discovery interfaces. NetApp's argument is not persuasive for a number of reasons. First, as noted above, the Examiner was discussing Figure 4, not Figure 5. Second, as Sun noted at the hearing, while the
Examiner at one point stated that the patentee had to choose between the inventions claimed in the two figures, the
Examiner nonetheless ended up allowing all claims. The Examiner's statements comparing the two figures, therefore, are
largely irrelevant. Third, Figure 5 has arrows labeled events between the interface and the fabric driver, distinguishing it
from Figure 4. Finally, the Examiner simply did not focus on whether anything other than the interface could be contained
in the communication channel in Figure 5. If anything, this prosecution history supports Sun's argument that there is no
requirement of a direct connection, as the applicant pointed out that such a phrase is not included in the specification.

The parties also rely on a great deal of extrinsic evidence -- namely dictionary definitions -- in support of their arguments.
NetApp argues that the patent does not provide a specialized meaning for the word "interface," so the term is subject to the
rule that "[i]n general, words used in a claim are accorded their ordinary and customary meaning." Cat Tech LLC v.
Tubemaster, Inc., 528 F.3d 871, 884 (Fed. Cir. 2008) (using standard dictionary definitions to construe term) (internal
citations omitted).

While NetApp's argument hinges largely on the common meaning of "interface," the proffered definitions do not require
NetApp's construction. NetApp relies on a number of dictionary and technical dictionary definitions generally defining
"interface" as a boundary: Webster's New World College Dictionary 3rd ed. 1997, p. 704) ("a plane forming the common
boundary between two parts of matter or space"); The American Heritage Dictionary (2nd College Edition 1991, p. 669) ("a
608-09) ("a mechanism for communicating between two devices" that "specifies the nature of the boundary between two
devices and determines the procedures and protocols that make it possible for the devices to exchange data"). NetApp's
expert notes that a person of ordinary skill in the art would understand that "just as a boundary is the edge of an object, that
an interface is directly connected to and directly communicates with the object." Long Decl. P 87. However, as Sun notes,
none of the proffered dictionary definitions include the word "directly" or any similar requirement. In addition, Sun offers
its own secondary dictionary definitions that do not discuss a single boundary or direct connection between two objects. See
Webster's New World College Dictionary (3rd ed. 1997, p. 704) ("a point or means of interaction between two systems");
Microsoft Computer Dictionary (5th ed. 2002, p. 279) ("software that enables a program to work with the user (the user
interface, which can be a command-line interface, menu-drive interface, or graphical user interface), with another program
such as the operating system, or with the computer's hardware").

The above definitions are not particularly helpful, as there is significant variation between them. In addition, some of
NetApp's dictionary definitions apply to physical interfaces, not software, as software is an intangible series of computer
instructions -- not a physical object with a "surface," nor one capable of forming a "plane." Kaliski Decl. P 34. The parties
agree that the discovery interface is a software interface. For this reason, Dr. Kaliski maintains that one of ordinary skill in
the art would not understand software to include a boundary. Id. Professor Long disagrees with this conclusion, giving a few
examples of software interfaces that provide a boundary and direct connection. Long Reply Decl. P 22. But Professor
Long's opinion is significantly undercut by his concession that there may be software between the discovery interface and
the fabric driver in this invention. Specifically, Professor Long stated that there could be "some steps in between [the
discovery interface and the fabric driver] provided by something else," although he noted that such steps or code provide no
additional functionality or transformation of the data. Hearing Tr. at 120-21. As Dr. Kaliski noted, Professor Long's
conclusion that an interface requires a logical direct connection does not flow from NetApp's proffered dictionary
definitions, which involve a physical connection. In fact, Professor Long acknowledged that attributing physical
characteristics to software does not make sense. Id. at 120 ("physical-proximity requirement of instructions . . . doesn't make
any sense inside a computer's memory"). In sum, neither the intrinsic nor the extrinsic evidence supports including a
directness requirement.

Turning to whether or not the phrase should be construed as providing information to an "application" or providing
information in a "specified format," NetApp notes that Figure 5 shows that interface 503 (containing discovery interfaces
520 and 522) provides information to administrative application 502, yet Sun's proposed construction omits stating that the
discovery interface provides information to an application. Sun responds that the proposed "application" requirement
violates the doctrine of claim differentiation, because independent claim 1 includes no reference to an "application," but
dependent claim 3 includes the limitation "wherein the processor is further configured to execute an application configured
to request the device centric discovery interface to provide a list of fabric devices attached to the fabric . . . ." '951 patent at
14:38-43. However, claim 3 gives a much more detailed description of "application" -- in fact, as NetApp points out, the
claim adds nineteen lines of additional requirements to those stated in claim 1. It does not merely add a generalized
"application" requirement. Therefore, reading this requirement into the term's meaning would not render the dependent

- 1806 -
claim superfluous. See Sinorgchem, 511 F.3d at 1139–40 (characterizing doctrine of claim differentiation as the "presumption that each claim in a patent has a different scope").

The Court agrees with NetApp that Sun's requirement that the discovery interface provide information "in a specified format," without stating what that format is, is confusing. Sun argues that reference to the specific format is clear, because of the surrounding claim language. Sun notes that the term "discovery interface" is prefaced by either "device centric" or "transport centric" in the claims. '951 patent at 14:24, 27, 41, 44, 15:10-11, 13, 26-27. Because these two types of discovery interfaces differ in the format of device information, the claims require that the discovery interface provide the information in a specified format, depending on the type of discovery interface. However, since the claims already specify that format, see, e.g., claims 13 and 21 referring to "device centric format," Sun's proposed language is redundant and potentially confusing.

In sum, the Court adopts a hybrid of the parties' constructions of the term "discovery interface" and construes the term as: "One or more software modules that receive information from a fabric driver and provide the information to an application."

PART THREE

The Disputed Claims

Avocent contends that ClearCube's accused products infringe claim 1 of the '997 patent, and claims 1, 6, and 16-18 of the '919 patent. n31 Claim 1 of the '997 patent, and claims 1, 16, and 18 of the '919 patent, are independent claims. Claim 6 of the '919 patent is dependent on claim 1, and claim 17 of the same patent is dependent on claim 16. Claim 1 of the '997 Patent recites:

1. A system for transmission of analog color video signals between a source of said signals and a video monitor, being at spaced locations, comprising: n32

   a plurality of computers, each providing, as a set, said color video signals;

   a switch receiving said sets of said color video signals, each with respect to a common reference, from said computers and providing a selected said set of said color video signals as an output;

   a signal transmitter at a first location responsive to said output of a set of said color video signals, said transmitter, including n33 an amplifier for each said color video signal of one of said sets for providing a color video signal output and wherein n34 at least a high frequency portion of each said color video signal has been amplified as a direct function of frequency and providing both an inverting and non-inverting signal, available as an output;

   a plurality of video transmission circuits, each said circuit having first and second ends, respectively, one circuit for each of said color video signals of one of said sets and each said circuit having an input responsive to an output of said transmitter at said first end, and each said circuit having a responsive signal output at said second end;

   a signal receiver at a second location responsive to each of said transmitted signal outputs and color video signal at said second end, including an amplifier for each said color video signal for providing a discrete color video signal with respect to a common reference; and

   signal means responsive to said receiver for providing each said color signal, each with respect to a common reference, to an analog color video monitor: n35

Claim 1 of the '919 Patent recites:

1. An extended-in-length computer video communications link for transmitting computer video signals comprising:
a source of computer video signals including red, green, and blue video signals,

a video transmitter comprising a plurality of amplifiers, one of each said amplifiers for each of said red, green, and blue video signals, each said amplifier comprising:

a signal input for receiving a one of said red, green and blue video signals,

frequency sensitive compensating circuitry responsive to a said video signal so that said amplifier provides a first video signal that increases in amplitude with increasing frequency at a first output and a second video signal that is an inverse of said first video signal at a second output,

a twisted pair of conductors for each said amplifier, with first and second conductors of said twisted pair coupled at one end to respective said first and second outputs of said amplifier,

an adapter for each of said twisted pair of conductors, each said adapter coupled to an opposite end of a respective one of said twisted pair of conductors, each said adapter receiving said first video signal and said second video signal and providing a respective said video signal as a single ended output, and further configured to provide a ground reference potential for said transmitter at said adapter, whereby need for a reference ground conductor between said transmitter and said adapter is eliminated. n36

--- Footnotes ---

n31 Doc. no. 1 (complaint); see also doc. no. 125 (Avocent Huntsville's Summary and Background of the Technology Embodied in the Claims of the Patents-in-Suit), at 1.

n32 The word "comprising" is a term of art in Patent law that means the claim includes all of the elements that follow in the body of the claim statement, but does not exclude additional, unrecited elements. See, e.g., Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327-28 (Fed. Cir. 1999). Claims that use "comprising" are sometimes referred to as "open claims." See, e.g., Vivid Techs. v. American Science & Eng'g, 200 F.3d 795, 811 (Fed. Cir. 1999).

n33 The word "including" is another term that, like "comprising," signals the claim statement encompasses all of the elements that follow, but does not exclude additional, un-recited elements. See Robert C. Faber, LANDIS ON MECHANICS OF PATENT DRAFTING § 7 (4th ed. 1999).

n34 The word "wherein" is another term of Patent art that customarily signals the claim includes all the elements that follow, but does not necessarily exclude additional, unrecited elements. See id.

n35 '997 patent, col. 13 & line 14 through col. 14 & line 15. A copy of the '997 patent is located, among many other places in the record, at doc. no. 79 (Avocent's Combined Memorandum), Ex. A(2).

n36 '919 patent, col. 18, lines 12-41. The '919 patent is located, among many other places in the record, at doc. no. 79 (Avocent's Combined Memorandum), Ex. A(1).

--- End Footnotes---

Claim 6 of the '919 Patent, which is dependent to claim 1 above, recites "[a] video communications link as set forth in claim 1 wherein said source of video signals comprises a termination point of another video communications link." n37

--- Footnotes ---

n37 Id., col. 19, lines 5-7.

--- End Footnotes---

Claim 16 of the '919 Patent recites:
16. A computer video signal communications system for selectively coupling sets of R, G, B computer color video signals from one of a plurality of computers to a separately located color monitor, said system comprising:

   a transmitter including:

   switching means for selectively providing a said set of said color video signals from a selected said computer, and

   a first signal format converter responsive to each said color signal of a said set of color signals from said switching means for converting a signal format of each said color signal from single ended format to a balanced format;

   a plurality of sets of twisted pair conductors, each set of said conductors having a first end and second end, with a said first end of each of said sets of conductors receiving a discrete color video signal from said transmitter;

   a receiver coupled to said second ends of said sets of said twisted pair conductors and including:

   a plurality of second signal format converters for converting a said balanced format of each said discrete color video signal from each said set of conductors from balanced to unbalanced format; and

   signal means responsive to unbalanced format signals from said receiver for coupling color video signals to a color video monitor.

Claim 18 of the '919 Patent recites:

18. A computer video signal communications system for selectively coupling a set of R, G, and B computer color video signals from one of a plurality of computers to a separately located color monitor, said system comprising:

   a transmitter including:

   switching means for selectively providing said set of R, G, and B computer color video signals from a selected said computer, and

   a first signal format converter responsive to each said R, G and B color video signal for converting a signal format of each said R, G and B color video signal from single ended format to a balanced format;

   a set of twisted pair conductors for each said balanced format R, G, and B color video signals, each said set of twisted pair conductors having a first end and a second end, with a said first end of each of said sets of twisted pair conductors receiving a discrete one of said balanced format R, G, and B color video signals from said transmitter;
a receiver coupled to said second ends of said sets of twisted pair conductors and including:

- frequency compensation means for boosting a frequency response of each said R, G and B color video signal directly as a function of frequency;
- a plurality of second signal format converters for converting said balanced format of each said R, G and B color video signal from each said set of twisted pair conductors from balanced to unbalanced format; and
- signal means responsive to said unbalanced format signals from said receiver for coupling said R, G and B color video signals to a color video monitor. n40

PART FOUR

Claim Construction Decisions

A claim construction hearing was held on February 22 and 23, 2006. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 372, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996) (holding that the first issue in any patent infringement case is that of "claim construction": the interpretation of words used in a patent's claim, "the portion of the patent document that defines the scope of the patentee's rights"); see also, e.g., Rockwell International Corporation v. United States, 147 F.3d 1358, 1362 (Fed. Cir. 1998) ("The first step in any invalidity or infringement analysis is claim construction.") (citations omitted). The memorandum opinion and order entered on March 15, 2006, set forth this court's interpretation of the following, disputed, claim terms. n41

n41 See doc. nos. 133 (memorandum opinion) and 134 (order).

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

"Twisted pair" wiring, which is used in the '919 patented invention to conduct analog video signals, may be either "shielded" or "unshielded."

The term "amplifier," as it is claimed in both the '997 and '919 patents, was defined as "a circuit (or a device when connected in a circuit) that draws power from a source other than the input signal and provides an output signal that reproduces the essential features of the input signal."

The term "discrete," as it is used in the claims of both patents, simply means that a color video signal (e.g., red) is separate or distinct from the other two color video signals (e.g., green and blue).

Finally, the phrase "for said transmitter," as recited in claim 1 of the '919 patent, was construed as meaning "from the signals received from the transmitter."

1375

In order to prevail in its argument for an on-sale bar, defendants must show that the subject matter sold or offered for sale fully anticipated each patent claim or would have rendered each claim obvious. Plaintiff contends that the Intelliguard 500 did not fully anticipate the patent's claim as to the utilization of a "discrete coded signal." '867 Patent Claim 1. Specifically,
plaintiff contends that the use of the term "discrete coded signal" in its claim encompasses a limitation requiring the use of a coded signal with a "button signature." Whereas each of the Intelliguard 500's transmitters has a set code which is fixed in relation to a specific button on the transmitter, plaintiff alleges that it has claimed a limitation requiring that the transmitter be button programmable so that the signal reflects the pressing of a particular button or series of buttons. In support of their respective positions, the parties offer conflicting "expert" declarations construing the meaning of "discrete coded signal" as used in the patent's claims.

The Federal Circuit has held,

Claim interpretation is a question of law amenable to summary judgment, and disagreement over the meaning of a term within a claim does not necessarily create a genuine issue of material fact. The terms in a claim are given their ordinary meaning to one of skill in the art unless it appears from the patent and file history that the terms were used differently by the inventors. Thus, where a disputed term would be understood to have its ordinary meaning by one of skill in the art from the patent and its history, extrinsic evidence that the inventor may have subjectively intended a different meaning does not preclude summary judgment. In such instance, there is no genuine dispute respecting a material fact.

Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387 (Fed. Cir.1992) (citations omitted) (emphasis in original). The Federal Circuit has also held,

a patentee can be his own lexicographer provided the patentee's definition, to the extent it differs from the conventional definition, is clearly set forth in the specification.

As to the term "discrete coded signal" in the instant patent claims, the Court agrees with the decision of the ITC Administrative Law Judge that "there is nothing in the common meaning of the words . . . which requires the use of a so-called 'button signature.'" Defendants' Brief Ex. A at 16. Having reviewed all the materials properly before the Court, the Court finds that there is no genuine issue of material fact as to whether the '867 patent's claims can be interpreted to require a "button signature."

The language of the '867 patent's specification compels the above result. As noted by the Administrative Law Judge, the '867 patent states:

In one embodiment, a first discrete code is hardwired in a transmitter and provides one code out of up to 65,536 separate codes which is specific to that transmitter. In another embodiment, the transmitter means includes a control means and a memory means for storing the discrete code.

'867 Patent col. 2, lines 49-54. The use of the term "discrete code" to denote a code which is "hardwired" into a transmitter embodiment strongly suggests that the term not be given the special meaning suggested by the plaintiff. According to plaintiff, the "button signature" limitation allegedly encompassed within the meaning of "discrete coded signal" requires that the button functionality be programmable rather than preset. See Second Declaration of Peter J. Stouffer ¶ 5. In the language quoted above, the patent specification clearly uses the term "discrete code" to represent a preset code. Such usage, as well as the patentee's failure to "clearly set forth in the specification" a differing definition, forecloses upon plaintiff's argument. Accordingly, the Court finds that the Intelliguard 500 anticipates every claim of the '867 patent. Therefore, under 35 U.S.C. § 102 (b), the '867 patent is invalid.

On appeal, NCR challenges, among other things, the district court's construction of the claim limitations a "plurality of discrete switches" and "means for entering data." Claim construction is a question of law that we review de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456 (Fed. Cir. 1998) (en banc). We begin our analysis with the words of the
claim. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). "In construing claims, the analytical focus must begin and remain centered on the language of the claims themselves, for it is that language that the patentee chose to use to particularly point out and distinctly claim the subject matter which the patentee regards as his invention." Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323, 1331 (Fed. Cir. 2001) (citations omitted). The ordinary and customary meaning of a claim term may be determined by reviewing a variety of sources, including "the claims themselves; dictionaries and treatises; and the written description, the drawings, and the prosecution history." Ferguson Beauregard v. Mega Sys., LLC, 350 F.3d 1327, 1338 (Fed. Cir. 2003) (citations omitted).

The limitation "plurality of discrete switches" appears in the '845 patent in claims 1-7, 9, and 12-15, and in the '478 patent in claims 6-9 and 11. The district court construed "plurality of discrete switches" to mean "two or more distinct and separate manual or mechanically actuated devices for making, breaking, or changing the connections in an electric circuit" (for shorthand, the "physical switch" definition). NCR, 217 F. Supp. 2d at 508. NCR argues that the proper construction of "plurality of discrete switches" is "more than one individually distinct programmed device for indicating that one of alternative states or conditions have been chosen" (for shorthand, the "programmed device" definition).

NCR asserts that the district court improperly construed "plurality of discrete switches" because the court adopted one dictionary definition of "switch" (as a physical switch) and ignored alternate definitions of the term "switch" in the same dictionary. See Tex. Digital Sys. v. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002) ("If more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all such consistent meanings."). NCR also asserts that the specification supports its proposed construction of "plurality of discrete switches" as programmed devices.

We agree with the district court's construction of "plurality of discrete switches." Preliminarily, we see a fundamental difficulty with NCR's arguments with respect to this claim limitation: the fact that the claimed invention contains various programmed components, some of which are programmed to respond to the closure of simple mechanical-electrical switches, does not in turn make the switches themselves "programmed." Nor does the fact that multiple components are necessary for the operation of the device's entire display system mean that all of such components are part of the "plurality of discrete switches," as that term is used in the patent claims. We think that one skilled in the art, reading both the plain language of the claims and the specification, would conclude that the "plurality of discrete switches" is nothing more than a set of simple switches, and that separate components are programmed to respond to the actuation of those switches. These separately claimed components all work together to enable dynamic interaction with the user.

We begin with the language of the claims. See Nystrom v. Trex Co., 374 F.3d 1105, 1120 (Fed. Cir. 2004). Taking claim 1 of the '845 patent as an example, the claims recite various elements, including:

- a plurality of discrete switches for entering data when actuated;
- said discrete display elements and said discrete switches being positioned in overlapping relationship relative to said panel to enable said switches to be actuated from said panel;
- control means for controlling the operation of said device including said discrete display elements and said discrete switches so as to facilitate the displaying and entry of data;
- said control means comprising:
  - means for storing data and a plurality of machine instructions; and
  - means for executing said machine instructions including means for selectively energizing said display elements so as to present on said panel that key information and those of said user instructions which are associated with those of said discrete switches which are to be used in association with said machine instructions being executed so as to present to said user a variable user instruction format and a variable key format which are a function of said machine instructions being executed as said machine instructions are executed so as to facilitate the entry of data[.]

'845 patent, col. 14, l. 67 - col. 15, l. 23.
NCR asserts that software is "integrated" into the "plurality of discrete switches" to reconfigure the key areas for the user. See Brief of Appellant, at 34 ("When the user actuates that yellow area, software reconfigures the active key switch areas and reassigns different functions to those areas[].").

However, this is contradicted by the claim language. The claims indicate that the invention includes "a plurality of discrete switches" and a separate "control means" for controlling, among other things, the "plurality of discrete switches." According to the claims, it is the "control means" for the "plurality of discrete switches," and not the "plurality of discrete switches" itself, that stores "machine instructions" (i.e., software) and reacts to a switch in the "plurality of discrete switches." The "means for executing said machine instructions" within the "control means," and not the "plurality of discrete switches," presents on said panel that key information and those of said user instructions which are associated with those of said discrete switches...so as to present to [the] user a variable user instruction format and a variable key format." (emphasis added). The reconfiguring of the keys in a "variable user instruction format," recited in the claims as part of the "control means," contradicts NCR's assertion that this is performed by programming within the "plurality of discrete switches." This type of construction is disfavored. See Innova/Pure Water, Inc. v. Safari Water Filtration Sys., 381 F.3d 1111, 1119 (Fed. Cir. 2004) ("While not an absolute rule, all claim terms are presumed to have meaning in a claim.").

Thus, we think that one skilled in the art, reading the claim language, would recognize that the invention includes a dynamic display arrangement, which functions with the help of several separately claimed elements. A "means for executing said machine instructions" energizes certain "display elements" on the handheld's panel, with different display elements representing a menu option or a particular task that the user wishes to perform. The "control means" contains software to energize the proper display elements. Accordingly, the plain language of the claims indicates that a "control means" and a "means for executing said machine instructions" are programmed to cause the display elements to be selectively energized. The "plurality of discrete switches" is separate from the "control means" and its programming.

In addition to the fact that a separate claim element performs what NCR claims that the "plurality of discrete switches" is "programmed" to do, other claim limitations support the district court's interpretation that "plurality of discrete switches" means an array of physical switches. All of the asserted claims containing the "plurality of discrete switches" limitation also contain a limitation similar to that in claim 1 of the '845 patent:

sought discrete display elements and said discrete switches being positioned in overlapping relationship relative to said panel to enable said switches to be actuated from said panel..

'845 patent, col. 15, ll. 1-4; see also id. col. 16, ll. 39-42 (independent claim 16); '478 patent, col. 16, ll. 34-37 (independent claim 6); id. col. 18, ll. 7-10 (independent claim 11). This limitation also comports with the district court's physical switch interpretation, as it indicates to one skilled in the art that the switches are precisely located physical components. It would be strange to describe the switches, with software, as in "overlapping relationship" to anything, because there would be no precise place where a "switch" would be located. An entire component of the switches—the software component—would be stored in memory and only rendered by software. 1 The plain language of the claims stands as an obstacle in NCR's attempt to import separate claim limitations into the "plurality of discrete switches" limitation in an effort to broaden the meaning of that term.

--- Footnotes ---

1 In addition, NCR has not pointed to any part of the specification that describes where the programming for the "plurality of discrete switches" is stored. The only memory elements disclosed are part of the "means for controlling the P terminal 12" shown in Figure 8, see '845 patent, col. 8, l. 31 - col. 9, l. 21, i.e., they are part of the "means for controlling the operation of said device." See '478 patent, col. 15, ll. 5-7 (claim 1).

--- End Footnotes ---

The specification confirms the understanding found in the claim language that the switches are simple physical switches which are coupled with separate programmed components to make the entire overall display system functional for the user. In short, the specification discloses an array of transparent switches that are no more "programmed" than a simple mechanical "on/off" light-switch. It is other components that are programmed to dynamically "highlight" the appropriate physical switches that the user should actuate to perform a desired task, and to respond to the switch closures resulting from
a user's pressure on a key area.

The preferred embodiment, shown in Figure 7 of both the '845 and '478 patents, discloses an array of simple open/closed physical switches that are fabricated as a set:

GET DRAWING SHEET 4 OF 14

The specification unambiguously recites those elements that are included in the "plurality of switches:"

The upper compartment 38-2 contains those elements included in the plurality of switches 30 and they are included in the bracket 30-1 in FIG. 7.

… The plurality of switches 30 included in the bracket 30-1 in FIG. 7 is comprised of a top, transparent, flexible, plastic-film layer 50 such as Mylar. … The lower side of the layer 50 has five, equally spaced, transparent strips or conductors 52-1, 52-2, 52-3, 52-4, and 52-5 [.

… The plurality of switches 30 (FIG. 7) also includes a thin, bottom, transparent, plastic-film layer 54, and this layer has nine equally-spaced, transparent strips or conductors 56-1, 56-2, 56-3, 56-4, 56-5, 56-6, 56-7, 56-8, and 56-9 deposited on the top surface of layer 54. … A spacer layer 58 is positioned between the top layer 50 and the bottom layer 54 to provide insulation between the conductors. … The layer 58 has a plurality of holes therein, with each hole being located at an intersection between one of the conductors 52-1 through 52-5 and one of the conductors 56-1 through 56-9.

'845 patent, col. 6, ll. 8-10, 24-29, 35-48 (emphasis added). No software is disclosed as part of the "plurality of switches 30." It is logical that none would be, because the above figure and description make clear that the "plurality of switches 30" is comprised merely of a few plastic-film layers and strips of conductive material. A spacer layer separates the conductors, and holes in the spacer layer allow the top and bottom conductive strips to contact each other at different points, thus forming a set of discrete open/closed, mechanical-electrical switches.

Figure 7 and its related description undermine NCR's arguments with respect to the specification. NCR has not explained how, without more, the disclosed pieces of plastic and conductive strips can be "programmed," as well as what the switches would be programmed to do that is not performed by elements separately claimed and disclosed apart from the "plurality of switches 30." Although NCR is correct that programming appears to be an integral part of the device's overall operation, the specification's description of switch actuation reinforces the point that the "plurality of switches" is merely a set of open/closed, mechanical-electrical switches:

When a user wishes to actuate one of the plurality of switches 30, as for example that one associated with key area 28-9 in FIG. 4, the user simply depresses that area 28-9 causing the conductor 52-5 in FIG. 7 to pass through the hole 60-9 and thereby contact the conductor 56-9.

'845 patent, col. 6, ll. 58-63. Thus, a switch in the "plurality of switches 30" is a mechanical-electrical switch that is either open (when the upper and lower conductive strips are not in contact through a particular hole) or closed (when the pressure from a user's finger or stylus causes two conductors to contact through a particular hole to form a circuit). The handheld also includes a separate "keyboard interface 106" which "includes a set of drivers. … to scan the rows of switches in the keyboard array 64 and to inform the microprocessor 46 of the switch closures." Id. col. 9, ll. 14-17 (emphasis added). The specification thus comports with the district court's understanding that the patents disclose "the use of a plurality of discrete physical switches whose closures are recorded by a microprocessor." NCR, 217 F. Supp. 2d at 529.

NCR proffers other passages from the specification as supporting its programmed device definition of "plurality of discrete switches." First, NCR cites the following passage:

It should also be noted that the key areas themselves have no captions or labels on them in the usual sense. The labels or designations are provided by the display 26 which lies below the plurality of switches 30.

'845 patent, col. 5, ll. 46-50. This statement does not support NCR's contention that "software creates a switch" 2 that is in the "plurality of switches." This merely explains how the display 26 is dynamically "re-labeled," so that the user is directed
to the proper physical switches to actuate (which are transparent and lie above the corresponding display element) in order to complete various tasks.

2 NCR's argument conflates "actuation" of a switch with whether other components in turn respond to switch actuation. The fact that a separate component is "programmed" to do something (or, in some cases, to do nothing) in response to the actuation of a simple mechanical-electrical switch does not logically make that switch itself a "programmed device."

Second, NCR argues that a related passage supports its construction:

While the actual (physical) switches in the plurality of switches 30 are always present on the top panel 24, they are outlined or highlighted only when they become necessary for a particular function or instruction being executed by the P Terminal 12[.]

'845 patent, col. 5, ll. 48-54. We think that this statement undermines, rather than supports, NCR's proposed construction. As discussed supra, the "plurality of switches 30" is unambiguously described as a set of open/closed mechanical switches which are actuated by contacting two pieces of conductive material through a hole to complete a circuit. The above-quoted statement merely observes that certain physical switches in the plurality of switches 30 are not always "highlighted." In reading the above statement, one must bear in mind how the switches are, in fact, highlighted. The specification explains that the key areas are "outlined or highlighted" by the display 26 positioned beneath the plurality of switches 30. Id. col. 6, ll. 63-65. Thus, the above-quoted statement merely explains that, when certain switches are not necessary for a particular function, those switches are not highlighted, i.e., the microprocessor does not send a signal to energize the display elements lying below those particular transparent switches. 3 We find nothing in that description to indicate that there is some type of software or logic within the switch itself. Rather, it further confirms that the switches themselves are of the simple mechanical-electrical variety, and that the only way to make the entire display apparatus appear dynamic to the user is to have software to alter the state of separately claimed components, such as the display elements, rather than the plurality of switches 30.

3 See, e.g., '845 patent, col. 7, l. 59 - col. 8, l. 4 (discussing "pixel selection" by the microprocessor).

NCR also would have us infer that the language "the actual (physical) switches in the plurality of switches 30," id. col. 5, ll. 50-51, means that the physical switches are only "part" of a broader, more abstract set of switches that includes software. Breaking this argument into its logical components, NCR argues that (1) the "plurality of switches 30" contains something more than the physical switches; and (2) that the "something more" is software.

We can accept the first proposition, but must reject the second. The language "actual (physical) switches in the plurality of switches 30" indicates that the specification is distinguishing certain physical switches from the entire plurality of switches 30, which, in the preferred embodiment, is a set of switches that is fabricated together. In Figure 7, there is indeed something more to the "plurality of switches 30" than the actual physical switches, but this "something more" is not software. In the preferred embodiment, each of the switches in the "plurality of switches 30" is fabricated from a layer of transparent plastic and conductive material. Consequently, portions of the top layer 50, and all of the spacer layer 58, for example, are part of the "plurality of switches 30" yet conceptually are not part of any one particular physical switch.

NCR points to a third statement in the specification in support of its position:

Although the fabrication of switches 30 has been described in a specific manner, it is not intended to exclude other alternative methodologies to fabricate "transparent" switches such as homogeneous or discrete capacitive-film switches and electrostatic-sensitive switches, for example.
'845 patent, col. 7, ll. 5-10. We do not see how this passage shows that there is a software component to the claimed switches. The quoted statement does not mention programming or software; it only refers to physical fabrication methods of discrete physical switches.

NCR also proffers extrinsic evidence in support of its proposed definition of "plurality of discrete switches," quoting an article titled "Back to Basics: How Touchscreens Work":

All touchscreen systems have three components. To process a user's selection, a sensor unit [physical switch] and a controller sense the touch and its location, and a software device driver transmits the touch coordinates to the computer's operating system.

NCR concludes from this description that (1) the patented display system is a "touchscreen" system and (2) consequently, the "plurality of discrete switches" must include software. Defendants urge us not to consider this extrinsic evidence, citing Elkay Manufacturing. Co. v. Ebco Manufacturing. Co., 192 F.3d 973, 976-77 (Fed. Cir. 1999).

Assuming arguendo that we should consider this extrinsic evidence, it does not support NCR's construction of "plurality of discrete switches." The patents claim a "touchscreen" not by using that term, but rather by claiming its separate components, namely: "a plurality of discrete display elements" (which display items for the user); "a plurality of discrete switches" (a set of physical switches); and a "control means" (including a set of drivers). 4 This separation of the "touchscreen" into different claim limitations within the claims is mirrored by the specification's separation of the elements: a "display 26"; a separate "plurality of switches 30"; and a separate "keyboard interface 106" which "includes a set of drivers... to scan the rows of switches in the keyboard array 64 and to inform the microprocessor 46 of the switch closures." '845 patent, col. 9, ll. 14-17. Thus, NCR's extrinsic evidence confirms that a software driver is not considered part of the switches. Rather, according to this definition, both the switches and drivers are separate components of a "touchscreen."

--- Footnotes ---

4 The drivers are described in the context of Figure 8, which discloses the "means for controlling" the "P terminal" or handheld, and are not disclosed as part of the "plurality of discrete switches." See '845 patent, col. 2, ll. 33-35; id. col. 8, ll. 31-33; id. col. 9, ll. 14-17.

--- End Footnotes ---

For these reasons, we affirm the district court's construction of "plurality of discrete switches" as "two or more distinct and separate manual or mechanically actuated devices for making, breaking, or changing the connections in an electric circuit."

1377

B. Role of "Disk Platform"

Veritas' next question deals with the role of the "disk platform." The preamble of claim 1 states:

In a mass storage mechanism for a system having mass storage devices . . . wherein the system includes a host processor including memory and disk management facilities and a disk platform connected from the host processor and controlling a plurality of disk drive units comprising the mass storage devices.

Id. at 18 (col. 20, l. 47-53). The claim later recites "a memory management mechanism for controlling operations of the disk platform for writing data blocks and parity blocks into the disk drive." Id. at 19 (col. 21, l. 3-5). Those are the only references to the disk platform in claim 1. The disk platform is mentioned elsewhere in the specification, for example:

To accomplish its unique improvements over the prior art, the disk platform 28 includes its own computing capability as represented by the computer block 40. As will be seen shortly, the computer 40 may, in fact, comprise multiple processing units; but, for the present it is sufficient to note that the disk platform 28 is not the "dumb" controller 14 of the prior art.
Id. at 12 (col. 7, l. 48-54).

Initially, SCC argues that the disk platform is not an element of the invention, but is rather a "workpiece," a part of the environment in which the invention operates, but not an actual element of the invention, citing ROBERT C. FABER, LANDIS ON MECHANICS OF PATENT CLAIM DRAFTING § 16A (4th ed. 1996). The Court agrees that stylistically, "disk platform" is recited more in the manner of context, rather than a claimed element. Drafting style, however, is not dispositive of the question.

The determination of whether preamble recitations are structural limitations or mere statements of purpose or use "can be resolved only on review of the entirety of the patent to gain an understanding of what the inventors actually invented and intended to encompass by the claim." The inquiry involves examination of the entire patent record to determine what invention the patentee intended to define and protect. Gerber Garment Tech., Inc. [v. Lectra Sys, Inc.] 916 F.2d 683, 689 (Fed. Cir. 1990) (noting that preamble recitations provided antecedent basis for terms used in body of claim); Corning Glass Works v. Sumitomo Electric U.S.A.,, 868 F.2d 1251, 1257 (considering the specification's statement of the problems with the prior art) . . . .

In this instance, the disk platform is discussed in the specification as a part of the invention. It likewise is included not only in the preamble, but also in the claim language. Furthermore, as the language quoted above from the specification indicates, the disk platform was cited by the patentee as addressing problems with the prior art. Accordingly, the Court holds that the disk platform is a limitation of the claim.

This raises the subsidiary question of what constitutes a disk platform. The parties agree that "disk platform" is not a term commonly used in the art, or expressly defined in the patent. It is, however, implicitly defined in pertinent part by the language quoted above. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) (in construing claim courts should look to "intrinsic" evidence of the claims themselves, the patent specification, and the patent's prosecution history). Although not a complete definition of "disk platform," the Court holds that the specification requires that a disk platform includes its own computing capability and is not the "dumb" controller of the prior art.

C. "Display"/"Present"

The parties appear to agree that "display" and "present" mean to make visible to a human user. The only dispute is whether this meaning is sufficiently clear from the claim language, as PAN contends, or requires clarification, as asserted by Fortinet. The court finds that clarifying the meaning of "display" and "present" may be helpful to the jury and thus construes "display" and "present" as make visible to a human user.

Display and Display Device mean "an output device on which display images can be represented."

13. "display" ('702 patent)
The Court finds that claim 53 expressly requires "a display of an advertising presentation" in addition to "a display of one of the corresponding service representations," both displays occurring concurrently. The Court finds that the fact that an advertisement can be displayed in a window does not necessarily limit a display to "a single window." The Court finds that Defendants' attempt to limit "display" to a single window is an impermissible attempt to limit the term to an embodiment in the specification. Thus, the Court construes the term "display" as "a visual representation of."

The term "display" is used in claims 1, 21, 24, 38, 44, 49, 56, and 59 of the '412 patent, claims 1 and 8 of the '521 patent, and claims 1, 3, and 12 of the '183 patent. IPI defines the term as "an image that includes a collection of display objects together with spatial display relations between them." Defendants suggest that the term means "device that can be attached to a computer in order present images." The parties agree that the term should have the same definition in all three patents. The principal dispute is whether "display" refers to an "image" or a "device."

The patents' claims contain conclusive evidence that the term "display" refers to a physical device. Most notably, claim 1 of the '183 patent calls for "a data processor that receives input signals from the user input device and provides output signals to the display; the output signals causing the display to present images that include display objects." '183 Patent at 43:62-65. An "image" cannot "present images" nor can it receive "output signals."

Nevertheless, IPI argues that a "display" is akin to a visual representation of a workspace that, in turn, can contain other "displays." IPI justifies this theory by pointing to Figure 5, element 100, which shows essentially a desktop filled with different workspaces. See '412 Patent at Figure 5; 6:39-40. Further, there are instances within the specification that use the word "display" to mean an image. See '412 Patent at 30:36-52 ("the implementation of exit workspace procedure 204 described above updates the workspace data structure to include data necessary for regenerating substantially the same display at a later time"). IPI suggests that this usage evidences the patentee's overall intention to use "display" consistently throughout the claims as meaning an "image."

The patents' various usages of the word "display" does not support this conclusion. First, the specification confusingly uses the word "display" as a noun, an adjective, and a verb. In addition, the word "display" is combined with other words to create a variety of different specialized terms such as "display system object," "display object," and "workspace display." Given the wide and varying uses of the term, the patentee clearly had no intention of using the term "display" consistently throughout the specification. As noted, the claims themselves do not support IPI's definition. Accordingly, consistent with the usage of "display" in the claims, the Court defines the term as a "device that can be attached to a computer in order to present images."

Defendants have moved for summary judgment on the limited ground that none of the accused products infringe claims 1, 2, 4, 5, 6 or 9 of the '327 patent because they do not contain a "display," which defendants contend is required by each asserted claim. The parties do not appear to dispute that the term "display," as used in the claims, should be given its ordinary meaning. However, they offer no suggestions about what the ordinary meaning is. By their silence on the matter, I understand them to suggest that this is a case where the "ordinary meaning of the claim language" is "readily apparent even
to lay judges." Phillips, 415 F.3d at 1314. Therefore, I turn to general purpose dictionaries for the "widely accepted meaning" of this "commonly understood" word. Id. Using a broad definition of "display," I construe the term to mean "a visual representation of information." American Heritage Dictionary, 521 (4th ed. 2000) (defining "display" as visual representation of information); Webster's New World Dictionary 415 (4th College ed. 2001) (defining "display" as visual representation of data, as on computer video screen).

**1383**

Display area

The Court construes the term "display area" to mean "an area of display that is defined prior to the step of determining how much display area would be left over." Microsoft argues the term should be construed to mean "a display is the entire screen capable of showing visual information to a user." Microsoft removed portions of its earlier construction at the claim construction hearing. Sklar proposes the phrase should be construed to mean "a defined area on the display screen for displaying item labels and category labels."

Sklar argues "display" is an adjective that modifies the noun "area." Sklar contends that Microsoft's proposed construction seeks to separately construe the words "display" and "area" as nouns, thereby, changing the term "display area" to "the display's area."

The specification describes a display 900 ('843 patent, Fig. 11) but does not require that display 900 be the entire screen surface of a computer monitor. The specification describes a computer monitor 20 that has a display surface 22 ('843 patent, Fig. 4). The specification does not make any inference that display 900 is the entire display surface 22 of the computer monitor 20. If that were the result intended, the terms would have been referenced as one instead of separately. Furthermore, display 900 in Fig. 11 has dynamic data fields 906 and navigation buttons along the bottom of the display 900. These additional items take up space on display 900 that cannot be used to display category and item labels. The specification consistently uses the term "display area" as an area for displaying and not the entire screen surface of a monitor.

The actual term "display area" is used in the specification only a few times. Alternatively, the processor might set a threshold count and tentatively open each category having a number of items equal to or less than the threshold count and then adjust the threshold count to shrink or expand the list to best fit the display area.

Using the category labels and item labels, a display area can be efficiently populated, while giving the user an indication of the overall organization of the data in the database.

'843 patent, Cols. 10:60-64, 11:8-10 (emphasis added). The patents-in-suit specifically refer to the area where items are to be displayed. The Court rejects Microsoft's argument as the specification does not require the "display area" to include the entire screen. Alternatively, Sklar's proposed construction provides little guidance about how much of the display is used. Therefore, the Court's construction clearly calls out the sequence required by the claims of the patents-in-suit.

**1384**

Display Data

"Display data" is "information that defines the size, position, and content of each displayed window or window portion." All three uses of the term in the specification refer to the substantive content of a display that is generated by a first process and is ultimately reflected in a display list. Col. 6:6-9; Col. 8:60-62, and Col. 9:1-7. Therefore, to the extent a window is displayed, the display data indicates content. Furthermore, according to the literal claim language, the display data also indicates the positions and sizes, as defined by the subrectangle list, of the windows to be displayed.
C. DISPLAY DEVICE

This term appears throughout the specification and the claims of the '788 patent. MCT argues that a display device converts electrical signals to images while DisplayLink argues that the display device as claimed in the '788 patent is limited to representing VGA signals. The parties propose the following constructions:

<table>
<thead>
<tr>
<th>Term</th>
<th>DisplayLink's proposed construction</th>
<th>MCT's proposed construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>display device</td>
<td>Electronic device for visually</td>
<td>Device that converts electrical</td>
</tr>
<tr>
<td></td>
<td>representing VGA signals</td>
<td>signals to images</td>
</tr>
</tbody>
</table>

Claims must be construed in the context of the invention. Phillips, 415 F.3d at 1314. All of the claims in the '788 patent refer to displaying VGA signals. For example, claim 1 states that a VGA controller is "connected to the display device for conveying VGA signals to the display device." '788 patent at 4:66-67. The specification states that "[t]he VGA controller in turn forwards the VGA signals to the display device for display by the display device." Id. at 2:38-40. Further, the specification notes that "an object of the present invention is to provide a USB-to-VGA converter which converts USB based display signals issued from a host computer into VGA signals that can be received and recognized by a display device whereby images to be displayed can be transmitted from the host computer in USB form." Id. at col.1:31-36. Thus, the patent claims and the specification only refer to the display device with respect to the display of VGA images. In the context of the '788 patent, the display device is a device used to display the VGA signals. Dr. Min confirmed this in his testimony:

Q. Regarding the display device, does the '788 patent disclose anything other than a VGA?

A. No.

Min depo. at 51:10-16.

DisplayLink appears to suggest in discussing its proposed construction that the display device can only display VGA images. There is no basis for limiting "display device" to one that can only display VGA images. It only must be able to display VGA images. The court's adoption of DisplayLink's proposed construction should not be construed to imply that a display device must exclusively display VGA images.

The court construes "display device" as follows:

"Display device" is an "electronic device for visually representing VGA signals."

Display list comprising data defining a display in accordance with said output data produced by the corresponding first process

The Court modifies Microsoft's proposed construction and construes this term to mean "a set of instructions and/or data defining a display of a first process." AVG proposes that one of ordinary skill in the art would interpret this term as requiring both text data and graphics data. Microsoft disagrees, noting that such a construction excludes the preferred embodiment, which describes separate display lists for text and graphics. See Col. 7:26-36, 9:57-62, 10:22-30. Microsoft further proposes that one of ordinary skill would interpret the display list as necessarily comprising "instructions." The Court is not persuaded by either party's arguments because they provide no basis to deviate from the plain and ordinary meaning of the term, which affirmatively requires neither instructions nor the combination of text and graphics data.
Nonin and BCI agree that the term "display means" in Claim 2 of the '052 Patent is presumptively written in means-plus-function format. Nonin argues that the presumption is rebutted, however, because the '052 Patent uses "display" as a noun and the term would be so understood by one skilled in the relevant art. BCI contends that the claim does not recite sufficient structure to perform the function of "displaying the sensed and determined blood oxygen saturation level" and that the term "display means" should be construed as limited to an LED display, which is the corresponding structure in the written description.

The Court here agrees with Nonin that the word "display" as used in the '052 Patent is a structural term. The OED includes a noun definition of "display" as "a visual presentation of data from a computer," and that is the sense in which the '052 Patent uses the term "display." The Court accordingly adopts Nonin's proposed construction of the term "display means," which is "a visual presentation of the sensed and determined blood oxygen saturation level."

IPI construes the term "display means" as a camera, scanner, television, laser printer, fax machine, or the like that is coupled to the video fill circuit and displays the enhanced image. The only mention of this term in Sony's materials that the Court was able to locate indicates that Sony interprets this term in accordance with its ordinary meaning. See Joint Claim Construction Chart at 24. Because Sony does not appear to contest IPI's definition, the Court adopts IPI's proposal.

With respect to the display of the dynamic bid and ask regions, and static price axis, we construe "display of a plurality of bids and a plurality of asks" and "displaying the bid and ask display regions" as "a display of one or more bids and one or more asks," eSpecd encourages us to limit the display to information that is displayed in a single window. We decline to do so. The claim contains no such limitation and while the preferred embodiment does suggest a single window display, we will not import such limitations into the claims. See Wilson Sporting Goods, Co., 442 F.3d at 1329 ("This court...declines to read a limitation from the written description into the claims"); Ionova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 381 F.3d 1111, 1117 (Fed.Cir. 2004) ("particular embodiments appearing in the written description will not be used to limit claim language that has broader effect").

Finally, plaintiff requests that we reconsider our construction of the term "plurality," in the '132 patent. In our previous order we construed "display of a plurality of bids and plurality of asks," and "displaying the bid and ask display regions," as "a display of one or more bids and one or more asks." TT Markman I, 2006 U.S. Dist. LEXIS 80153, 2006 WL 3147697, at *9. Suggesting that "[i]t is well established in patent law that the term of art 'a plurality' calls for 'more than one,' and thus precludes 'one' from the definition" (TT's motion, at 14), TT argues that we erred in our construction. None of the defendants addressed plaintiff's contentions and, therefore, we assume none has a strong disagreement with plaintiff's construction. n6 As the term "plurality" has been previously construed in patents to mean "more than one," "at least two," and "two or more" (Bilstad v. Wakalopoulos, 386 F.3d 1116, 1123 (Fed.Cir.2004); ResQNet.com, Inc. v. Lansa, Inc., 346 F.3d 1374, 1383 (Fed.Cir.2003); York Products, Inc. v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1575 (Fed.Cir.1996); NCR Corp. v. Palm, Inc., 217 F.Supp.2d 491, 508 (D.Del.2002)), and the ordinary meaning of plurality is
"[t]he state or fact of being plural" (WEBSTER'S II NEW COLLEGE DICTIONARY (2001)), we grant plaintiff's motion to reconsider. We construe "display of a plurality of bids and plurality of asks" as "a display of more than one bid and more than one ask."

n6 CQG includes an unenlightening footnote on the subject. It reads, in relevant part: "To the extent that the Court decides it is appropriate to reconsider 'plurality' as it is used in terms such as 'dynamic display of a plurality of bids and a plurality of asks,' CQG asserts that its proposed construction of the greater term properly reflects the meaning of plurality as subsumed by the larger term."

2. "display unit"

The district court construed "display unit" to mean "a unit for displaying real-time data provided by the data acquisition unit." Claim Construction Op. at 7. Paragon disagrees. Paragon argued to the district court that "a display unit" should be construed as "an assemblage of inter-related components that unify the function of displaying data from the electronic positioning device and the physiological monitor." Id. at 5. On appeal, Paragon argues that the district court's construction was wrong in three respects, each of which we address in turn.

First, Paragon argues that the district court was wrong to construe "display unit" as displaying data "provided by the data acquisition unit." Rather, Paragon argues, the claim language permits the data to be provided by the individual components of the data acquisition unit--namely, the electronic positioning device and the physiological monitor. We agree with Paragon. Claim 1 recites "a display unit configured for displaying real-time data provided by said electronic positioning device and said physiological monitor." '759 patent col.28 ll.3-5 (emphasis added). The claim unambiguously states that the data provided to the display unit comes from both the electronic positioning device and the physiological monitor. Likewise, the specification makes clear that the electronic positioning device and the physiological monitor may be independently in communication with the display unit, to provide data used in the display. See, e.g., id. col.3 ll.3-5 (disclosing "a display unit (or component) configured for displaying data provided by the electronic positioning device and the physiological monitor"); id. col.7 ll.32-34 ("The system of FIG. 1 generally comprises an electronic positioning device 5 and a physiological monitor 6, both of which are in electrical communication with a display unit 7."); id. figs.1 & 2. Nothing identified by the parties in the prosecution history undermines the conclusion that the display unit displays data provided either independently or over a common transmission path from both the electronic positioning device and the physiological monitor.

The district court's construction combined the sources of data by incorrectly substituting "data acquisition unit" for "said electronic positioning device and said physiological monitor." Because we have determined that the data acquisition unit may be made up of multiple structures, it is important to make clear that the data displayed by the display unit may be obtained from the claimed electronic positioning device and the claimed physiological monitor either separately or over a common transmission path.

Second, Paragon argues that "display unit" should not be limited to a single structure, just as "data acquisition unit" should not be limited to a single structure. Preliminarily, we note that there is nothing in the district court's construction that would appear to limit "display unit" to a single structure. The district court merely concluded that the display unit must be a "unit"--which is the exact claim term. Moreover, there is no reason why the word "unit" in the term "display unit" would be limited to a single structure, when the patentee used the word "unit" in "data acquisition unit" to refer to one or more structures. "We apply a presumption that the same terms appearing in different portions of the claims should be given the same meaning unless it is clear from the specification and prosecution history that the terms have different meanings at different portions of the claims." PODS, Inc. v. Porta Stor, Inc., 484 F.3d 1359, 1366 (Fed. Cir. 2007) (quoting Fin Control Sys. Pty., Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001)); see also, e.g., Phillips, 415 F.3d at 1314 ("Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the
meaning of the same term in other claims."). The parties have identified nothing in the claims, the specification, or the prosecution history that would suggest that "unit" in "display unit" means anything different from "unit" in "data acquisition unit." The claimed "display unit" may therefore be multiple structures.

Finally, Paragon argues that "display unit" should not have been construed to require "displaying real-time data," because the claim recites merely that the display unit is "configured for displaying real-time data." '759 patent col.28 l.3 (emphasis added). Contrary to Paragon's argument, the district court did not construe "display unit" to require "displaying real-time data." Rather, it construed "display unit" as "a unit for displaying real-time data." Claim Construction Op. at 7 (emphasis added). The district court explained further that "for' denotes a function for which the display unit is configured." Id. Paragon was therefore wrong to characterize the district court's construction as requiring the display unit to actually "display[] real-time data," rather than merely to be configured to do so.

In sum, we modify the district court's construction of "display unit" and construe "display unit" as used in the '759 patent as "a structure or set of structures, separate from the data acquisition unit, for displaying real-time data provided by both the electronic positioning device and the physiological monitor independently or over a common transmission path."

b. "Displayed Image"

For the term "displayed image" in claim 146, IP proposes the following construction: an image presented by a display device. Lexmark and Dell propose this definition: an image displayed on a display device. Lexmark and Dell's proposed definition excludes printers as a permissible type of display device. As discussed above, we conclude that printers are within the scope of the 780 patent. Therefore, we construe this term to mean an image presented by a display device.

12. displaying a plurality of . . . play lists; displaying a plurality of . . . lists

The term "displaying a plurality of . . . play lists" appears in claims 3 and 7 of the '725 patent. The term "displaying a plurality of . . . lists" is found in claim 74 of the '725 patent. The plaintiff proposes a construction of "concurrently displaying more than one play list" for each of the above terms. The defendant's counter-proposal is "using a display to identify a plurality of [play]lists." The parties' dispute, as set forth in the briefs, is whether the contents of the list must be displayed (the plaintiff's construction) or whether it is sufficient that only the titles of a plurality of lists be displayed (the defendant's construction). The patent discloses the display of a plurality of play list titles (and titles alone) in Figure 4J. Based on this disclosure, it appears that this term embraces the situation where only the titles of the play lists are displayed. As a result, the court construes this term to mean "the simultaneous display of at least the titles of two or more play lists."

Displaying an item label for each item in the at least one open category and other open categories, if any, and a category label for each unopen category

The Court accepts Sklar's proposed construction and construes the term to mean "at least one category is designated as open and an item label is displayed for each item in this open category and any other open categories. A category label is displayed for each unopen category." Microsoft argues the term should be construed to mean "showing in the display an item label for every item in every open category and a category label for every unopen category. An 'item label' is all text and/or graphics used in the display to represent an individual item. A 'category label' is all text and/or graphics used in the display to represent a category of items."

At the Court's claim construction hearing, Microsoft agreed to remove the last two sentences of its proposed
construction related to defining an "item label" and a "category label" as all text and/or graphics to eliminate Sklar's concerns over their inclusion in the definition. Thus, the primary area of dispute between the parties has been resolved. The Court, however, adopts Sklar's proposed construction finding it better clarifies and simplifies the term.

21. "[D]isplaying in the second set of fields, the information identified by selection of fields of the first set of fields:" This construction flows from the plain and ordinary meaning of the limitations, and is illuminated by the construction of "field" supra.

TERM # 14: "and displaying, on said issuer's computer display, information associated with said bid including said computed interest cost value" - Defendants' proposed construction is an admitted restatement of the argument they lost on summary judgment. We will not revisit that issue. Based on our earlier constructions, this phrase means: "showing information associated with the submitted bid, including the bid's previously computed interest cost value, on the issuer's computer display."

"displaying … options and … choices"

JVL contends "displaying … options and … choices" means "simultaneously displaying both all video game menu options and separately displaying all video game menu choices when the video game menu options are available for selection." Def.'s '717 Presentation at 23. The principal disagreement is whether, as JVL argues, the options and choices must be "simultaneously" displayed.

JVL's reliance on the claim language to support its construction is misplaced. Indeed, the differences in the language in elements (b) and (c) contradict JVL's position. The term "displaying … options and … choices" is in element (b) of claim 1, describing a video display. The language also appears in element (c), describing a display controller. Claim limitation (b) of claim 1 reads "A video display for displaying and selecting the video game menu options and choices, the video game menu options being available for selection as video game menu choices." Nothing in the cited language suggests the "options" and "choices" must be displayed simultaneously.

Claim 1(c) states "a display controller for simultaneously displaying video game menu options and video game menu choices on the video display when the mode selector is in the programming mode, and for displaying video game menu choices when the mode selector is in the menu choice selection mode." The patentee's specific use of the word "simultaneously" in limitation (c) to indicate that the options and choices are displayed at the same time when in the programming mode undermines JVL's argument that "displaying … options and … choices" must always be read to be done simultaneously. See Phillips, 415 F.3d at 1314. Claim terms are presumed to be used consistently throughout the patent claims. Research Plastics, Inc. v. Fed. Packaging Corp., 421 F.3d 1290, 1295 (Fed. Cir. 2005). The insertion of "simultaneously" into JVL's construction would render 1(c) redundant and infuse 1(b) with unfounded meaning.

The prosecution history does not support JVL's construction. As discussed above, Merit distinguished its invention from the
Super Duper Casino prior art by noting that claim 1 of the '717 patent "discloses simultaneously listing all of the selectable games as options … and separately listing all of the games which are choices." Def.'s Suppl. Br., Ex. E at 15. Like JVL's construction, this statement describes "simultaneously" listing "all" options and choices, but it was not made to limit the invention to that capability. Rather, it was made to distinguish the '717 system from the programming setup of the Super Duper Casino prior art which provides a single list of all games and allows for each game to be switched "on" or "off." It does not include a separate list of "video game menu choices" in the programming mode. Id.

In certain instances "displaying … options and … choices" may mean, as JVL posits, the simultaneous and separate display of those options and choices. But, in those instances, such meaning is clear from the surrounding claim language. There is no basis for imposing JVL's suggested meaning on this term throughout the claims regardless of the context in which it appears. The term "displaying … options and … choices" as used in the '717 patent does not have a technical meaning that must be deciphered. The constructions for "video game menu options" and "video game menu choices" have already been discussed and the term "displaying" is unambiguous. Its plain and ordinary meaning is clear. Thus, construction of this language is unnecessary.

B. The Disputed Limitations

On the merits, the parties dispute the meaning of two related limitations in the '982 patent, "distributing" and "displaying" a combined order book to a trader. Independent claim 9 recites both limitations:

9. A data processing method for providing trading information to traders in a security or commodity from two or more alternative trading systems, comprising the steps of:

   receiving order book information from each participating alternative trading system in order book information protocols native to the particular alternative trading system;

   converting the information to a common system order book protocol;

   integrating the order book information from each alternative trading system into a single order book;

   distributing the combined order book to the traders in the common system order book protocol; and

   displaying said combined order book to the traders.

'982 patent, col. 14, ll. 1-14 (emphasis added). The district court construed the disputed limitations during a Markman hearing without issuing a formal claim construction order. Instead, the district court stated its claim construction from the bench at the close of the hearing. A district court retains discretion to rule in this manner, but in this instance the trial court's oral recitation provides a very sparse explanation of the findings and reasoning supporting the claim construction.

Regarding the distributing limitation, the district court concluded that it "simply means distributing the combined order book -- that means in terms of the specification the consolidated order book -- pertaining to all orders from all ECN members." Claim Construction Order at 442-43. In other words, the distributing limitation requires the distribution of the whole combined order book to the trader. The district court similarly construed the displaying limitation, concluding the system must display the whole combined order book for the trader. Upon review, the district court's interpretation of the "distributing" and "displaying" limitations conflicts with the plain meaning of claim 9 and excludes embodiments disclosed in the specification.

According to its preamble, claim 9 "provides trading information to traders in a security or commodity" rather than "all" securities or commodities. '982 patent, col. 14, ll. 1-2 (emphasis added). By selecting the word "a" instead of "all," the Applicant set forth a method wherein the traders may request and receive information for only a subset of the securities (i.e., one or more). See KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000) (the word "a" generally means "one or more" in open-ended claims). Thus, the language of the claim itself does not require the system to distribute or
display the whole combined order book.

Furthermore, the specification discloses embodiments that distribute and display information for only a subset of the combined order book. As an example, the specification describes one embodiment in which

the CCS 100 collects orders from each ECN, (ECN150 and ECN251) and electronic exchanges (NASDAQ 52), distributes a composite order book to the customers according to each customer's memberships in the ECNs and rights to use an electronic exchange. Thus customer 10 may only receive a subset of the complete order book compiled by the CCS 100 corresponding to where the customer 10 is permissioned.

'982 patent, col. 6, ll. 59-66 (emphasis added). n1 According to this embodiment the customer only receives a "subset" of the combined/complete order book from the system. Thus, this embodiment must also make the system capable of "distributing" less than the whole combined order book to the customer - i.e., a subset of the combined order book.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n1 While NASDAQ information comes from a particular electronic exchange rather than an alternative trading system, claim 9 is an open-ended claim that encompasses more than simply information from alternative trading systems. See U.S. Patent No. 6,278,982, col. 2, ll. 16-29, col. 14, l. 3.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The specification also discloses an embodiment in which bid and offer prices for Dell, a single security, are displayed on a market data screen:

Fig. 4 depicts a typical market data screen 250 of the present invention. Such screens can be customized as to data or order to conform to the customer's trading style. . . . The security under review is Dell Computer Corp. It was elected by inserting its ticker symbol DELL in space 252.

'982 patent, col. 8, ll. 47-54. This embodiment is further described in reference to Figure 5:

FIG. 5 shows pricing data that would be available to a customer of the present invention. Here, space 251 has been checked on screen 280 and ECN information integrated into the display. Screen 280 shows not only NASDAQ Level II data but also the full order book for the following three ECNs: Instinet, Island and Strike. For these ECN's, there are multiple bids and offers available for DELL, as opposed to just the best bid and offer. . . . Screen 280, thus, offers access to a greater amount of pricing information (thus greater liquidity), consolidated in one display. Thus, the entire order books of all ECN members and the market makers' bids and offers are consolidated into a single informative screen for any particular security. This additionally provides the customer with the ability to take advantage of price variations in a rapidly changing environment.

Id. at col. 9, ll. 9-25. Hence, the specification discloses embodiments that distribute and display information for only a subset of the securities (e.g., one in the embodiment of Figures 4 and 5) in the combined order book.

Reading the claim language and these embodiments in the specification, one of ordinary skill in this art would not limit the distributing and displaying limitations in the manner suggested by the district court. See Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) (en banc) ("Importantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification."). Rather, one of ordinary skill in the art would construe the distributing and displaying limitations as covering an embodiment that distributes and displays information for only a subset of the combined order book.

For at least these reasons, this court sets aside the district court's claim construction. Because the final judgment orders are premised on the flawed claim construction, they too must be set aside. The case is remanded to the district court for further proceedings consistent with this opinion.
9. Displaying Said Monochromatic Characters on Said Character-based Output Device

The phrase "displaying said monochromatic characters on said character-based output device" means transmitting the monochromatic characters to a character-based output device for display.

6. Displaying the cartographic data

The third subpart of claim 1 reads: "a display connected to the processor and capable of displaying the cartographic data." The disputed phrase is underlined. Plaintiff defines "displaying" as "graphically depicting." Defendant maintains that the term needs no construction, or in the alternative, that it should be construed as "showing." Defendant's definition is consistent with the ordinary meaning of the term "display." ("To show or exhibit; make visible." Webster's College Dictionary 380 (2d ed. 1999)). To define "displaying" as "graphically depicting" would add unnecessary confusion to an otherwise straightforward concept. Graphically depicting suggests that there may be graphs involved in the display and graphs come in a variety of forms. Plaintiff argues that, "[t]he phrase 'capable of displaying the cartographic data' is contextually defined in the specification of the '873 patent and should be construed consistent with such disclosure," dkt. # 56 at 28-29, but there is nothing in the claim or the specification to support or explain the use of the term "graphically." I construe the phrase, "displaying the cartographic data" as "showing the cartographic data."

4) "playlist" (claims 1, 15, 16)

STV Asia asserts that "playlist" means "program selection." In its Reply, it proposes in the alternative, "a list of selected audiovisual clips" or "selected audiovisual clips." Defendants assert the term should be construed as follows: "a list of video clips that are to be displayed at a retail store or stores. The playlist is created by a user who is located in a distribution center." The parties agree that a "playlist" at least includes the ordering or sequencing of audiovisual material. They disagree, however, as to whether a "playlist" also includes the sequenced audiovisual material itself. STV Asia asserts that it does, while Defendants argue it does not.

Defendants assert that the term "playlist" is defined in the specification and that that definition should be adopted by the Court in construing the term. In particular, the specification states that "[p]laylists are lists of video clips that are to be displayed at each of the retail stores," '069 patent, col. 9, ll. 44-45, and that "a playlist is a particular program sequence requested by a user who is located in the distribution center." '069 patent, col. 2, l. 67 - col. 3, l. 2.

STV Asia, however, points to the latter statement as evidence that the playlist includes not only the sequencing of audiovisual materials but also the actual audiovisual materials themselves. It also points to the following statements in the specification that it asserts support such a dual meaning of the term:

.. "The Playlist Database has . . . a contents table for each playlist that gives information on the clips (e.g. clip sequence number) included in each playlist." '069 patent, col. 11, ll. 16-24.

.. "When playlists or [sic] created or updated, the program determines which additional video clips are needed at the stores and sets a pending flag." '069 patent, col. 12, ll. 17-20.

.. "After the clips have been received and stored in the receiving sites, the system's software scheme performs the on-line program formation automatically in order to form the playlists. In the preferred embodiment, users enter the desired playlists for each receiving site into the system from the technical operation center. The user may enter one set of playlists
for many stores, etc. For each individual receiving site, the software assembles the desired playlist with the clips stored in that receiving site, and then forwards the clips to monitors for display." '069 patent, col. 5, ll. 5-15.

STV Asia also points to the usage of the word "playlist" in the claims. In particular, STV Asia asserts that while claim 16 appears to use the term "playlist" to refer only to include the sequencing of the audiovisual material, claims 1 and 15 use the term in a manner that suggests it may include the sequencing or the content.

A number of the citations to the specification offered by STV Asia in support of its proposed construction are not persuasive. It is unclear, for example, why the statement "The Playlist Database has . . . a contents table for each playlist that gives information on the clips (e.g. clip sequence number) included in each playlist" shows that the "playlist" includes the content of the playlist. See '069 patent, col. 11, ll. 16-24. Similarly, the statement "When playlists or [sic] created or updated, the program determines which additional video clips are needed at the stores and sets a pending flag" does not provide strong support for STV Asia's position. '069 patent, col. 12, ll. 17-20.

Nonetheless, the Court finds support for STV Asia's proposed construction in at least one statement in the specification, found in col. 5, ll. 5-15 (quoted above), and in claim 1. In both places, the inventor appears to have used the word "playlist" as a shorthand to refer to the assembled audiovisual clips on the playlist. Claim 1 refers to a "network management system forming playlists" and "display units for displaying the playlists." While the first usage of "playlist" appears to refer to the list of audiovisual clips, it seems fairly clear that the second use of the term "playlist" refers not to the sequencing of the clips but rather, to the assembled audiovisual clips themselves. Similarly, when the specification states that the software "assembles" the "playlist with the clips stored in that receiving site," '069 patent, col. 5, ll. 13-14, the common-sense reading of that statement is that the "playlist" is the audiovisual clips themselves.

In reaching this conclusion, the Court is mindful of the general presumption that "the same terms appearing in different portions of the claims should be given the same meaning unless it is clear from the specification and the prosecution history that the terms have different meanings at different portions of the claim." Fin Control Sys. PTY, Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001). Here, however, the Court concludes, based on the description of the invention in the specification, that the inventors used the term "playlist" both to refer to the sequencing of audiovisual material and as a shorthand for the sequenced material itself. In particular, when the inventors used the phrase "displaying the playlists" in claim 1, they were referring to the audiovisual clips themselves. All other references to "playlists" in the disputed claims are to the sequencing of the audiovisual clips.

The Court construes the claim term "playlist" as follows: "a particular program sequence requested by a user who is located in the distribution center." The Court construes the phrase "displaying the playlists" as "displaying the audiovisual content listed in the playlists."
Rate Map that may be used to make a flood zone determination for the real property." The defendants contend that the clause means "FEMA designations that may be used to make a flood zone determination for the real property." Although the two definitions are close, the plaintiff's construction is too limiting. The claim language only requires data that "may be used" to make a flood zone determination. As a result, the defendants' construction appears proper, and the court adopts it.

1403

G. "disposed above"

The final claim of the '776 patent requires that there be a "second conductive gate disposed above and insulated from said first conductive gate." '776 patent, 14:6-7. Although defendant originally asserted in the joint claim construction statement that the upper gate had to be "aligned" above the lower gate, it did not argue that position in its briefs. The parties now appear to agree that although the second conductive gate must be "above" and separated from the first conductive gate, it need not be perfectly aligned. Seeing no evidence to suggest that the gates must be aligned, the Court agrees that this is the ordinary interpretation of this phrase and construes the claim accordingly.

1404

C. Claim Construction of "Window Disposed Adjacent to the Hole"

Claim 1 refers to a rotatable platen "having a hole formed therethrough" and an endpoint detector compromising "a window disposed adjacent to the hole formed through the platen, the window rotating with the platen and intermittently providing a pathway for the light beam to impinge on the wafer." ('454 Patent, Col. 16, lines 26-28, 35-38). Plaintiff argues that the claim only requires that the window rotate with the polishing pad. Specifically, Plaintiff points to the three (3) figures that are a part of the patent specification. Figures 3A-3C represent simplified cross-sectional views of respective embodiments of the windows. Figure 3A shows a window as an insert made of light transmissive material which is mounted securely in a hole in the platen.

[SEE FIG. 3A IN ORIGINAL]

Figure 3B represents an embodiment that allows the pad itself to be used as a window. The light is transmitted through the hole in the platen and through a light-transmissive portion of the polishing pad surface, thereby allowing light to transmit through the pad.

[SEE FIG. 3B IN ORIGINAL]

Figure 3C - the window is essentially a plug that is inserted into the pad.

[SEE FIG. 3C IN ORIGINAL]

Defendants argue that Figure 3A does not conform with the specification because the claim requires that the window be a part of the pad. Defendants focus on the limitation that the "window moves with the polishing pad." Defendants' interpretation would require that when the pad is removed from the machine, the window must still be attached.

The Court does not interpret the claim the same. Looking at the claim language, it is clear that Plaintiff intended to incorporate all three figures as part of the patent. Dependent Claim 2 states "wherein the window compromises an insert mounted within the hole in the platen, the insert being transmissive to the light beam" and is depicted as Figure 3A. Dependent Claim 6 describes the window as comprising "a portion of the polishing pad, the portion being at least partially transmissive to the light beam" as depicted in Figures 3B and 3C. ('454 Patent, Co. 16, lines 57-59). Several other dependent claims also refer to both embodiments of the window:

. Dependent Claim 14: "wherein the window comprises a light-transmitting insert mounted in a hole through the platen."
Dependent Claim 18: "wherein the window comprises a light-transmitting portion of the polishing pad." ('454 Patent, Col. 17, lines 39-40).

Dependent Claim 25: "wherein the polishing pad support comprises a metal portion and the window comprises a hole through the metal portion of the polishing pad support." ('454 Patent, Col. 18, lines 17-20).

Dependent Claim 26: "wherein the window comprises a light-transmitting portion of the polishing pad." ('454 Patent, Col. 18, lines 22-24).

Defendants' construction is inconsistent with the claim language and seeks to limit the claim language only to the embodiment in dependent Claim 6.

Additionally, the specification clearly describes Figures 3A-3C as part of the preferred embodiments of the apparatus. The specification goes into great detail to explain the difference in the figures and how to achieve the results as tested in the embodiment. ('454 Patent, Cols. 6-7). There is no additional evidence provided by the prosecution history.

The plain and ordinary meaning, which is not contradicted by the intrinsic evidence, would leave a person to conclude that the window must move with the polishing pad while the machine is in motion. Accordingly, the Court FINDS that the "window disposed adjacent to the hole formed through the platen" encompasses windows that are both in and near the hole of the platen.

F. "disposed entirely over"

The '750 patent requires "a second gate electrode . . . disposed entirely over said first gate electrode." '750 patent, 13:1-3. The parties have raised the same arguments as with the "disposed above" term of the '776 patent. The addition of the term "entirely" in this patent, however, requires that the phrase be construed differently. If the upper gate electrode overhangs the lower gate electrode, it is not "entirely over" in the normal meaning of that phrase. The Court holds that the '750 patent requires that the second gate electrode must be located above the first gate, and that no portion of the second gate electrode may extend horizontally beyond the edge of the first gate electrode.

C. "a plurality of pixel electrodes disposed on cross points"

Plaintiff argues that "a plurality of pixel electrodes disposed on cross points" should be construed to mean "pixel electrodes arranged such that each transistor controlling a pixel electrode is located at the intersection of a signal and a scanning line"; plaintiff contends that the word "on" should be construed in the sense of "on the corner" of two streets. Defendants argue that the phrase should be construed to mean "pixel electrodes atop the intersection of the signal and scanning lines." The parties' constructions differ in only one relevant respect. In plaintiff's construction, it is the transistor controlling each pixel that is located at the intersection of the lines. In defendants' construction, the pixel electrode itself must not only be at the intersection, but "atop"—i.e., directly above—the intersection.

The use of the word "on" in the claims, rather than "at," strongly favors defendants' proposed construction. Plaintiff's gas station analogy notwithstanding, the word "on" generally denotes more than just proximity; an object is "on" another object when it is above or supported by that object.

The specification is fully consistent with defendants' proposed construction. Several passages are relevant to the geometry of the electrodes. The first passage appears at column 2, line 62 to column 3, line 1:

- 1830 -
Also, in the pixel element, a most projected portion is in a region where the scanning lines and the signal lines are superimposed one on another, and in the region, not only the scanning line, the signal line, an inter-layer insulation film for separating those lines from each other, but also a pixel electrode, a black matrix and so on are laminated one on another.

Id. at 2:62-3:1 (emphasis added). The second passage, between column 4, line 62 and column 5, line 2, states as follows:

Id. at 4:62-5:2 (emphasis added). These two passages describe the points of highest elevation on the lower substrate, where the circuit elements in the middle of the matrix are stacked so high that "the scanning lines and the signal lines are short-circuited between the top and the bottom through the spacers, thereby causing the point defect and the line defect." Id. at 3:12-14. In order to accommodate the high elevation, within the interval correction means "the first support members 301, 302 and 303 and the second support members 701 are designed so as to be superimposed one on the other, thereby being capable of making the step of the substrate interval maintaining means nearly equal to the height of the region in which the thickness of the matrix circuit is maximum." Id. at 4:51-56. The cited language corresponds to embodiments 4 and 5 in the patent, as depicted in Figures 12 through 15. In embodiments 4 and 5, the pixel electrode is disposed "atop" the intersection of signal and scanning lines.

The third relevant passage consists of Figure 2 and its accompanying narrative, which shows how the matrix circuit is formed in Embodiment 1. Of particular note is Figure 2E, showing the completed pixel circuit. In Figure 2E the pixel electrode, 228, is located directly above the gate electrode, 209, of the pixel TFT. See also id. Fig. 2A. The gate electrode, in turn, is a part of the scanning line 302. Id. at 8:10-12. Similarly, the other electrodes for the pixel TFT, 224 and 225, which are also located directly below the pixel electrode, are part of the signal lines 303. Id. at 9:28-40. In Embodiment 1, as well as in Embodiments 4 and 5, the pixel electrode thus appears to be directly atop the intersection of the signal and scanning lines.

The court therefore adopts defendants' proposed construction: "a plurality of pixel electrodes disposed on cross points" is construed to mean "pixel electrodes atop the intersection of the signal and scanning lines."
## A. Claim Construction

On February 16, 2006, the Court held a claims-construction hearing in this matter. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The Court considered the '136 Patent and prosecution history, the parties' Markman briefs, the applicable law regarding, inter alia, claim construction, indefiniteness, and means-plus-function claims, and the argument of counsel. On May 25, 2006, this Court rendered a claims-construction order (Doc. # 292), which construed the terms as following:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Construed Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Debit Card&quot;</td>
<td>&quot;a prepaid card for exchange of value&quot;</td>
</tr>
<tr>
<td>ID information [stored on the debit card]</td>
<td>&quot;encrypted data, excluding the card number, stored on the debit card in the form of merchant ID, store ID, or terminal ID&quot;</td>
</tr>
<tr>
<td>&quot;Terminal&quot;</td>
<td>&quot;a point-of-sale apparatus, which includes a central processing unit, a card reader, a keypad, and a communications interface&quot;</td>
</tr>
<tr>
<td>ID information [stored on the terminal]</td>
<td>&quot;data stored on the terminal in the form of merchant ID, store ID, or terminal ID&quot;</td>
</tr>
<tr>
<td>Stored thereon prior to the transaction</td>
<td>&quot;stored on the terminal prior to the consumer presenting the debit card to the merchant&quot;</td>
</tr>
<tr>
<td>&quot;Relates . . . in a predetermined manner&quot;</td>
<td>&quot;prior to a transaction, ID information stored on the debit card and ID information stored on a terminal are capable of being matched&quot;</td>
</tr>
<tr>
<td>&quot;Matching&quot; and &quot;Matched&quot;</td>
<td>&quot;determining whether ID information stored on the debit card and corresponding ID information stored on the terminal are equal or identical&quot;</td>

1409

Claim Language  Fast Memory's Proposed Construction  Defendants' Proposed Construction

"a first doped region disposed under the edge of the stacked gate"  a part of the doped source region located beneath the edge of the stacked gate the part of the doped source  region located directly under the edge of the stacked gate

The parties agree that the first doped region must be near the edge of the stacked gate, in order to effectively redirect the current away from the damaged area. This dispute concerns whether the first doped region must be located directly under the edge of the stacked gate, or merely under it. Fast Memory argues that the gouge caused by the SAS etch removes silicon on the substrate and makes it impossible for the source side substrate to be directly under the edge of the stacked gate.

Expert testimony does not resolve the technical question of whether the SAS etch gouge prevents the first doped region from being located directly under the edge of the stacked gate. In his deposition, Dr. Liu stated that the etch may remove the silicon from the edge of the stacked gate and that the doped source region will be lower than "directly under the stack[ed] gate etch." 51 Dr. Liu concluded that locating the source region directly under the stacked gate would render the patented invention unworkable. 52 Defendants' expert, Dr. Taylor, states that the first doped region must be located directly under the stacked gate edge, because locating the first doped region away from the surface of the source exponentially diminishes the strength of the electric field, thereby reducing the ability of the doped regions to redirect the erase current. 53 However, Dr. Taylor does not address whether the SAS gouge prevents the first doped region from being located directly under the edge of the stacked gate.

51 Pl.'s App. at 431 (Liu Dep. 94:15-24).
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

Fast Memory contends that the claim language provides for all possible locations of the first doped region. In response, Defendants cite to a preferred embodiment, which states that the first doped region is located "directly under the edge of the stacked gate." 54 Yet, the specification also describes the implanted source region as disposed "under the edge of the stacked gate." 55 Neither do the figures in the patent conclusively show that the first doped region must be located directly under the edge of the stacked gate. 56 The mixed evidence in the record does not show that the "character of the invention requires the limitation be a part of every embodiment," and the Court declines to import the "directly under" limitation urged by the Defendants into the claim. 57 The Court construes "a first doped region disposed under the edge of the stacked gate" as: "a part of the doped source region located beneath the edge of the stacked gate."

any electrically conductive layers that may be disposed upon the passivating layer; and 3) to provide a flat, level surface so as to assure a uniform thickness for any layer of liquid crystal material disposed thereon.

Id. (emphasis added). DNP has proposed that this term means:

Placing a separate and distinct, continuous layer of transparent, electrically insulating material on top of and separate from the layer of material that prevents passage of light and the light influencing material, wherein the passivating material is adapted to, and must be deposited to a depth sufficient to perform the following critical functions: 1) to level the underlying filter and opaque layers to a continuous, flat surface to serve as a base upon which subsequent layers may be formed; 2) to electrically insulate the light influencing element from any electrically conductive layers that may be disposed upon the passivating layer; and 3) to provide a flat, level surface so as to assure a uniform thickness for any layer of liquid crystal material disposed thereon.

Dkt. No. 117 at 42-43 (emphasis added).

a. Objections

DNP argues that "the passivating material also itself must be electrically insulating because that's the plain ordinary meaning of that claim [sic, term]." Objections Tr. at 20:10-15; see also Dkt. No. 126 at 6-7. DNP submits that while the written description specifies three functions of the passivating layer, the Order merely requires that any two of these three functions be satisfied. Objections Tr. at 21:19-22:8; see also Dkt. No. 126 (citing Pharmacia & Upjohn Co. v. Mylan Pharms., Inc., 170 F.3d 1373, 1377 (Fed. Cir. 1999) & Heuft Systemtechnik GMBH v. Indus. Dynamics Co., Ltd., Nos. 2007-1417, 2007-1462, 282 Fed. Appx. 836, 2008 WL 2518562, at *4 (Fed. Cir. June 25, 2008). As further support, DNP notes that the requirement of a continuous passivating layer indicates that the passivating layer is electrically insulating because continuity is required to achieve electrical insulation. Id. at 23:4-8; Dkt. No. 126 at 9-10. DNP also argues that as to prosecution history, "the electrically insulating function of ATI's passivating layer was the only possible grounds for patentability over Haneda. Dkt. No. 126 at 10. DNP further argues that the list of "two critical functions" in the specification is really a list of two functions, despite including a three-part list, because two parts of that list refer to leveling to create a flat surface. Id. at 8-9. Therefore, DNP argues, the specification presents "two critical functions," including electrically insulating, that must be claim limitations. Id. at 9. DNP also submits that "[t]he Order erred . . . by deleting the word 'critical' and adding the words 'of the following,' thereby incorrectly making critical functions optional." Id.

ATI responds that "[t]he specification says that the passivating material must perform at least two of three functions, only one of which is insulating." Id. at 31:12-14; Dkt. No. 130 at 5. ATI submits that the patentee "acted as his own lexicographer" in defining the passivating material. Dkt. No. 130 at 6-7. ATI also submits that "DNP incorrectly concludes that if the layer is continuous it must insulate." Id. at 7. As to prosecution history, ATI argues that "[n]either that inventor nor the USPTO examiner ever stated that the optional insulating function of the passivating layer was a point of distinction over Haneda." Id. at 8. ATI also argues that because several differences existed between rejected and allowed claims, no clear disavowal of claim scope occurred by amendment. Id. at 8-9.

DNP replies that "the specification clearly says that all three of those [listed] elements are critical. . . . [T]he ['critical'] adjective precedes the list." Id. at 33:15-17. DNP also asks the Court to "consider and rely on the dictionary definition offered by DNP." Dkt. No. 140 at 4. DNP also argues that "[r]ecognizing electrical insulation as a 'critical function' also avoids the mistake of interpreting the phrase 'critical functions' as 'optional functions' . . ., and further avoids the Order's error of replacing the phrase 'two critical functions' with the unsupported phrase 'two of the following.'" Dkt. No. 140 at 5. DNP further argues that "disclosure of only insulating materials supports that the passivating layer is electrically insulating."
In sur-reply, regarding prosecution history, ATI argues that allowed application claim 15 recites a "liquid crystal subassembly" that "includes both the color filter and the transparent conductive layer" while "the Haneda patent is limited to a color filter but does not disclose a subassembly with electrodes." Dkt. No. 147 at 2. Regarding the Certificate, ATI submits that "even assuming arguendo that the correction did not broaden the claim, whether a broadening correction would have been apparent to one of ordinary skill in the art, and thus allowed under 35 U.S.C. § 255, is a question of fact for the jury." Id. at 3 (citing Arthocare Corp. v. Smith & Nephew, Inc., 406 F.3d 1365, 1374-75 (Fed. Cir. 2005)).

b. Discussion

The parties agree that the patentee provided meaning for "passivating material" where the specification discloses as follows regarding the "passivating material 26":

'T71 Patent at 7:22-31; see ATT's Opening Brief Regarding Claim Construction, Dkt. No. 81 at 15-16; Sharp's Response Claim Construction Brief, Dkt. No. 83 at 12; DNP's Response Claim Construction Brief, Dkt. No. 84 at 6 and 15. The specification thus discloses that the passivating material "must be [] deposited to a depth sufficient to perform at least two critical functions." Id. (emphasis added). Although a person or skill in the art could speculate that the patentee intended all three of functions "1)," "2)," and "3)" to be described as "critical" but erroneously stated "two critical functions" instead of "three critical functions," the actual text of the specification should be given weight. Further, the specification does not elsewhere clarify whether or not all three of the "critical functions" must be performed by the passivating material 26. Because the parties agree that the specification defines "passivating material" and because the specification describes certain functions as "critical," the Court's construction should parallel the specification by requiring that the "passivating material" is configured such that "at least two" of the "critical" functions are satisfied. 'T71 Patent at 7:23.

As to the prosecution history, no prosecution disclaimer occurred at least because the patentee did not amend or argue over Haneda. Instead, the examiner allowed application claim 15 as originally filed and the patentee simply amended claims to depend therefrom. See 3/17/1993 Office Action and 3/30/199[3] Amendment, Dkt. No. 84 at Ex. D.

As the Order found, "[h]ad the inventor intended to require that all three functions be required and were 'critical' to be a passivating layer, then he could have used the word 'three.'" Dkt. No. 117 at 37. The Order properly found that the three functions of the "passivating layer" are distinct functions. In particular, the Order found that function "1)" and function "3)" are separate because these functions are listed separately, affect different layers, and are directed to different purposes. Id. at 41-42. The Order also properly found that the description of a "transparent, insulating, passivating material 26" is identified as a "preferred embodiment" and that the electrically insulating function is not required. Id. at 37-38. Further, the Order properly found that "[r]ecognizing the fact that the inventor required a conductive layer be placed on the passivating layer does not lead to the conclusion that the passivating layer cannot be conductive." Id. at 38. Finally, the Order properly found no prosecution disclaimer requiring that the passivating layer be electrically insulating. Id. at 39-40.

The Order construed "passivating material" to mean "a material that performs two of the following functions," but neither the Order nor the specification indicate that two and only two functions are performed. Instead, the specification itself discloses that "at least two critical functions" are performed. For clarity, the construction of "passivating material" should include "a material that performs at least two of the following functions." As to whether the word "critical" should be included in the construction, the specification uses the word "critical," but including the functions in the construction already requires that these functions must be satisfied. The term "critical" should accordingly be omitted to avoid surplusage and to avoid confusion about the meaning of "critical."

For at least the foregoing reasons, the Court should construe the term "disposing a continuous layer of transparent, passivating material atop said layer of opaque material and said light influencing material" to mean "placing a continuous,
separate layer of transparent, passivating material atop the separate layer of opaque material and the light influencing material, where the passivating material is a material that performs at least two of the following functions: 1) levels the underlying filter and opaque layers to a continuous, flat surface to serve as a base upon which subsequent layers may be formed; 2) electrically insulates the light influencing element from any electrically conductive layers that may be disposed upon the passivating layer; and 3) provides a flat, level surface so as to assure a uniform thickness for any layer of liquid crystal material disposed thereon."

II. Claim Construction

On appeal, we must decide whether the district court properly construed the claim term "distinct." In the asserted claims, the term "distinct" is used to describe how the metacode map and the mapped content are stored. Specifically, the claims say the metacode map is stored in "distinct map storage means" or "distinct storage means." See, e.g., '449 Patent col.16 ll.20, 25-26, 53-54. Analogously, the document's content is stored in "mapped content storage," id. at col.16 ll.22-23, or "mapped content distinct storage means." Id. at col. 15 l.51 (emphasis added).

Before the district court, Microsoft argued that "distinct" added two requirements: (1) storing the metacode map and mapped content in separate files, not just separate portions of the computer's memory; and (2) the ability to independently edit the document's content and its metacode map "independently and without access" to each other.

The district court rejected both of Microsoft's proposed limitations. Based on its review of the claim language, the specification, and prosecution history, the district court concluded that "distinct" did not require storage in separate files. Similarly, it concluded that the user's ability to independently edit the document's structure or content was a benefit of separate storage, not a claim limitation. The district court then defined "distinct map storage means" in more general terms, as "a portion of memory for storing a metacode map." "Mapped content distinct storage means" was defined as "a portion of memory for storing mapped content."

On appeal, Microsoft renews both arguments about the meaning of "distinct." We review the district court's claim construction de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1454-55 (Fed. Cir. 1998) (en banc). To ascertain the scope and meaning of the asserted claims, we look to the words of the claims themselves, the specification, and the prosecution history. Phillips v. AWH Corp., 415 F.3d 1111, 1115-16 (Fed. Cir. 2004) (holding that the claims are not "presumed" to be restricted to the embodiments disclosed in the specification). We conclude that the district court properly rejected both of Microsoft's proposed limitations.

A. Separate Files

To determine whether "distinct" adds the requirement of storage in separate files, we begin with the claim language. See Phillips, 415 F.3d at 1312. In this case, the claim's plain language does not require storage of the metacode map and mapped content in separate files. The term "file" appears nowhere in the '449 patent. Instead, the claims use "storage means"; the specification uses "structures." '449 Patent col.16 ll.22-26, 53; see also id. at col.4 ll.7-13, 21-24. Both "storage means" and "structures" are broader terms than "file," suggesting no particular format. At trial, i4i's expert testified that a person of ordinary skill in the art would understand "structures" to store and organize data, but not as limited to a particular storage format. Indeed, the specification arguably renounces particular formats by defining "document" as a "non-random aggregation of data irrespective of its mode of storage or presentation." Id. at col.4 ll.57-59 (emphasis added).

Turning to the specification, we similarly see no "clear intent[] to limit the claim scope" to storage in files. Abbott Labs. v. Sandoz, Inc., 566 F.3d 1282, 1288 (Fed. Cir. 2009). The sample algorithms do not say the storage means is restricted to "files." '449 Patent col.8 ll.53-62; see Innova/Pure Water, 381 F.3d at 1121-22. Instead, they use the more generic term "storage space," creating one for the mapped content and another for the metacode map.

As for the prosecution history, we do not read it as limiting storage to files. During prosecution, i4i distinguished its invention from U.S. Patent No. 5,280,574 ("Mizuta") prior art in part because Mizuta stored "all document information …
in one file … the document file." But this is not all i4i said. i4i then explained that Mizuta "lacked any notion of a metacode map" or "distinct storage means." In evaluating whether a patentee has disavowed claim scope, context matters. Together, these statements make clear that what distinguished the Mizuta prior art was not the storage type (file or no file), but rather the separation of a document's content and structure. The statements Microsoft now plucks from the prosecution history do not "clear[ly] and unmistakabl[ely] disavow" storage means that are not files. Computer Docking Station Corp. v. Dell, Inc., 519 F.3d 1366, 1374 (Fed. Cir. 2008) (citing Purdue Pharma L.P. v. Endo Pharms., Inc., 438 F.3d 1123, 1136 (Fed. Cir. 2006)).

Because the claims themselves do not use the word "file" and the specification discloses embodiments where the storage format is not a file, we conclude that "distinct" does not require storage in separate files. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 907-08 (Fed. Cir. 2004) (declining to limit the invention's scope to the disclosed embodiments when the specification did "not expressly or by clear implication reject the scope of the invention" to those embodiments); see also Boston Scientific Scimed, Inc. v. Cordis Corp., 554 F.3d 982, 987 (Fed. Cir. 2009).

B. Independent Manipulation

The closer question is whether "distinct" requires independent manipulation of the metacode map and mapped content. Several of the embodiments in the '449 patent allow the user to manipulate only the metacode map or mapped content. '449 Patent figs. 4, 5, 6, 8. However, based on our review of the claim language, the specification, and the prosecution history, we conclude that the claims are not limited to these particular embodiments.

Generally, a claim is not limited to the embodiments described in the specification unless the patentee has demonstrated a "clear intention" to limit the claim's scope with "words or expressions of manifest exclusion or restriction." Liebel-Flarsheim, 358 F.3d at 906; see also Teleflex, Inc. v. Ficsa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002). By the same token, not every benefit flowing from an invention is a claim limitation. See Computer Docking, 519 F.3d at 1374; Verizon Servs. Corp. v. Vonage Holdings Corp., 503 F.3d 1295, 1302-03 (Fed. Cir. 2007).

We begin again with the claim language. None of the claims mention "independent manipulation" of the mapped content and metacode map, an omission we find significant. Had the inventors intended this limitation, they could have drafted the claims to expressly include it.

Similarly, the specification refers to "separate," rather than "independent," manipulation of the document's architecture and content. The specification goes on to describe the storage of the metacode map and content as "distinct and separate." "Distinct" and "separate" are not the same as "independent." Moreover, the specification teaches that "separate manipulation" describes the user's ability to work on only the metacode map or content. Behind the scenes, the invention keeps the metacode map and content synchronized. For example, Figure 9 teaches that updates to the content may require the invention to make corresponding changes to the metacode map. '449 Patent col. 14 l.49-col. 15 l.5.

Microsoft is correct that the specification refers to working on "solely" the document's structure (metacode map):

The present invention provides the ability to work solely on metacodes. The process allows changes to be made to the structure of a document without requiring the content. A metacode map could be edited directly without the mapped content. Additionally a new map can be created based solely on an existing map without requiring the content.

Id. at col.7 ll.6-11 (emphases added). Read as a whole, however, these statements are best understood as describing the advantages of separate storage, the real claim limitation. See Abbott Labs., 566 F.3d at 1289-90. The specification's permissive language, "could be edited," "can be created," and "ability to work," does not clearly disclaim systems lacking these benefits.

An examination of the prosecution history similarly reveals no statements that unequivocally narrow the claims to require independent manipulation. Initially, the examiner rejected several claims as obvious, explaining that "[s]torage is always distinct, even if at distinct addresses." In response, i4i stated:

[T]he architecture of a document can be treated as a separate entity from the content of the document. Thus, the architecture of the document can be treated as an entity having distinct storage from the content of the document. This
separation allows distinct processes to operate on the content and the architecture, with or without knowledge of the other. In other words, using the present invention, one could change the architecture, (layout, structure, or presentation formation) of a document without even having access to the actual content of the document. This is achieved by extracting the metacodes from an existing document and creating a map of the location of the metacodes in the document and then storing the map and the content of the document separately.

The reason for the examiner's rejection helps us understand i4i's response. In context, i4i's response is best read as clarifying why the invention's "storage means" are more than just "distinct addresses." i4i's subsequent discussion of the benefits of separate storage is not sufficiently "clear and unmistakable" to disavow embodiments lacking independent manipulation. Purdue Pharma, 438 F.3d at 1136.

In light of the specification's permissive language, the prosecution history, and the claim language, we conclude that "independent manipulation" is a benefit of separate storage, but not itself a limitation.

C. Different Operating System

Veritas next argues that the operating systems on the first and second microprocessors must be of different types, i.e., they could not both be UNIX. The language of claim 1 requires that "said second microprocessor employs a second operating system distinct from said first operating system." SCC argues that this language requires only that both microprocessors do not share a single instance of the operating system, i.e., not be a multiprocessor operating system where both microprocessors are under the direction of a single instance of the operating system.

Veritas supports its view by citing to the repeated references in the specification and file wrapper indicating that the principal purpose of the invention was to permit computers of different, incompatible types to coexist on the same network and to use the same storage system. The implication is that the invention has no point if the client and storage server have the same variety of operating system.

SCC replies that the incompatibilities the invention was to accommodate were incompatibilities in the client operating systems. The invention enables a variety of clients with otherwise mutually incompatible operating systems to communicate with a single storage server; nothing in the invention precludes the idea that one or more of those clients might use the same species of operating system as the storage server. SCC notes the specification expressly acknowledges that possibility. E.g., id. at 82 (col. 4, l. 65-67) ("More particularly, if the client computer and storage management system both utilize the same operating system . . . ."); id. at 84 (col. 8, l. 22-25) ("the storage management system may utilize the same file format and operating system utilized by the majority of client computers connected thereto . . . .").

The Court holds that the specification supports SCC's construction and that "distinct" should be construed and meaning a different instance, and not a different type.
Both parties' proposed claim construction for Term 2 are deficient. Akamai's proposal essentially reads out the limitations in the claim requiring the DNS established by the service provider to be "alternative" and "distinct," while Limelight's proposed construction does not read on the preferred embodiment.

The Brief Summary of the Invention describes the "object of the present invention" as "provid[ing] a network architecture that moves content closer to the user." ('645 Patent, col.2 11.49-50.) This is accomplished by "replicating content over a large network of distributed servers." (Id. col.2 ll.46-47.) The task of determining which of this multiplicity of servers should supply content to a particular user's request is handled by the alternate and distinct DNS system:

The determination of which hosting server to use to serve a given embedded object is effected by other resources in the hosting framework. In particular, the framework includes a second set of servers (or server resources) that are configured to provide top level Domain Name Service (DNS). In addition, the framework also includes a third set of servers (or server resources) that are configured to provide low level DNS functionality. 4

To locate the appropriate hosting servers to use, the top-level DNS server determines the user's location in the network to identify a given low-level DNS server to respond to the request for the embedded object. The top-level DNS server then redirects the request to the identified low-level DNS server that, in turn, resolves the request into an IP address for the given hosting server that serves the object back to the client.

(Id. col.3 11.29-36, 42-49 (Summary of the Invention) (emphasis added.).) The specification emphasizes the difference between the invention and the operation of "regular DNS servers" which return the Internet Protocol ("IP") addresses of one or more DNS or content servers without any consideration of where the user or the server is located:

[T]he global hosting architecture of the present invention manipulates the DNS system so that the name is resolved to one of the ghosts that is near the client and is likely to have the page already. . . . The top level DNS servers [for the inventive global hosting framework] have a special function that is different from regular DNS servers like those of the .com domain. The top level DNS servers include appropriate control routines that are used to determine where in the network a user is located, and then to direct the user to . . . a low level DNS[.] server that is close-by.

(Id. col.9 11.40-44, 49-55 (emphasis added.).) Akamai confirmed the character of this alternative, distinct DNS at the Markman hearing:

. . . the Domain Name System described in the patent is, one, something that is established by, set up by, run by the content delivery network. And, second, it is different in that it has intelligence that will direct -- that will inform the translation of character strings into IP addresses. 5

(Hr'g Tr., 59:10-15, May 17, 2007 (emphasis added.).) Thus, read in the context of the specification, the meaning of "distinct" and "alternative" describes a domain name system established and controlled by a content delivery network service provider, which includes control routines "different from regular DNS servers like those of the .com domain." ('645 Patent, col.9 11.50-51.)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 The first set of servers are the framework's hosting servers (also referred to as ghost servers or ghosts). (See '645 Patent, col.5 11.65-67.)

5 In addition to the intelligence in the top-level DNS servers that determines the location of the user and chooses a particular close-by low-level DNS server to service that user, the specification also describes intelligence in the low-level DNS servers, not present in regular DNS servers, which provides other claimed functionality. (See '645 Patent, col.11 11.53-55 ("The low-level DNS servers monitor the various ghost servers to take into account their loads while translating virtual ghost names into real addresses.") (emphasis added.).)

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -
E. "Said Preprogrammed Memory . . . for use in controlling operation of said vehicle in a distinguishable protocol in addition to those provided by said originally provided program and in lieu of control provided by said originally provided program"

This term means that the additional program within the preprogrammed memory not only controls the operation of the vehicle but it does so in a different manner than the original program. Again, Hypertech's proposed additional limitation of "while the vehicle is in normal operation" is not supported either by the written description or the prosecution history cited and goes beyond the court's conclusion that an "in transit" limitation must be read into the claims.

b. Construction of "distributed along said busses"

The second disputed phrase, "distributed along said busses," acquires different meanings depending on whether there is "one," or there are "more [than one]" MOS capacitors comprising the capacitance means. See '830 patent at 6:21. The ordinary meaning of "distributed" is dispersed, spread, or meted out. Where the word is used to describe a single substance or article, it connotes that the substance or article is spread out. In the context of the claims, the capacitance means, that is, the capacitor plates, would be spread out along (and underneath) the busses. In the alternate case of a plurality of capacitance means, the plain meaning is that the capacitors are located at various positions along (and underneath) the busses. Also implicit in this terminology is the suggestion that the longer of the lateral dimensions of the capacitor plates is along the direction of the bus wires, and the transverse dimension is shorter. This suggestion is strongest when there is only one capacitor, but as the number of different capacitors distributed along the device increases, the weight of the meaning imparted to "distributed along" shifts to the connotation that the individual parts are dispersed, not just anywhere over the chip, but along the busses.

The specification does not discuss in any detail what is meant by "distributed along said busses" so as to substantively limit the plain meaning of the claim. There is no teaching with respect to the meaning of distributed when there is only one capacitor. For example, the disclosure does not imply, as AMD contends, that a single capacitor must run underneath the entire length, or a substantial part of the busses. The specification does allow for "empirical observations" to guide the practitioner in determining how much capacitance might be needed in a particular circumstance. '830 patent at 5:10. The disclosure simply does not teach what minimum level of distribution of capacitance means is required by the claims.

The Court construes the term "distributed along said busses" to mean either multiple capacitance means located at various points along, and in a layer beneath, the busses, or a single capacitance means having plates whose long dimension is spread out along, and in a layer beneath, the busses. The Court does not read in any minimum fraction of the length a bus along which capacitance means must be deployed. The disclosure instructs that empirical observation may be the guide.

2. "distributed computer system"

The district court construed "distributed computer system" to require that there be "a stand alone computer in each processor system." SeaChange, 313 F. Supp. 2d at 398. The phrase "distributed computer system" appears in the preamble of method claim 37. Thus, a preliminary question exists as to whether "distributed computer system" is a claim limitation. See Catalina Mktg. Int'l v. Coolsavings.com, Inc., 289 F.3d 801, 807-08 (Fed. Cir. 2002). "In general, a preamble limits the invention if it recites essential structure or steps, or if it is 'necessary to give life, meaning, and vitality' to the claim." Id. at 808 (quoting Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999)). "If the preamble helps to determine the scope of the patent claim, then it is construed as part of the claimed invention." NTP, Inc. v. Research In Motion, Ltd., 392 F.3d 1336, 1358 (Fed. Cir. 2004).
In this case, the preamble notes that the claimed method is for storing data in a "distributed computer system" which has "at least three processor systems." '312 patent, col. 22, ll. 17-18. The preamble further describes the components of a "processor system" to be "at least one central processing unit" and "at least one mass storage subsystem." Id., col. 22, ll. 19-20. The body outlines the claimed method, the steps of which repeatedly involve "said processor systems." Id., col. 22, ll. 22-29 (emphasis added). The preamble provides the only antecedent basis and thus the context essential to understand the meaning of "processor system"; therefore, the preamble, including the phrase "distributed computer system," limits the scope of the claimed invention. NTP, 392 F.3d at 1358-59 (relying on preamble of method claim to define scope of limitations that derived their antecedent basis from preamble).

The issue then is how, if at all, the preamble phrase "distributed computer system" impacts the scope of "processor system." The parties agree that the ordinary meaning of "distributed computer system" is a "computer system in which several interconnected computers share the computing tasks assigned to the system." IEEE 375 (defining "distributed system"). The parties dispute whether a "distributed computer system" requires that each processor within the system operate on its own power supply and clock, i.e., that each processor "stand-alone." Seachange argues that the IEEE definition implies multiple "stand-alone" computers and that "stand-alone" computers are necessary to implement RAID-5 at the system level. However, the IEEE definition does not say that computers must have a separate clock and power supply. Furthermore, Seachange points to nothing in the specification to suggest that the processors must "stand-alone" in order to achieve redundancy at the system level. Indeed, neither the claim nor the written description states such a requirement. See, e.g., '312 patent, col. 22, ll. 17-29; col. 2, ll. 17-23; col. 3, ll. 27-35; col. 4, ll. 36-44; col. 5, ll. 52-58. The written description describes a system where if one processor fails, another can perform the task that the failed processor was performing. See, e.g., id., col. 16, ll. 23-27. Such a system is consistent with the requirement that the processors "share computing tasks."

Because it is improper to import a limitation into a claim where the limitation has no basis in the intrinsic record, Ecolab, Inc. v. Envirotech, Inc., 264 F.3d 1358, 1366 (Fed. Cir. 2001), we conclude that the district court erred in requiring that each processor system "stand-alone," i.e., have a separate clock and power supply. "Distributed computer system" should be given its ordinary meaning, which both parties agree is "a computer system in which several interconnected computers share computing tasks assigned to the system."

1417

a. Distributed manufacturing plant

ITI suggests that the phrase "distributed manufacturing plant" appears in the preamble and appears to argue that the language does not constitute a claim limitation. A preamble is considered a claim limitation only if, when read in the context of the claim as a whole, it recites essential structure or steps or is "necessary to give life, meaning, and vitality" to the claim. Eaton Corp. v. Rockwell Intern. Corp., 323 F.3d 1332, 1339 (Fed. Cir. 2003) (quoting Catalina Mktg. Int'l, Inc. v. CoolSavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002)). If, therefore, the limitations in the body of the claim "rely upon and derive antecedent basis from the preamble," then the preamble acts as a necessary component of the claimed invention and constitutes a limitation. Id. Several limitations within claim 18 derive antecedent basis from the "distributed manufacturing plant" language in the preamble. Specifically, the claim mentions "the plant," six times, which clearly refers to the "distributed manufacturing plant" language in the preamble. Accordingly, the phrase constitutes a claim limitation and must be construed.

ITI contends that the limitation refers to a plant which makes a variety of products using different machines. Defendants counter that the phrase means a manufacturing plant consisting of unconnected machines that are spread out over the manufacturing plant. Defendants claim that the patent supports its inclusion of "unconnected" in the definition. They cite a sentence under the section "Description of the Prior Art" that states, "Most manufacturing plants or factories are distributed in that they consist of heterogeneous, unconnected workstations." U.S. Patent No. 4,796,194, col. 1, lines 21-23. Because this sentence appears within a discussion describing prior art and the term does not appear elsewhere in the patent, the Court is hesitant to conclude that the claim phrase denotes a manufacturing plant with unconnected workstations. When defining terms, courts are directed to give words their broadest reasonable construction that is consistent with the use of the term in the patent. See In re Am. Acad. of Sci. Tech Ctr., 367 F.3d 1359, 1364 (Fed. Cir. 2004). In short, the Court sees no reason to limit distributed manufacturing plants to those with unconnected workstations.
Later in the section describing prior technology, the specification states in general terms that "[a] distributed manufacturing plant is capable of fabricating a variety of products through ordered-process sequences of process steps. Each process step can be performed by at least one workstation in the factory." U.S. Patent No. 4,796,194, col. 1, lines 27-30. The Court concludes that "distributed manufacturing plant" should be construed as a factory that makes a variety of products using machines in workstations throughout the plant.

1418

5. "distributed packet manager"

The next term is "distributed packet manager." The plaintiff argues that this term means "a device, process or algorithm that is located within each packet data source, that controls how the packet data source accesses a portion of the bandwidth assigned to the packet data." The defendants propose "a decentralized mechanism that performs all the functions required to aggregate and synchronize packet data to the time-division multiplexed bus and to prevent packet collisions." The defendants' proposed construction limits the claim by requiring, essentially, an entirely decentralized mechanism for performing "all" of the functions required to aggregate and synchronize packet data to the bus. In addition, the defendants' construction requires the packet manager to prevent packet collisions.

The court is not persuaded that either limitation is appropriate. The specification does not require the elimination of all of the central control functions. Moreover, the doctrine of claim differentiation counsels against the requirement that the packet manager prevent packet collisions. Claim 9 recites "only one of the plurality of packet data sources accesses the . . . predefined bandwidth at a time" whereas claim 7 does not require that "only one" packet data source can access the bus at a time. Claim 9 thus expresses the concept of preventing packet collisions by allowing only one of the packet data sources to access the predefined bandwidth at a time. The defendants' proposed construction would incorporate limitations from the preferred embodiment that are not required by the language of the claims. As such, the court construes the term to mean "a device, process or algorithm located within each packet data source, that controls how the packet data source accesses the time-division multiplexed bus."

1419

"Distributed Switching Network"

NT proposes the following construction for "distributed switching network": "A network in which the switching function is distributed over a number of switching or routing elements, components or devices." Peerless's proposed construction is:

"a routing tandem network that links tandem access points and tandem switches together so as to provide an end to end managed tandem network that provides alternative routing and call completion management capabilities which is both competitor neutral and technology neutral, not part of a proprietary network or a competitor network and is not reliant upon one particular technology platform, is without end users, and provides tandem switching and transport services."

Peerless argues that the terms "distributed switching network" and Neutral Tandem Network are synonymous and that both should therefore have the same limitations. However, those limitations with respect to the term Neutral Tandem Network have been rejected, as set out above. Also, the report of Dr. Arthur Brody, Plaintiff's expert, confirms that Plaintiff's construction is consistent with how one skilled in the art would understand the term. Therefore, the term "distributed switching network" is construed as "a network in which the switching function is distributed over a number of switching or routing elements, components or devices."

1420

3. "distributed Viterbi decoder"
The process of Viterbi decoding is used to decode a trellis encoded signal. Claims 9 and 19 of the '627 patent require a "distributed Viterbi decoder." The plaintiff proposes that this term means "a Viterbi decoder having multiple Viterbi decoding processes operating on separate portions of a stream of data to be decoded." The defendants argue that the term means "two or more Viterbi decoders operating in round-robin fashion on separate portions of a stream of encoded data." The issue is whether there needs to be more than one Viterbi decoder operating in round-robin fashion.

The defendants point to the specification which shows separate Viterbi decoders that are accessed sequentially. '627 patent, Fig. 4, 3:13-20. The plaintiff, on the other hand, contends that the defendants are attempting to limit the term to a preferred embodiment. According to the plaintiff, a distributed Viterbi decoder can be implemented as a single Viterbi decoder that emulates through software the function of multiple devices. The relevant passage from the specification supports the plaintiff's argument. '627 patent, 9:61-66 ("multiple trellis encoders and decoders can be realized using a single program routine which, through the mechanism of indirect addressing of multiple arrays within memory, serves to provide the functions of each of the multiple devices.").

In light of this passage from the specification, the court is persuaded that the plaintiff's construction is correct. The court concludes that this term means "a Viterbi decoder having multiple Viterbi decoding processes operating on separate portions of a stream of data to be decoded."

B. The Disputed Limitations

On the merits, the parties dispute the meaning of two related limitations in the '982 patent, "distributing" and "displaying" a combined order book to a trader. Independent claim 9 recites both limitations:

9. A data processing method for providing trading information to traders in a security or commodity from two or more alternative trading systems, comprising the steps of:

   receiving order book information from each participating alternative trading system in order book information protocols native to the particular alternative trading system;

   converting the information to a common system order book protocol;

   integrating the order book information from each alternative trading system into a single order book;

   distributing the combined order book to the traders in the common system order book protocol; and

   displaying said combined order book to the traders.

'982 patent, col. 14, ll. 1-14 (emphasis added). The district court construed the disputed limitations during a Markman hearing without issuing a formal claim construction order. Instead, the district court stated its claim construction from the bench at the close of the hearing. A district court retains discretion to rule in this manner, but in this instance the trial court's oral recitation provides a very sparse explanation of the findings and reasoning supporting the claim construction.

Regarding the distributing limitation, the district court concluded that it "simply means distributing the combined order book -- that means in terms of the specification the consolidated order book -- pertaining to all orders from all ECN members." Claim Construction Order at 442-43. In other words, the distributing limitation requires the distribution of the whole combined order book to the trader. The district court similarly construed the displaying limitation, concluding the system must display the whole combined order book for the trader. Upon review, the district court's interpretation of the "distributing" and "displaying" limitations conflicts with the plain meaning of claim 9 and excludes embodiments disclosed in the specification.

According to its preamble, claim 9 "provides trading information to traders in a security or commodity" rather than "all"
securities or commodities. '982 patent, col. 14, ll. 1-2 (emphasis added). By selecting the word "a" instead of "all," the Applicant set forth a method wherein the traders may request and receive information for only a subset of the securities (i.e., one or more). See KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000) (the word "a" generally means "one or more" in open-ended claims). Thus, the language of the claim itself does not require the system to distribute or display the whole combined order book.

Furthermore, the specification discloses embodiments that distribute and display information for only a subset of the combined order book. As an example, the specification describes an embodiment in which

the CCS 100 collects orders from each ECN, (ECN150 and ECN251) and electronic exchanges (NASDAQ 52), distributes a composite order book to the customers according to each customer's memberships in the ECNs and rights to use an electronic exchange. Thus customer 10 may only receive a subset of the complete order book compiled by the CCS 100 corresponding to where the customer 10 is permissioned.

'n82 patent, col. 6, ll. 59-66 (emphasis added). n1 According to this embodiment the customer only receives a "subset" of the combined/complete order book from the system. Thus, this embodiment must also make the system capable of "distributing" less than the whole combined order book to the customer - i.e., a subset of the combined order book.

The specification also discloses an embodiment in which bid and offer prices for Dell, a single security, are displayed on a market data screen:

Fig. 4 depicts a typical market data screen 250 of the present invention. Such screens can be customized as to data or order to conform to the customer's trading style. . . . The security under review is Dell Computer Corp. It was elected by inserting its ticker symbol DELL in space 252.

'id at col. 9, ll. 9-25. Hence, the specification discloses embodiments that distribute and display information for only a subset of the securities (e.g., one in the embodiment of Figures 4 and 5) in the combined order book.

Reading the claim language and these embodiments in the specification, one of ordinary skill in this art would not limit the distributing and displaying limitations in the manner suggested by the district court. See Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) (en banc) ("Importantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification."). Rather, one of ordinary skill in the art would construe the distributing and displaying limitations as covering an embodiment that distributes and displays information for only a subset of the combined order book.
For at least these reasons, this court sets aside the district court's claim construction. Because the final judgment orders are premised on the flawed claim construction, they too must be set aside. The case is remanded to the district court for further proceedings consistent with this opinion.

4. "Distribution interface."

The technical background of "interface" and much of the analysis of "request interface" applies to this term. USVO proposes to define "distribution interface" as "hardware and/or software that allows two elements (a central data facility and a switched telephone network) to work together in the manner recited in the claim." Time Warner suggests:

A device (distinct from the request interface) that is connected to the central data facility and that (1) initiates a connection over the switched telephone network with each remote recipient, in response to requests for video programs received by the request interface, and (2) downloads each requested video program over the network to a single intended remote recipient.

Claim 1 describes a distribution interface, connected to the central data facility and the telephone network, which "initiates connections over the telephone network with remote locations in response to requests received," by the request interface and transmits to the remote location the compressed video programs previously requested through the request interface. As with request interface, Time Warner argues that the distribution interface must be a hardware device and is separate from the request interface.

Time Warner also takes the position that the distribution interface only performs two functions, and that these two functions can only be done with respect to a single remote viewer at a time. USVO again argues that "interface" should be given its common meaning and that the distribution interface does not have to be distinct from the request interface.

The court has already addressed Time Warner's arguments that the distribution and request interfaces are separate, that an interface must be a hardware device, 5 and that every embodiment must allow for remote requesting in the context of request interface. Time Warner's position that the construction should recite two functions performed by the distribution interface would be overly repetitive, as Claim 1 already states what the distribution interface does. "792 Patent, col. 7, ll. 50-59.

5 Defendants' strenuous argument in connection with the next disputed term, that the phrase "said distribution interface initiates" means that the distribution interface itself begins calls over the distribution network, is at odds with their position that the interface is merely hardware. Hardware without a program is not likely to receive a signal, choose a recipient, and initiate a call.

Time Warner's final point is that the program must be transmitted to a single recipient. While Time Warner did not agree with the court's proposed definition for this term at the hearing, Tr. at p. 93, l. 19- p. 94, l. 8, this definition adequately addresses Time Warner's concern that the program is transmitted only to the requesting customer. At the hearing, USVO agreed with the court's proposed construction of this term. Tr. at p. 93, ll. 15-16. The court will define this term as follows:

"Distribution interface" means "the connection that permits data to be conveyed from the central processor through the telephone network to the requesting customer."
2. "distribution stage"

NICE's Construction

The stage that serves for retrieval of recorded information and providing it in a human recognizable form and/or serves for archiving the recorded information to removable storage.

Witness's Construction

Plain meaning.

The parties dispute the meaning of "distribution stage," as used in claim 1 of the '372 patent. NICE contends that the specification supports its construction, citing col. 11:40-48:

Generally, the distribution stage serves for retrieval of recorded information and providing it in a humanly recognizable form, i.e., as an image, a printout, a sound clip or others. In a preferred embodiment, the distribution stage also serves for archiving the recorded information to a removable storage, such as magnetic tape, magnito-optical storage device, DVD, or others.

(col. 11:42-48.) Witness contends that NICE's proposed "and/or" language makes the retrieval element of the term optional, which is not supported by the specification.

In light of the claim language and specification, the Court construes "distribution stage" to mean "The stage that serves for retrieval of recorded information, providing it in a human recognizable form, and, in some instances, archiving the recorded information to removable storage." NICE's proposed "and/or" language is not supported by the patent's specification.

A. First and second row groups

Claims 1, 6, 7, and 8 of the '865 patent describe the relevant memory cell array as "being divided into first and second row groups." NEC argues that this language does not require any physical division between the first and second row groups and that, as a result, Hyundai's DRAM devices, in which the "groups" are physically intermingled, infringe the '865 patent. Put another way, NEC contends that the terms of the '865 patent include "folded bit line" architecture, while Hyundai argues that the "first and second row groups" language narrows the patent so that it necessarily requires "open bit line" architecture. The issue is significant as the accused Hyundai product employs folded bit line architecture.

Open bit line architecture and folded bit line architecture refer to two different methods of arranging bit lines in a memory cell array. In such an array, pairs of bit lines extend from circuits commonly called sense amplifiers (but called "differential amplifiers" in the '865 patent) to connect a column of memory cells. The differential sense amplifier is the circuit that must detect and amplify small electrical signals in a DRAM chip. In early DRAM chips, differential sense amplifiers were placed in the center of an array of memory cells, with one bit line extending up and one bit line extending down from each differential sense amplifier to connect a column of memory cells. This architecture is called "open bit line."

As discussed above, word lines run across and perpendicular to bit lines and control access to all the memory cells in a particular row. In open bit architecture, any given word line crosses only one of the two bit lines entering a differential sense amplifier. When the word line is activated to access the row of memory cells, it creates electrical "noise" in every bit line it crosses. The noise can cause the differential sense amplifier to supply erroneous information. To reduce or eliminate this problem, folded bit lines were introduced in the 1970s. With folded bit lines, the row of differential sense amplifiers is placed on one side of an array of memory cells, and both bit lines extend from the same side of each differential amplifier to the corresponding column of memory cells. This way, every word line crosses both bit lines entering a differential sense amplifier, and equal amounts of electrical noise are introduced to each bit line. Because the differential sense amplifier responds to the difference in voltage between the two bit lines, adding the same electrical noise to each one has no effect.
6 Folded bit line architecture was introduced in U.S. Patent 4,025,907 (the '907 patent), issued on May 24, 1977. Hyundai contends that the device described in the '907 patent should be considered prior art to the '865 patent, since testimony indicates that the circuitry disclosed in the '907 patent was developed in the fall of 1974, several months before the '865 patent's effective April 30, 1975, filing date in Japan. See 35 U.S.C. § 102(g). NEC argues that this testimony is not sufficiently corroborated to establish the '907 patent as prior art.7 A diagram comparing open bit line and folded bit line architecture may be found in Appendix 3 to this opinion.

In open bit line architecture, then, word lines (and thus row columns lying along word lines) are physically divided into two groups: those lying above and those lying below the differential sense amplifier. In folded bit line architecture, the differential sense amplifiers do not so divide the word lines, though the word lines are functionally and electrically identical in folded bit line and open bit line architecture. NEC contends that the reference in claim 1 of the '865 patent to first and second row groups merely refers to two sets of word lines identified by distinct functions. In other words, according to NEC, a "group" of word lines (as that word is used in the '865 patent) refers to any set of word lines that shares a common characteristic. While in open bit line architecture, one group of word lines connects to those memory cells above the differential sense amplifiers and one group connects to those below the differential sense amplifiers, in folded bit line architecture one "group" of word lines controls memory cells connected to the right side of each differential sense amplifier and one "group" of word lines controls memory cells connected to the left side of each differential sense amplifier. NEC argues that the fact that the row groups are physically intermixed in folded bit line architecture does nothing to mask their separate identities.

The starting point in the analysis is the language of the claim, which makes clear that it is the memory array itself—in other words, the two-dimensional arrangement of memory cells—that is divided into first and second row groups. If the division of the array into row groups is understood as a physical division, in which one set of row groups arranged along word lines is physically separate and distinct from the second set of row groups arranged along word lines, the claims must necessarily cover only open bit line architecture.

Figures 1 of the '865 patent discloses the "prior art" as understood by the '865 inventor, while Figure 4 represents the invention. NEC concedes that both figures depict open bit line architecture. Nor is this depiction of the invention surprising, since claim 1 of the '865 patent appears to contemplate open bit line architecture. First, claim 1 requires "a plurality of memory cells arranged in an array of rows and columns," and goes on to require that the "said memory cell array [be] divided into first and second row groups." Thus, the claim requires the division of the physical, two-dimensional arrangement of cells that is the array into two parts; such language strongly suggests physical division. The language of claim 1 in combination with the illustrations of the invention in Figures 4-6 of the '865 patent indicate that the inventor intended to include only open bit line structures or architecture within the terms of the patent.

Moreover, claim 1 of the '865 patent requires that each differential sense amplifier have a first input terminal connected to memory cells in the first row group in one column, and a second input terminal connected to memory cells in the second row group in the "same column as that connected to said first terminal." Looking at Figure 4 of the '865 patent, for example, this requires that the left-most sense amplifier (12) be connected to the left-most column of memory cells (10, 10'), which runs from the top to bottom of the page through input terminals (1, 2) connected to the left-most bit lines (16, 16'). Again, the language of the claims and the patent figures suggest that the half bit lines must be connected to half bit lines extending to memory cells in separate row groups in the same column. Such construction is inconsistent with folded bit line architecture. Thus, the "said memory array being divided into first and second row groups" element in claims 1, 6, 7, and 8 is correctly understood as referring to two physically separated rows of word lines and hence includes only open bit line structures or architecture.

A different conclusion in this regard would entail the somewhat surprising result that the scope of the '865 patent would include a feature not yet publicly known at the time of the '865's filing. According to the parties, folded bit line architecture was first disclosed in U.S. Patent No. 4,025,907, filed on July 10, 1975, months after the April 30, 1975, filing date for the '865 patent.
Given this construction, Hyundai's accused devices do not literally infringe the '865 patent as they employ folded bit line architecture. Whether the devices infringe under the doctrine of equivalents is a question of fact that remains open for trial.

2. "dividing said first image frame of pixel intensity data into a regular grid of kernels forming a plurality of rows"

Plaintiffs' construction: dividing the frame of image data acquired during the first scan of the subject into an ordered grid of curved or rectilinear cells arranged in multiple rows

Defendant's construction: dividing the frame of image data acquired during the first scan of the subject into a ordered grid of curved or rectilinear zones arranged in multiple rows and columns, each zone containing multiple pixels of data of varying intensity

At the claim construction hearing, plaintiffs said that they "could live with" defendant's construction, with two modifications. Instead of "multiple rows," the modified construction uses the phrase "one or more rows." In addition, in the modified construction, the adverb "potentially" is inserted before the words "vary intensity." Plaintiffs indicated that defendant agreed that these modifications were appropriate and defendant did not dispute this characterization. Accordingly, I will adopt the modified construction.

Court's construction: dividing the frame of image data acquired during the first scan of the subject into a ordered grid of curved or rectilinear zones arranged in one or more rows and columns, each zone containing multiple pixels of data of potentially varying intensity

"Dividing said selected portions of said information database into a prioritized set of tiers, wherein all the selected portions of said information database in each tier are transmitted at a corresponding repetition rate." Used in claims 1 and 16.

The specification describes a division of the database into "tiers" or groups for transmission at different times depending on the anticipated, and the requested, demand for the information. 505 patent, col. 13, 11. 63 -- col. 14, 11. 51. Root information, which provides an index to the information database, is transmitted most frequently. Depending on their priorities, other groups of the information are transmitted at less frequent intervals.

n3 The court is aware that a patent is presumed to be valid. To that end the court considered whether a disclosure of a microprocessor plus software, without any algorithm other than a repetition of the function might have been sufficient in 1995 when the patent was issued. As an analogy, qualified immunity of officers is based upon the law at the time of their action, not the law at the time of trial. The Court examines patents through the eyes of one of ordinary skill in the art at the time the patent is issued, not based upon later advances of science. But even in 1995 it was clear that patentees should have known that in means-plus-function cases, where the structure linked to the recited function was a computer, the patentee had to disclose not only that there was a computer with software, but also disclose the steps, formula, or equation (the "algorithm") the software performed. See eg. In Re Alappat, 33 F.3d 1526, 1543 (Fed. Cir. 1994), Freeman, 573 F.2d at 1245-47 (1978).
with the deletion of "exclusively" and the substitution of "designated" for "specified."

There is no indication that the word "dividing" had a special meaning to one skilled in the art. Nothing in the claim language, nor in the specification, indicates that the same information could not be part of a "first tier," transmitted, say four times an hour, and also part of a "fifth tier," transmitted perhaps only once every twenty-four hours.

DirecTV argued that the ordinary and common meaning of the word "dividing" implies an exclusive partition. But under an "ordinary and common meaning" approach, if A is the set of all of the information in the system, it could be divided into subsets B, C, and D. Subset B could have some elements in common with C and D, while, at the same time subset C might have no overlap with D. The court concludes that adding the word "exclusively" improperly places a limit on the claim, which is found neither in the claim language nor in the specification.

The parties also differed over whether "designated repetition rate" or "specified repetition rate" should be used to define the claim term "corresponding repetition rate." The claim states that the portions of information in each tier are "transmitted at a corresponding repetition rate." Table 1 at col. 14, 11. 20-33 gives an example of tiers with corresponding rates of transmission. The specification also provides the following: "The particular repetition rates associated with each tier of data and the amount of data allocated to each tier are selectable parameters that will need to be carefully considered in order to maximize the utility of the system for most subscribers." 505 patent, col 14, 11. 37-41.

While "specified" and "designated" mean almost the same thing, they could imply, especially to a lay juror for whom the terms are defined, that there is a required or unchanging repetition rate. "Selectable" as used in the specification, implies some choice, and that change is possible. The disputed term will be defined as follows:

"Dividing said selected portions of said information database into a prioritized set of tiers, wherein all the selected portions of said information database in each tier are transmitted at a corresponding repetition rate" means "placing each part of the information database selected for transmission into one or more groups of information, and transmitting each group at a chosen repetition rate."

The parties also differed over whether "designated repetition rate" or "specified repetition rate" should be used to define the claim term "corresponding repetition rate." The claim states that the portions of information in each tier are "transmitted at a corresponding repetition rate." Table 1 at col. 14, 11. 20-33 gives an example of tiers with corresponding rates of transmission. The specification also provides the following: "The particular repetition rates associated with each tier of data and the amount of data allocated to each tier are selectable parameters that will need to be carefully considered in order to maximize the utility of the system for most subscribers." 505 patent, col 14, 11. 37-41.

While "specified" and "designated" mean almost the same thing, they could imply, especially to a lay juror for whom the terms are defined, that there is a required or unchanging repetition rate. "Selectable" as used in the specification, implies some choice, and that change is possible. The disputed term will be defined as follows:

"Dividing said selected portions of said information database into a prioritized set of tiers, wherein all the selected portions of said information database in each tier are transmitted at a corresponding repetition rate" means "placing each part of the information database selected for transmission into one or more groups of information, and transmitting each group at a chosen repetition rate."

1. dividing said tracks into a plurality of concentric annular blocks (claim 1)

Plaintiff's construction: "segregating the tracks into nonoverlapping, ring-shaped regions on an optical disk"

Defendants' construction: "segregating the tracks into non-overlapping, ring-shaped regions on an optical disk, in which no track ever belongs to more than one block"
for example, be in zone one at one time and be in zone two at the second time, according to the claim which also requires that the "f" be different between blocks, that you would have two "f"s for the same track and the claim does not allow that. The claim requires that the "f" be changed according to the radius of the track which never changes, and therefore it follows that the "f" never changes and it follows that the block -- the division never changes.

Dkt. # 186, at 91. As claim 1 indicates, "f" is the reproduction speed.

If I understand it correctly, defendants' argument has several premises on which their conclusion relies: (1) the position of each track on a disk is constant; (2) because the position of the tracks is constant, the radius for that track is constant; (3) because the radius is constant, the reproduction speed is constant; (4) because the reproduction speed is constant, the blocks must be permanently fixed. Defendants' logical procession is far from self evident. In particular, the fourth and final premise appears to be a non sequitur. The patent says only that the reproduction speed, or "f" is constant within a particular block. It is silent (and therefore neutral) on the question whether the virtual boundaries must be drawn the same way each time the disk is rewritten. Because the patent does not prohibit the invention in claim 1 from changing the blocks with respect to each recording, I cannot read in the limitation that defendants propose. Although one could argue that no construction of this term is needed, I will adopt plaintiff's construction because it is written in language that a jury might find a bit more accessible than the language of the claim itself.

Court's construction: "segregating the tracks into nonoverlapping, ring-shaped regions on an optical disk"

6. Dividing the Digitized Broad Band Information

The term "dividing the digitized broad band information" means grouping, or segmenting, the digitized information into a predetermined cell structure where each cell contains the same pre-selected number of digital words.

5. The term "docking with the host computer" in claim 34 is construed as "plugging or inserting into the host computer without the use of an intermediate bus structure;"

2. "Document": Plaintiff proposes the meaning "a discrete collection of textual and/or graphic information, which may be electronic." Defendant proposes "a hard copy document or a nontextual electronic representation of a hard copy document (e.g. a scanned hard copy document stored on a hard drive.)"
7. "Domain monitor": n7 A network monitor that receives and analyzes data from service monitors.

'n7 '203, '212 and '615 patents, multiple claims.

('203 patent, col. 3, ll. 23-27)

"domain name"

The '135 patent, claims 1 and 10 and the '180 patent, claims 1, 17, and 33 contain the term "domain name." VirnetX contends that "domain name" means "a series of characters that corresponds to an address of a computer or group of computers that is to be sent to a domain name service (DNS)." Microsoft contends that "domain name" means "a hierarchical name for a computer (such as www.utexas.edu) that the Domain Name Service converts into an IP address."
The parties dispute whether "domain name" can correspond to a group of computers or only a single computer, whether "domain name" is a hierarchical name for a computer, whether "domain name" is limited to web site names, and whether "domain name" is limited to a computer name being converted into an IP address.

The claims themselves describe "domain name." Claim 1 states "a Domain Name Service (DNS) request that requests an IP address corresponding to a domain name associated with the target computer." Col. 47:23-26. Also, claim 10 states "a DNS proxy server that receives a request from the client computer to look up an IP address for a domain name." Col. 48:6-7. In both claim 1 and claim 10 an IP address corresponds to a domain name. Thus, the domain name corresponds to an IP address. Accordingly, the Court construes "domain name" as "a name corresponding to an IP address."

VirnetX proposes that "domain name" corresponds to a group of computers (IP addresses) or a single computer because claims 1 and 10 of the '135 patent refer to IP address using the indefinite article "an." The Federal Circuit has stated, An indefinite article 'a' or 'an' in patent parlance carries the meaning of 'one or more' in open-ended claims containing the transitional phrase 'comprising.' That "a" or "an" can mean "one or more" is best described as a rule, rather than merely as a presumption or even a convention. The exceptions to [the "indefinite article"] rule are extremely limited: a patentee must "evince [] a clear intent" to limit "a" or "an" to "one."
The subsequent use of definite articles "the" or "said" in a claim to refer back to the same claim term does not change the general plural rule, but simply reinvokes that non-singular meaning. An exception to the general rule that "a" or "an" means more than one only arises where the language of the claims themselves, the specification, or the prosecution history necessitate a departure from the rule.

Baldwin Graphic Sys., Inc. v. Siebert, Inc., 512 F.3d 1338, 1342-43 (Fed. Cir. 2008) (citations omitted). Claims 1 and 10 of the '135 patent are open-ended construction claims using the word "comprising" and use the indefinite article "an" to refer to "IP address." See Col. 47:20-26; see Col. 48:3-7. By the "one or more" rule, these claims allow for one or more IP addresses. Any subsequent use of the definite article "the" to refer to "IP address" simply refers back to the previously used "IP address" and thus reinvokes the non-singular meaning. See Col. 47:39-40; see Col. 48:8. Microsoft does not assert any evidence to show that an exception to the "one or more" rule exists. Thus, there may be more than one IP address, and thus more than one computer, that corresponds with the domain name. This would allow for a situation where the IP address that corresponds to the domain name is not the IP address of the target computer. See Col. 38:23-42. Accordingly, "domain name" can correspond to more than one computer.

Microsoft contends that the patents limit "domain name" to a hierarchical name for a computer under traditional hierarchical
DNS format. However, Microsoft relies largely on extrinsic evidence—including expert testimony and Microsoft's own technology tutorial—to support its contentions, which does not carry great weight in light of the fact that claim language provides guidance on the meaning of "domain name." Also, where Microsoft uses intrinsic evidence for support, Microsoft only refers to non-limiting language from the specification. For instance, Microsoft suggests that the examples used in the specification for domain names, which include "Yahoo.com" and "Target.com," show that the patents use "domain name" in its traditional hierarchical DNS format. Microsoft further suggests that "domain name" is limited to a traditional hierarchical name because the patents do not provide a single example of "domain name" that is not written in traditional hierarchical DNS format. However, Microsoft argues only the presence and absence of examples rather than any enforceable language of limitation. The specification's disclosure or omission of examples does not create limitations on claims. Accordingly, Microsoft does not offer sufficient support for limiting "domain name" to a hierarchical name for a computer.

Microsoft also contends that the patents limit "domain name" to web site names. However, no such limitation is found in the claims, and Microsoft merely references its arguments on construing "web site" without showing how "domain name" is necessarily linked to web site names. Accordingly, "domain name" is not limited to web site names.

Finally, Microsoft contends that "domain name" is limited to a computer name being converted into an IP address. Microsoft supports this proposed limitation by arguing that a "domain name" has the capacity to be converted by DNS into an IP address and that the specification emphasizes this point by describing that identical DNS requests may result in conventional domain name resolution, "host unknown" error messages, or VPN initiation, depending not on whether something is a "domain name" but on what type of web site was requested. However, Microsoft incorrectly argues that a "capacity" to be converted by DNS into an IP address demonstrates a required limitation. A mere capacity to perform an act does not make that act necessary. Thus, Microsoft has not sufficiently supported limiting "domain name" to a computer name being converted into an IP address. Accordingly, the Court construes "domain name" as "a name corresponding to an IP address."

Akamai describes the domain name portion of a URL as "an expression that identifies the content provider's servers." (Docket # 81 Ex. A, 26.) This is broader than the normal use of the term to describe the address of a particular host or server that can be resolved to establish a network connection with that server. 17 (Cf. Akamai Technologies, Inc. Tutorial -- Corrected Version (Docket # 84), 20 ("The first portion of a URL relates to the computer or a group of computers on which a resource may be located. This is the portion of the URL that is resolved by a domain name service to an IP address."). There is nothing in the specification or claims to indicate that the term is being redefined by the patent to be broader than its

### Term 13 (703 Patent, Claims 5, 15) 16

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

16 The term to be construed appears in claim 15 and claim 1, upon which claim 5 depends.

- - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - - -

<table>

<td>… domain name and path …</td>
<td>… a name or other identifier that defines a network connection to the embedded object at a content provider server and is used to retrieve the object in the absence of a content delivery network …</td>
</tr>
</tbody>
</table>

- 1853 -
normal usage. At the Markman hearing, Akamai conceded that the domain name "has to be something recognized by the Domain Name System . . . ." (Hr'g Tr., 187:25 - 188:3, May 17, 2007.)

17 To support its construction of the term "domain name," Akamai cites to the glossary definition of the term "domain" alone at an obscure ISP site. (See Docket # 68, 37 n.13). Not only is "domain" a different term than "domain name," but the popular dictionary definition of "domain name" eschewed by Akamai for its proposed construction is very close to Limelight's proposed construction. See Webster's II New College Dictionary 337 (2001) (defining "domain name" as "[a] series of alphanumerical strings separated by periods, such as www.hmco.com, that is the address of a computer network connection and that identifies the owner of the address.").

The path contains the name and location of the file, e.g., the object, on the server. (Docket # 81 Ex. A, 26.) Together, the domain name and path form the URL which provides a client computer with the information necessary to identify the server and retrieve the object from that server on the network. Both claims describe "modifying" the URL of an embedded object and claim 15 describes the domain name and path as "content provider-supplied." ('703 Patent, Claims 5, 15 (emphasis added.).) Read in light of the specification explaining that "according to the present invention, a virtual server hostname is prepended into the URL for a given embedded object," the terms domain name and path in claims 5 and 15 would be understood by one skilled in the art to refer to the URL used to retrieve the embedded object in the absence of a content delivery network. (Id. col.7 11.24-28 (emphasis added.).)

"Domain Name Service"

The '135 patent, claims 1 and 10 and the '180 patent, claims 1, 17, and 33 contain the term "Domain Name Service" ("DNS"). VirnetX contends that "Domain Name Service" means "a service that receives requests for computer network addresses corresponding to domain names, and which provides responses." Microsoft contends that "Domain Name Service" means "the conventional lookup service defined by the Internet Engineering Task Force ("IETF") that returns the IP address of a requested computer or host." The parties dispute whether "Domain Name Service" is limited by the definition given in the IETF that defines Domain Name Service as the conventional scheme or if it more broadly includes both conventional and modified Domain Name Service that is described in the specification.

The specification's description of DNS is consistent with construing DNS as "a lookup service that returns an IP address for a requested domain name." The specification states

Conventional Domain Name Servers (DNSs) provide a look-up function that returns the IP address of a requested computer or host. For example, when a computer user types in the web name "Yahoo.com," the user's web browser transmits a request to a DNS, which converts the name into a four-part IP address that is returned to the user's browser and then used by the browser to contact the destination web site.

Col. 37:22-29. According to this excerpt, a DNS "provides a look-up function" and "returns the IP address of a requested computer or host." A "computer or host" includes domain names as exemplified by the specification's reference to "Yahoo.com" and "destination web site" as "a requested computer or host." Accordingly, the Court construes "DNS" as "a lookup service that returns an IP address for a requested domain name." 5

5 See below for the Court's construction of "domain name."
### Door Control System

The '628 Patent includes the term "door control system." The parties propose the following meanings for this term:

<table>
<thead>
<tr>
<th>Braun's Proposed Construction</th>
<th>VMI's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>An electronic system for controlling movement of a vehicle door.</td>
<td>A combination of a door, a door motor, a driver, a controller to control the door motor and a communication pathway used together to operate the vehicle door.</td>
</tr>
</tbody>
</table>

Braun claims that its proposed definition is based on the ordinary and customary meaning of the words "door control system." It gives no further justification for its position. VMI submits that a door control system without a door, a door motor, a driver, a controller to control the door, and a communication pathway is not a door control system; all these parts are necessary.

VMI's proposed construction does not comport to the language of claim 1. This claim recites an invention comprising, among other things, a controller coupled to a communication pathway and a door control system. According to claim 1, door control system is separate from the controller and communication pathway. Moreover, since "door control system" controls the operation of the door while the ramp is being operated, door control system is separate from a door; it is a system that affects the door. However, it is consistent with the language of the claims to construe "door control system" to include a door motor and a driver. Hence, the Court finds that "door control system" is an electronic system, that also includes a door motor and a driver, for controlling movement of a vehicle door.

### Door Operation Commands

Independent claims 1 and 11 and their dependent claims use the term "door operation commands." The parties propose the following meanings to this term:

<table>
<thead>
<tr>
<th>Braun's Proposed Construction</th>
<th>VMI's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Instructions in the form of coded data that cause a door function, such as lock, unlock, open, or close, to occur.</td>
<td>Door control system specific signals sent to the controller that controls door functions, such as, open, close, lock/unlock.</td>
</tr>
</tbody>
</table>

The principal disagreement between the parties is over the word "commands." Citing to Webopedia Computer Dictionary, Braun insists that "[a] 'command' is 'an instruction to a computer or device to perform a specific task.' An 'instruction' is defined as 'a code that tells a computer to perform a particular operation.'" From this Braun concludes that "[w]hen these definitions are combined 'door operation commands' means 'instructions in the form of coded data that cause a door function, such as lock, unlock, open, or close, to occur.'" (Braun Claim Constr. Br. at 7.) Moreover, Braun points out that the embodiment in Figure 26 illustrates that "door operation commands" are sent and received in coded data. Finally, Braun
relied on prosecution history to claim that "door operation commands" are instructions in the form of coded data.

VMI argues that "door operation commands" are not limited to coded data and that Braun's definition is too narrow. VMI refers to the specification illustrating Chrysler Town & Country minivan and points out that its Body Builder's Guide Manual shows lock and unlock commands as electric door operations commands, not coded commands. In addition, VMI argues that, since Figure 26 is a later added embodiment, "door operation commands" cannot be limited to just binary signals. Finally, VMI insists that the examiner of the '628 Patent gave no reason to believe that the current invention was distinguished from prior art by the insertion of "door operation commands" to mean coded data.

The Court finds that Braun's proposed definition is too narrow; rather, "door operation commands" are not limited to coded data instructions but include other manners of instruction as generally known to those skilled in the art. Braun relies on that portion of the specification that explains that a "door command" is "a serial data signal in binary form" that controls the operation of door features such as opening and closing. (The '628 Patent cols. 4:57-5:4; 5:11-15.) However, the very next sentence of the specification states that "[i]t is contemplated that receiver can communicate with control module in other manners as generally known by those skilled in the art." (Id. at col. 5:14-16.) This sentence refers specifically to the transmission of door commands from the receiver to the control module, which the previous sentence described as communicating in binary form. Thus, by inserting it immediately after the description of the coded signals, the inventors sought to avoid the narrow interpretation that door commands are only coded data signals.

Similarly, while Figure 26 refers to a bidirectional serial bus on which the commands would be coded, this embodiment does not exclude other forms of commands, and the independent claims are not limited to a serial bus.

Braun's reliance on Webopedia Computer Dictionary is not convincing. Braun derives the definition from an "online encyclopedia dedicated to computer technology," (see Ex. 3 at 1.), thus presuming that the word "command" is an exclusively computer related word. Moreover, Webopedia's definition of the word contemplates computer and internet technology applications not car or wheelchair access mechanism parts, albeit containing computer parts.

Finally, Braun's reference to the prosecution history does not establish that the examiner narrowly interpreted "door operation commands" as coded data. Braun argues that claims 1-10 were immediately allowed as they included the claim limitation "door operation commands," but claims 11-16 were initially rejected as not including the term and that after adding "door operation commands" they were allowed. Yet, claim 1 also included the term "selectively delay execution" of the door operation commands, which claim 11-16 did not include. Braun added the term "selectively delay execution" of the door operation commands to all of the rejected claims and a Notice of Allowance followed. Therefore, there is no absolute basis to hold that the examiner allowed the claims because he narrowly read door operation commands to include only coded data operation commands. The prosecution history is not convincing enough to override the language of the claims that is broader in scope than Braun's proposed interpretation. Therefore, the Court adopts VMI's proposed construction:

"door operation commands" are door control system specific signals sent to the controller that controls door functions, such as, open, close, lock and unlock.

3. "having said third dopant concentration"

Claim 1 of the '046 Patent claims, in pertinent part:

a second region formed in said semiconductor material, said second region being of said first conductivity type and having a third dopant concentration greater than said second dopant concentration to form a drain region . . .

a fourth region formed in said semiconductor material, said fourth region being of said first conductivity type and having said third dopant concentration to form a source region.

(See '046 Patent at 7:34-54.) MPS contends that "having said third dopant concentration" should be construed to mean "intending to have the same dopant concentration as the second region and implanted at the same time as the second region." Micrel initially argued that "having said third dopant concentration" should be construed to mean "having
substantially the same dopant concentration as the second region." However, at the hearing Micrel informed the Court that it agreed with the portion of MPS's proposed construction defining the disputed term as "intending to have the same dopant concentration as the second region." Thus, the only issue for the Court is whether the disputed term should also be construed to as "implanted at the same time as the second region."

In support of its proposed construction, MPS points to a reference in the specification regarding one preferred embodiment stating "[a] second phosphorus or implantation process is then used to form the N+ source 32 and N+ drain region 34." The specification merely provides that the source and drain regions may be formed by using the same doping or implantation process, but cannot be read to require or limit the '046 Patent to this method. MPS also relies on the figures in the '046 Patent showing the source and drain regions (the second and fourth regions) at the same depth. However, Micrel explained at the hearing that there are methods to ensure that the source and the drain regions form at the same depth other than by doping those regions at the same time. For example, the depth of the source and the drain could be controlled by the energy level at which these regions are created. Therefore, the Court concludes that the intrinsic evidence does not support MPS's proposed construction to require that the source and drain regions (the second and forth regions) be formed at the same time, and thus limits the construction of the disputed term to "intending to have the same dopant concentration as the second region."

D. "first doped region" and "second doped region"

The parties agree that the claimed memory device must have a drain region and a source region. Defendant argues that the "first doped region" must be the drain and the "second doped region" the source of the device. Plaintiff argues that each term can refer to either the drain or the source.

The specification supports defendant's construction. The claim states that a portion of the third doped region must "extend[] from" the first doped region. "Extension from" describes physical contact. Figure 5 of the specification, an alternative embodiment, shows the third doped region (labeled as region 33) touching only the drain (region 18), not the source (region 16). If the claim were construed to allow the first doped region to be the source, then the specification would depict a device in which no portion of the third doped region "extended from" the first doped region, a device not covered by the claim language.

The same analysis holds true for the preferred embodiment, depicted in Figure 1 of the specification. Although that diagram shows portions of the third doped region touching both the source (region 16) and the drain (region 18), region 33b, the portion of the third doped region depicted as touching the source region, is described as optional, whereas region 33a, the region depicted as contacting the drain, is required. '776 patent, 10:6-9. If the optional portion is absent, and the claim were construed to allow the first doped region to be the source, then this preferred embodiment would also not be covered by the claim language because no portion of the third doped region would extend from the first doped region. It is "rarely, if ever, correct and would require highly persuasive evidentiary support" to construe a claim such that the preferred embodiment in the specification falls outside the scope of the patent. Vitronics, 90 F.3d at 1583. Here, plaintiff's construction could exclude both the preferred and the alternative embodiments.

Plaintiff's argument in response is based on an amendment to the claim. The claim originally required "spaced apart doped source and drain regions . . . [and] a third doped region . . . electrically connected to said drain region." Hudson Decl. Ex. C at 27. During the proceedings before the patent office, the applicants amended the claim to read "spaced apart first and
second doped regions . . . [and] a third doped region . . . extending from said first doped region." '776 patent, 12:51-65. The Court is not certain whether this amendment was made to broaden the claim or for some other purpose, such as to avoid confusion with the use of the term "source" to describe the third doped region as a source of charge carriers for the floating gate. The Court therefore finds that there is not the kind of "highly persuasive evidentiary support" required by Vitronics, and holds that the "first doped region" must be the drain, and the "second doped region," by extension, the source.

1439

H. "third doped region"

The '776 patent requires "a third doped region . . . a portion of said third region extending from said first doped region into said substrate area between said first and second doped regions to define the length of said channel, another portion of said third doped region extending appreciably under the edges of said field stop regions." '776 patent, 12:60-13:1. Defendant argues that this requires a single contiguous third doped region (called the "tunnel implant region"); plaintiff argues that the region may be "segmented."

Plaintiff is correct. The patent specification states that the tunnel implant region "may consist of two segments," which are depicted in Figure 1 as being non-contiguous. '776 patent, 10:4. The patent should only be construed to forbid such an embodiment on the basis of "highly persuasive" evidence. Vitronics, 90 F.3d at 1583. Defendant's arguments do not rise to that level. The use of the term "region" in the singular in the claim does not indicate that the region must be contiguous, given the contrary use of the term in the specification. Nor does the Court accept defendant's argument that the claim language requires the second doped region to define only one end of the channel. Even if the third doped region defines both ends of the channel, as depicted in Figure 1, the portion of the third doped region extending from the first doped region can still be described as extending into the area between the first and the second doped regions. The Court holds that the "third doped region" need not be contiguous, but can be as depicted in Figure 1.

1440

2. "doping . . . with . . . atomic hydrogen"

This term is part of the phrase "selectively doping the semiconductor substrate with an effective amount of dopant to induce acceptable conductivity, together with an effective amount of atomic hydrogen to act as a compensator and block unacceptably high occurrences of other compensators" which appears in claim 10 of the '499 patent. The Court construed this term to mean "incorporating atomic hydrogen not produced by disintegration of ambient gases."

As plaintiff points out (Pl. Mem. at 13, n.8), this construction was contrary to the Court's first, intuitive reaction to the term, expressed at the Markman hearing "I think, read literally, as long as you dope the semiconductor with atomic hydrogen together with a suitable dopant, or effective amount of dopant to induce acceptable conductivity, it doesn't make any difference whether that atomic hydrogen started out as molecular hydrogen or started out as an element of ammonia." (Tr. 128:10-15.). The Court was persuaded to change this initial, literal construction of the term on the primary basis of an argument made by plaintiff during prosecution of the application for the '499 patent. The Examiner rejected application claim 20 (patent claim 10) as unpatentable over a prior publication of Fan, et al., stating, "Since in the Fan process the crystal is grown in a hydrogen ambient it is believed that hydrogen is inherently incorporated into the ZnSe layer." (Cree Op. Br., Ex. B at 5.) Plaintiff did not challenge the Examiner's statement about the inherent creation and incorporation of hydrogen in Fan's process, but instead responded by arguing, "Fan describes the use of molecular hydrogen (H gas). Claim 20 specifically describes the use of atomic hydrogen." (Id., Ex. F at 2.) The Court concluded that this response implied a construction of the claim term to exclude processes of the type disclosed in Fan, in which an ambient hydrogen-containing gas could inherently disintegrate under the conditions present in the reaction vessel, creating atomic hydrogen, which could dope the semiconductor crystal being grown therein.

This implication was reinforced by the fact that the specification of the '499 patent did not mention the possibility of obtaining atomic hydrogen from the disintegration of ambient hydrogen-containing gases, but instead disclosed (at 3:62 to
4:9) two more cumbersome (and presumably more expensive) processes for generating atomic hydrogen. Thus the Court ruled that plaintiff had effectively disclaimed the use of atomic hydrogen derived from the disintegration of ambient hydrogen-containing gases.

Now, after reconsideration, the Court believes that its initial, literal construction of this claim term (Tr.128:10-15) was correct and that the construction set forth in the Opinion and Order of May 3, 2007 should be withdrawn. A careful analysis of the controlling decisions relating to prosecution history estoppel convinces this Court that plaintiff's response to the rejection based on the Fan, et al., publication did not constitute such a clear, unambiguous and deliberate disavowal of claim coverage as to require modification of the plain meaning of the claim term by the addition of exclusionary language.

In Omega Engineering, Inc. v. Raytek Corp., 334 F.3d 1314, 1323-26 (Fed. Cir. 2003), the Court thoroughly reviewed the relevant decisions of the Supreme Court and the Federal Circuit and summarized the applicable law as follows:

We indulge a "heavy presumption" that claim terms carry their full ordinary and customary meaning, CCS Fitness [v. Brunswick Corp.], 288 F.3d [1359] at 1366 [(Fed. Cir. 2002)], . . . unless the patentee unequivocally imparted a novel meaning to those terms or expressly relinquished claim scope during prosecution, see Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325-26 (Fed. Cir. 2002). . . . To balance the importance of public notice . . ., we have thus consistently rejected prosecution statements too vague or ambiguous to qualify as a disavowal of claim scope. E.g., Schwing GmbH v. Putzmeister AG, 305 F.3d 1318, 1324-25 (Fed. Cir. 2002). . . . Rather we have required the alleged disavowing statements to be both so clear as to show reasonable clarity and deliberateness . . . Consequently, for prosecution disclaimer to attach, our precedent requires that the alleged disavowing actions or statements made during prosecution be both clear and unmistakable.

(Footnote omitted.) In Northern Telecom Ltd. v. Samsung Electronics, Co., 215 F.3d 1281, 1294-95 (Fed. Cir. 2000), the Court stated:

In sum, we find that the prosecution history fails to prove Samsung's assertion that "plasma etching" in claim 1 of the '967 patent requires the exclusion of ion bombardment. That is, under these circumstances, we cannot conclude that Samsung has demonstrated that the patentees-with reasonable clarity and deliberateness, see In re Paulsen, 30 F.3d 1475, 1480 (Fed. Cir. 1994)-defined "plasma etching" as excluding ion bombardment. See Johnson Worldwide [v. Zebeo Corp.], 175 F.3d [985] at 989 [(Fed. Cir. 1999)] (noting the "heavy presumption in favor of the ordinary meaning of claim language").

In the present case, in response to the Examiner's rejection of the claim as unpatentable over the Fan reference, plaintiff merely stated that "Fan describes the use of molecular hydrogen (H gas). Claim 20 specifically describes the use of atomic hydrogen." (Cree Op. Br. Ex. F at 2.) The essential message of these two sentences is that Fan does not describe the use of atomic hydrogen, which is undeniable true. Even if molecular hydrogen, under the conditions in Fan's reaction chamber, inherently breaks down to create atomic hydrogen, this was not "described" by Fan. Nor is there the slightest indication that Fan was aware that this would happen or that it could result in doping of the semiconductor or that such doping would serve any useful purpose. Thus Fan also does not describe the "use" of atomic hydrogen. This reading of plaintiff's response is eminently reasonable.

This response was surely not a "clear and unambiguous" disavowal of coverage of processes in which the atomic hydrogen is derived from the breakdown of hydrogen-containing gases. And it surely was not a "deliberate" disavowal of such coverage, because this would render claim 10 and all the claims dependent on it a practical nullity. As plaintiff points out (Pl. Mem. at 13), atomic hydrogen cannot be not found in nature (at least on this earth) and can only be obtained from the disintegration of hydrogen-containing compounds. Even the two exemplary methods of generating atomic hydrogen mentioned in the specification of the '499 patent necessarily involve the disintegration of hydrogen-containing compounds (unless some modern alchemist has discovered a way to transmute atoms of other elements into hydrogen atoms). Clearly plaintiff did not deliberately disclaim the use of atomic hydrogen produced in the simplest and cheapest way-the disintegration of ambient hydrogen-containing gases. She obviously realized that, if the claims of her patent excluded coverage of that convenient source of atomic hydrogen, commercial producers of LEDs using the methods taught by her patent would not likely rely on any other source. She was certainly not trying to persuade the Examiner to allow claims she knew would be worthless.

Without a clear, unambiguous and deliberate disavowal of the excluded coverage, the prosecution history furnishes no
justification for disregarding the plain and ordinary meaning of the words of the claim. The Court's previous failure to give due consideration to the controlling precedents discussed above furnishes ample—indeed compelling—basis for granting in part plaintiff's motion for reconsideration.

The Court therefore withdraws its previous construction of the term "doping . . . with . . . atomic hydrogen" and now construes it to mean:

doping with atomic hydrogen (from any source).

b. "a double layered metal gate"

LGD contends that the term "a double layered metal gate" means "a patterned structure of an electrically conductive material that includes two sequentially deposited metal layers and includes a portion that controls current flow through the channel between the source electrode and drain electrode." D.I. 376 at Exh. G-4. According to LGD, the use of the term "includes" in the claim language and in its proposed construction is open-ended and permits the inclusion of additional features, such as additional layers, which LGD contends the specification does not exclude.

AUO contends that this term means "a gate electrode having a two-layered step structure." D.I. 378 at 44; D.I. 376 at Exh. G-4. According to AUO, its construction is consistent with the specification because it captures the key features the inventors sought to claim with respect to the gate structure: (1) that it is composed of two layers, and (2) at the edges, the layers have a stepped structure with each other and with the substrate upon which they rest. AUO contends that the patentee's choice of the term "double-layered" denotes only two layers in a step structure.

CMO contends that this term means "a gate that has only two metal layers." Like AUO, CMO contends that the claim does not recite a structure with a triple layer or with a plurality of layers. CMO further contends that the patentee distinguished the claimed two layer gate from a three layered gate in the prior art, and therefore, a three-layered or multi-layered gate is not within the scope of the claims.

Reviewing the claim language in light of the specification, the Court concludes that "a double layered metal gate" means "a patterned structure of an electrically conductive material that includes two sequentially deposited metal layers and includes a portion that controls current flow through the channel between the source electrode and drain electrode." In reaching this conclusion, the Court does not read the patent as precluding the possibility that additional layers could be added to the double layered gate. CMO cites to the patentee's statement in an office action distinguishing prior art to suggest that the patentee disavowed a double gate structure with additional layers, but the Court does not read the patentee's remarks in that manner. Rather, the patentee distinguished Miyago on other grounds and in so doing, recognized that Miyago starts with a double-layered gate:

Miyago does use an aluminum layer in a double-layered gate and does recognize a hillock problem which occurs along a top surface of a bottom aluminum layer located between the aluminum layer and a top layer. Miyago provides an entirely different solution by providing a clad structure for causing the top-surface hillock problem to be reduced. More specifically, Miyago teaches that in order to solve the top-surface hillock problem, a first tantalum layer is put on the Al-Mo double layer structure then a TaOx layer is put on the Ta layer.

JX F1 (Response dated November 17, 1998 at 3). Accordingly, the Court cannot find a clear disavowal of the possibility that additional layers can be added to the double gate structure. In addition, the Court does not find support in the specification or claim language for adding the "step structure" limitation proposed by AUO.

10. "down converter" ('190 and '021 patents)
SynQor's Proposed Construction
"a switching regulator where
the output voltage is lower
than the input voltage"

Defendants' Proposed Construction
"a converter where the output
voltage is lower than the input
voltage"

The parties have very similar constructions, but disagree as to whether the down converter is a "converter" or a "switching regulator." Both parties agree that it is an item "where the output voltage is lower than the input voltage." SynQor argues that the specification defines the down converter at issue as a non-isolated switching regulator as illustrated in Figure 2. See '190 patent, 4:51-53. SynQor argues that the "regulation stage" is a non-isolated switching regulator that steps-down the input voltage to a lower output voltage. Id. at Fig. 2. Defendants argue that because the claimed phrase specifies a "down converter," that the construction should use the term converter, not a different switching regulator.

The Court finds that the specification never equates a "converter" to a "switching regulator." In addition, the dependent claims of the patents-in-suit show that there is a difference between "switching regulators" and "down converters." For example, dependent claim 2 of the '190 patent requires that the regulation stages of claim 1 be switching regulators, whereas claim 3 requires that the regulation stages of dependent claim 2 (i.e., switching regulators) be down converters. Further, while claim 2 of the '190 patent states that the regulations stages are "switching regulators," other claims also using the term "down converter," such as claims 21 of the '190 and '021 patents, do not have the "switching regulator" limitation. Thus, requiring a "down converter" to be a "switching regulator" is not only without support in the specification but is inconsistent with the claims. Thus, the Court construes the term "down converter" to mean "a converter where the output voltage is lower than the input voltage."

A

Network Commerce objects to the district court's construction of the term "download component "and appears to support the construction it argued to the district court: "any part of a computer system - including a program, an application, or a data or text file - that安排s for, or works together with one or more other parts of the system to arrange for, the transfer or delivery of the requested electronic data from one computer or server to another." Network I, 260 F. Supp. 2d at 1039. Under this construction, Network Commerce argues that both the metafiles and the Windows Media Player satisfy the claim limitation because each "works together with one or more other parts of the system to arrange for, the transfer or delivery of the requested electronic data from one computer or server to another." We reject this proposed construction, and agree substantially with the district court's construction of the term. n4

n4 Network Commerce also argues that the district court changed its construction of "download component" on summary judgment by requiring that the download component coordinate or control the download of information on its own. We reject this argument. The district court simply clarified its previous construction in the summary judgment order, wherein it had already rejected the contention "that the 'download component' could possibly be a completely inactive data file or that the active functions referred to in the claims could be carried out by some other component." Network Commerce, Inc. v. Microsoft Corp., 260 F. Supp. 2d 1034, 1040 (W.D. Wash. 2002).

We start with the language of the claims. The '124 patent has four independent claims, all with similar requirements. Each independent claim of the '124 patent (that is, claims 1, 7, 11, and 14) uses the term "download component." First, each independent claim states that the download component is either sent to or received by a computer in response to a request for electronic data. n5 Second, the download component must coordinate the download of electronic data. n6 Finally, the download component must request electronic data from (or control the download of electronic data from) a computer other than the computer from which the download component was sent or received. n7 Thus, the claims define how the download component is obtained and in general terms what the download component does.

- 1861 -
 customer's computer "extracts [from the download file] the executable boot program and component list." See id. at col. 9, merchant "downloads and installs the download file" on the customer's computer. This file when downloaded into the
specification explains that the download file resides in the computer of an online merchant or is accessible to that computer.
not use the term "download component," presumably because this claim terminology was added during prosecution after the
specification had been prepared. The specification does describe a "download file." n8 It appears from the function and
description of the "download file" that this item corresponds most closely to the download component of the claims. The
parties seem to agree that Windows Media Player and metafiles taken together would constitute a "download component" if downloaded
together from a store computer. They differ, however, as to whether metafiles or Windows Media Player standing alone
constitutes a "download component." The claims also assume that the "download component" is a component of a larger software system, that is, the download component does not alone direct the computer hardware to perform the designated tasks. The difficulty is that the claim
language is not clear as to what other programs are to be used with the "download component." At oral argument (though
unfortunately not in the briefs) the parties agreed that the download component at least operates in conjunction with the
computer's basic operating system, and that the operating system is not part of the download component. The parties also
agree that Windows Media Player and metafiles taken together would constitute a "download component" if downloaded
together from a store computer. They differ, however, as to whether metafiles or Windows Media Player standing alone
constitutes a "download component." We construe a claim term as having its "ordinary and customary meaning," that is, "the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention." Phillips, 415 F.3d at 1313. In some cases, it is possible to construe a claim term by applying "the widely accepted meaning of commonly understood words." Id. at 1314. "Download component" is not a claim term amenable to construction in this manner because it has no commonly
understood meaning reflected in general dictionaries or similar sources. We may also rely on a term's "particular meaning in a field of art" when construing claims. Id. As the parties seem to agree, the term "download component" does not have a specialized meaning in the relevant art. Microsoft urges that "download component" does not have a particular meaning in the computer art; and that the term does not appear in computer dictionaries and treatises. Network Commerce also agrees that a definition of the term "download component" as a whole does not exist, but invites the court to combine individual
dictionary definitions of "download" and "component." Under that construction, any part of a system involved in the transfer of data from one computer to another would be a download component. This is not a tenable theory in light of the specification.

B

In general "the specification necessarily informs the proper construction of the claims" and it is "appropriate for a court . . . to rely heavily on the written description for guidance as to the meaning of claims." Id. at 1317. Here, the specification does not use the term "download component," presumably because this claim terminology was added during prosecution after the specification had been prepared. The specification does describe a "download file." n8 It appears from the function and
description of the "download file" that this item corresponds most closely to the download component of the claims. The
specification explains that the download file resides in the computer of an online merchant or is accessible to that computer. See '124 patent at col. 9, ll. 34-37 & Fig. 3. When the merchant receives an online request for electronic content, the online merchant "downloads and installs the download file" on the customer's computer. This file when downloaded into the customer's computer "extracts [from the download file] the executable boot program and component list." See id. at col. 9,
ll. 37-39. n9 The specification defines the capability of the boot program to include the ability to read "the component list to determine what [electronic content] . . . to download . . . from the appropriate contents supplier server," and the ability to request the appropriate content from the supplier server. Id. at col. 9, ll. 41-45. Thus, while the download file may contain different things, the specification indicates that it must contain at least the boot program.

The specification describes no programs mediating between the boot program and the operating system. Moreover, figure 8 identifies the boot program as a file called "SAFEBoot.exe." An "exe file" is a file in "binary code" and "a Windows exe file (e.g., the Windows Media Player application) is an executable file because it is a sequence of bits arranged in such a way that it can be executed by . . . the computer's operating system." (J.A. at 1494-95.)

In summary, the specification makes clear that the download component must include a boot program, and that the boot program interacts directly with the operating system of the computer without the assistance of any other program. Accordingly, we construe "download component" to mean a file or program either sent to or received by a computer in response to a request for electronic data that 1) requests (or controls the download of) electronic data from a computer other than the computer from which the program was sent or received; 2) coordinates the download of electronic data; and 3) interacts directly with the operating system of the computer without another program mediating between it and the operating system. This construction of the term "download component" is similar to the definition of "application" adopted in Eolas Technologies, Inc. v. Microsoft Corp., 399 F.3d 1325 (Fed. Cir. 2005). There we approved the district court's construction of "application" to mean "a computer program, that is not the operating system or a utility, that is designed to allow an end-user to perform some specific task." Id. at 1336. In addition, we see nothing in the prosecution history that remotely suggests that our interpretation of "download component" is incorrect.

Network Commerce relies on the declaration of its expert, Theodore Coombs, for the proposition that the "download component" need not contain the boot program. In his declaration, Coombs quotes various passages from the specification, and concludes: "I understand [these passages] to mean that there are possible embodiments of this invention that use a 'download component' that does not contain a boot program or executable code." (J.A. at 1035.) Coombs' declaration provides scant support for Network Commerce's position. As we recently reaffirmed in Phillips, "conclusory, unsupported assertions by experts as to the definition of a claim term are not useful to a court." Phillips, 415 F.3d at 1318. Here Coombs does not support his conclusion with any references to industry publications or other independent sources. Moreover, expert testimony at odds with the intrinsic evidence must be disregarded. Id. ("[A] court should discount any expert testimony that is clearly at odds with the claim construction mandated by . . . the written record of the patent.") (internal quotations and citation omitted). That is the case here. n10

Network Commerce also argues that there is an embodiment of the invention disclosed in the specification wherein the boot program already resides on the customer's computer when the download component is received by the customer computer, and that the term "download component" should therefore not be construed to include the boot program. In support of this argument, it points to language in the specification stating that "a minimum number of components are
downloaded" and that "embodiments of the invention also support the secure execution of requested merchandise and minimize the number of components needed to securely download, license, and execute the requested merchandise." '124 patent, col. 4, ll. 64-65 & col. 8, ll. 17-20. However, the specification makes clear that the boot program must be downloaded from the merchant computer in response to a request for electronic content at least once. Download of the boot program is discussed repeatedly, and no other method of obtaining the boot program is disclosed.

Downloadable code storage

Lantronix contends "downloadable code storage" should be construed as "a device on which instructions/software are kept and can be retrieved/accessed and into which the instructions/software can be transferred to a remote source." Digi contends the term should be construed as "a component or set of components on which instructions or software are kept and from which the instructions or software can be retrieved or accessed from a remote source." Lantronix says it would adopt Digi's construction except that Digi's construction does not account for the code storage being "downloadable." Digi criticizes Lantronix's construction because "into which the instructions/software can be transferred from a remote source" is not mentioned in any cited intrinsic evidence.

During the hearing the parties agreed this term should be construed as "a component or set of components on which instructions or software are kept, from which the instructions or software can be retrieved or accessed, and into which the instructions or software can be transferred." The Court agrees that this compromise construction appropriately reflects the term's meaning.

13. "Downloader": "A computer that retrieves web pages and embedded objects from the internet." This construction is consistent with claim 16 and the specification: col. 2, ll. 45-55. Although in preferred embodiments downloaders may store web pages and embedded objects for later use, storage is not required by the claim language. Storage may occur in an "image server database" instead.

1. Downloading

The term "downloading" is found throughout the '189 patent, which, at its core, concerns a method and apparatus for transferring data structured in particular ways from one computer, generally a server, to another, generally a personal computer with limited storage capacity. Skyline fails to provide a specific proposed definition of "downloading" in either of its claim construction briefs, but Google characterizes Skyline's proposed construction as "transferring from a remote server to a local computer." Since this definition seems to comport with Skyline's understanding of the "plain and ordinary meaning" of the term discussed in its Reply brief and because the parties appear to have engaged in negotiations over disputed terms, I will accept this definition as an accurate reflection of Skyline's position. Google argues for a more specific and narrow definition, namely "requesting over a network and receiving in local memory from a separate computer." n4

n4 At the November 1, 2006 Claim Construction Hearing, Google indicated a willingness to drop "local memory" in favor of simply requiring a download to the local computer. See Nov. 1, 2006 Transcript, p. 7:8-23; Defendants' Claim Construction Hearing Slides, p. 10 ("Requesting over a network and receiving by the user's computer from a separate computer' is an acceptable and accurate construction.").
Google's proposed definition would add several limitations. First, it would make clear that nothing is "downloaded" until it has actually been received by the requesting computer. This limitation comports with the ordinary meaning of the term as it would have been understood by one skilled in the art, and it corresponds to the way the term is used at various points in the '189 patent. n5 Use of the term "transferring" would, by contrast, be ambiguous as to whether the files transferred must necessarily be received by the target computer to be considered "downloaded." Because I find that the data must be received for the download to be complete, I adopt a construction of this element of the term that makes both "requesting" and "receiving" critical steps in the download process.

Google originally sought a limitation that the requested data blocks be received in "local memory" to be considered downloaded. As a matter of construction, this initially appeared to present a close question. Such a specific limitation is not necessarily imposed by the phrase "downloading," when used in a general context. One skilled in the art seems likely to have understood "downloading" as a phrase that required additional information, namely where the downloaded material would be sent (downloaded to a hard drive, etc.). The end point would in many cases be the local memory of a machine (RAM, cache memory, virtual memory, or other local memory options), but it could also be a disk drive, hard drive, or other storage device.

As used in the '189 patent, however, it is clear from the claims and specifications that "downloading" necessarily means that the data blocks arrive in the "local memory." The clearest indication that this is the case is in Claim 12 (and repeated verbatim in Claims 13, 14, 15, 16, and 18), which describes the apparatus covered by the patent. The claimed apparatus has three parts: a local memory, a communication link, and a processor. The communication link is described as something "through which the memory receives the data blocks from a remote server" (col. 18, 11. 19-20) (emphasis supplied). The only reasonable construction of this phrase is that "the memory" refers to the "local memory" that is part of the apparatus described immediately above. The apparatus as described contains no other memory, so there is no non-local memory for the communication link to access. Consequently, the communication link must download into the local memory.

This reading is supported by Claim 7, discussed in more detail below, which describes "downloading . . . excess blocks . . . to fill up the local memory." (col. 17, 11. 58-60) No claim makes reference to downloading excess blocks for any other purpose, and Fig. 8 clearly indicates that excess blocks are discarded when the local cache memory is full, not moved to more permanent storage locations. n6 Although "downloading" could theoretically mean something other than "downloading to the local memory," the fact remains that any time the term is qualified in the '189 patent, it specifies or strongly implies the use of local memory. Regardless, since both parties have agreed that "local memory" is not a necessary component of the claim construction, I will omit this term.

Google argues that Fig. 8 supports this position but I disagree. As noted in the patent, Fig. 8 "is a flow chart illustrating the actions of cache manager. . . ." The cache manager is described in the specification as something that preferably "manages a group of blocks and/or sub-blocks in a cache memory." (col. 11, 11. 39-40) Cache memory is "used [in the '189 patent] generally to refer to any relatively small memory which can be accessed rapidly by the processor and is used to save data which is most likely to be used by the processor." (col. 11, 11. 59-61) Based on this definition, cache memory is quintessentially local memory, because the entire purpose of local memory is to store often-used data for rapid access.

The description of Fig. 8 indicates that the cache manager starts by "downloading the first batch of level 1 blocks" and then moves into a wait state. Skyline reads this statement to imply that the initial download is received into something other than...
"local memory." However, this proposition fails to take into account the character of the cache manager. As Fig. 5 makes clear, the cache manager is part of the processor on the local machine, so any memory to which it has rapid access is fundamentally "local memory" as well, particularly as the term was initially construed. Skyline Software Sys. v. Keyhole, Inc., 421 F.Supp.2d 371, 389 (D. Mass. 2006) ("Memory easily accessible to the user's processor . . . and distinct from the memory of the remote server from which data must be downloaded."). Skyline does not specify where it thinks the block in Fig. 8 is downloaded when it first enters the cache manager, but it seems clear that, wherever the downloaded block is initially held, it must be within the realm of local memory as previously construed. The apparatus descriptions in Claims 12, 13, 14, 15, 16, and 18 further reinforce the notion that the processor and cache manager are closely linked, by assigning tasks to the processor (providing data blocks to the renderer, etc.) that the cache manager is described as performing in various preferred embodiments.

Construction: (downloading) Requesting over a network from a separate computer and receiving on a local computer

1447

3. Downloading . . . if the provided block from the local memory is not at the indicated resolution level [if the first block is not from the indicated level]

Google argues that the conditional nature of these phrases requires the requesting computer make a determination as to whether the condition has been satisfied before taking any action, and proposes a construction of "downloading . . . upon a determination of whether the first data block is not of the indicated resolution level." Skyline proposes "downloading . . . when the first data block is not of the indicated resolution level."

Basic logic, as manifested in computer programming, makes clear that Google's argument must be correct. Although Skyline argues that the proposition "[w]hen an action is conditional, a computer program must make a determination as to whether the specified condition is met in order to take appropriate action" is not true, its rationale for this argument is unconvincing. Skyline attempts to read into "make a determination" a requirement that the computer test directly whether the conditional is satisfied. No such limitation is implied. The necessary determination may be made indirectly, by testing for a related condition, for example, or by forcing the conditional always to be satisfied, but these indirect tests do not eliminate the need to make some determination as to whether the conditional is satisfied before actions predicated on it are taken. n10 Computers are logic-based machines -- they do not just "know" when a condition X is true without testing for X in some manner. Therefore, I find that some determination, although not necessarily a direct test, is necessary before conditional actions are undertaken.

--- Footnotes ---

n10 Skyline acknowledged at the November 1, 2006 Claim Construction Hearing that some determination was necessary, but disagreed with the functional approach Google described. See Nov. 1, 2006 Transcript, pp. 19:1-20:7.

--- End Footnotes ---
E. "Downloading Into A Memory Storage Device."

Finisar contends that this term should mean "transferring data into a memory storage device." In contrast, Comcast argues that the term should mean "transferring the data packets into a device whose purpose is to save them indefinitely until the subscriber retrieves them." "Storage" is a commonly understood word even in the context of computers. Information comes to rest at a certain place for some amount of time so that it can be accessed later. "Downloading" is similarly understood as a transfer of data from one system or location to another.

--- Footnotes ---

5 The Texas Court first addressed this term in claim construction, where it held that "downloading into a memory storage device" meant "the data filter transfers into a memory storage device the data packets specified in the filter data." Later, on a motion for clarification of the construction of the phrase, the Court held the term as used in claim 16, asserted herein, to mean "transferring into a memory storage device the data packets specified in the filter data" (Melgar Decl. Exh. D at 4).

--- End Footnotes ---

This term appears as a limitation in several of the independent claims, including claim 16. In part, it recited (col. 21:34-68):

16. An information transmission system comprising the steps of:

* * *

- receiving said transmitted stream of data packets at subscriber stations;

- at each subscriber stations, storing filter data corresponding to a subset of said indices, said filter data specifying a set of requested data packets which comprises a subset of said transmitted data packets; and

- at each subscriber station, downloading into a memory storage device those of said received data packets which match said specified set of requested data packets.

Finisar contends that any construction of this term should be broad enough to encompass temporary storage in a buffer. Comcast would require the data packets to be stored so as to be retrievable later.

Claim 26, which depended from claim 16, helps to illuminate what was meant by this term. It recited (col. 23:15-27):

26. The information transmission of claim 16, said receiving and downloading steps including:

- at each subscriber stations, temporarily storing received data packets in a buffer, storing a filter list comprising said filter data referencing said specified set of requested data packets, comparing said data packets temporarily stored in said buffer with said filter data and then forwarding those data packets in said buffer which match said filter data to a predefined destination;

- whereby each subscriber station receives all transmitted data packets but forwards only requested data packets to said predefined destination.

Claim 26 added the limitation of storing the data packets temporarily in a buffer before forwarding them to a predefined destination. While temporarily stored in the buffer, the incoming data packets are matched up to a filter list that specifies the requested data packets and sends them on to a predefined destination. Claim 26 depended from Claim 16. Therefore, all of the limitations of claim 16 were part of claim 26, and the claim 26 limitations simply narrowed further the scope of the claim 26 invention. The further limitations in claim 26 narrowed the "receiving" and "downloading" steps. The first claim 26 limitation narrowed the "receiving" step of claim 16 to call out expressly the temporary storage of the received data packets in a buffer and comparing the packets stored in the buffer against the filter list and then forwarding the packets that match to "a predefined location." The "downloading" step was narrowed to transmission of requested data packets to the predefined destination.
This order holds that the term "predefined destination" must be a "memory storage device." This follows as a matter of law due to the dependence of claim 26 from claim 16. Significantly, the use of the buffer in claim 26 was not as a memory storage device. Rather, it was a refinement on the filtering step.

Claim 16 called out two distinct steps (at the subscriber station). One was the filtering step. The other was the downloading step -- very specifically "downloading into a memory storage device." The specification consistently separated the two steps. It consistently referred to the second step as storage in "the memory of the subscriber's workstation," or another "computer," "host computer," or "tape recorder" (col 5:30-35; col 8:31-46; col 11:34-57; col 16:53-64). Anyone skilled in the art would understand that the filtering step utilizes the buffer and the downloading step utilizes a different and separate memory storage device capable of retaining the received data packets until they are desired for further use by the subscriber's system.

Finisar argues that a "memory storage device" should not be limited to any particular device. In support, it points out that the specification taught that the data could be downloaded to RAM, or random-access memory, on a subscriber's computer (col. 5:31-35, Fig 2). RAM is volatile memory that can be overwritten, however, RAM can still be accessed again after the information has been downloaded. Storage need not be permanent, but being able to view content at a time after it has been downloaded is a key feature of this invention (col. 1:53-66; 6:15-26; 17:1-10).

Comcast argues that a "view-it-or-lose-it" system, such as streaming data or video, is not a storage device. The problem is that the Court does not yet know how the accused system works. Possibly the streaming utilizes some form of downloading to a memory storage device, even if the information is retained only briefly. The Court is unwilling on this record to speculate. All that can be said with assurance at this point is that the buffer used in the filter step will not do double duty as the storage memory device for the downloading step. Whether or not some other buffer can serve as the memory storage device remains to be seen.

This order takes pains to point out that the limitation requires that the "received data packets" be downloaded. The patentee made clear what he meant by a "data packet" as described in Figure 6 of the patent. It includes the data itself, as well as a packet ID, function code, timestamp, and an error detection code. This raises the possibility that a system similar to the claimed system could download only part of the received data packets. Some portions in the packet described by Figure 6 could be omitted, or possibly replaced with other information or error correction codes. This would presumably avoid literal infringement of claim 16.

Accordingly, this claim construction order holds that "downloading into a memory storage device" means transferring the desired data into a device capable of saving it for later access.

1449

11. download(ed)

The term "downloaded" appears in claims 96 and 112 of the '725 patent and claims 43 and 68 of the '345 patent. The term "downloading" appears in claims 45, 46, and 74 of the '725 patent and claims 32, 57, 87, and 93 of the '345 patent. The term "downloads" appears in claims 9, 22, 46, and 84 of the '725 patent. With respect to the term "downloaded," the plaintiff proposes a construction of "some collection of data transferred from a memory to another memory via a communications link." The defendant proposes "retrieved and stored in a disk or other non-volatile storage." With respect to the term "downloading," the plaintiff proposes a construction of "transferring some collection of data from a memory to another memory via a communication link." The defendant proposes "retrieving and storing in a disk or other non-volatile storage." With respect to the term "downloads," the plaintiff proposes a construction of "transfers some collection of data from a memory to another memory via a communications link." The defendant proposes "retrieves and stores in a disk or other non-volatile storage."

The dispute between the parties is whether downloading includes streaming. Although the defendant cites cases that draw a distinction between downloading and streaming in the copyright context, the terms of these patents use downloading in a manner that includes streaming. For instance, claim 49 of the '725 patent recites "wherein for at least some of the media items the processor downloads media items from the remote inventory via the communications link at substantially the same
time the corresponding media item is presented to the user." This language captures the essence of streaming, which is a process for transmitting information from a host site over a communications link and presenting it to the user at substantially the same rate (i.e. the same time) it is transmitted. As such, the court construes the term "downloads" to mean "retrieves and stores in volatile or non-volatile storage."

"Downloads into a memory storage device those of said received data packets which match said specified set of requested data packets." Used in claims 1, 16, 37, 39, and 44.

This dispute is somewhat unusual in that it does not depend on definitions of technical terms, but rather on grammatical construction. The parties agree that "downloads" means "transfers." They also agree that what is transferred are data packets, and that the data packets are transferred to a memory device.

The claim states that the data filter is part of the subscriber station, and that the data filter stores filter data. See Claim 1, 505 patent, col. 18, 11. 28-30. The filter data specifies the requested data packets. col. 18, 11. 31-33. The specification describes this process in more detail, but gives no indication that the claim language should be given anything but the ordinary and customary meaning. See col. 8, 11.37-46, col. 11, 11. 34-57 and Figure 7.

Finisar argues that the data packets to be transferred are "specified" by the filter data. DirecTV argues that the data filter actually transfers the data packets to the memory device. Both are, in a sense, correct.

Claim terms are to be read according to the rules of ordinary English grammar. In re Hyatt, 708 F2d 712, 714 (Fed. Cir. 1983). Accordingly, it is the data filter "that stores filter data . . . and that downloads into a memory storage device . . ." the data packets. col. 18, 11. 30-35. On the other hand, the claim and specification also make it clear that the data packets to be downloaded are those specified or requested in the filter data. This term will be defined as follows:

"Downloads into a memory storage device those of said received data packets which match said specified set of requested data packets" means "the data filter transfers into a memory storage device the data packets specified in the filter data."

H. Limitation 7: drain conductive region

35. The next element of Claim 1 is as follows: "a drain conductive region remote from said common region and separated therefrom by said relatively lightly doped major body portion." An example of this "further region" is the N+ substrate on which the lightly doped epitaxial layer is formed. (col. 3, lines 64-65.) This claim element is properly construed to include any region carrying a substantial portion of device current that is separated from the common conduction region (between the bases) by the lightly doped layer.

B. "Drive Bay Slot"

Comaper suggests that this term means "the relatively narrow opening in the housing of a computer that leads to the drive bay." (Pl.'s Constr. Mem. at 4.) Comaper arrives at this definition by interpreting the individual meaning of the words within the term. A "slot", Comaper contends, is a well-known term for an opening or passage; a "drive bay" is a common term for the particular space inside a computer that is dedicated to accommodate a drive. Id. Comaper further argues that there is no special meaning ascribed to the term "slot" in the intrinsic record, and therefore the plain and ordinary meaning should prevail in its interpretation. Id. at 5.
Antec interprets the term "drive bay slot" to mean "the area inside a computer enclosure having an independent opening capable of housing a drive." (Defs.' Constr. Mem. at 10.) Antec contends that Comaper's construction contradicts its use of the term in Claim 1 which recites "a case configured to mount within said drive bay slot of said computer such that said case occupies substantially the entire drive bay slot." Id. According to Antec, a case would be "far larger" than the narrow slot leading to the drive bay. Id. Antec also reasons that the term "slot" cannot mean opening because opening was used during the application process, and yet the Examiner still insisted on inserting the term opening. (Defs.' Reply. Mem. at 11.) Using Antec's construction would result in "drive bay slot" and "drive bay" meaning the same thing. This was not the intent of the patentee.

The Court concludes that the term "drive bay slot" means "the relatively narrow opening in the housing of the computer that leads to the drive bay." The prosecution history supports this construction. As stated above, courts are free to consider the prosecution history, the record of correspondence and communications between the inventor and the PTO, which is kept on file at the PTO and made available for public inspection. "Although the prosecution history can and should be used to understand the language used in the claims, it too cannot 'enlarge, diminish, or vary' the limitations in the claims." Markman, 52 F.3d at 980 (citation omitted). "If a patentee takes a position before the PTO, such that a 'competitor would reasonably believe that the applicant had surrendered the relevant subject matter,' the patentee may be barred from asserting an inconsistent position on claim construction." Katz v. AT&T Corp., 63 F. Supp. 2d 583, 591 (E.D. Pa. 1999) (citing Cybor Corp. v. FAS Technologies, Inc., 138 F.3d 1448, 1457 (Fed. Cir. 1998)); see also Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996).

The parties agree that the term "slot" was added during prosecution at the Examiner's insistence. (See Pl.'s Constr. Mem. at 4; Defs.' Reply Mem. at 11.) Furthermore, Comaper concedes that the term was added as a way to distinguish the '955 Patent from the device in Pollard. (Pl.'s Constr. Mem. at 4.) It is also clear that the term "opening" existed elsewhere in the patent language and the use of the term "slot" was to convey a different meaning than a mere opening.

Omax proposes that this phrase should be construed as the "portion of a machine tool that receives motor commands and electronically controls motor functions. It may or may not include one or more controllers that interpret and adjust motor commands." Flow's interpretation uses the same first sentence, and then continues: "The drive circuit may contain a force command interpreter, a position command differentiator, or a position command interpreter, as defined in the patent. The drive circuit does not include add-in cards or intermediate command interpreting controllers."

This Court already has concluded that "the specification as a whole does not suggest 'that the very character of the invention requires the [direct connection] limitation [suggested by defendant] to be part of every embodiment.'" Order, Dkt. # 52 at 6 (quoting Alloc, Inc. v. Int'l Trade Comm'n, 342 F.3d 1361, 1370 (Fed. Cir. 2003)). Flow has attempted to account for this conclusion by suggesting that the claim be construed as allowing certain intermediate connectors, but not the add-in card or other controllers that are the hallmark of the Flow device. The Court continues to hold that the character of the invention does not require the absence of the intermediate steps that Flow attempts to preclude through its proposed construction. The Court therefore adopts Omax's proposed construction.

The parties agree that a controller may consist of a device or group of devices to control the communication of data between a host computer and drive electronics. Defendants' 527 Br. at 18; Plaintiffs' Reply at 11. Plaintiffs ask the court to construe the term "drive controller" to exclude external translation circuitry, insisting that the patent specification and prosecution history teach away from the use of translation circuitry. Defendants, by contrast, argue that a controller is not defined by...
physical boundaries, but by elements necessary to accomplish the purpose of the controller. Id. at 19. Accordingly, they assert that, absent any express intention to exclude translation circuitry in the claims, specification, or prosecution history, translation circuitry may be included in the construction of "drive controller" where translation circuitry is employed to accomplish the purpose of the controller.

Defendants contend that if plaintiffs' construction is adopted, such that a "drive controller" excludes translation circuitry, the result would be that none of the accused devices would be infringing because they all comply with ATAPI. They assert that all ATAPI devices must engage in translation as sector addresses in CD-ROM devices are recorded in "minutes, seconds and fractions" ("MSF") format. However, because the host computer sends ATAPI commands in logical block address ("LBA") format, the communication between host computer and an ATAPI CD-ROM requires translation of address information in ATAPI command packets from LBA format to MSF format. In response to this argument, plaintiffs clarify that their proposed construction does not seek to exclude all translation circuitry, rather it seeks to exclude external translation circuitry, such as the external interface or host adapter card which the invention expressly sought to eliminate. See, e.g., 527 patent at 2:41-3 ("This would obviate the need for an additional host adapter card and associated electronics.").

Plaintiffs support their position by pointing to several disclaimers found in the specification. The 527 patent states as the purpose of the invention that "it would be desirable to provide a CD drive with built-in controller functionality and a standard connection. This would obviate the need for an additional host adapter card and associated electronics." 527 patent at 2:39-43. It also emphasizes, "This invention reduces the cost of a host adapter card or additional ISA bus interface electronics." Id. at 5:45-48; see also id. at 7:24-32. They also point to a disavowal of claim scope in the prosecution history. In response to a December 3, 2001 office action, the inventors stated with regard to a "host interface" that "directly" connects that "the quoted limitations cannot be met where a controller requires a translator card or other intervening circuitry between the controller and the IDE bus to translate or manipulate command data due to the inability of the controller to properly handle native ATA command." Schwartz Decl., Ex. C at ZC001817.

Plaintiffs contend that the inventors were distinguishing prior art translation devices such as the Mitsumi prototype created by Oak prior to its development of the OTI-11, which had an external card housing the translation circuitry. In their sur-reply briefing, the parties dispute whether the Mitsumi prototype was overcome during patent prosecution. The court finds that this discussion is unhelpful to the determination of whether the inventors disclaimed external translation circuitry.

The court finds that the inventors disclaimed external translation circuitry. Thus, the proper construction of "drive controller" includes translation circuitry but excludes circuitry necessarily located on an external adapter card.

First, Nintendo argues that the definition of "drive signals" is unclear from the claim language. It is true that the term "drive signal" is a fairly generic term of art. However, the language of the claims in the '659 patent limits the claimed "drive signals" to those "phase-related to said clock pulses." '659 pat., col. 18, l. 64. Nintendo argues that we must look to the written description for a further definition of the claim limitation "drive signals." In particular, Nintendo argues that "drive signals" are defined in the '659 written description as:

The HORIZONTAL DRIVE/CHROMA signal is produced during each horizontal synchronizing interval and is used to trigger the horizontal deflection circuitry in the television camera. . . .
The VERTICAL DRIVE signal is used to trigger the vertical deflection circuitry in the television camera.

'659 pat., col. 6-7, ll. 56-46 (emphasis added). We hold that the meaning of the term "drive signals," as claimed in the '659 patent, is broader and is clear from the language of the claims. The phrases cited by Nintendo above are not a definition of the term "drive signal." Nintendo is, essentially, arguing that we should import one example from the written description into the claims as the complete definition of a claim term. This we cannot do, as "what is patented is not restricted to the examples, but is defined by the words in the claims . . . ." Specialty Composites v. Cabot Corp., 845 F.2d 981, 987, 6 U.S.P.Q.2D (BNA) 1601, 1604 (Fed. Cir. 1988). The passage from the '659 written description quoted above is but one example of the use of a drive signal, and is not a further limitation to be imported into the claims. The words in the claims do not specify a television camera, and Nintendo's argument that the accused systems, lacking a television camera, cannot infringe is therefore incorrect. The accused systems clearly do produce drive signals as contemplated by the claim language. GO BACK

1456

M. "the driver"

The term "driver" is recited in Claims One, Two, Eleven, Fourteen, and Fifteen of the '399 Patent: in Claim One, the host device "comprises drivers for input/output devices customary in a host device," col. 12:43-44; in Claim Two, "the drivers for input/output drivers customary in a host device comprise a hard disk driver," col. 13:14-15; in Claim Eleven, the host device "comprises a multi-purpose interface and a specific driver for this interface," col. 13:52-53, and "the host device communicates with the interface device by means of the specific driver for the multi-purpose interface," col. 14:13-15; in Claim Fourteen, the host device "comprises drivers for input/output devices customary in a host device," col. 14:32-33, and "the host device communicates with the interface device by means of the usual driver for the input/output device" customary in a host device, col. 14:55-57; and in Claim Fifteen, "the drivers for input/output devices customary in a host device comprise a driver for a storage device and in particular for a hard disk drive," col. 14: 63-65. The '449 Patent references "driver(s)" multiple times as well: in Claim One, the host device "comprises drivers for input/output devices customary in a host device," col. 11:47-48; in Claim Seventeen, the host device "comprises a multi-purpose interface and a specific driver for this interface," col. 13:15-16, and "the host device communicates with the interface device by means of the specific driver for the multi-purpose interface," col. 14:1-3; and, in Claim Eighteen, the host device "comprises drivers for input/output devices customary in a host device," col. 14:9-10.

The Camera Manufacturers propose that the word "driver" be construed to mean "the set of software routines used to control an input/output device." CMs' Markman Br. at 24. They note the IEEE Dictionary definition for driver "as a computer program, i.e., a set of software routines that controls a peripheral device and reformats data for transfer to and from the device." Id., see The New IEEE Standard Dictionary of Electrical & Electronics Terms 387 (5th ed. 1993) ("New IEEE Dictionary") (attached to CMs' Markman Br. as Ex. G). According to the Camera Manufacturers, "the driver must be what actually enables the host device to communicate with and control an input/output device." CMs' Markman Br. at 25.

Papst disagrees, noting that not all IEEE definitions for the word "driver" contain the word "control" because "control is possible but not necessary." Papst's Reply at 26. Papst urges the Court to consider the definition offered by its expert, Dr. Locke: "A driver translates generic commands (such as to 'read' or 'write' a file) from high level computer programs into a sequence of very specific commands that a particular hardware device can understand (such as 'seek' or 'load register')." Id. at 27.

As the Court explained above in the discussion of "host device," drivers are software programs used to communicate with hardware:

[T]he host device must have internal drivers, i.e., software, to instruct hardware how to operate. As Papst acknowledged, drivers "are the software programs that are used by the computer[ ] to communicate with the hardware that's attached to the computer. So for each and every hardware device that you connect to a computer there has to be a driver that allows the computer to communicate with that hardware device." Tr. 1:5 (Papst). The specification explains that such drivers can instruct a hard drive (the preferred embodiment) that is internal to the computer, or such drivers can instruct a printer that is external to the computer. In all instances, the driver instructs the how and when of hardware operation and thus directs it.
In addition, the specification makes it clear that a driver is a set of routines required to drive a device. See '399 Patent, col. 12:14-16 ("using a driver software for the multi-purpose interface which comprises the BIOS routines customary in host device"); '449 Patent, col. 11:16-18 (same); see also '399 Patent, col. 11:32-42 (the hardware-oriented side of the "ASPI manager" is matched to an interface and the other side is the user software side); '449 Patent, col. 10:32-42 (same). Accordingly, the Court construes "driver" to mean "the set of software routines used to direct a device, for example, an input/output device or a multi-purpose interface."

A. Driver

The term "driver" appears in all claims for the '511, '392, and '694 patents. It also is used in claims 1 and 2 of the '382 patent, as well as claims 1-3, 5, 9-17, and 25-26 of the '617 patent.

The claims indicate that a driver may perform a variety of functions. These functions include accessing and storing information. See '511 patent, claims 1 and 2. Claim 10 of the '511 patent lists other functions that a driver may perform, including:

* selecting directories where data sources are located;
* searching directories for data files;
* displaying data to be input or updated;
* loading general information and data definitions from data sources;
* creating database tables configured for storing information from data sources;
* saving general information and data definitions from data sources;
* loading data definitions codes, "rollup information," and data into a database.

See also '511 patent, Col. 10:47-51 ("Each driver includes a plurality of defined processes or functions 901 through 909. Each function may include computer program instructions 912, e.g., to implement and carry out one or more of the steps described below and depicted in FIG. 10."). The '511 patent specification also notes (at least in the context of one embodiment) that the drivers "are processes having multiple functions for analyzing and accessing" different types of source data. '511 Pat., Col. 9:31-32.

Timeline's proposed construction of the term "driver" is both simple and broad: "Computer software which performs functions such as accessing, processing, or storing data." ProClarity's proposed construction is considerably more detailed: "A self-contained set of multiple functions, distinguishable from and connected to an application level program, performed by a computer including the ability to perform analysis and intelligent interrogation of a data source and which can identify what is required to store a standard form of the data source, e.g. for reporting and analysis." Timeline's proposed construction, although quite broad, is not inconsistent with the use of the term "driver" in the claims themselves. The claims plainly indicate that a driver may perform a variety of functions, including but not limited to accessing and storing data. n2

Footnotes:

n2 Timeline also notes that a computer dictionary from 1995 defines the term "database driver" as "a software routine that accesses a database. It allows an application or compiler to access a particular database format." The Computer Glossary (7th ed. 1995). However, the claims use the term "driver," not the term "database driver." In addition, the dictionary
definition offered by Timeline only indicates that a database driver "accesses" a database. It makes no mention of "storing" or "processing" data, much less the other functions that the claims indicate that a driver may perform. As a result, the dictionary definition offered by Timeline does not lend significant support to its proposed construction.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

ProClarity's more narrow construction of "driver" includes a number of limitations. For example, ProClarity asserts that a driver must be "self-contained." n3 ProClarity does not cite any language from the specification that uses the term "self-contained" in connection with the term "driver." However, ProClarity argues:

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n3 ProClarity also suggests that a driver must be "distinguishable from and connected to the application level program." However, ProClarity offers only a cursory argument in support of this limitation in its opening brief and does not explicitly address this limitation in its rebuttal brief.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The patent describes drivers as "function modules 804a through 804d" and clarifies that each driver is a "different module[]." '511 Pat., 12:34, 53-54. A module, in the context of software, is a self-contained unit. Thus, the driver of the patent must be "self-contained."

Def.'s Opening Brief at 20. In response, Timeline argues that this language from the '511 patent simply describes a preferred embodiment in which the drivers are modular. Timeline notes that a characteristic described in a preferred embodiment cannot be read as a claim limitation. See, e.g., Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 2002) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations.") Timeline also points out that the '511 patent specification expressly states:

Although in the above description, the various drivers 804 can be provided as separate DLL [dynamic link library] files and are dynamic in the sense that as many as desired can be added simply by storing additional DLL files in the proper directory, it would also be possible to make an operable version of the invention in which the function performed by the function modules are provided as portions of or subroutines called by the main procedure 802 rather than being separately stored modules.

'511 patent, Col. 19:28-32.

ProClarity also argues that a driver must have the ability to perform "intelligent interrogation" of a data source. ProClarity bases this argument on language from the '511 patent specification, which states:

Preferably, loading of the data definition includes interrogation of the data to obtain information. . . . The interrogation of the data in the "load data definition" step is intelligent interrogation in the sense that it can conform to virtually any data source and identify what is required to store a standard form of the data source, e.g. for reporting and analysis.

'511 patent, Col. 14:23-34. As before, Timeline argues that this language describes a preferred embodiment of the '511 patent and cannot be construed as a claim limitation.

The court agrees that ProClarity's proposed construction would improperly limit the scope of the term "driver" based on preferred embodiments described in the specification. The claims themselves do not include the limitations that a driver must be "self-contained" or must perform "intelligent interrogation."

However, Timeline's proposed construction is also not ideal. Timeline's proposed construction is not only quite broad, but also differs somewhat from a proposed construction that Timeline advanced in prior litigation in this court involving the '511 patent. In the Timeline v. Sagent case, the court observed that "[t]he parties agree that drivers are 'processes performed by computer software having multiple functions for analyzing and processing data.'" See Ex. A to Pl.'s Opening Brief at 3. Here, Timeline proposes that a driver performs functions "such as accessing, processing, and storing data," but does not
include "analyzing" data.

At the same time, it is difficult to construe the term "driver" with great precision, given the variety of functions that a driver may perform. For example, in claim 1 of the '511 patent, the driver is used to "access" information. In claim 2, the driver is used to "store" information. Claim 10 lists multiple other functions that a driver may perform. The specification also indicates that in at least some embodiments, a driver "analyzes" data. As a result, a broad construction of the term may be necessary in order to ensure that the meaning of the term is the same in all claims in which it appears. See Nazomi Comm'ns, Inc. v. Arm Holdings, PLC, 403 F.3d 1364, 1370 (Fed. Cir. 2005) (noting that claim term that appears in more than one claim must be construed the same in each).

Therefore, the court construes the term "driver" to mean "computer software which performs functions." The functions performed by a driver may include accessing, storing, and analyzing data, as well as selecting and searching directories, displaying data, loading general information and data definitions, creating database tables, saving general information and data definitions, and loading data definitions codes, rollup information and data. Therefore, the court construes the term "driver" to mean "computer software which performs functions." The functions performed by a driver may include accessing, storing, and analyzing data, as well as selecting and searching directories, displaying data, loading general information and data definitions, creating database tables, saving general information and data definitions, and loading data definitions codes, rollup information and data.

PolyVision's proposed construction

A software program that receives and processes control signals and, in response, generates a command to a selected application program for updating the screen video display in accordance with the pressure applied to the touch-sensitive display screen.

Smart's proposed construction

A driver structure and/or steps in a computer that receives control signals and, in response to the control signals, generates a command to a selected application program for updating the screen video display in accordance with the pressure applied to the touch-sensitive display screen, and structural equivalents thereof.

This is a means-plus-function limitation, requiring the Court to examine the specification for the structure for performing the specified function. Referring to Fig. 19, the specification states that "a memory resident device driver is loaded." (Col. 11, ll. 50-51.) It further states, referring to Fig. 9 and the installation and testing steps of the custom network structure, that "on entry (700), the software driver for the custom network adaptor or controller (located in computer 5) is loaded (701)." (Col. 7, ll. 25-27.) Essentially, the specification calls for a driver, which, as used in the ordinary sense by one skilled in the art, is a program that controls a device. PolyVision's construction, which identifies the driver means as software, is an accurate definition.

MKS contends that the phrases "driving current in the primary winding" and "driving the primary winding of the transformer with a current" used in independent claims 1, 19, 29, 42, and 44 of the patent in suit means "the power supply producing alternating current that drives current in the primary winding." (D.I. 103 at 6). MKS further contends that "whether there is an electronic component between the power supply and the load is not relevant." (D.I. 103 at 30). Advanced Energy contends that the disputed phrases "do not include driving current through an impedance matching network." (D.I. 110 at 21-23).
With regard to these phrases, the parties' dispute centers on the absence or presence of an impedance matching network. As discussed previously, after reviewing the patent specification and prosecution history, the Court concludes that the invention was not intended to encompass an impedance matching network. (D.I. 94 N.J.L. 480, 111 A9 col. 2 ln. 22-26, A12 col. 7 ln. 49-60, A13 col. 10 ln. 19-21, A121-22, 124, A169-70). Accordingly, the phrases "driving current in the primary winding" and "driving the primary winding of the transformer with a current" mean the power supply producing alternating current that drives current in the primary winding and not through an impedance matching network.

"Dropping Packets When the Detected Congestion Exceeds a Predetermined Severe Congestion Threshold"

Alcatel's proposed construction of this term is "dropping packets after the detected congestion exceeds the predetermined severe congestion threshold." Cisco's proposed construction is "beginning to drop packets for the purpose of reducing congestion only after the detected congestion exceeds the predetermined severe congestion threshold." The difference in the constructions turns on whether the claim allows the packets to be dropped before the detected congestion exceeds the predetermined severe congestion threshold, as Alcatel proposes, or only after the predetermined severe congestion threshold is detected, as Cisco proposes.

Alcatel argues that the specification discloses situations where packets are dropped other than when the severe congestion threshold is exceeded. Specifically, the specifications describe a scenario in which frames are queued in a "holding queue" that has a maximum length. "When that length is exceeded, frames are dropped." Watt, at 4:27-32.

Cisco argues that the plain meaning of the claim language supports its construction. "As we have often stated before, as a general rule, all terms in a patent claim are to be given their plain, ordinary and accustomed meaning to one of ordinary skill in the relevant art." Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001); see also Toro Co. v. White Consol. Indus., Inc., 199 F.3d at 1299 ("[W]ords in patent claims are given their ordinary meaning in the usage of the field of the invention, unless the text of the patent makes clear that a word was used with a special meaning."). In claim 1, the claim language shows that the dropping of packets is the last step in a three-step progression of dealing with increasing congestion in the network. Additionally, the specification describes the dropping of frames as starting after a frame-relay link is severely congested. See Watt, at 6:17-20. However, the specification also contains language describing frames as being dropped when "the addition of the frame would cause the link output queue to exceed the severe congestion threshold . . . " Watt, at 6:26-30 (emphasis added). In this situation, the language indicates that the frame is dropped when its addition would cause the severe congestion threshold to be exceeded. Therefore, in this scenario, the initial dropping of the frame must necessarily take place before the severe congestion threshold has been exceeded.

Thus, although the claim language indicates that packets will be dropped after the detected congestion exceeds a predetermined severe congestion threshold, nowhere in the plain meaning of the language does the claim require packets to begin being dropped only after such a threshold is exceeded. In fact, in looking to the specification, the patent indicates instances where packets are in fact dropped prior to exceeding the threshold. Therefore, the Court construes the term "dropping packets when the detected congestion exceeds a predetermined severe congestion threshold" as "dropping packets after the detected congestion exceeds the predetermined severe congestion threshold."

[Noise] Due to Independent Operation of Said Transistors

The Court adopts ST's proposed construction of "[noise] due to independent operation of said transistors" and construes the term to mean "noise caused by operation of a plurality of on-chip transistors whose operation is not contingent upon operation of the memory array." The Court agrees that the transistors are on-chip and that "independent operation" refers to the relationship between the transistors and memory array. Moreover, the Court rejects Motorola's proposed definition in part because of the term "asynchronous." As discussed supra, the Edwards patent discusses independent operation, and the
LGD contends that the term "dummy conductive patterns" means "portions of the layer that do not receive or convey voltages or signals." D.I. 1388 at P 133. Refining this construction further, LGD contends that this construction requires that the dummy patterns do not conduct or convey signals "at least during testing or operation of the display." D.I. 1387 at 6. In this regard, LGD further contends that dummy patterns are structures that are put into the design of a product to aid in the manufacturing of the product, but do not have a function during the operation of the display. D.I. 1388 at P 136-138. LGD contends that AUO has changed its position on the construction of this term, and that this change in position demonstrates that AUO's currently proposed definition should not be accepted.

AUO contends that the term "dummy conductive patterns" refers to "one or more metal patterns in the specified region that are not in contact with any of the wiring." D.I. 1384 at 24. AUO acknowledges that this construction is different than its previously proposed construction which was "a metal pattern that does not conduct signals or current used in the operation of the display." Id. at 25. However, AUO contends that its previous construction was too restrictive. In this regard, AUO contends that the wiring recited in the claims connects the connection pads to the transistors in the TFT array. AUO contends that dummy patterns are not needed for the operation of the transistors of the TFT array, and therefore, they "are not in contact with any of the wiring" that is "in communication with at least one of the transistors in the TFT array." Id., citing '629 patent, col. 8, ll. 14-19. However, AUO maintains that there is nothing in the intrinsic evidence that precludes the dummy conductive patterns from performing some function, such as conducting a voltage or signal used in the operation of a display, so long as they are not in contact with the TFT wiring. AUO points out that even under its prior construction, nothing required dummy conductive patterns to be unable to receive any voltages or signals, and that the dummy conductive patterns could still be connected to a ground or voltage supply. D.I. 1384 at 24-26.

As the Federal Circuit has recognized, the Court's task in claim construction is not to decide which of the adversaries is correct, but to independently determine the meaning of disputed claims. Exxon Chem. Patents, Inc. v. Lubrizol Corp., 64 F.3d 1553, 1556 (Fed. Cir. 1995). For this reason, the Court does not take AUO's change in its claim construction position to be indicative of the merits of its current argument.

Reviewing the disputed term in light of the claim language and specification, the Court concludes that the term "dummy conductive patterns" is properly construed to mean "conductive patterns in the specified region that are not in contact with any of the wiring." The claim terms expressly state that the dummy conductive patterns must comprise "at least about 30% of the area" and "are not in contact with any of the wiring." '629 patent, col. 8, ll. 13-19, 57-63. The Court does not read the claims or the specification from precluding the dummy conductive patterns from performing some function, so long as that they are not in contact with the TFT wiring. Accordingly, the Court concludes that LGD's claim construction and AUO's prior claim construction were both too restrictive, and that "dummy conductive patterns" are "conductive patterns in the specified region that are not in contact with any of the wiring."

The parties agree that this term should be construed consistently with the prior term. (D.E. 68, pg. 23). For the reasons
detailed in the "determining the total delivery time" section, the Court does not construe this claim.

**1464**

D. "during iterative processing"

As to this term, this Court ordered the following claim construction:

The claimed steps can be repeatedly performed by the automated negotiations engine while performing multiple rounds of bargaining involving an offer and multiple counteroffers between two participants where each round is related to prior rounds.

Tr. 26:24-27:8.

**1465**

E. "During Variation of the Number of Channels in the WDM Optical Signal"

For the following reasons, the court construes the term "during variation of the number of channels in the WDM optical signal" in claims 2, 7, 10, and 15 to mean:

While the number of channels in the WDM optical signal changes.

Fujitsu first presented this term for construction as, "during the process of changing the number of optical channels in the WDM optical signal." (Dkt. No. 90, Ex. B at 1.) Fujitsu then proposed the following clarifying construction: "During the process of changing the number of optical channels in the WDM optical signal (including before the variation in the number of channels is complete)." (Dkt. No. 92, Ex. B at 1.) Tellabs construed the term in its rebuttal as, "while the number of channels changes." (Dkt. No. 91, Ex. A.)

A review of the specification reveals that each channel is associated with a different wavelength and that the number of channels can change. ('681 patent, col. 2:10-13.) Several problems, however, arise when the number of channels is changed. The specification refers to the time when the number of channels changes as, "during the variation (that is, before the variation in the number of channels is complete)." (681 patent, col. 2:13-17.) Thus, during variation, which includes the time before the variation in the number of channels is complete, simply means, "while the number of channels in the WDM optical signal changes."

**1466**

3. multi-pulse portion having a given duty ratio z = t2/(t2+t3)(claim 1)

Plaintiff's construction: "a multi-pulse portion has a given ratio, z, where z is the result of dividing (i) the pulse width at high power (t2), by (ii) the sum of the pulse width at high power (t2) plus the pulse width at low power (t3)"

Defendants' construction: the entire multi-pulse portion having a given ratio of pulse duration to pulse period equal to z = t2/(t2+t3)

Plaintiff's proposed construction is a primarily a translation of the equation into word form. Defendants' version is substantially different from plaintiff's, but the only part of their own proposed construction for which they advance an argument is the word "entire." Defendants say that, whatever the multi-pulse portion is, the entire portion must have the same "duty ratio." It is not clear whether plaintiff disputes defendants' position because plaintiff combined its argument for this term with its argument for "multi-pulse portion," which also involved the word "entire" but in a different context. To the
extent that plaintiff intended to object to inclusion of the word "entire" in the construction of this term, I agree with
defendants that the word should be included.

The claim itself does not specify whether the "entire" multi-pulse portion has a given ratio or whether only a part of it does,
but in context it is clear the claim implies that all of the multi-pulse portion has the same ratio. When one says that
something has a particular property, the natural inference is that all of it has that property unless it is otherwise specified.
For example, if someone says that "the ball is red," this would suggest that all of the ball was red, rather than half red and
half another color. Or if one made a statement that "the ratio of women to men in the class was three to one," this would
mean that if one counted all of the women and all of the men in the class, there would be three times as many women. If a
particular subset of men and women were intended, this would be specified ("the ratio of women in the class with blonde
hair to men with blonde hair was three to one"). Similarly, one would expect that the inventor would have specified that
only a part of the multi-pulse portion had the given ratio if that is what the inventor intended. The claim says that "the"
multi-pulse portion has the ratio, not a part of it.

However, I cannot adopt the rest of defendants' proposed construction. The phrases "pulse period" and "pulse duration" are
not included in the claim or anywhere else in the patent and defendants do not otherwise explain why those terms should be
introduced. Accordingly, I will adopt plaintiff's construction, with the exception that I will add the word "entire."

Court's construction: "the entire multi-pulse portion has a given ratio, z, where z is the result of dividing (i) the pulse width
at high power (t2), by (ii) the sum of the pulse width at high power (t2) plus the pulse width at low power (t3)"

F. Dynamically

Leader's Construction  Facebook's Construction
plain and ordinary meaning  Automatically and in response
to the preceding event

The term "dynamically" appears in Claims 1, 9, 17, 21-23, and the dependent claims thereof. Leader contends that the term
"dynamically" requires no construction because it is commonly used in the computer science field, and one of ordinary skill
in the art understands its meaning. (D.I. 179, at 25.) Leader agrees that the ordinary meaning of "dynamically" can be
"automatically," but contends that the rest of Facebook's proposed construction reads limitations into the term which are not
supported by the intrinsic record. (Id.) Facebook contends that the term "dynamically" cannot be understood without
reference to how the automatic action is triggered. (D.I. 191, at 20.) According to Facebook, the intrinsic record supports its
proposed construction because "[n]owhere in the claims or specification does the '761 patent identify an action taking place
'dynamically' without such action being in response to the preceding action by the user." (Id.) Further, Facebook contends
that the file history, which shows that occurrences of the term "automatically" in each independent claim were replaced with
the term "dynamically," confirms that "dynamically" means more than just "automatically." (Id. at 21-22.) Because the
parties agree that "dynamically" means "automatically," the only issue to be decided by the Court is whether the term
"dynamically" contains Facebook's proposed limitation of "in response to the preceding event."

When read in the context of the entire '761 patent, including the specification, the Court concludes that the term
"dynamically" means "automatically and in response to the preceding event."
Admittedly, neither the phrase "in response to
the preceding event" nor the terms comprising that phrase explicitly appear in the Claims or the specification. However, in
each of the Claims, the actions identified as taking place "dynamically" only occur after some identified action by the user.
The specification provides further support for this limitation. "As a user creates a context, or moves from one context to at
least one other context, the data created and applications used previously by the user automatically follows the user to the
next context. The change in user context is captured dynamically." '761 patent, col. 3:1-5. Thus, a change in context is
captured "automatically," but it is only automatic upon the user creating a context or moving from one context to another.
Accordingly, the Court concludes that "dynamically" means "automatically and in response to the preceding event."
Dynamic Display/Dynamically Displaying

The parties dispute the meaning of the term "dynamic" in the claim language "dynamic display" and "dynamically displaying." The defendants argue that "dynamic" requires movement, up or down the price axis, for example. Plaintiff contends that "dynamic" is captured by the updating of the bid and ask quantities as new information is received from the market. Based on our understanding of the record, we construe "dynamic display" to be "[a] display of a plurality of bids and asks that are updated in response to new market information such that the bids and asks change positions relative to the static display of prices when the market changes." Updates based on the changing market data cause the displayed quantities of bids and asks to appear to move along the static price axis. Similarly, we construe "dynamically displaying" as "[u]pdating the first (second) indicator in response to new market information such that the first (second) indicator changes positions relative to the common static price axis when the market changes."

Defendants argue that plaintiff disclaimed use of the term "update" during the prosecution of the patents. During that time, patentee's counsel distinguished patentee's invention from the Silverman et al prior art:

The present invention, as claimed, is patentable over the Silverman et al references. As described above, the present invention includes a dynamic display for a plurality of bids and for a plurality of asks in the market for a given commodity and a static display of prices corresponding to the plurality of bids and asks for the commodity...While it appears that both the central system book and the keystation book of the Silverman et al references show a plurality of bids and asks for a given traded commodity, in contrast to the present invention, the references disclose that these pluralities are displayed "dynamically" only in the sense that the bids and offers are updated....There is no disclosure that the listing of bids and asks actually move along any axis.

(Petition to Make Special, eSpeed claim construction, exh. F, eS64848-9). Based on this language, defendants argue that plaintiff cannot now reclaim in construction something patentee disclaimed during prosecution. They are correct in theory. See SanDisk Corp. v Memorex Products, Inc., 415 F.3d 1278, 1286 (Fed.Cir. 2005) ("The court must always consult the prosecution history, when offered in evidence, to determine if the inventor surrendered disputed claim coverage"). We do not think, however, that the patentee disclaimed the use of "update" in this case. The Petition to Make Special continues:

Furthermore, unlike the present invention, neither the central system book nor the keystation hook of the Silverman et al references includes a static display of prices corresponding to a plurality of bids and asks for a traded commodity. There being no static display of prices, the references also do not disclose that the pluralities of bids and asks are dynamically displayed in alignment with the prices corresponding thereto.

(eSpeed claim construction, exh. F, at eS64849). Unlike plaintiff's invention, the Silverman prior art did not combine the static display of prices with the dynamic display of bids and asks. Therefore, it only updated the prices. The present invention, by contrast, not only updates the prices, but because the bid and ask values are shown relative to the static price axis, the user can visually track the movement of the market by the movement of the bids and asks along the price axis. That visual shift, in addition to the updating, is what makes the plaintiff's invention distinguishable from the Silverman et al references.

Once we allow use of the term "updating" in construction of the claims, we address defendants' additional arguments. Defendants point to such language as "[t]he values in the Bid and Ask columns however, are dynamic; that is, they move up and down (in the vertical example) to reflect the market depth for the given commodity" (amend, and reply, eSpeed claim construction, exh. E, eS64873). They argue that such language proves that the term "dynamic" must indicate movement specifically. We decline to adopt such language in the construction. Like the specification language, "The 'Mercury' display and trading method of the present invention ensure fast and accurate execution of trade by displaying market depth on a vertical or horizontal plane, which fluctuates logically up or down, left or right across the place as the market price fluctuates," the prosecution history focuses "movement" on the market depth. Such a focus allows that the term "dynamic" alone can refer to updates received from the market, and the movement occurs simply because changed bid or ask values correspond to different prices in the static price display. Therefore, we construe "dynamic display" as "[a] display of a plurality of bids and asks that are updated in response to new market information such that the bids and asks change
positions relative to the static display of prices when the market changes." We construe "dynamically displaying" as "[u]pdating the first (second) indicator in response to new market information such that the first (second) indicator changes positions relative to the common static price axis when the market changes." We construe "indicator" in its plain and ordinary meaning as "something that indicates."

4. Capable of dynamic partitioning

All of the asserted claims of the media processor patents recite the phrase "dynamic partitioning" or a similar limitation. The plaintiff urges that "capable of dynamic partitioning" means "able to divide the data into separate and distinct operands on an instruction by instruction basis." The defendants contend that the disputed phrase means "capable of dividing width-wise into a variable number of elements for simultaneous parallel processing of any combination or permutation of media data types in any size."

The parties' briefs and their hearing presentation focused on whether the court could (or should) consider an Appendix filed with the PTO in connection with this term. The court has concluded that resort to the Appendix is unnecessary, and that the specification is sufficiently illuminating to permit construction of this term. The specification of the 840 patent shows a Table I. Table I is an illustration of an instruction set for the media processor. That table illustrates data can be partitioned into byte-sized portions. Table I does not show partitioning of data on any basis other than a byte, or 8-bit level, nor does it show an instruction set capable of operating on data divided into different partition widths in the data path for any given 32-bits of data. Although Table I does not necessarily exclude a processor with the capability to partition data to the extent required by the defendants' proposed construction, Table I is more consistent with the plaintiff's proposed definition, as it illustrates precisely the type of dynamic partitioning that the plaintiff's construction permits. After considering the submissions of counsel and the intrinsic record, the court construes "capable of dynamic partitioning" to mean "capable of dividing width-wise into a variable number of elements."

10. Dynamically adding information

Claim 37 of the '755 patent recites:

A plurality of logical resource drivers, each said logical resource driver being operative on at least one said programs for dynamically adding information during program execution to instructions of said one program, said information identifying at least the user context file for said one program . . . .

The next dispute is whether the "dynamically adding information" language requires the addition of specific types of information, beyond that set forth in the claim. Biax contends that this term requires no additional instruction. The defendants contend that "dynamically adding information" means "dynamically adding to each instruction during program execution information composed of (1) the context/LRD identifier that is issuing the instruction, (2) the current procedural level of the instruction, and (3) the process identifier of the current instruction stream."

To support their construction, the defendants point to the description of the preferred embodiment found in columns 34-35 of the patent. The claim language, however, is not limited to the preferred embodiment and in fact states that the information need only identify "the user context file for said one program." As a result, the court rejects the defendants' attempt to further limit this term.

9. *dynamically modifiable library of code* (claim 20)
Flow argues that this phrase should be construed as a "potentially changeable code in a collection of code." Omax argues that this phrase appears "to indicate a group of source code that is modifiable on the fly in real time by the user." The Court construes the term "dynamically" consistent with its prior definition of the term, and therefore adopts Flow's proposed construction.

7. Dynamically partition data received from the data path to account for an elemental width of the data wherein the elemental width of the data is equal to or narrower than the data path

The court construes "dynamically partition data received from the data path to account for an elemental width of the data wherein the elemental width of the data is equal to or narrower than the data path" to mean "dividing width-wise into a variable number of elements no wider than the data path, based upon the size of the data elements received from the data path."

8. Dynamically partitionable arithmetic unit

The court construes "dynamically partitionable arithmetic unit" to mean "the arithmetic unit can be divided into a variable number of elements."

3. Dynamically receiving data

Claim 9 describes "[a] navigation aid method for performing a detour route calculation, comprising . . . ." The first subpart of claim 9 reads: "dynamically receiving data relating to a portion of a particular thoroughfare in a route." The parties agree that "dynamically receiving" means "receiving in real time." The dispute is whether to insert the term "user-selected" prior to "portion," as plaintiff advocates. According to plaintiff, the only possible type of "dynamically received data" is "data input by a user of the device." Plt's Br., dkt. # 56 at 26. Plaintiff is wrong. Plaintiff bases its argument on a portion of the specification which states:

By way of example and not by way of limitation, the additionally received dynamic data can include dynamic data input by a user of the device indicating that the user is not satisfied with the new route . . . .

"615 pat., col. 9, Ins. 40-43. This does not suggest that the only way the device can receive data is via user input. It would be inappropriate to insert this proposed limitation into the claim, particularly when it does not appear explicitly in the specification. As defendant points out, dkt. # 54, at 91, the specification makes it clear that the navigational device may communicate with remote servers via various communications channels ("615 pat., col. 7, Ins. 1-32). I construe "dynamically receiving data relating to a portion of a particular thoroughfare in a route" to mean "receiving in real time data relating to a portion of a particular thoroughfare in a route."

10. Each said thoroughfare . . . intersects

Claim 6 reads:
The navigation device as set forth in claim 5, wherein each said thoroughfare in said first set of thoroughfares intersects said thoroughfare upon which said vehicle is being navigated, and wherein said selected one of said sets is said first set.

The disputed phrase is underlined. Plaintiff contends that the only construction necessary is for "thoroughfare." Defendant's proposed construction ("every road, waterway, and channel in the first set crosses the road, waterway or channel on which the car is traveling") amounts to unnecessary and unsubstantial rewording of the claim language. In particular, defendant seeks to replace the word "each" with "every." The claim language is clear as written. Aside from construing "thoroughfare," I leave the claim language undisturbed.

GO BACK

4. "Each channel having a separate control circuit that is adapted to control the operation of its associated transceiver to complete radio frequency communication paths to mobile units as instructed by the telephone switch." Each channel is operated via a separate control circuit consistent with the instructions downloaded from the central control station. (554 patent, col. 5, lns. 3-13; col. 14, lns. 61-68; col. 31, lns. 1-5; col. 32, lns. 16-42)

GO BACK

2. "time slot assigned to each of said application programs"

Claim 1 also requires that the remote units receive messages from the master unit and respond in a "time slot assigned to each of said application programs." The parties' dispute concerns whether the "assignment" function must occur at initialization of the application program (the defendants' construction) or whether it may occur at any time. The plaintiff argues that the defendants' construction is inconsistent with the disclosure because the remote units can request additional time slots during data transmission, which is after initialization. See '819 patent, 2:18-26, 3:7-11. The defendants argue that the specification repeatedly discloses time slots assigned to applications at initialization. See '819 patent, 2:46-49, 5:42-43, Fig. 6, Fig. 7.

Although the specification refers to the assignment of time slots during initialization, there is nothing in the patent that requires the claims to be limited in this manner. The court construes "time slot" to mean "an interval of time during which data from an application program is transmitted." All other terms have their plain and ordinary meaning.

3. "dividing a period of a clock in said master unit into a number of subframes, dividing each subframes into a number of slots, each corresponding to transmission times for one of said remote units, and assigning a slot to each of said application programs"

This phrase appears in claim 14 of the '819 patent. The defendants contend that the phrase needs clarification because it is not clear what "each" refers to. They also urge that the file history indicates a disclaimer that messages sent from the master unit to the remote units are not packetized. The court has reviewed the cited portions of the prosecution history and is not persuaded that the patentee limited the claim to outbound non-packetized messages from the master unit. The court therefore construes "each corresponding to transmission times" to mean "each subframe corresponding to transmission times." All other terms have their plain and ordinary meaning.

GO BACK

Matters are trickier when considering the pre-Springwood products, because there is no evidence contradicting TM's conclusion that IBM's and TM's switches operate identically to the extent that a particular message's designated output circuit is free. TM is of course correct that there is a doctrine known as part-time infringement, and that if a claim reads on a part of an accused device, the device infringes. See Suntiger, Inc. v. Scientific Research Funding Group, Inc. 189 F.3d 1327, 1336 (Fed. Cir. 1999), citing Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 623
IBM does not deny the existence of the part-time infringement doctrine (which was recognized in this Circuit nearly a century ago, see Wright Co. v. Herring-Curtiss Co., 211 F. 654, 655 (2d Cir. 1914)). Nor does it deny that its pre-Springwood products infringe TM's patent if one focuses solely on the operation of the crossbar in non-contention situations. Instead, IBM argues that part-time infringement is precluded in the case of the '773 patent by the very terms of the claim limitation language.

IBM's argument derives from Claim 1's use of the phrase "for each message." As noted above, the claim language does require that the switch perform the decoding, establishing and maintaining functions for each message that arrives at an input circuit. IBM contends that this claim language requires that one look at how the product functions in connection with each and every message that passes through the system (i.e., in both contention and non-contention situations), so that if its products do not literally infringe all of the time (i.e., in connection with the routing of each message), they do not infringe at all. Since IBM argues that there is no evidence from which a reasonable juror could conclude that messages which are diverted to the central queue literally infringe Claim 1 -- a proposition with which I have already indicated agreement -- IBM concludes that its product does not infringe Claim 1 of the '773 patent. In IBM's view, only a device that infringes with respect to each message can infringe the '773 patent.

These arguments point to a gaping hole in the Court's Markman decision. At the Markman hearing, the parties did not focus on the meaning of the word "each" in the phrase "for each message," and the Court did not discuss that term in its opinion (having no idea that it was disputed). Indeed, the parties appeared to agree that "all of the recited functions of the 'switch' claim must be performed on each and every message, without exception." (IBM 10/4/00 Letter at Ex. 5, citing, inter alia, Pl's Reply Mem. at 39, n.34.) However, it has become clear to me as I worked my way through the papers submitted on the instant motion that the parties do dispute, quite vigorously, what is meant by the term "each" in the phrase "for each message."

IBM contends that the word must be read literally; that is, that the switch, having decoded the address element of each and every message, must designate its path to the output circuit ("establish" the path) and maintain the same. Under such a reading, as far as I can discern, the only embodiment that would fall under the claim language is one in which a message where a direct path to the output circuit is in use would nonetheless have a path established by the switch, would then be buffered, and once released from the buffer would proceed to the path set for it by the switch before it was buffered.

TM argues that IBM's reading of the term "each" is overly restrictive. It contends that the invention claimed in Claim 1 will work only in the non-contention situation, when in fact each message can be routed directly to its designated output along a maintained path, and that one must proceed to Claim 2 in order to address the message contention situation. Indeed, TM notes that even the preferred embodiment shows a system in which the switch (1) established a path to the designated output when there is no contention for that output circuit, but (2) established a path to the buffer (the structure added in dependent Claim 2) in contention situations. TM's affidavits reveal that, when the designated output circuit is free, the message does not necessarily proceed out of the buffer and to the output along a path that was set by the switch prior to the message's arrival at the buffer. (See, e.g., Kuszmaul Aff. P 5.)

This newly-crystallized dispute adds a wrinkle to the situation. However, I must side with IBM on this issue, because it is not possible to read the word "each" in a way that supports TM's claim of part-time infringement. Doing so would violate the first maxim of the Markman decision.

The first principle undergirding the Markman hearing was set forth as follows:

"In construing the patent . . . I have adopted the principle that, where the language of the claim is clear and unambiguous, I will read nothing additional into it."

TM Patents, LLP v. IBM Corp., 72 F. Supp. 2d at 380. There is nothing unclear of ambiguous about the words "for each message." Each is not synonymous with "every." Thus, had I been aware at the Markman phase that the parties disputed the meaning of the word "each," I would have given it a literal interpretation -- notwithstanding the fact that the preferred
embodiment apparently does not establish and maintain a path to the output circuit for each message in a contention situation. The Markman decision is deemed amended accordingly.

Reading "each" as "some" would also allow TM to recapture certain elements that it disclaimed in order to obtain allowance of the '773 patent. In claim element iii of Claim 1 of the '773 patent, TM originally used the following language:

(iii) a switch connected to said input circuits for decoding at least one address element of each message received by said input circuits to identify therefor an output circuit, said switch establishing a path from at least some of said input circuits to the output circuits identified for the messages received thereby to facilitate the transfer of message elements there between. . . .

As allowed, the relevant claim language reads as follows:

(iii) a switch connected to said input circuits for, for each message received by said input circuits, decoding one address element of the message to identify therefor an output circuit, said switch establishing a path for said message between the input circuit which received the message and the identified output circuit to facilitate the transfer of message elements of said message there between. . . . 20

--- Footnotes ---

20 I here highlight the language that is relevant to my analysis of the parties' arguments. I note that, at the Markman hearing, the parties focused on the meaning of the word "one," used elsewhere in this limitation. That issue is discussed extensively in the Markman opinion and is also the subject of a supplemental order, dated December 17, 1999 (which supplemental order ought to be appended to the published Markman decision -- an omission the Court will rectify). That language is omitted from this discussion, because it has nothing to do with the dispute here identified.

--- End Footnotes ---

TM added the words that limited claim (iii) to "each message received by said input circuits" after the patent had been rejected by the Examiner on the basis of prior art -- specifically, the Lawrence patent. This rejection is discussed in some detail in the Markman opinion. See TM Patents, L.P. v. IBM Corp., 77 F. Supp. 2d 480 (S.D.N.Y. 1999) (unpublished) ("Supplemental Markman Ruling").

In making this and other changes to the claim in order to avoid rejection, TM made the following representation to the Examiner:

One benefit of the invention recited in claim 35 [now claim 1] is that a router node can, when it receives enough of a message to determine an output circuit over which it will transmit the message, will establish a path from the input circuit to the output circuit, which it will maintain until the entire message has been transmitted. . . .

It should be noted that this explanation does not focus on the use of the phrase "for each message." But, fairly read, it supports the Court's prior finding that paths must be established all the way from input circuit to output circuit as soon as the router node receives enough of a message to decode its address. The claim does use the language "for each message," and there is no indication in either the claim or in the prosecution history that this benefit of the invention applies only to some of the messages that are passing through the system.

The Examiner, as noted in the Markman decision, distinguished Lawrence when it finally issued the patent. However, he did not do so on the basis of the addition of the "for each message" language. He did so because Lawrence taught a "store and forward" system of message routing, rather than a wormhole routing system. See Supplemental Markman Ruling at 3. While he sets forth the very language from TM's "persuasive" response to his prior rejection that I have quoted above, he says nothing explicit about the need for this system to apply to "each" message. Thus, nothing in the language on which I relied in the Markman decision would support a finding that the "for each message" language was inserted to overcome Lawrence.

However, Lawrence is not the only prior art of relevance. IBM points the Court to additional prior art that was neither
focused on at the Markman hearing nor specifically mentioned by the Examiner. Specifically, it calls my attention to an article by Lermani and Kleinrock, "Virtual Cut-Through: A New Computer Communication Technique," (IBM 11/13/00 at Ex. 5), which TM cited to the Patent Office in a September 24, 1992 Information Disclosure Statement. Having reviewed Kermani and Kleinrock, I conclude that it disclosed a system in which a path is established for at least some messages. (See id. at "Abstract" and p. 268). Just two months after receiving this prior art citation from TM, the Examiner stated, "The art of record fails to teach or remotely suggest the claims in their verbatim as they states and/or as argued by the applicant in his response. . . ." (emphasis added) "In their verbatim," the claims apply to each message, not just to some messages. In view of the fact that the art of record includes a system that establishes a path for some messages, I see no way around the conclusion that TM's invention is limited to a system that establishes a path "for each message," and that the insertion of that precise language was done to overcome the impact of prior art. It has long been settled that a patentee cannot recapture subject matter that was surrendered during prosecution of the patent, and that post-hoc, litigation inspired argument cannot be used to reclaim subject matter that the record in the PTO clearly shows has been abandoned. See Desper Prods., Inc., v. QSound Labs, Inc., 157 F.3d 1325, 1340 (Fed. Cir. 1998).

In its briefs and at the hearing, TM revealed that the switch in the preferred embodiment does not establish a path between the input and output circuits when there is message contention, but only establishes a path from the input circuit to the buffer. But this does not resurrect its abandoned claim; it merely indicates that the preferred embodiment set forth in the patent file teaches both Claims 1 and 2, and does not show a system that embodies only Claim 1. To the extent that the Court made any statement in its Markman opinion which suggested it was adopting the logical fallacy TM propounds here, 21 I can only apologize and correct my error here.

21 TM points to the following Markman opinion sentence, "If that identified circuit is busy, then the head of the message must proceed to a message buffer, which will be discussed later," to support its claim that the Court, either explicitly or sub silentio, recognized that the word "each" meant "some." If my language left this impression, I apologize. As noted above, this aspect of the claim language was not the subject of argument by the parties and was not thought about, let alone addressed, by this Court. Frankly, I was too busy trying to make sense of what the parties were arguing to hypothesize about what they might have argued.

Therefore, I must reject TM's "part-time infringement" argument. IBM is correct that no reasonable trier of fact, in view of the claimed requirement that the switch establish and maintain a path all the way to the output circuit for each message, rather than for some messages, could define the "switch" as the crossbar, or could look to the operation of IBM's message routing products in non-competition situations alone. The logic used in the pre-Springwood chips when there is message contention and the central queue is used is identical to that used in the post-Springwood chips -- that is, messages are transmitted in chunks; paths consisting of wires and logic are established and maintained only as long as a particular chunk is in transit, and certainly are not maintained until the "last of the serially-received message elements for the message have been transferred to the identified output circuit." Therefore, because the part-time infringement doctrine cannot be applied in this unique case, there is no literal infringement of the patent by IBM's products. 22

22 In addition to patent estoppel, IBM argues that TM is trying to stand the concept of independent and dependent claim on its head, by positing a situation in which the dependent claim was broader, not narrower, than its associated independent claim. It argues that, because the dependent claim covers both contention and non-contention situations, while the independent claim covers only non-contention situations, the dependent claim is broader than the independent claim.

Of course, it is well settled that a dependent patent claim must be narrower than its associated independent claim, see 35 U.S.C. § 112, P 4, and must incorporate by reference all of the limitations of the independent claim from which it refers. See Slater Elec., Inc., v. Thyssen-Bornemisza Inc., 650 F. Supp. 444, 464 (S.D.N.Y. 1986). However, IBM's superficially appealing argument is logically fallacious. A dependent claim may well be "narrower" (i.e., more restrictive) than its associated independent claim while nonetheless expanding on the type of situation in which the patent would be infringed. For example, suppose a patent has the following two claims:
1. An automobile having an engine, four wheels and a drive train for transmitting driving power to at least one opposed pair of said wheels.

2. An automobile as described in Claim 1 in which said drive train includes both forward and reverse gears and means for shifting between said gears to cause the driven wheels to be driven in either the forward or reverse direction as desired.

Obviously Claim 2 is narrower than Claim 1. Yet Claim 1 will be infringed by an automobile which can be driven only in the forward direction, while Claim 2 is infringed (only) by an automobile which can be driven in either direction.

Thus a narrower (dependent) claim may, and frequently does, cover a device capable of more types of operation (handling more "situations") than a device that would be covered by a broader (independent) claim.

--- End Footnotes ---

I emphasize that it is only because I reached my conclusion about the meaning of the phrase "for each message" and the reason for its use in the patent that I find no literal infringement by the pre-Springwood products. If I am wrong about the inapplicability of part-time infringement in this case, then I would have reached the opposite result, because no reasonable juror could possibly conclude that the patent was not literally infringed in non-contention cases. Indeed, I search IBM's voluminous papers in vain for a single suggestion that this is not the case.

GO BACK

1479

ii. Claim Construction of "by at least 5 \( \mu \) m"

Of the two Kurachi patents, only the ’694 patent recites the limitation "wherein each of said impurity diffusion layers of said buffer MOSFETs is separated from one of said impurity diffusion layers of said protection MOSFETs by at least 5 \( \mu \) m."

’694 patent at claim 1.

The "by at least 5 \( \mu \) m" limitation is a "wherein" clause that further defines the scope of the claim with respect to "said impurity diffusion layers" of both the buffer MOSFETs and the protection MOSFETs. Therefore, the interpretation of the clause must be made in view of the previous limitations already introduced for all the elements involved. See Lindemann Maschinenfabrik GmbH v. American Hoist and Derrick Co., 730 F.2d 1452, 1459 (Fed. Cir. 1984) (holding that claims are not to be treated as "mere catalogs of separate parts, in disregard of the part-to-part relationships set forth in the claims and that give the claims their meaning").

In its Supplemental Reply, AMD sets forth two arguments in support of its claim interpretation. The first is that the key word in this limitation is "one," which means "one' rather than 'all' or 'every.'" Suppl. Reply Br. at 31. AMD contends that this limitation simply requires that each buffer MOSFET impurity diffusion layer be separated by the recited distance from any one of the impurity diffusion layers of the protection MOSFETs; therefore the 5 \( \mu \) m limitation can be satisfied by any random pair of buffer and protection MOSFETs on the chip. So long as one pair of impurity diffusion layers are sufficiently separated, any other pair need not meet this limitation, that is, other pairs may be more closely spaced, including there being no separation.

AMD also contends that the "open" format of the independent claim (the claim elements are introduced using the word "comprising") permits the addition of extra elements. According to this alternative construction, impurity diffusion layers that lie within 5 \( \mu \) m of another are such "extra elements." Instead of bringing the device outside the claim scope, devices with impurity diffusion layers of protection and buffer MOSFETs within 5 \( \mu \) m of one another fall within the scope of the claim by virtue of the open claim language, provided at least one buffer MOSFET is separated by at least 5 \( \mu \) m from one protection MOSFET.

In contrast, Oki contends that "each buffer MOSFET impurity diffusion layer must be separated from any one of the diffusion layers in each of the protection MOSFETs" by the recited distance. Suppl. Opp. Br. at 20-21. More simply, the minimum separation between each buffer MOSFET impurity diffusion layer and any protection MOSFET impurity

- 1887 -
diffusion layer must be at least 5 [μ m].

The plain meaning of the claim adheres to neither of these proposed constructions. First, as noted above, the interpretation of this limitation must be consistent with the other limitations of the claim. AMD's construction would negate the "interposed field oxide film" limitation because it would allow for no separation between the impurity diffusion layers at issue. Oki's interpretation, that a 5 [μ m] separation is required as a minimum separation between all relevant diffusion layers, does not negate the earlier limitation, but the plain meaning of the limitation is not so restrictive.

The plain meaning of the claim does not preclude a smaller separation distance from a second impurity diffusion layer. "One" means one. The claim does not read, for example, that "each of said impurity diffusion layers of said buffer MOSFETs is separated from the nearest one of said impurity diffusion layers," which implies a claim scope closer to that advanced by Oki. The claim calls for no more than that one of said impurity diffusion layers of the protection MOSFETs is separated, by the requisite distance, from each of the impurity diffusion layers of those buffer MOSFETs.

The specification of the '694 patent is not inconsistent with the plain meaning inferred from the claim language. As stated earlier, one of the thrusts of the invention is the separation of the impurity diffusion layers from one another. This general idea is manifested in the "field oxide film" limitation. The more specific limitation regarding the separation distance ("interval") between impurity diffusion layers is only addressed in a short passage in the specification. See '694 patent at 6:55-67. Referring to Fig. 3, the specification teaches that, with respect to the distances between the diffusion layers of two different buffer MOSFETs and the diffusion layers of a protection MOSFET, "each of the intervals t1 and t2 may preferably be set to at least 5 [μ m]." Id. at 6:60-61. This passage teaches that the individual intervals may differ from one another. The specification continues by stating that each interval may be "set as short as possible," demonstrating that shorter distances were contemplated by the patentee. Id. at 6:65.

The prosecution history suggests that the patentee intended to claim the more restrictive interpretation, but it does not establish that such a restrictive interpretation was actually claimed as the invention. The claim originally recited "wherein said impurity diffusion layers of said buffer MOSFETs are separated from said impurity diffusion layers of said protection MOSFETs by at least 5 [μ m]." Prelim. Amd., June 24, 1996., at 10. Upon rejection in the first office action under section 112, P 2 for indefiniteness, the patentee amended the claim by inserting "all of" before each instance of "impurity diffusion layers." Response to Office Action, May 15, 1998, at 4. The claim was allowed, but an Examiner's Amendment, consented to by the patentee, changed the language to its issued form, that is, to using the phrase "separated from one" rather than "separated from all of."

The record does not reveal whether the Examiner's amendment was entered as a condition for allowance or to clarify an ambiguity. In any event, the patentee had the opportunity to first comment on the Examiner's amendment, and then to correct the language via either a certificate of correction or through a reissue proceeding if it was not satisfied with the claim. The patentee did not pursue these options.

Claim construction cannot turn on the subjective intent of a patentee. Markman v. Westview Instruments, Inc., 52 F.3d 967, 985 (Fed. Cir. 1995) (en banc), aff'd, 517 U.S. 370, 372, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The court "must construe the claims based on the patentee's version of the claim as he himself drafted it." Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1356-57 (Fed. Cir. 1999). The Court is not now to "interpret the claim differently just to cure a drafting error." Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 951 (Fed. Cir. 1993). To revive the meaning of the claim prior to the amendment would be to interfere with the function of claims, which is to put competitors on notice of what the inventor considers to be their invention. Id.

The Court thus concludes that the limitation "wherein each of said impurity diffusion layers of said buffer MOSFETs is separated from one of said impurity diffusion layers of said protection MOSFETs by at least 5 [μ m] m" requires that one of said separation distances be at least 5 [μ m], but that in no case should a field oxide film not be interposed between the impurity diffusion layers of buffer MOSFETs and protection MOSFETs, as required by the "interposed field oxide film" limitation.
A. "Each of Said Plurality of Computers"

The parties agree that the word "plural" means two or more. They disagree, however, as to what is meant by the word "each," when used to modify the phrase "of said plurality of computers." As noted above, the '377 patent describes a "computer system having a shared addressable memory space, comprising . . . a plurality of computers, each of said plurality of computers sharing the shared addressable memory space." '377 patent, 15:58-63 (emphasis supplied).

Oracle asserts that the quoted language requires all of the computers participating in the shared memory system to share the shared addressable memory space. Oracle's position rests upon its interpretation of the words which describe a "plurality of computers" participating in a shared memory system, and require that "each of said plurality" share the shared addressable memory space. In other words, according to Oracle, if the "plurality" of computers participating in the system is five, then all five of those computers (i.e., each computer making up said plurality) must share the shared addressable memory space.

Mangosoft, on the other hand, says the phrase "each of said plurality" requires only that two or more of the computers in the overall system actually share the shared addressable space. That is, Mangosoft asserts that the phrase "each of said plurality" does not modify the "plurality of computers" that form the system, but instead refers to a smaller subset of computers (i.e., a new plurality). So, according to Mangosoft, if the plurality of computers participating in the shared memory system is five, only two of those computers need actually share the shared addressable memory space. The court disagrees.

Mangosoft's interpretation of the disputed claim language is not supported by the precedent upon which it relies, nor is it consistent with customary uses of the words "each" and "said." Had Mangosoft intended the interpretation it advances here, it likely would have used language such as "comprising . . . a plurality of computers, some of which share the shared addressable memory space." Alternatively, it might have said "a plurality of which" or "two or more of which" or "a subset of which" share the memory space. It did not. Instead, the '377 patent uses very specific language, which must be given meaning. Mangosoft's interpretation of the disputed language does not give meaning to the words "said" or "each" and, instead, "render[s] the contested terms surplusage." Wright Med. Tech., Inc. v. Osteonics Corp., 122 F.3d 1440, 1444 (Fed. Cir. 1997). See also Lantech, Inc. v. Keip Mach. Co., 32 F.3d 542, 546 (Fed. Cir. 1994) ("All limitations in a claim must be considered meaningful.").

As used in the '377 patent, the phrase "said plurality" refers to the plurality of computers that form the system. And, the word "each" refers to that same plurality of computers; it does not refer to a new, smaller subset of the original plurality of computers. Accordingly, the court construes the disputed language - "A computer system having a shared addressable memory space, comprising . . . a plurality of computers, each of said plurality of computers sharing the shared addressable memory space" - to mean: a computer system having a shared addressable memory space, comprising two or more computers, every one of which of those two or more computers participating in the system has access to, and may contribute to, the shared addressable memory space.

The court, however, agrees with Mangosoft to the extent it says that not all computers on a particular network must necessarily participate in the system described in the '377 patent. In other words, the '377 patent teaches a system in which fewer than all computers on a network may participate in the described shared addressable memory system. See, e.g., "Summary of the Invention," '377 patent at 2:22-29 ("The invention provides systems that can create and manage a virtual memory space that can be shared by each computer on a network and can span the storage space of each memory device connected to the network.") (emphasis supplied). See also "Abstract," 377 patent at page 1 ("Distributed shared memory systems and processes . . . that optionally spans across each memory device connected to the computer network. Accordingly, each node on the network having the distributed shared memory system of the invention can access the shared memory.") (emphasis supplied).
Echo Returns, Echo(es), and Reflections: Lufkin's proffered claim construction limits the definition of echo returns, echo(es), and reflections (collectively “Echo Returns”) to the process described in the '399 Patent. Lufkin argues that this Court should reject the plain meaning of Echo Returns, as submitted by Echometer, because it is too broad and general. Lufkin maintains that Echo Returns are acoustic signals created when an acoustic pulse, transmitted down a borehole, encounters tubing collars and other discontinuities located in the borehole.

Conversely, Echometer asserts that Echo Returns are acoustic signals created when an acoustic pulse encounters a discontinuity as it is transmitted through a medium. To support its position, Echometer relies on standard dictionary definitions. The Federal Circuit has indicated that "dictionaries, encyclopedias and treatises, publicly available at the time the patent is issued, are objective resources that serve as reliable sources of information on the established meanings that would have been attributed to the terms of the claims by those of skill in the art." Tex. Digital Sys. v. Telegenix, Inc., 308 F.3d 1193, 1202-03 (Fed. Cir. 2002).

In this instance, this Court concludes that the ordinary meaning of Echo Returns is applicable. An "echo" is defined as a "repetition of a sound by a reflection of sound waves from a surface." THE AMERICAN HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE (3d ed. 1992). The language of the '399 Patent does not appear to rebut the ordinary meaning of this term, rather the specification language appears to support interpreting Echo Return broadly:

When the acoustic pulse produced by gun 86 is transmitted down the annulus 54, it strikes the tubing collars, such as 42 and 44, and produces a reflection from each of the collars. A reflection is further produced by the liquid level surface 80. In addition, should there be any other objects, such as tubing anchors, within the annulus 54, a reflection will be produced by each of these objects. Anything that changes the cross sectional area of the annulus, either larger or smaller, produces a reflection that is within the return signal.

The Court therefore construes the term Echo Returns in accordance with Echometer's proffered definition; Echo Returns are acoustic signals created when an acoustic pulse, encountering a discontinuity or surface, is reflected as it is transmitted through a medium.

"edges defining the sides"

The '776 patent requires "field stop regions in said substrate having edges defining the sides of said channel." '776 patent, 12:56-57. Solely on the basis of extrinsic expert declarations, defendant argues that the term "edge" means "the point at which conduction would be stopped." In the absence of ambiguity or confusion about the meaning of the term, such reliance on extrinsic evidence is improper. See Vitronics, 90 F.3d at 1584. The Court does not believe the term "edge" is ambiguous and holds that it has its ordinary spatial meaning of "the line where an object or area begins or ends." Webster's Ninth New Collegiate Dictionary 396 (1984).

"editing"

The disputed term, "editing," appears in two claims of the '705 Patent and in multiple claims in both the '995 Patent and the
'839 Patent. Claim 2 of the '995 Patent is illustrative:

2. An audio/video transceiver apparatus as in claim 1 further comprising editing means, coupled to said random access storage means for editing the time compressed representation of said audio/video source information stored in said random access storage means and for restoring the edited time compressed representation of said audio/video source information in said random access storage means; and wherein said output means is operative for receiving the edited time compressed representation of said audio/video source information stored in said random access storage means for transmission away for said audio/video transceiver apparatus.

Both parties agree that "editing" means "modifying." The court first looks at the ordinary meaning of "editing" to determine its definition, which can be found by examining the claim. Teleflex, 299 F.3d at 1325. Editing is described in the specifications as rearranging, altering, changing, deleting, inserting, enhancing, superimposing, removing, increasing or decreasing volume or frequency components, and filtering. '995 Patent at 6:27-33 (rearranging), 6:44-48 (deleting, inserting, enhancing, selecting), 9:14-54 (superimposing, altering, removing, adding components); '839 Patent at 12:46-52 (rearranging, increasing or decreasing volume, enhancing through filtering techniques). The court finds that "modifying" encompasses all of these functions and is the proper definition of the term "editing."

Apple argues that "editing" should be narrowed to mean "modifying the representation of the audio/video source information, not including the creation of playlists or modification of metadata." The court finds no reason to carve out these two functions, and the ordinary meaning of "editing" will not bear such limitations. Both of the disputed functions could conceivably be a form of "editing" if they involve modification of some object. This determination is properly a part of infringement analysis not claim construction. "A claim is construed in the light of the claim language, the other claims, the prior art, the prosecution history, and the specification, not in light of the accused device." SRI Int'l v. Matsushita Elec. Corp. of America, 775 F.2d 1107, 1118 (Fed. Cir. 1985). Thus, it would be improper for the court to construe "editing" with respect to modifying metadata or creating a playlist because these features are a part of the accused device.

Macromedia contends that this phrase (hereinafter the "editing phrase") should be construed to mean "altering, adapting or refining how the displayed waveform looks on the computer screen, for example, by selecting a portion of the waveform by highlighting it, cutting, pasting or deleting a selected portion, displacing the waveform along the time axis, or overlaying the waveform with a sound characteristics control line and displacing the line." (D.I. 243 at 13).

Adobe contends that Macromedia's proposed construction is not supported by the express language of Claim 20. (D.I. 305 at 21). Specifically, Adobe contends that Claim 20 defines the editing phrase as displaying a sound characteristics control line, displacing it in segments, and altering the stored waveform accordingly, but not performing any of the conventional functions such as cutting, pasting, or deleting. (D.I. 305 at 21). Adobe contends that these conventional editing functions are only supported by method Claims 31-33. (D.I. 305 at 21). Because Macromedia is no longer asserting these Claims against Adobe, Adobe contends that Macromedia is improperly attempting to reclaim the scope of Claims 31-33 by broadly construing the editing phrase in Claim 20. (D.I. 305 at 21). Additionally, Adobe contends that Macromedia's proposed construction ignores the language of Claim 20 and the specification of the '998 Patent, which require that the appearance of the visually displayed waveform be changed. (D.I. 305 at 22). Adobe contends that, according to Macromedia's construction, sliding or displacing the sound characteristics control line up and/or down in linear segments suffices to edit the appearance of the visually displayed waveform, simply because the sound characteristics control line overlays the waveform in a position different from its previous position. (D.I. 305 at 22). According to Adobe, displacing the sound characteristics control line does not "alter the appearance of the waveform" because the '998 Patent specifically provides that the control line and waveform are distinct from one another. For these reasons, Adobe contends that the editing phrase should be construed to mean "altering, adapting or refining how the displayed waveform looks on the computer screen by direct manipulation of a sound characteristics control line."
In construing the editing phrase, the Court has considered the specification and prosecution history of the '998 Patent, as well as the express language of the '998 Patent's claims. (D.I. 248, Ex. B, '998 Patent, Col. 1, lines 33-40, Col. 4, lines 19-40, Col. 5, lines 10-46, Col. 119, line 30 - Col. 120, line 68; D.I. 248, Ex. C). After a review of these sources, the Court concludes that the editing phrase does not exclude conventional editing functions, such as cutting pasting or deleting. In defining the step of editing, the language of Claim 20 provides "the step of editing comprises ..." While Claim 20 does not go on to specifically define editing to include conventional editing functions, the term "comprises" is a term of art in patent claim drafting which is synonymous with including, containing, or characterized by, and does not exclude additional unrecited elements. MANUAL OF PATENT EXAMINING PROCEDURES § 2111.03 (8th Ed. 2001). Because the term "comprises" is open-ended, and because neither specification nor prosecution history of the '998 Patent specifically define the step of editing to exclude conventional editing functions, the Court will construe the editing phrase to include conventional functions.

The Court also concludes that a plain reading of Claim 20 reveals that sliding or displacing the sound characteristics control line up and/or down in linear segments suffices to "edit the appearance of the visually displayed waveform." Specifically, Claim 20 provides:

wherein the step of editing comprises:

displaying a sound characteristics control line adjacent to the displayed waveform; and

displacing at least one segment of the sound characteristics control line adjacent to a portion of the displayed waveform;

wherein the step of editing comprises altering a specified characteristic of a portion of the stored waveform corresponding to the portion of the displayed waveform adjacent to the displaced line segment.

(D.I. 248, Ex. B, '998 Patent, Col. 119, lines 30-57). Because the Court is persuaded that this language defines editing to include overlaying the waveform with a sound characteristics control line and displacing the line, the Court will not construe the editing phrase to be limited to direct manipulation of the visually displayed waveform. In sum, the editing phrase will be construed to mean "altering, adapting or refining how the displayed waveform looks on the computer screen, for example, by selecting a portion of the waveform by highlighting it, cutting, pasting or deleting a selected portion, displacing the waveform along the time axis, or overlaying the waveform with a sound characteristics control line and displacing the line."

1. Educational Information

The term "educational information" 1 is used in the preamble of Claim 1 to set forth the intended use of the invention claimed. The term is also used in the recitation of the claim elements expressly and by the use of "said information." Accordingly, the term, in particular the word "education" as a modifier of "information," is part of the claim elements defining the invention. Compare Loctite Corp. v. Ultraseal Ltd., 781 F.2d 861, 868 (Fed. Cir. 1985) overruled on other grounds by Nobelpharma AB v. Implant Innovations, Inc., 141 F.3d 1059 (Fed. Cir. 1998). In other words, the word "educational" modifies "information" so that the claim does not reach all information but, rather, that subset of information that is "educational."

Footnotes

1 For some reason, the examiner substituted "educational" for "instructional" and the patentee accepted the change (Tr. 19) All references to "Tr." herein are to the transcript of the claim construction hearing held on June 9, 2003.

End Footnotes

The claim refers to "educational information" as being entered, transmitted and displayed. 2 Inasmuch as the word
"educational" cannot be read out of the claim, it necessarily follows that information that can be entered, transmitted and displayed could be educational or could be non-educational. Information, per se, has no inherent character as educational or non-educational. The characterization necessarily is determined by the context in which the information is entered, transmitted and displayed.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 The claim also states that the information "appears on" monitors which is the same as its being "displayed."

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

It may well be the case that all, or virtually all, conceivable information could be entered, transmitted and displayed in an educational context. For example, this very paragraph could be considered "educational information" if entered, transmitted and displayed in a course on how to, or perhaps how not to, write a good claim construction decision. On the other hand, the information in this paragraph cannot realistically be viewed as "educational" in its current context as part of a judicial claim construction decision that informs the parties of the Court's opinion. Thus, the Court rejects Plaintiff's contentions that any communication that informs, necessarily educates, so that any witness would be considered to be "educating" a judge and jury 3 (Tr. 36), a lawyer communicating a settlement offer would be deemed to be "teaching" opposing counsel the amount which the client will accept to settle a case, (Tr. 29) etc.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

3 It is, of course, conceivable that an expert witness in certain situations could be viewed as "educating" the judge and jury.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

A clear, but not exclusive, illustration of an educational context is provided in the '520 Patent itself. A student in a classroom 4 can enter information (such as text or a drawing) which is displayed on the student's and teacher's monitor, the teacher can add information (text or nontextual markings), which is displayed on the student's and the teacher's monitors. The information that is thus being entered, transmitted and displayed would be "educational information" as that term is used in Claim 1.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 Physical or virtual for that matter.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Examples of situations in which information was being entered, transmitted and displayed in a context in which there is no teacher/student or student/teacher relationship would include lawyers negotiating by marking up a contract draft, a buyer and seller collaborating on the design of an item (e.g. a cake, a label, a microchip) etc. In such contexts the persons sharing a common whiteboard would not be entering, transmitting and displaying "educational information" as that term is used in Claim 1.

Of course, there may be factual issues as to whether information in particular contexts is, or is not, "educational" as that term is used in Claim 1. Thus, a fact finder might find that a company's display of a picture of a new product to its sales force who could respond by marking the picture would be educational and yet find that the company's display of the same picture to a customer who could place an order by marking the picture would not be.

The Court notes that it appears unlikely that there will be any material issue turning on the precise definition of "educational information." The '520 Patent makes claims for a system which has the capacity to facilitate two or more persons in the entry, transmission and display of "educational information." If a particular accused system can facilitate the entry, transmission and display of educational information, the fact that it may be able to do so for non-educational information as well does not appear to be of particular significance. 5
The Court concludes that "educational information" shall be construed to mean information that is entered, transmitted and displayed in a context in which there is a teacher/student or student/teacher relationship between a person who enters and transmits the information and a person who views the shared display of the information.

1487

The parties disputed six terms used in the claims of the '843 patent. The Court has construed those terms as follows:

a) "Waveguiding structure" is used interchangeably with "waveguide" and is defined as: "A structure formed by a waveguiding film and a substrate and containing a diffraction grating";

b) "Waveguide film" means: "A film which, in combination with a sample having a lower index of refraction and a substrate can guide light along a path";

c) "Diffraction grating" means: "Any arrangement in the waveguiding structure that imposes a periodic variation of amplitude and/or phase on an incident wave";

d) "Wavelength" means: "A wavelength of light at which the optical sensor, including the waveguiding structure, waveguiding film, and diffraction grating, detects chemical, biochemical or biological substances in the sample";

e) "Effective index" means: "A number that relates the propagation velocity of light guided in a waveguide to the speed of light in a vacuum";

f) "Measuring the effective index and effective index change" means: "determining the effective index" and "determining the effective index change."

(D.I. 156).

1488

The dispute regarding the first element of claims 1, 13, 25 of the '761 patent and claims 1, 10, and 21 of the '282 patent centers around the meaning of the following underlined limitation:

first operational means for storing a plurality of prescribed response messages, each of which, when played back, effectively corresponds to the voice of the operator who is on-line with and services incoming calls; and

second operational means, coupled to said first operational means and operable in conjunction with the on-line operator's servicing of an incoming call, for selectively accessing a response message from among said plurality of stored response messages in dependence upon information contained within said incoming call being serviced by said on-line operator and which is representative of the type of call to which said incoming call corresponds, and causing said selectively said accessed response message to be played back to said incoming caller.

The parties agree that claim 1 in the '761 and '282 patents is written in the "means-plus-function" form pursuant to 35
U.S.C. § 112 P 6. The parties, however, disagree how the claims should be interpreted.

Construction of a means-plus-function limitation involves two steps. First, this Court must identify the claimed function. After identifying the claimed function, the Court must then determine what structure, if any, disclosed in the specification corresponds to the claimed function. See Cardiac Pacemakers, Inc. v. St. Jude Med., Inc., 296 F.3d 1106, 1113 (Fed. Cir. 2002).

Rockwell contends that the function described in the "first operational means" is: "storing a plurality of prescribed response messages, each of which, when played back, effectively corresponds to the voice of the operator who is on-line with and services incoming calls." Docket No. 121 at 9 (emphasis added). Rockwell further contends that the structure disclosed in the specification associated with the "effectively corresponds" claimed function requires "adjustment by automatic level control circuitry" to ensure that there is effectively no difference in the audio level of the recorded voice played back to the caller and the 'live' voice spoken by the operator." Docket No. 121 at 11.

Golden Voice, however, contends that the function described in the "first operational means" is: "storing a message." Golden Voice argues that the subject phrase -- "each of which, when played back, effectively corresponds to the voice of the operator" -- describes the message that is recorded, not the function of recording the message. Golden Voice, therefore, claims that the phrase "effectively corresponds to the voice of the operator" is not limited to the structure described in the specification under 35 U.S.C. § 112 P 6. Its only requirement is that the operator record the message in his or her own voice. Docket No. 122 at 8. This Court agrees.

The function of the "first operational means" is simply "storing a message," and the subject phrase merely describes the message that is being stored. The automatic control circuitry does not relate in any way to the "storing" of a message. At the storing level, all that is required is that the operator record the message in his or her own voice. Moreover, the subject phrase -- "each of which, when played back, effectively corresponds to the voice of the operator who is on-line with and services the incoming calls" -- is not part of the second element that describes how the messages are actually played back to the caller. If the first claim element was meant to incorporate a limitation that the messages are manipulated by the same automatic level-control circuitry as the operator's voice signals when played back, that limitation would have to be included in the play-back second element of the claims, not the first. That second element (the second operational means), however, does not include any such phrase. Rather, the second element relates to the means for selectively accessing and playing a prerecorded message based on information from the incoming call.

Further, under the doctrine of claim differentiation, no limitation requiring that the voice signals and the recorded message signals be adjusted in the same manner can be read into the independent claims at issue. Each of the independent claims at issue that contain this phrase have dependent claims which further limit the way in which messages are played back through the automatic control circuitry by "adjusting in effectively the same manner, at least one prescribed characteristic of each of said voice message from the operator and the played back message." 7 See DX 1, '761 patent claims 4, 8, 11, 17, 21, 24, and 27; and DX2, '282 patent claims 4, 9, 13, 17, 20, and 23. Independent claim 33 also contains this same limitation as its added element ("c"). Because claim 33 and like dependent claims employ different language to recite a single audio interface with a voice level adjustment that is automatically applied to the recorded voice as well as the live operator voice, such a limitation should not be read into the independent claims at issue.

7 As noted earlier, the parties agree that the language "adjusting, in effectively the same manner, at least one prescribed characteristic of each of said voice message from said operator and said played back message" incorporates using automatic control circuitry to adjust the recorded voice and the operator's voice.

The specification also supports this construction of the claims. The specification does not specifically describe "effectively correspond" as requiring "adjustment by automatic level control circuitry." 8 The specification throughout, however, does describe a way for the recorded messages to compare closely to the live operator's voice -- they are recorded by that operator. DX 1, '761 patent, Abstract, 1:57 - 64, 7:33 - 38. In describing the recording of the operator's voice, the patent specification states that "because the operator is able to record his/her voice in a time frame approximate that during which
the operator will be on-line with incoming calls, characteristics of the voice as stored in memory will be substantially identical to that of the operator when the operator is on-line." DX 1, '761 patent, 7:33 - 38. Although the preferred embodiment described in the specification routes the play-back of prerecorded messages and the live voice of the operator through a common level adjustment control amplifier 103, nothing in the subject claim language requires that setup. Nor is the subject claim language written as the function of the "first operational means" in claim 1.

--- Footnotes ---

8 It is common sense that no dictionary would define "effectively correspond" as requiring "adjustment by automatic level control circuitry." "Corresponds" simply means "to compare closely." Docket No. 122, Ex. F.

--- End Footnotes ---

This Court's claim interpretation is in full conformance with the prosecution history. The claims which were modified to become the independent claims at issue contained the phrase "effectively corresponds to the voice of the operator who is on-line with and services incoming calls" in the original submission to the Patent Office. In that same submission, there were claims that depended from these claims that included the language "adjusting, in effectively the same manner, at least one prescribed characteristic of each of said voice message from said operator and said played back message." As explained above, in the first July 12, 1985, Office Action the examiner distinguished those dependent claims from the prior art and explained that the claims would be allowed if they were written in independent form.

The prosecution history shows there is a distinction between claims (such as '761 patent claim 33) which require adjusting the operator's voice signal and the played back message on a common output, i.e., having a voice-level adjustment that is automatically applied to the operator's voice and the messages, and those claims which merely recite that the stored message, when played back, "effectively corresponds to the voice of the operator who is on-line with and services incoming calls." By drafting independent claims with the limitation of "adjusting, in effectively the same manner" without any argument over the examiner's statements regarding the meaning of this phrase, the applicant accepted that meaning for those claims. Applicants further showed that the independent claims which contain the phrase "effectively corresponding . . ." do not require adjusting the voice message and the automatic message with a common automatic voice level adjustment. Applicants never argued that the claims containing this phrase were equivalent to the other claims, and therefore should be allowable under the distinction the examiner made.

The interplay between the examiner and the applicants in the prosecution history makes it clear that the phrase "effectively corresponds to the voice of the operator" simply means that the recorded message must be in the voice of the operator. In the summary of the September 17, 1985 interview with the examiner, the applicants' attorney described the invention as "stored messages plus following real-time conversation of an operator, in the same voice."

In the September 30, 1985 Amendment following the telephone interview, the applicants specifically explained that the correspondence between the operator's voice and the recorded message was as achieved "through a scheme providing response messages . . . which . . . have been previously recorded in the voice of the operator who is attending to the servicing of the call . . . the calling party hears the same voice, whether it be the live operator's voice at the servicing console or a played-back voice from the prerecorded message source."

In the November 27, 1985 second Office Action, the examiner rejected the claims containing the phrase "effectively corresponds to the voice of the operator" stating that having the voice messages recorded in the operator's own voice was simply an obvious variant over prior art answering machines. In responding to the examiner in the December 30, 1985 Amendment, the applicants did not assert that the distinction over the prior art was that the claims required adjusting both the operator's live voice and the prerecorded messages along a common output path, which the examiner had already accepted as a distinction. Instead, the applicants argued that the claims were distinguishable from the prior art because the operator who had recorded the messages was actually on-line with the caller and that, based on the information received, the operator could selectively access and play a recorded message.

Thus, the plain language of the claims, the specification, and the prosecution history establish that "effectively corresponds to the voice of the operator who is on-line with and services incoming calls" in Claims 1, 13, and 25 of the '761 patent and Claims 1, 10 and 21 of the 282 patent simply requires that the messages be recorded in the voice of the operator who is on-
Defendants' second objection is that the Magistrate's interpretation of the words "effectively corresponds" is inconsistent with the specification and reads the word "effectively" out of the claims. The limitation that the prerecorded message "effectively corresponds to the voice of the operator" appears in claims 1, 13, and 25 of the '761 patent and claims 1, 10, and 21 of '282 patent. The Report and Recommendation holds that this limitation simply means that the prerecorded message of the operator must be in the voice of the operator who is on-line with the caller. Doc. No. 140 at 28.

Defendants contend that effective correspondence means that the device itself controls the quality of the playback in such a manner that the caller does not know the recording is a recording. Defendants state that the specification makes it clear that the invention requires two things in order to accomplish this: the use of the operator's own voice and the use of automatic level control circuitry. Accordingly, Defendants argue that the proper construction of the phrase should be: "a response message that is adjusted by automatic level control circuitry to ensure that there is effectively no difference in the audio level of the recorded voice of the operator played back to the caller and the 'live' voice spoken by the same operator." Doc. No. 142, at 14.

In support of their position, Defendants cite the following descriptions provided by applicants in the "Summary of Invention" for the '761 patent:

The audio interface contains automatic level control circuitry which ensures that there is effectively no difference in the audio level of the recorded voice played back to the caller and the 'live' voice spoken by the operator. As a result, because the recorded message is in the operator's own voice and both live voice and played-back voice are coupled over the same signal flow path, the storage and retrieval system is effectively listener transparent.

DX 1 ('761 patent) at col.2, lines 25-33.

More specifically, the voice that is heard by the caller 70, whether it be the operator's own voice supplied from the operator's microphone over input link 71, or from the audio output from the synthesizer over input line 21, appears to the same voice in terms of quality and amplitude. The quality is the same because the voice message is a message in the voice of the operator who is actually providing the service at the telephone facility handling the caller's incoming call. In addition, because both the operator's voice signal supplied from his/her microphone and synthesized voice signal supplied from the digital storage equipment are coupled to the same amplification and level adjustment circuitry, there is no sharp inflection or level change between the two voice signals. Thus, the storage and retrieval and audio processing circuitry is effectively listener transparent.

Id. at col. 9, lines 50-60.

Finally, the "Summary of Invention also states:

At the same time the present invention permits the operator to follow-up the played-back message with a conversation with the caller, without the caller detecting a difference in the characteristics of the played-back voice and the "live" operator's voice so that the operator voice response message storage and retrieval system is effectively transparent to the caller.

Id. at col. 1, line 63 to col.2, line 2.

Elsewhere the specification states:

The audio interface contains automatic level control circuitry which ensures that there is effectively no difference in the recorded voice played back to the caller and the "live" voice spoken by the operator.

Id. at Abstract. see also Rockwell Initial Markman Brief at 11-15.
The Court finds this argument unpersuasive. First, as the Magistrate noted, the specification does not specifically describe "effectively correspond" as requiring "adjustment by automatic level control circuitry." Doc. No. 140 at 25. The patent specification states that "because the operator is able to record his/her own voice in a time frame approximate to that during which the operator will be on-line with incoming calls, characteristics of the voice as stored in memory will be substantially identical to that of the operator when the operator is on-line. DX 1, '761 patent, 7:33-38. Although the preferred embodiment described in the specification routes the play-back of prerecorded messages and the live voice of the operator through a common level adjustment control amplifier 103, nothing in the subject claim language requires that arrangement. Doc. No. 140 at 25.

The prosecution history also supports the Magistrate's construction. As noted above, the original patent application presented independent claims 1, 14, 27, 30, 36, and 41. Dependent claims were 4, 9, 13, 17, 22, 26, 29, 31, 37, and 42, all of which further provided: "adjusting, in the same manner, at least one prescribed characteristic of each said voice messages from said operator and said played back message." Doc. No. 122, Ex.C at 28-33 and 35-38. In the first Office Action, the examiner rejected all of the independent claims but stated that the dependent claims "would be allowable if written in independent form," recognizing that these claims "require adjustment of characteristics of messages from both the operator and the playback source." 1d. at 58-59 (emphasis added).

In their second application, filed on September 26, 1985, applicants rewrote in independent form the dependent claims the examiner had approved because they contained the above cited language. This provision was not included in the other independent claims. Those claims continued to contain the language in dispute, "which message, when played back, effectively corresponds to the voice of the operator."

Although the examiner clearly approved the original dependant claims because they required adjustment of message characteristics from both the operator and the message playback source at a common path output, Defendants argue that the limitation in claim 1 requires adjusting only the response message through the use of automatic level control circuitry so that it matches the live voice of the operator. They suggest that this could be accomplished, for example, by measuring the volume of the operator's live voice and adjusting only the volume of the response message to match the volume of the live voice. However, the communications between the examiner and the applicants show that this was never applicant's intent.

As previously described, there were several discussions between the examiner and the applicants over whether simply recording a message in the voice of the operator was precluded by prior art. Once the examiner approved the independent claims which required adjustment of both the operator and the response message at a common path output, applicants continued to press for acceptance of the pending independent claims which did not contain that language. Applicants argued that these claims were distinguishable over prior art, not because the claims required adjusting both the operator's live voice and the prerecorded messages along a common output path, or because effective correspondence could be achieved by adjusting only the response message by use of automatic level control circuitry, but because the operator who had recorded the messages was actually on-line with the caller and that, based on the information received, could selectively access and play a message recorded in his or her own voice. The patent was ultimately granted allowing applicants' language to stand.

As the Magistrate noted, the prosecution history shows that applicants made a clear distinction between claims which require adjusting the operator's voice signal and the played back message on a common output, and those claims which merely recite that the stored message, when played back, "effectively corresponds to the voice of the operator who is on-line with and services incoming calls." 8 Accordingly, the Court adopts the Magistrate's construction of the phrase.

--- Footnotes ---

8 It should also be noted that the provisions from the Summary of Invention and the specification cited by Defendants undercut their argument. Two of the four references clearly state that the effective correspondence is achieved by having both the operator's live voice and the played-back voice coupled over the same signal flow path. None of the citations state that such correspondence can be achieved by adjusting only the response message.

--- End Footnotes ---
2. "Machine processing effectiveness parameter" (claims 1, 3, 5)

TriPath urges me to construe "machine processing effectiveness parameter" according to its ordinary meaning: "a predetermined value that is an indication of whether a machine has examined the specimen properly." Cytyc argues for a more specialized construction: "a parameter, relating to a normal/abnormal diagnosis made by the machine, that describes how effectively a particular machine performs the processing." The dispute between the parties turns on whether the parameter relates to a normal/abnormal diagnosis.

The specification indicates that "machine processing effectiveness parameter" does not relate to a normal/abnormal diagnosis. Although the entire term, "machine processing effectiveness parameter," does not appear in the specification, portions of it do. These portions shed light on the term's meaning. Consider the following excerpt from the "Background of the Invention" section of the specification:

Machine effectiveness measures, such as the percentage of requested fields of view that were focused adequately or the percentage of acquired images that had saturated pixels, are measures of how well the automated cytology system has begun to process a slide and how it proceeds to process a slide.

'327 patent at col. 1, 11. 17-22. "Effectiveness" appears to be the ability to process a slide properly. The specification uses "processing parameters" and "measures" interchangeably. See id. at col. 5, 11. 41-43. Combining these terms, a "machine processing effectiveness parameter" indicates whether the machine has examined the specimen properly. It relates not to the normal/abnormal diagnosis made by the machine, but to the reliability of that diagnosis.

This construction makes sense in the context of the entire patent. The invention at its essence is a suitability testing machine. It conducts thirteen tests and computes a score indicating how accurate a diagnosis is likely to be. The "machine processing effectiveness parameter" to which claims 1, 3, and 5 refer relates to whether a slide has been suitably processed n10. It is separate from the diagnosis of normal or abnormal.

Cytyc argues that the prosecution history supports construing "machine processing effectiveness parameter" as related to a normal/abnormal diagnosis. The examiner initially rejected the claims because prior art disclosed methods of determining processing effectiveness, such as the condition of the slide and its position and movement on the microscope stage. Cytyc/Callahan Decl. Ex. 35 ('327 File History, December 18, 1995 Amendment (C0129883)). In the Amendment dated December 18, 1995, the patentee distinguished his invention by noting that the prior art did not disclose measuring and checking at least one machine processing effectiveness parameter. Id. The patentee emphasized that his invention identifies errors caused by the machine, not just the condition of the slide. Id. He further explained that "the machine processing referred to in the instant specification relates to processing the biological specimen slide to determine if the slide is normal or abnormal." Id.

Cytyc seizes upon this language to justify its proposed construction. The Amendment clearly defines machine processing as the method by which the machine arrives at a diagnosis of normal or abnormal. This, however, does not support Cytyc's definition of "machine processing effectiveness parameter." Again, the parameter is an indicator of the effectiveness of the machine processing. It relates to the ability of the machine to make a diagnosis, not the diagnosis itself.

Therefore, to be consistent with the specification and the prosecution history, the proper construction of "machine processing effectiveness parameter" is "a predetermined value that is an indication of whether a machine has examined the specimen properly."
"First plurality of egress queues"

"Second plurality of egress queues"

Cisco's proposed construction for the phrase "first plurality of egress queues" is "two or more queues consisting of the organization in memory of the first units of data (claim 1) or frames (claim 6)." Cisco's proposed construction for "second plurality of egress queues" is "two or more queues, different from the first plurality of egress queues, consisting of the organization in memory of the first units of data (claim 1) or frames (claim 6)." Alcatel's proposed construction of the two phrases are "two or more queues consisting of the organization in memory of data generated from the egress traffic of a network," and "two or more queues, different from the first plurality of egress queues, consisting of the organization in memory of data generated from the egress traffic of a network," respectively.

Since the construction of the phrase "second plurality of egress queues" is agreed upon between the parties - in that it is two or more queues that are different from the first plurality of egress queues, and incorporates the same construction of "first plurality of egress queues" as proposed by each party - the Court will adopt this agreed upon construction of "second plurality of egress queues," and simply determine the proper construction of "first plurality of egress queues."

Cisco's proposed construction effectively reads out the word "egress" from the term. Instead, Cisco proposes to construe the term based on the constructions for the terms "first units of data" and "frames." Curiously, Cisco also argues, as discussed below, that "first units of data" requires no construction. Therefore, were the Court to adopt Cisco's proposed construction, "first plurality of egress queues," as used in claim 1, would be interpreted as simply two or more queues consisting of the organization in memory of a first set of data units, without any regard for the direction that those units are traveling, which is an explicit component of the term. This Court will not ignore the word "egress" in construing the term "first plurality of egress queues." See Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1562 (Fed. Cir. 1991) (recognizing that all limitations in a claim are considered meaningful).

Moreover, Cisco offers no evidence from the patent to support its proposal, other than its claim that since claim 1 refers to "first units of data" as comprising the "first plurality of egress queues," and claim 6 refers to "frames" in the same context, the term should be construed based on those terms. As mention above, construing "first plurality of egress queues" based on the terms "first units of data" and "frames" ignores the use of the word "egress" in the claim term, and therefore does not provide a proper construction of the term. Even Cisco's reliance on the testimony of its expert does not support its construction. Prof. Acampora bases the reasoning behind his proposed construction of the term, which, of course, is identical to Cisco's proposed construction, on the opinion that "one of ordinary skill in the art would be very familiar with queues, and would understand them to be logical organization of data in memory." Acampora '032 Report, at 4-5. However, this claim is not simply dealing with queues, but rather with egress queues; it is this very limitation that Cisco fails to recognize in its proposed construction.

Alcatel's proposed construction comports with the language of the claim, as well as the patent specification. In particular, the patent identifies "egress queues," and the word "egress" in general, as coming from the direction of a network. See Valizadeh, at 1:35-40, 2:60-67. Therefore, the Court adopts Alcatel's proposed construction of "first plurality of egress queues" as "two or more queues consisting of the organization in memory of data generated from the egress traffic of a network." Accordingly, the proper construction of "second plurality of egress queues" is "two or more queues, different from the first plurality of egress queues, consisting of the organization in memory of data generated from the egress traffic of a network."
phrase be construed as "data that has exited a network and is directed to customer premise equipment."

In support of its proposed construction, Alcatel points primarily to the "background" section of the patent where the egress traffic is directed towards customer premises equipment. See Valizadeh, at 1:30-38, 1:58-65. Additionally, certain other points in the specification also indicate CPE as the recipient of the traffic leaving the network. See id. at 3:66-4:2, Fig. 1. Moreover, Alcatel claims that the following statement in the background section shows a clear intention to define "egress traffic" as data being transmitted to customer premises equipment: "data received from the common carrier ATM network (i.e. 'egress traffic') is transmitted correctly to the customer premises equipment." See id. at 1:30-38.

Alcatel's arguments are unpersuasive. Aside from attempting to limit the claims to the description in the preferred embodiment, Alcatel's contention that the above sentence demonstrates a clear attempt to define "egress traffic" in accordance with Alcatel's proposed construction is incorrect. First, that sentence simply indicates that egress traffic would encompass the situation where traffic was traveling from an ATM network to CPE. It does not limit egress traffic to that situation. Second, the phrase "i.e. 'egress traffic'" is included after the phrase "data received from the common carrier ATM network." If it was intended to be limited to traffic directed to CPE, it would have been included after the phrase "transmitted correctly to the customer premises equipment." Third, the specification also indicates that it is not limiting the schemes described in the specification to the exact scenario disclosed in the specification. See Valizadeh, at 3:19-24 ("The queuing and servicing schemes described herein may be readily adapted to any system wherein additional granularity is desired . . ."). Finally, in the "Object of the Invention" section of the patent, nowhere does it state that the egress traffic must be directed toward customer premise equipment. "[I]t is an object of the present invention to provide an improved buffering and servicing scheme in the egress direction. This and other objects of the invention are provided by a method for queuing and servicing egress traffic of a network." Id. at 2:6-11.

As Cisco points out, the term "egress traffic of a network" is included in several claims (claims 1, 5, 6, 9, 12, 13, and 14), and the term is only explicitly limited to traffic moving towards customer premise equipment in claims 6 and 9. Thus, where the inventor intended to limit the patent to egress traffic moving towards CPE, he was capable of doing so explicitly. Cf. CFMT, Inc. v. Yieldup Int'l Corp., 92 F.Supp. 2d 359, 372 (D. Del. 2000) (recognizing that when one term is used in the specification and a different term was used in the claim, the inventors were capable of referring to the first term if that was what they had intended to convey). Therefore, as discussed previously, it would be improper to read the limitations from claims referring to customer premises equipment into the claims that specifically do not refer to customer premises equipment.

While the proper construction of "egress traffic of a network" in this patent does not require the traffic to be directed to customer premises equipment, there is still some dispute over whether Cisco's proposed construction is proper. Cisco proposes the construction, "traffic being transmitted out of a network." On the other hand, Cisco's expert claims that one of ordinary skill in the art would understand the phrase to mean "traffic on its way out of a network." Lumish Decl., Ex. AA ("Acampora '032 Report"), at 4. Neither of these definitions, however, allow for the existence of "transit traffic," which, according to Alcatel's expert, is "traffic that is being transmitted within the network, between the first and last node of the network." Lucantoni '032 Decl., at P 28. Essentially, under Cisco's proposed construction, all traffic eventually destined to exit the network would qualify as "egress traffic," instead of traffic that actually is exiting the network. In the patent, however, "egress traffic" is always in the process of actually exiting the network, as the entire patent is designed to create a method for queuing and servicing traffic in the process of exiting the network. Thus, the claims are clearly referring to only that traffic that has exited or is exiting the network, not all traffic that will eventually exit the network.

Furthermore, while the claim language and specification do not limit the type of "network" to an ATM network, the claims and the specification are not referring to "egress traffic of a network" as simply any traffic that has exited or is exiting any "distinct set of interconnected elements used to communicate data," as is the proper construction of the term "network," discussed above. Since all traffic in the patent is flowing from one type of network to another, all traffic is both entering and exiting a "distinct set of interconnected elements used to communicate data" at the same time, and thus Cisco's proposed construction would not limit "egress traffic of a network" to traffic flowing in any particular direction. Instead, the patent and claim language are more accurately referring to traffic flowing from a network operating at a faster data rate (such as a common-carrier ATM network) to a network operating at a slower rate, and possibly using different protocols (such as customer premises equipment comprising a Frame Relay network). See, e.g., Valencia, at 1:30-32, 37-39, 2:46-48, 3:25-29, 40-43, Figs. 1-2. Thus, when the patent discusses "egress traffic of a network," it is referring to the network operating at a faster rate, whether it is an ATM network or not.
Therefore, the proper construction of "egress traffic of a network" is "traffic that has exited or is exiting a network operating at a faster data rate and directed towards a network operating at a slower data rate."

3. The phrase "EITHER . . . OR" (claim 19) means that a minimal requirement of the signal is that a significant component is derived from at least one or the other signal. Thus, the claim language requires at least one, but does not exclude the possibility of both.

Element [d] is described as "a first electrical conductor connecting the ground mechanism to the utility box for electrically grounding the utility box." Senior Industries puts forth that the correct interpretation of this element is "a structure (possibly including several elements such as grounding wire and a clamp), which can transmit electricity from the utility box to the ground mechanism so as to ground the utility box." Thomas and Betts argues that "a ground wire connected at one end to the ground rod and at the other end to the meter box enclosure." Senior Industries interpretation is supported by the language of the specification. The specification states the following:

For example, a conduit 16 holds a large size grounding wire which is connected through a clamp 20 to an elongated grounding rod 22 sunk into the ground G. Typically, this grounding rod 22 may be six feet or more in length and is located within three feet or other close proximity to the base of the building. Ground wire 18 is then connected to a grounding bracket (not illustrated) within the electric box in a known manner.

(The '960 patent, col. 3, lines 54-62).

This passage confirms that the inventor intended the claim terms to be accorded their ordinary meaning and the specification supports Senior Industries interpretation of such. Therefore, Senior Industries's more descriptive claim construction shall be applied to element [d].

A. CONDUCTIVE PATH.

For the first, second, and third conductive path claim terms, the patent uses the word "means," followed by a recitation of function, resulting in the rebuttable presumption that the element is a means-plus function element subject to 35 U.S.C. § 112, P 6. Leviton, thus, has the burden of overcoming the presumption by showing that the claim element recites sufficiently definite structure to perform the specified function. See Envirco Corp. v. Clestra Cleanroom, Inc., 209 F.3d at 1364.

The Court finds that Leviton has met its burden because the term "conductive path" connotes sufficient structure, especially when coupled with the surrounding terms that provide location and formation descriptions. In determining whether a term itself is a structural term as understood in the art, courts frequently examine dictionary definitions. See Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1360 (Fed. Cir. 2004) ("[W]e have looked to the dictionary to determine if a disputed term has achieved recognition as a noun denoting structure, even if the noun is derived from the function performed."); Linear Technology Corp. v. Impala Linear Corp., 379 F.3d at 1320 (consulting technical dictionary to determine whether "circuit" connotes structure); Envirco Corp. v. Clestra Cleanroom, Inc., 209 F.3d at 1365 (referring to dictionary definition of word "baffle" to determine whether it is structural term). Merriam Webster's Collegiate Dictionary 241 (10th ed. 1993) defines "conductor" as "a material or object that permits an electric current to flow easily." Because the term "conductor" -- a material or object -- imparts structure, the Court finds that a person with ordinary skill in the field would understand that the related term "conductive path" also imparts structure. Cf. Linear Technology Corp. v. Impala Linear Corp., 379 F.3d at 1320 (holding that term "circuit" connotes structure).
Furthermore, the contextual claim language describes the particular structure for each conductive path. In particular, each element provides further location and formation detail apart from the function itself. The "first electrical conductive path means" element, after describing its function as "conducting electricity," further states that it must be "capable of electrically connecting to a source of electricity." This statement provides a location and formation for the conductive path, which is more than just a general description of any structure that will perform a particular function. 3 Cf. Phillips v. AWH Corp., 415 F.3d at 1311 (holding that term "baffles" is structural because claim characterizes baffles as "extend[ing] inwardly" from steel shell walls); Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996) (holding that claim which described not only the structure (perforations) but also its location (extending from leg band to waist band) and extent (extending through outer impermeable layer) recites too detailed a structure to constitute a means-plus-function element); MediaCom Corp. v. Rates Technology, Inc., 4 F.Supp.2d 17, 27 (D. Mass. 1998) (holding that "switch means operatively connected to said first jack means for disconnecting said first telephone from said network" was not a § 112, 6 means-plus-function statement because it describes structure that supports disconnecting function (i.e. a switch or switches) and describes it as connected to adjacent structure, the first jack). Similarly, the second electrical conductive path describes additional location and formation detail when it states that it is "capable of electrically connecting to at least one load when electrical continuity between said first and second electrical conductive path means is made." The third electrical conductive path also provides additional structure: "capable of electrically connecting to at least one user accessible load when electrical continuity between said first and third electrical conductive path means is made."

3 The Court disagrees with the Defendants' interpretation that this phrase describes further function, rather than structure.

Leviton's expert, Dr. Jaime De La Ree, also confirmed that a person of ordinary skill in the field would understand that the term "conductive path" connotes structure, especially in light of the contextual language following the term. That the terms may not connotate a precise physical structure does not compel a finding of insufficient structure. See CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d at 1370; Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d at 1583. For this reason, the Court declines to adopt the opinion of Defendants' expert, Dr. John Choma, who opined that the term "electrical conductive path" can only impart sufficient structure if the claim contains a delineation of the material used in the conductive path or a description of the geometry, shape, size, or conductive quality of the path. The case law indicates that such a precise physical structure is not required to find sufficient structure. See id. The Court also declines to adopt Dr. Choma's opinion that the term "electrical conductive path" conveys only a schematic depiction of a hard-wired connection between two arbitrary points, A and B. His opinion does not take into account the language following the term "conductive path," which conveys location information as to the connecting points for the conductive path. For example, the term "first electrical conductive path" imparts more than just a connection between two arbitrary points; rather, it imparts a hard wired connection (structure) to a source of electricity. Finally, the Court notes that Dr. Choma's opinion actually supports its finding that the term "conductive path" connotes structure, because a hard-wired connection between points imparts structure.

The Defendants primarily rely on two distinguishable cases in support of their position: Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533 (Fed. Cir. 1991), and Unidynamics Corp. v. Automatic Prods. Int'l, Ltd., 157 F.3d 1311 (Fed. Cir. 1998). In Laitram Corp. v. Rexnord, Inc., the Federal Circuit held that the claim language "means for joining said pluralities to one another so that the axes of said holes of said first plurality are arranged coaxially ..." was a means-plus-function element. 939 F.2d at 1535-36. That case is inapposite because, unlike here, the claim did not provide a specific structure for what the "means" was. In this case, the claim states a structure before the term "means," for example, "first electrical conductive path means." The term "conductive path" has a structural meaning to those skilled in the art of GFCI devices, as evidenced by its dictionary definition and by the expert opinions of both Dr. De La Ree and Dr. Choma. Furthermore, use of the term "conductive path" coupled with the additional structural language in the claim sufficiently tells a person skilled in the art what it is structurally. "Conductive path means" conveys far more structure than simply "means," and therefore, the case of Laitram Corp. v. Rexnord, Inc. is not controlling.

Unidynamics Corp. v. Automatic Prods. Int'l, Ltd. is likewise distinguishable. In that case, the Federal Circuit held that the claim phrase "spring means tending to keep the door closed" is a means-plus-function element. See 157 F.3d at 1319. In doing so, it distinguished Cole v. Kimberly Clark Corp. by reasoning that in that case the claim term not only described
sufficient structure (perforations) but also described the location and extent of the structure. See Unidynamics Corp. v. Automatic Prods. Int'l. Ltd., 157 F.3d at 1319. In contrast, in Unidynamics Corp. v. Automatic Prods. Int'l. Ltd., "spring" was the only recitation of structure, which the court found insufficient. See id. The claim phrase in this case, by contrast, not only describes sufficient structure ("conductive path"), it also describes the location and formation of the structure (e.g., "capable of electrically connecting to a source of electricity"). The holding in Unidynamics Corp. v. Automatic Prods. Int'l. Ltd. is therefore also inapplicable to this case. 4

The Defendants also cite a number of other cases in support of their position: Sage Products, Inc. v. Devon Industries, Inc., 126 F.3d 1420 (Fed. Cir. 1997); Sule v. Kloehn Co., 149 F.Supp.2d 115 (D.N.J. 2001); Nilsson v. Motorola, Inc., 80 F.Supp.2d 921 (N.D. Ill. 2000); and Fairchild Semiconductor Corp. v. Nintendo Co., 30 U.S.P.Q.2d 1657 (W.D. Wash. 1994) (unpublished opinion). The Court finds these cases similarly distinguishable for the following reasons: the terms "conductive path" and "circuit interrupter" impart sufficient structure, as evidenced by their ordinary definitions and by the expert opinions of Dr. De La Ree and Dr. Choma, and the language following the terms imparts additional location information that adds structural detail. The combination of these factors distinguishes the elements at issue in Claim 3 from those in the cases cited by the Defendants.

The Court additionally finds the case of Leviton Manufacturing Co., Inc. v. Universal Security Instruments, Inc., 2005 U.S. Dist. LEXIS 6911, 2005 WL 936990 (D.Md. April 22, 2005)(unpublished opinion), distinguishable. That case not only involves different claims (Claims 1, 2, and 4) of the '558 patent, but also different terms. See id.2005 U.S. Dist. LEXIS 6911 [WL] at *13-14. Moreover, in that case, Leviton's own expert stated that the term "reset lock-out" had no standard meaning in the art and that he had never used the term before his work in that litigation. See id.2005 U.S. Dist. LEXIS 6911 [WL] at *28. Leviton also produced no evidence to demonstrate that "reset mechanism" has a well understood meaning as structure to a person of ordinary skill in the art. See id. 2005 U.S. Dist. LEXIS 6911 [WL] at *36. The expert opinions in this case are in stark contrast: both experts acknowledge that the terms "conductor" and "circuit interrupter" impart structure. The expert opinions in this case in combination with the dictionary definitions set the elements at issue in Claim 3 apart from the elements in Leviton Manufacturing Co., Inc. v. Universal Security Instruments, Inc.

For all the above reasons, the Court concludes that the terms "first electrical conductive path," "second electrical conductive path," and "third electrical conductive path" are not subject to 35 U.S.C. § 112, ¶ 6. The Court will thus construe these terms using standard claim construction rules, as set forth in Leviton's Claim Construction chart.

GO BACK

1496

Electrical instructions are sent thereto for interpretation by the loaded program

Lantronix contends this term should be construed as "electrical signals are sent to the circuitry and are acted upon by the loaded program." Lantronix argues that the specification reveals that the functionality described in this claim phrase is not limited to one particular implementation and Lantronix's construction is intended to encompass all the implementations. Lantronix contends a number of devices can send instructions that configure the connector, see 470 patent, 2:10-32, and the instructions can be implemented in multiple ways, see 470 patent, 3:58-63,4:15-17. Lantronix objects to Digi's construction for the same reasons it objected to Digi's construction of "electronically communicate. . . ."

Digi contends the term should be construed as "the connector receives an electrical signal from an external electronic device and uses that signal to change the protocol, parameters, and pin-outs." Digi argues the "phrase describes the connector's receipt of an electrical signal from one of the external devices and subsequent use of that signal, through the loaded program, to adapt itself into a desired connecting configuration and/or function between the devices." See 470 patent, 1:21-24. As Digi previously contended, its contents here that the physical configuration is accomplished by changing the protocol, parameters or pin-outs so that the two devices can communicate with each other. See 470 patent, 2:10-14. Digi criticizes Lantronix's use of "loaded program," which is contained in the claim.

The Court construes "electrical instructions are sent thereto for interpretation by the loaded program" to mean "electrical
signals are sent to the circuitry and are acted upon by the loaded program." As discussed above, Digi's "protocol, parameters, and pin-outs" limitation is inappropriate. Lantronix's proposed construction, which the Court adopts, includes all of the invention's embodiments that are discussed in the specification.

5. "Electrical outlet"

This term appears in claims 1 and 30-31 of the '368 patent. SercoNet maintains that the definition of electrical outlet does not need construction in claim 1, as it is merely in the preamble of the patent, and the six elements of the body of the claim completely define the invention at issue. For claims 30 and 31, SercoNet proposes the customary meaning of an electrical outlet, which is "a point on the wiring system at which current is taken to supply utilization equipment" from the authoritative dictionary of the standard setting organization, the Institute of Electrical and Electronics Engineers ("IEEE"). Netgear's proposed construction for the term in all claims is "a powerline termination from which electric power can be obtained by inserting a plug." Netgear's definition derives from the McGraw-Hill Electronics Dictionary.

Starting with the claim language, claim 1 of the '368 patent describes: "An electrical outlet for configuring a local area network in a building, the network including a powerline wiring carrying frequency multiplexed power and data signals, the electrical outlet comprising..." Claims 30 and 31 of that patent refer to "the device according to claim 18 [which describes a device for configuring a LAN in a building], wherein said device is pluggable into an electrical outlet" or where the device is "attachable to an electrical outlet", respectively. Claim 31 explicitly states that a device may be attachable to an electrical outlet, as opposed to being "pluggable" into such an outlet as described in claim 31. The claim language, therefore indicates that power need not be obtained from an electrical outlet by "inserting a plug."

Turning to the specification, Figure 5 of the '368 patent shows a connection from an SIC to the electrical power main. The specification also notes that part or all of an SIC can be housed within an electrical outlet so that the electrical outlet allows connection to the local area network as well as to electrical power. '368 patent at 8:24-26. Power can be fed to an "optional" electrical appliance, and the figure shows that the appliance contains a plug. The specification also states that typical house mains have a connection to a single feeder with multiple distribution points and outlets. Id. at 9:61-63. The intrinsic evidence, therefore, seems to show that while electric power may be obtained by inserting a plug into an outlet, this is not required, and an outlet more generally described as a point of connection for electrical power.

Both parties' definitions come from technical dictionaries. Neither is really directly supported by intrinsic evidence. However, because there is nothing directly limiting an outlet to something by which a plug must be inserted to obtain power, and because the claim language clearly states that a device may either be attachable to or pluggable into an electrical outlet, NetGear's definition imports an extraneous limitation that is not supported by the claim language or specification, and SercoNet's proposed construction does not suffer from the same problem. While NetGear's definition might make more sense to a layperson, SercoNet's definition comes from an engineering standards setting organization, and therefore constitutes a plain meaning to one skilled in that art.

As for whether the term in the preamble of claim 1 of the '368 patent need be construed, the term outlet appears in the body of the claim and refers back to the term "electrical outlet" in the preamble. Therefore, the term gives life and meaning to the claim, and should be construed. See On Demand Mach. Corp., 442 F.3d at 1343.

In sum, and for all the reasons set forth above, the court adopts SercoNet's proposed construction of "electrical outlet" and construes the term "electrical outlet" as: "a point on the wiring system at which current is taken to supply utilization equipment." This term shall be so construed in the both the claim preamble and the body of the claims.
On the instant motion, P3 initially argued that the term "electrical parameters" as used in Claim 1 should be construed as meaning the "direct attributes of the current" or the "measurable aspects of the electricity itself." 4 In opposition, UPM contends that "electrical parameters" should be construed as any two of the following: "present time, voltage value, current value, watt number, kilowatt-hour, apparent power value, [and] power factor." This list is taken from dependant Claim 2 of the '850 Patent, which provides that "the plurality of electrical parameters indicated on the display unit comprises present time, voltage value, current value, watt, kilowatt-hour, apparent power value, and power factor." In reply, P3 first agrees that the list of electrical parameters set forth in Claim 2 is a list of examples of "electrical parameters" as that term is used in Claim 1. P3 also notes that UPM correctly points out that some such electrical parameters are detected by the circuit, such as voltage and current, and that other parameters, such as power, kilowatt hour, and cost are calculated by the CPU based on those detected parameters. By listing cost in its reply submission, P3 shifted from its initial argument that "electrical parameters" are only the direct or measurable attributes of the electricity and do not include cost.

--- Footnotes ---

4 P3 took this position in response to UPM's invalidity contentions, which had relied on a Japanese patent application that disclosed an energy meter that displayed only costs.

--- End Footnotes ---

P3's argument in reply describes as well another part of Claim 1 -- the "display unit." P3 points out that the display unit in Claim 1 must display at least one of the plurality of electrical parameters that is "detected by the control circuit." P3 thus argues that the list of electrical parameters in Claim 2, some of which are detected by the control circuit and some of which are calculated based on those detected parameters, does not affect the requirement in Claim 1 that the display unit must display at least one of the "plurality of electrical parameters detected by the control circuit." (Emphasis supplied.) To the extent that UPM seeks to construe the term "electrical parameters" in Claim 1 to cover only any two of those parameters listed in Claim 2, it is in error. "In the patent claim context the term 'comprising' is well understood to mean 'including but not limited to.'" See, e.g. CIAS, Inc. v. Alliance Gaming Corp, 504 F.3d 1356, 1360-61 (Fed Cir. 2007) (noting also that this usage of the term "comprising" embraces the term "comprises" as well). Thus, the term "electrical parameters" in Claim 1 is not limited to only those specific parameters listed in Claim 2, but could include additional parameters as well. Rather, the intrinsic record evidence demonstrates that the ordinary meaning of "electrical parameters" is the measurable attributes of electricity and the attributes that can be calculated from such attributes and other data.

1499

B. "Electrical Potential"

Defendants seek construction of the claim limitation "electrical potential." Defendants resort to Webster's New World Dictionary of the American Language (2d ed. 1972) to determine the ordinary and customary meaning of "electrical potential." The dictionary describes "potential" as "Elec. the relative voltage at some point in an electric circuit or field with respect to some reference point in the same circuit or field." Defendants therefore submit the proper construction of the claim limitation "electrical potential" should be "the relative voltage at some point in an electric circuit or field with respect to some reference point in the same circuit or field." Defendants contend the '166 patent specification is consistent with this definition because the specification figures use voltmeters in each invention embodiment. Moreover, defendants assert nothing in the prosecution history contradicts their proposed construction.

Dicon argues that by asserting a voltmeter must be used to measure electrical potential, defendants improperly import a particular embodiment into claim 1 and misconstrue the specification. Dicon contends the patent description provides means other than a voltmeter, including potentiometric, galvanostatic and amperiometric means, for sensing electrical potential. See Def. Mot. at Ex. A, Col. 7, Ins. 21-26. Dicon further asserts the "electrical potential" language is contained in a "whereby" clause; therefore, the claim does not require that a change in electrical potential be created. Rather, Dicon contends the clause states that if a change in electrical potential is created, the means used for electrical measurement must detect that change.
Again, Dicon criticizes defendants' claim construction without offering a claim construction of its own. Further, Dicon's arguments miss the mark. The issue here is not the means by which electrical potential changes must be measured. Rather, the issue is the proper construction of the term "electrical potential," regardless of how electrical potential is measured. Defendants' construction of "electrical potential" is sound and consistent with the intrinsic evidence. The phrase must be given its ordinary and customary meaning. Johnson Worldwide Assocs., Inc., v. Zebco Corp., 175 F.3d 985, 989 (Fed. Cir. 1999). Therefore, the court construes "electrical potential" to mean "the relative voltage at some point in an electric circuit or field with respect to some reference point in the same circuit or field."

1500

We disagree, however, with the district court's construction of the claim term "electrically conductive fibers" to the extent that it encompasses carbon fibers. This court has recognized that "[w]here the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question." Scimed Life Sys. v. Advanced Cardiovascular Sys., 242 F.3d 1337, 1341 (Fed. Cir. 2001). It is true, as the district court noted, that the '879 patent's written description did not expressly define "electrically conductive fibers," as it did for "fuel injection system component." Nevertheless, based on the disclosure in the written description, which demeaned the properties of carbon fibers, we conclude that the patentee thereby disavowed carbon fibers from the scope of the '879 patent's claims.

The written description contains the following disclosure:

Stainless steel also has the advantage of requiring smaller quantities for providing the required conductivity than other conductive fillers, such as carbon black. '879 Patent, col.3 ll.56-60 (emphasis added).

Other electrically conductive fillers, such as the aforementioned carbon, act as stress concentrators and, at the relatively high filler loadings required to achieve conductivity, restrict the ability of the resin matrix to yield under stress. Id., col.4 ll.1-5 (emphasis added).

Also, stainless steel fibers are ductile and non-rigid unlike straight or metallized carbon fibers. . . . This allows stainless steel fibers to maintain their integrity better during melt-processing. Id., col.4 ll.5-10 (emphasis added).

Unlike the non-metallic fibers, stainless steel fibers also do not increase mechanical strength or stiffness of the base resin significantly. Other metal fibers with high aspect ratios can be satisfactorily substituted for stainless steel. Id., col.4 ll.10-14 (emphasis added).

In making the above statements, the patentee informed its readers specifically why carbon fibers would not be suitable as "electrically conductive fibers" in the claimed invention. If the written description could talk, it would say, "Do not use carbon fibers." There is no other way to interpret the written description's listing of all the reasons that metal fibers fare better than carbon fibers for use in the claimed invention, even though both materials are electrically conductive, viz., that metal fibers require smaller quantities to achieve the desired conductivity than carbon fibers, create less stress concentration, are more ductile, are less rigid, and increase the mechanical strength of the polymer housing. Contrary to the district court's understanding, the written description has gone beyond expressing the patentee's preference for one material over another. Its repeated derogatory statements concerning one type of material are the equivalent of disavowal of that subject matter from the scope of the patent's claims.

In reaching this decision, we reject Honeywell's argument in support of the district court's construction of "electrically conductive fibers." Honeywell argues that the written description did identify carbon fibers as electrically conductive fibers, and that stainless steel fibers were merely preferred embodiments. Honeywell's argument misses the point. It is precisely because the written description has identified carbon fibers as electrically conductive, and yet it denigrated carbon fibers' applicability to the claimed invention, that we find a disavowal of that subject matter. Moreover, it is irrelevant whether stainless steel fibers are a preferred embodiment of the claimed invention. We are not here modifying the district court's claim construction to limit its scope to stainless steel fibers. We only modify it to exclude carbon fibers from the scope of the '879 patent claims.
4. The "electrically conductive layer" limitation

The accused Nevamar products are of two classes: those using a phenolic resin and those using a melamine resin in the conductive layers. Making all reasonable inferences in favor of Charleswater, the resistivity of the conductive layers containing phenolic resin is as low as 4,200 ohms per square and the resistivity of the layers containing melamine resin is 145,000 ohms per square or greater.

2 Nevamar argues that the resistivity of the phenolic resin-impregnated paper is at least 88,000 ohms per square and that the resistivity of the melamine resin-impregnated paper is at least 108 ohms per square.

The district court construed the "electrically conductive layer" limitation to mean that the measured resistivity of the layer in the final product must be less than 30,000 ohms per square. The district court based this construction on the definition of "conductive" provided in the written description of the '040 patent as well as this court's previous construction of the term "nonconductive" as used in the '040 patent to mean "resistivity greater than 30,000 ohms [per square]." See Charleswater Prod. Inc. v. Spaulding Fibre Co., 12 U.S.P.Q.2D (BNA) 1916, 1918 (Fed. Cir. 1989) (nonprecedential). Based on this construction, the court concluded that the "electrically conductive" limitation does not read on the accused Nevamar products in which the alleged conductive layer comprises a melamine resin, either literally or under the doctrine of equivalents, because the lowest measured resistivity of the layer in the finished product is higher than 30,000 ohms per square. The district court also concluded that a genuine issue of material fact exists as to whether this limitation reads on the accused products in which the alleged conductive layer comprises a phenolic resin and denied Nevamar's noninfringement summary judgment motion concerning those products. We hold that the district court's judgment concerning this limitation is correct with respect to both classes of products.

a. Literal infringement

Charleswater argues that the district court erred in construing the "electrically conductive" limitation and asserts that determining whether an alleged layer is electrically conductive is properly based on "indicia of conductivity." Charleswater also appears to argue in the alternative that determining whether a layer is conductive or not should be done by determining the relative conductivities of the alleged conductive and nonconductive layers. Both of these arguments fail.

The written description of the '040 patent states that a layer is conductive if its resistivity is less than about 30,000 ohms per square. See '040 patent, col. 1, ll. 15-17 ("approximately 30,000 ohms per square surface resistivity or less, for example, 5,000 ohms"); id. at ll. 38-42 ("less than about 30,000 ohms/square inch; for example, 10,000 or 5,000 ohms/square inch of surface resistance"). Charleswater cannot avoid this definition by its argument that "indicia of conductivity" is an equivalent or more accurate method of determining whether a layer is conductive, because the resistivity definition is in the written description and the "indicia" definition is not. Similarly, determining whether a layer is conductive or not by comparing its resistivity to the resistivity of the nonconductive layer is not discussed in the written description. Whether technically plausible or not, these arguments cannot overcome the resistivity measurement-based definition of a conductive layer provided in the written description. See Unidynamics, 157 F.3d at 1317, 48 U.S.P.Q.2D (BNA) at 1103 ("In defining the meaning of key terms in a claim, the court may refer to the specification, the prosecution history of a patent, prior art, and other claims.").

Viewing the evidence and making all reasonable inferences in favor of Charleswater, there is no genuine issue of material fact as to whether the "conductive layer" limitation literally reads on the accused products in which the conductive layer comprises a melamine resin because their lowest measured resistivity is 145,000 ohms per square. As a matter of law, this claim limitation does not literally encompass those products. However, because the lowest measured resistivity of the conductive layer in the accused products containing a melamine resin is less than 30,000 ohms per square, there is a genuine
issue of material fact as to whether the "conductive layer" limitation literally encompasses those products.

GO BACK

1502

3. "An electrically conductive layer embedded in said first contact hole up to a level higher than the gate electrode such as to be contacted with said electrically conductive layer"

For this very long "term," Toshiba proposes an even longer construction: "An electrically conductive layer is deposited in the first contact hole of an insulating film, with the electrically conductive layer covering the first contact hole. Thereafter, the electrically conductive layer is etched to expose the surface of the insulating film in which the first contact hole is formed with the electrically conductive layer left in the first contact hole at a height that is higher than the gate electrode. The electrically conductive layer is in contact with the 'second contact hole.'" Jt Cl Const, Ex A at 19. Hynix contends that this phrase should not construed because it is indefinite but alternatively proposes replacing "embedded" with "fixed firmly." Id.

Hynix contends that this term is indefinite because "one skilled in the art would not understand what structure of the claimed device must be 'contacted with said electrically conductive layer.'" In particular, Hynix contends it is unclear whether the "electrically conductive layer" is claim 1 is in contact with itself, the "first inter-layer insulating film," "first contact hole," "second inter-layer insulating film," "second contact hole" or the "gate electrode." Hynix Br at 9.

While the court agrees that this "term" is quite poorly written, its meaning is not ambiguous if read in light of the specification. The clause in which this term appears states in full (with the term emphasized):

wherein at least one of said storage node contact hole and bit line contact hole includes a first contact hole made in a first inter-layer insulating film formed over said gate electrode and a second contact hole made in a second inter-layer insulating film formed over an electrically conductive layer embedded in said first contact hole up to a level higher than the gate electrode such as to be contacted with said electrically conductive layer.

Figure 1(b) depicts an embodiment encompassed by this claim; Figures 2(b), 3(b), 4(b), 5(b), 6(b), 7(b) and 8(b) and their accompanying text describe how the embodiment pictured in Figure 1(b) was created. First, a metal-oxide semiconductor field-effect transistor (MOSFET) is formed on a substrate, with a gate electrode 6 and source and drain regions 4a and 4b. See FIGS 1(b), 2(b). An inter-layer insulating film 13 (corresponding to the "first inter-layer insulating film" in the claim) is then laid on top of the MOSFET. See FIG 3(b). The inter-layer insulating film 13 is then etched to create a first storage node contact hole 14 and a first bit line contact hole 15 (corresponding to the "first contact hole" in the claim). See FIG 4(b). The contact holes are then filled with a heavily doped polycrystalline silicon film 16 (corresponding to the "electrically conductive layer" in the claim) up to a level higher than the gate electrode. See FIG 5(b). A storage node electrode 20, capacitor insulating film 21, plate electrode 22 and inter-layer insulating film 23 (corresponding to the "second inter-layer insulating film") are then laid on top of the polycrystalline silicon film 16. FIG 7(b). Finally, the inter-layer insulating film 23 is etched to create a bit line contact 24 (corresponding to the "second contact hole" in the claim). Accordingly, this embodiment makes clear that, as Toshiba argues, claim 1 teaches that the "second contact hole" is "contacted with said electrically conductive layer." The other embodiments in the specification appear to be mere variations on this first embodiment and also support this conclusion. See, e.g., '579 patent at 12:38-43. (Embodiment 6: "Provided on the MOSFET is an inter-layer insulating film 23 which in turn is opened with a contact hole. The polycrystalline silicon layer 16 as the embedded layer is formed as contacted with the n-type diffusion layers 4a and 4b through the contact hole opened in the inter-layer insulating film 23."). See also Allen Engineering Corp v Bartell Industries, Inc, 299 F3d 1336, 1348 (Fed Cir 2002) ("[O]ne skilled in the art would understand the bounds of the claim when read in light of the specification.").

Turning to the construction of the "term," Hynix contends that "embedded" should receive its purported ordinary meaning of "fixed firmly." Hynix Br at 8-9. Toshiba instead contends that "embedded" has a special meaning in this patent because the specification "describes two [different] methods of filling the contact hole with electrically conductive material -- by an 'embedding' process or by a 'selective growth' process." Toshiba Br at 8. See, e.g., '579 patent at 8:1-5 ("Although the polycrystalline silicon film has been embedded all over and then again subjected to the etching in the foregoing steps, the polycrystalline or monocrystalline silicon film may be selectively grown only in the contact cavities as an example."); id at 14:32-35 ("Although the polycrystalline silicon film has been embedded all over and then again subjected to the etching in
the foregoing steps, the polycrystalline or monocrystalline silicon film may be selectively grown only in the contact cavities as an example."); id at 16:64-68 (same).

Nonetheless, the court cannot conclude that these embodiments necessarily indicate that the patentees intended to "act[ ] as [their] own lexicographer[s] and clearly set forth a definition of the disputed claim." CCS Fitness, 288 F3d at 1366. Indeed, dependent claim 7 suggests that the term "embedded" encompasses both "embedding" and "selective growth" processes. That claim states:

7. A semiconductor memory device as set forth in any of claims 1 to 5, wherein said electrically conductive layer is grown to have a thickness larger than a depth of said first contact hole and to be expanded over a top of the first contact hole.

The patentees' use of the word "grown" here suggests that the "embedded" film in claim 1 could be deposited through a "selective growth" process. Hence, the court rejects Toshiba's construction.

The court also rejects Hynix's proposed substitution of "fixed firmly" for "embedded" given that the ordinary meaning of "embedded" is sufficiently clear and need not be redefined.

In sum, the court finds that the present term is not indefinite and declines to construe the term.

A. The Claims and Specification

SPI contends that the claims in the '285 Patent contain a common limitation. Both Claim 1 and Claim 6, the only independent claims in the patent, include a description of the material of the first strip as follows: "a first strip formed of a first electrically conductive material having a resistance, . . ., the first material being carbon." SPI argues that the only proper interpretation of this language is that the strip must be formed of carbon and nothing else. Stowe concedes that the claims should be construed to require the conductive material in the first strip to be carbon. However, Stowe contends that nothing in the claims or specification requires that the entire first strip be formed only of carbon.

In addition to the language in the claims themselves noted above, SPI points to language in the specification in support of its suggested construction. The specification describes the first strip as "preferably formed of a homogeneous, constant property material" and states "preferably, the strip is formed of carbon." SPI concludes that this language must mean that the strip is formed of carbon, and no other material.

Stowe responds that SPI is attempting to import the term "formed entirely of" into this claim and its specification. As Stowe points out, it did use the term "formed entirely of" in other portions of the specification which described embodiments of the invention that were not pursued with the patent office. For example, in describing an embodiment in Fig. 11 and Fig. 12 of the '285 Patent, the specification states: "The ink traces 43 and 45 are formed entirely of highly conductive material such as silver." Ex. A 22:17-18. The specification goes on to state: "According to one embodiment, the ink traces 47 and 49 may be formed entirely of force sensitive resistive material having a low saturation value relative to the anticipated nip load." Ex. A 22:37-40. Thus, the term "formed entirely of" was used in other portions of the specification, while only the term "formed of" was used in the specification for the pursued embodiment. Based on this distinction, it would be understood that there was no intent for the claim to include such a limitation.

With regard to its use of the term homogenous in the specification, Stowe asserts that it used that term to describe the conductive material alone, rather than the material of the entire strip. More importantly, however, Stowe contends that one of ordinary skill in the art would know that carbon inks, and thus carbon strips, must contain more than just carbon. First, Stowe attempts to introduce several excerpts from the book Polymer Thick Film, published in 1996 by Ken Gilleo in an attempt to help "the court understand the technology and how one of ordinary skill uses terms." The court finds, however, that these excerpts are inadmissible hearsay evidence in that Stowe has failed to present a witness to testify that a person skilled in the art would consider the text to be authoritative. See Fed. R. Evid. 803(18).
Stowe next points to the use of the term "carbon" by Constantin Trantzas, an employee of CIR Systems, Inc., the supplier of the accused E-Nip device for SPI. Stowe notes that in certain pre-litigation documents, Trantzas, who invented certain of the components of the E-Nip system, referred to one of the strips used in the E-Nip device as the "carbon" strip and the material used on the strip as the "carbon mixture." SPI responds that Stowe is improperly attempting to refer to the alleged infringing product to define what Stowe meant in its claims. See SRI Int'l v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1118 (Fed. Cir. 1985) (en banc). The court disagrees. The reference to "carbon" by Trantzas simply indicates how someone skilled in the art, as Trantzas presumably is, would describe such a strip made of carbon as well as other materials. Though Trantzas does refer to the material as a "carbon mixture," he also describes it as only "carbon," though the strip in the E-Nip device is composed primarily of other materials in addition to a smaller percentage of carbon. Such a reference supports Stowe's argument that a person of ordinary skill in the art would understand that the first strip described in the '285 Patent would include carbon as the key conductive material, but that it could contain other materials as well.

With regard to the claim and specification, Stowe finally contends that SPI's proposed claim construction would not cover the preferred embodiments in the '285 Patent. The Federal Circuit has stated that a "claim construction that does not encompass a disclosed embodiment is . . . rarely, if ever, correct." Medrad, Inc. v. MRI Devices Corp., 401 F.3d 1313, 1320 (Fed. Cir. 2005) (quoting Johns Hopkins Univ. v. CellPro, 152 F.3d 1342, 1355 (Fed. Cir. 1998)). Stowe asserts that carbon itself is not an ink and is not able to adhere to a plastic surface. Thus, because it must have some adhesive to stick to the strips of the invention, carbon in its pure form could not be used. In addition, carbon itself is not flexible and would break if used on the sensor alone, even if it could adhere to the plastic. Therefore, Stowe concludes that a claim construction that required a sensor made only of carbon would not cover the preferred embodiment.

SPI contends that, even if Stowe's assertions are true, the patent would be invalid for failure to disclose the best mode, that is, the use of carbon plus an adhesive. See 35 U.S.C. § 112, P1 ("The specification . . . shall set forth the best mode contemplated by the inventor of carrying out his invention."). In the '285 Patent, however, the claims appear to be identifying only the crucial conductive material and those skilled in the art would understand that an adhesive is needed to get that material, carbon, to stick to the strip. Thus, the adhesive would not necessarily be key to the invention or part of the best mode of its application, rather the key would be the use of carbon as the crucial conductive material.

B. Prosecution History

Along with the claims and the specification, a court may also properly consider the prosecution history of a patent in construing a claim. As previously described, Stowe's original patent application included a broader description of the first and second strips and failed to specify the materials of which the sensors would be composed. After the patent examiner rejected Stowe's patent claims based on the prior art, including the Goldman patent, Stowe amended its claims to specify the material for both strips. SPI contends that this amendment was made solely to distinguish Stowe's claims from the Goldman patent, which disclosed a mixed carbon material sensor that combined carbon with other materials. Though SPI acknowledges that Stowe was compelled to make an additional amendment related to the sensor width to obtain final approval, it points to the earlier amendment as well as Stowe's response in regard to the patent office's later action based on double patentability to support its contention that Stowe had narrowed its claims to include a sensor material for the first strip composed entirely of carbon.

Specifically, SPI points to the language of the amendment itself: "the first material being carbon." Ex. B at 220 (emphasis added). This language remains in the final claims of the '285 Patent. SPI also notes Stowe's attorney's statement during prosecution that "applicants submit that neither of these references can fairly suggest strips of the materials recited in amended Claim 1, i.e. that the first electrically conductive material is carbon and the second electrically conductive material is selected from the group consisting of silver and gold." Ex. B. at 217 (emphasis added). Finally, SPI cites Stowe's attorney's defense to the issue of double patentability: "All of the pending claims recite, inter alia, 'a first strip formed of a material selected from the group consisting of silver and gold.'" Ex. B at 258 (emphasis added). SPI contends that, throughout the prosecution history, Stowe took pains to describe the material as carbon and nothing else, both to distinguish its claims from those in the Goldman patent and from its own claims in the previous patent. Thus, SPI concludes that this history supports its proposed construction of the claims in the '285 Patent to include a first strip with a material of 100% carbon and forecloses any of Stowe's present assertions to the contrary.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
The court recognizes that, even if the narrowing amendments were not actually necessary to overcome the prior art, plaintiff would nevertheless remain bound by the narrower scope. See Springs Window Fashions LP v. Novo Indus., LP, 323 F.3d 989, 995 (Fed. Cir. 2003).

Stowe first responds that SPI has incorrectly read the prosecution history. Stowe admits that it added the specific materials to its claims to distinguish them from those of the Goldman patent. Stowe contends, however, that the distinction is not between pure carbon and a carbon-based material but between two strips composed of the same material, as in Goldman, and two strips composed of different materials with different conductivity, as in the '285 Patent. In Goldman, the specification describes two thin, flexible backing sheets or substrates, each of which is provided with a suitable conductive electrode pattern. U.S. Patent 5,821,433 at 2:44-48. That conductive pattern "may be silver deposited from a silver-based ink that may be screen-printed, for example, on the substrates." U.S. Patent 5,821,433 at 2:48-51. Then,

A layer of pressure sensitive resistive material 309, 409 is deposited over each of the conductive patterns 302, 402. The pressure sensitive resistive material may be a carbon molybdenum disulfide material in a polyester binder. Other pressure sensitive resistive materials and high temperature thermoplastic binders may be used as well.

U.S. Patent 5,821,433 at 2:56-61. Thus, Stowe contends that it amended its claims to state that the first material was composed of carbon and the second of silver or gold to distinguish from Goldman which described two conductive patterns where both are composed of silver and the layer of pressure sensitive resistive material in between is composed of a carbon-based material.

Stowe also asserts that its comments to the patent office in regard to the issue of double patentability did not state that the material at issue was entirely carbon. Instead, Stowe contends that it was noting that Moore's prior patent had failed to mention any materials, whereas the current claims did include a description of the materials.

The court finds Stowe's arguments compelling. First, the attorney's statement during prosecution, "the first electrically conductive material is carbon," simply seems to indicate that the conductive material in the first strip is carbon, not necessarily that the entire strip must be made of 100% carbon. Moreover, the patent examiner stated the following in comparing the proposed claims to the Goldman patent:

Also, since layers 302, 402 may be silver deposited from a silver-based ink and layers 309, 409 may be a carbon based material, the measuring area may be silver, carbon or any suitable conductive pattern of material thus the reference still stands.

With this language, the patent examiner rejected the application. The patent examiner may have failed to see the distinction raised by Stowe between the two strips formed of the same material in the Goldman patent and the two strips in the proposed invention which were formed of different conductive materials, i.e. carbon and either silver or gold. Regardless, the court believes that this language indicates that the patent examiner also failed to see a distinction between a material described as carbon based and one described simply as carbon.

In conclusion, the court finds that, as a matter of law, it cannot hold that SPI's proposed construction of the '285 Patent is supported by the intrinsic evidence. Instead, the intrinsic evidence, as well as the extrinsic evidence of Trantzas's use of the term "carbon," supports a construction of the '285 Patent wherein the conductive material in the first sensor is carbon. The language of the claims states the following: "a first strip formed of a first electrically conductive material having a resistance . . ., the first material being carbon." The "first material" refers to the first electrically conductive material, not to the entire first strip which may also include adhesives, fillers, or other materials, so long as they are not the primary conductive material.

Nevertheless, SPI's E-Nip sensor is composed of more than simply carbon and an adhesive. In fact, the sensor is composed of approximately 70% titanium dioxide in addition to either carbon or graphite. Constantin Trantzas has previously testified that titanium dioxide as well as graphite are the components that determine the resistivity of the resistive electrode in the E-Nip sensor. Thus, because titanium dioxide is not simply an adhesive, but acts in conjunction with the conductive carbon, SPI concludes that the accused infringing device does not infringe on the '285 Patent. Stowe responds, however, that the
titanium dioxide is used only to counter the conductive qualities of the carbon on the more resistive electrode. Thus, according to Stowe, the primary conductive material in the E-Nip sensor is still carbon, which would infringe upon the claims of the '285 Patent. Though the construction of the '285 Patent claims is a matter of law for the court, this dispute regarding literal infringement raises factual questions that are not appropriate on a motion for summary judgment. Furthermore, even if SPI is correct that there is no literal infringement based on its use of titanium dioxide in the E-Nip sensor, there could still be a claim for infringement under the doctrine of equivalents, unless it were deemed barred by prosecution estoppel.

The court notes that SPI has claimed that, because Stowe has not presented any specific evidence of literal infringement or infringement under the doctrine of equivalents, Stowe cannot meet its burden of demonstrating infringement and, in fact, has conceded the issue. The court does not believe that Stowe was required to present evidence of infringement under either theory in responding to SPI's motion for partial summary judgment. Such evidence would have been properly submitted had Stowe filed its own cross motion for partial summary judgment of infringement of the '285 Patent. Yet, Stowe did not file such a motion. SPI's motion for partial summary judgment of noninfringement was based solely on the theory that the material of the first strip should be construed to be carbon alone. Stowe has properly responded to that issue. To the extent that SPI briefly addressed the issue of whether carbon plus titanium dioxide is equivalent to carbon plus adhesive or filler, Stowe's response raises factual issues to be decided at a later time, as noted above. Therefore, Stowe remains free to pursue its claims of infringement under either doctrine.

IV. Whether Prosecution Estoppel Bars Stowe's Use of the Doctrine of Equivalents

If a claim is not literally infringed, there can still be liability under the doctrine of equivalents. Prosecution history estoppel may serve as a bar to use of the doctrine of equivalents, however, with regard to subject matter surrendered by the patentee during prosecution. See Cybor Corp. v. FAS Technics., Inc., 138 F.3d 1448, 1460 (Fed. Cir. 1998). In other words,

Prosecution history estoppel limits infringement by otherwise equivalent structures, by barring recapture by the patentee of scope that was surrendered in order to obtain allowance of the claims. Thus, by actions taken during patent prosecution the patentee can be estopped from reaching subject matter that otherwise meets the criteria of equivalency.

SPI contends that Stowe narrowed its claims during the prosecution history as described above, both in the amendment made to include the materials for the first and second strips and through the argument made by Stowe's attorney during the prosecution. SPI also asserts that the amendment was made to overcome the prior art. SPI finally argues that the materials used in the E-Nip sensor's resistive electrode, i.e. titanium dioxide and either carbon or graphite, were well known at the time of the prosecution and amendment and thus were plainly foreseeable at the time of the amendment. See Glaxo Wellcome, Inc. v. Impax Labs, Inc., 356 F.3d 1348, 1352 (Fed. Cir. 2004) (patentee's narrowing amendment bars foreseeable equivalents existing at the time of amendment). Thus, if the court had construed the material in the claims of the '285 Patent to be 100% carbon based upon Stowe's amendment and statements during prosecution of the patent, SPI's product could not be deemed infringing under the doctrine of equivalents, even if the change in its product is unimportant and insubstantial when compared to that described in the '285 Patent, so long as the material used is not 100% carbon.

For the reasons stated previously, however, the court has construed the material in the first strip described in the '285 Patent to be carbon plus some adhesive, filler or other material, so long as carbon is the primary conductive material. The court agrees that Stowe would be estopped by the prosecution history of the '285 Patent to claim that a product infringed under the doctrine of equivalents if carbon was not the primary conductive material in one strip or electrode of an allegedly infringing product. However, Stowe would not be barred from making such a claim with regard to a strip wherein carbon is the primary conductive material, even if it is not composed entirely of carbon.
reading of the public record." See Vitronics Corp., 90 F.3d at 1584. If it can, then the Court is not permitted to consider extrinsic evidence. If it cannot, then the Court may consider extrinsic evidence so long as it is not "used to vary claim terms from how they are defined, even implicitly, in the specification or file history." See id. at 1584-1585.

The Special Master discussed the intrinsic evidence in Section III(C)(1) of his December 14, 2009, R&R, and concluded that "the intrinsic evidence alone does not provide a compelling basis to conclude whether 'electrically connected' encompasses a connection created by means of electromagnetic induction." December 14, 2009, R&R at 19. 6 Accordingly, the Special Master proceeded to consider extrinsic evidence.

6 When quoting the Special Master's R&R throughout this Opinion and Order, the Court deletes all emphasis used by the Special Master unless otherwise noted.

In its first objection, Microsoft contends that it was reversible error for the Special Master to consider extrinsic evidence because the intrinsic evidence is unambiguous regarding the meaning of "electrically connected." According to Microsoft, "[t]he intrinsic evidence points to one conclusion. 'Electrically connected' . . . does not include connections through electromagnetic induction." Microsoft's Objections to December 14, 2009, R&R at 8 (docket entry 520).

In order to evaluate Microsoft's initial objection, it is necessary to set forth the reasoning underlying the Special Master's conclusion that "the intrinsic evidence alone does not provide a compelling basis to conclude whether 'electrically connected' encompasses a connection created by means of electromagnetic induction, as in an isolating transformer." December 14, 2009, R&R at 19.

The Special Master began his analysis by examining the language used in the patent, noting that

[w]ith the exception of the title of the invention, every disclosed connection that the patent describes as an "electrical connection" is a connection in the form of an electrically conductive wire or line, without any non-conductive gap as occurs in the case of a transformer (utilizing electromagnetic induction) or a capacitor. It is never used in the patent to describe or claim a connection that includes a non-conductive gap, such as exists in isolation transformers that function using electromagnetic induction.

Id. at 14 (footnote omitted). The Special Master is saying essentially two things. First, the term "electrically connected" is used consistently throughout the patent (except in the title of the invention) to describe the same kind of connection - a connection in the form of an electrically conductive wire or line. Second, the term "electrically connected" is never used to describe a connection utilizing electromagnetic induction.

In reaching this conclusion, the Special Master noted significant facts. First, the Special Master noted that "[a]sserted claim 39 used the phrase 'electrically connected' three times to describe the relationship between various claimed components," December 14, 2009, R&R at 8, and that "[i]n every one of th[ose] uses of the term, . . . the corresponding 'electrical connection' disclosed in the specification and drawings is by means of electrically conductive wire or line, with no disclosed gap as would exist if there were a capacitor or transformer interposed between the connected components." Id. at 9-10.

Second, the Special Master noted that "[t]he phrase ['electrically connected'] was apparently not used during the prosecution history of the '125 Patent." Id. at 9.

Third, the Special Master noted that "['e]lectrically connected" (or 'electrically connecting') is used just four times outside of the claims." Id. The first two times it is used outside of the claims is in the title of the invention, which appears twice in the patent.

In accordance with Pitney Bowes, supra, the Special Master correctly recognized that "the title of a patent is entitled to little if any weight in claim construction analysis," id. at 11, while at the same time noting that the context in which the title appears supports Hochstein's position that electromagnetic induction should be included within the scope of "electrically
connected." Ultimately, the Special Master concluded that "[i]n view of the Pitney Bowes holding, . . . the patent's title, though supporting Hochstein's arguments concerning claim construction, is entitled to limited weight in this claim construction analysis." Id. at 12-13.

With regard to the third "electrically connected" reference found outside of the claims, the Special Master concluded that there is "no indication in the specification or in Figures 2 and 3 that the connection described . . . is anything other than an electrically conductive wire or line." Id. at 13. The Special Master reached the same conclusion with regard to the fourth "electrically connected" reference found outside of the claims. Id.

Summarizing the intrinsic evidence as it relates to the use of the phrase "electrically connected" in the patent, the Special Master stated:

[w]ith the exception of the title of the invention, every disclosed connection that the patent describes as an "electrical connection" is a connection in the form of an electrically conductive wire or line, without any non-conductive gap as occurs in the case of a transformer (utilizing electromagnetic induction) or a capacitor. It is never used in the patent to describe or claim a connection that includes a non-conductive gap, such as exists in isolation transformers that function using electromagnetic induction.

Id. at 14 (footnote omitted).

Next, the Special Master proceeded to examine the language in the patent used to describe connections utilizing electromagnetic induction. The Special Master noted, "it is particularly significant to the present analysis to consider the terminology that the patent did use to describe [connections utilizing electromagnetic induction]" since "[t]his phenomenon is at the heart of the present claim construction controversy." December 14, 2009, R&R at 14 (emphasis retained). After closely examining the language used in the patent, the Special Master correctly noted that the specification and claims use all of the following words to describe the connections formed by electromagnetic induction: "couplers," "coupling," "connect," "connecting," and "directly connecting." Id. at 19. Accordingly, the Special Master wrote:

the pattern of using terminology other than "electrically connected" to describe the connection of the isolation transformers to associated elements, coupled with the use of the term only to describe direct and conductive connections, weighs against Hochstein's interpretation that "electrically connected" should encompass electromagnetic induction and isolation transformers.

Id. at 16.

Next, Special Master Grauer consider[ed] other portions of the patent where some form of 'connected' is used dozens of times to refer to connections via current-carrying conductors, without the associated 'electrically' qualifier." Id. In other words, the Special Master proceeded to examine how the term "connected" is used in the patent, either alone or with a qualifier other than "electrically." The Special Master noted that "connected" is used in the patent to describe the same type of connection that is described elsewhere in the patent as "electrically connected." Id. at 16-17. That is, "connected" is sometimes used to describe connections by an electrically conductive wire or line. And, as discussed above, "connected" is also used to describe connections formed by electromagnetic induction. Because "connected" is used in the patent to describe both electrically conductive and non-conductive connections, the Special Master concluded that "the patent is not consistent in its use of [the terms 'connected' and 'electrically connected'], there being some arbitrariness in the choice of terms both in the specification . . . and in claim 39 itself." Id. at 16-17. For this reason, the Special Master thought it necessary to consult extrinsic evidence to aid in the construction of the disputed term "electrically connected."

C. The Parties' Positions Regarding the Admissibility of Extrinsic Evidence

1. Microsoft's Position

In its first and second objections to the Special Master's December 14, 2009, R&R, Microsoft argues that the Special Master should not have considered extrinsic evidence; he should have concluded his analysis after finding that (1) "electrically connected" is used consistently, with the exception of the title of the invention, to describe a connection in the form of an electrically conductive line or wire, (2) "electrically connected" is never used to describe a connection utilizing
electromagnetic induction, and (3) other terms—and not the term "electrically connected"—are used to describe connections utilizing electromagnetic induction.

Microsoft faults the Special Master for allowing the patent's use of a broader term, "connected," to create an ambiguity with regard to the meaning of a narrower term, "electrically connected," when it claims the narrower term, "electrically connected," is used consistently throughout the patent to describe one type of connection (one by a electrically conductivewire or line) that does not involve electromagnetic induction:

The Special Master's stated reason for not resolving the controversy on the basis of the intrinsic evidence alone was his observation that a different term — "connected" — is used in the patent to describe both electrically conductive and non-conductive connections. But this is irrelevant as a matter of both law and logic: "electrically connected" is a subset of "connected." . . . Whenever the patent discussed "electrical connections," the Special Master found that "electrical connections" referred consistently to electrically conductive connections. The fact that the patent also generically refers to them as "connections" is in no way inconsistent, and certainly does not undercut the clear meaning of "electrically connected."

Microsoft's Objections to December 14, 2009, R&R at 3-4 (docket entry 520). In other words, Microsoft argues that it is not inconsistent, as the Special Master found, for the patentee to use a broad term ("connected") to describe two narrower terms (direct connections using a line or wire, and connections utilizing electromagnetic induction), both of which fall under the broader "connected" umbrella. Because, according to Microsoft, the Special Master's decision to consider extrinsic evidence "rests [solely] upon [this] non-existent inconsistency," Microsoft argues that extrinsic evidence—which is what led the Special Master to reach his recommended claim construction—is inadmissible.

2. Hochstein's Position

Hochstein concurs with the Special Master's analysis and conclusion regarding the admissibility of extrinsic evidence to aid in the construction of the disputed term "electrically connected." According to Hochstein, "the Special Master correctly recognized that the intrinsic evidence does not define electrically connected and does not address whether 'electrically connected' includes or excludes electromagnetic induction." Hochstein's Resp. to Microsoft's Objections to December 14, 2009, R&R at 1 (docket entry 522).

D. The Special Master's April 4, 2010, Supplement to the R&R of December 14, 2009

Special Master Grauer's supplement dated April 4, 2010, reaches the same conclusion as his December 14, 2009, R&R; that "electrically connected" should be construed to encompass connections via electromagnetic induction. 7 The April 4, 2010, Supplement addresses, inter alia, the FederalCircuit's 2001 decision in Bell Atlantic.

- - - - - - - - - - - - - Footnotes - - - - - - - - - - - - -

7 As noted supra, this conclusion is contrary to Special Master Grauer's Report and Recommendation of June 30, 2009, which recommended that electromagnetic induction be excluded from the scope of the term "electrically connected."

E. Bell Atlantic & Its Progeny

In Bell Atlantic, the Federal Circuit reviewed the trial court's decision to construe the disputed claim term "mode" narrowly, despite the fact that "[i]t may be true that the ordinary meaning of the word . . . supports a broader meaning." 262 F.3d at 1269. The court considered whether to alter the meaning of a disputed claim term that may have had a broader ordinary and accustomed meaning. Because "the patentee may act as his own lexicographer by using the specification to define terms either expressly or 'by implication,'" the court "look[ed] at the intrinsic evidence to determine whether the patentee ha[d] given the term an unconventional meaning." Id. An examination of the intrinsic evidence revealed that the disputed term was consistently used narrowly throughout the specification. Id. at 1272-1273. The prosecution history of the patent also supported a narrower definition of the disputed term. See id. at 1273-1274. Because the term was used consistently, the Federal Circuit found that "the patentees [had] defined the term 'mode' by implication, through the term's consistent use
throughout the . . . patent specification." Id. at 1273. The Federal Circuit reached this conclusion despite the fact that the ordinary and accustomed meaning of the disputed term may have been broader.

Several Federal Circuit cases have applied the Bell Atlantic holding, and each of them inform this Court's analysis. First, in Nystrom v. TREX Co., 424 F.3d 1136, 1142 (Fed. Cir. 2005), the parties disputed whether the claim term "board" should be construed broadly to include planks made from any material, or narrowly to include planks made from wood only. Both parties acknowledged that the latter (narrow) construction reflected the ordinary meaning of the term. Id. at 1145. Although there was no language expressly limiting the term "board" to planks made from wood, the Federal Circuit noted that "[t]he written description and prosecution history consistently use the term 'board' to refer to wood decking materials cut from a [wooden] log." Id. Thus, even though there was "no disavowal of [claim]scope in the written description or prosecution history," id., the Federal Circuit concluded that the presumption in favor of the term's ordinary meaning had not been rebutted and that the disputed term had been defined through its consistent narrow usage in the patent: "Broadening of the ordinary meaning of a term in the absence of support in the intrinsic record indicating that such a broad meaning was intended violates the principles articulated in Phillips." Id. at 1145-1146.

Second, as summarized by the Federal Circuit in Nystrom, the court had recently stated, in AquaTex Indus., Inc. v. Techniche Solutions, 419 F.3d 1374 (Fed. Cir. 2005):

[T]he patentee consistently used the term "fiberfill" throughout the written description to refer to synthetic materials. Although the written description indicated that the composition of the fiberfill was not known to be critical, we held that "the context of the specification 'makes clear that the patentee did not intend the term [fiberfill] to encompass' natural materials." In particular, we noted that "[n]one of the patents [incorporated by reference] discusses the possibility of using natural fibers as commercial fiberfill batting." Although there was no disavowal of natural materials, we held that the consistent use of the term "fiberfill" to refer to synthetic materials and the extrinsic definitions supporting that interpretation led to the conclusion that a person of ordinary skill in the art would have understood the term to be limited to synthetic materials.

Nystrom, 424 F.3d at 1145 (citations omitted).

Third, in Irdeto Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004), the parties disputed whether the term "group key" should be construed broadly to include all subscribers or narrowly to include only subsets of all subscribers. The court noted that the disputed term had no accepted meaning in the art and, relying on J.T. Eaton & Co., Inc. v. Atl. Paste & Glue Co., 106 F.3d 1563, 1570 (Fed. Cir. 1997), emphasized that "absent such an accepted meaning, we construe a claim term only as broadly as provided for by the patent itself." Irdeto Access, 383 F.3d at 1300. The court then examined the specification and determined that it "consistently uses the term 'group' to refer to a subset of all subscribers." Id. at 1301. Thus, the Federal Circuit construed the term narrowly in accordance with Bell Atlantic's holding that a claim term may be implicitly defined by consistent usage in the specification:

while the specification does not contain any statements of explicit disavowal or words of manifest exclusion, it repeatedly, consistently, and exclusively uses "group" to denote fewer than all subscribers, manifesting the patentee's clear intent to so limit the term.

Id. at 1303. See also id. at 1302 (discussing two additional Federal Circuit cases (Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898 (Fed. Cir. 2004), and Brookhill-Wilk 1, LLC. v. Intuitive Surgical, Inc., 334 F.3d 1294 (Fed. Cir. 2003)), both of which apply the Bell Atlantic holding).

F. The Special Master Improperly Considered Extrinsic Evidence

Both parties agree with the Special Master's determination that, excluding the title of the patent, "'electrically connected' is used in the specification and claims only to describe connections by means of electrically conductive wires." December 14, 2009, R&R at 18-19. The parties further agree that, excluding the title of the patent, the disputed term, "electrically connected," "is never used to describe a connection with an intervening gap, such as occurs in an isolating transformer that utilizes electromagnetic induction to couple two circuits across a gap." Id. Instead, other words—such as "connected" or "couple"—are used in the patent to describe connections through electromagnetic induction.
Microsoft argues that the Court should not consider extrinsic evidence in light of these undisputed conclusions because "electrically connected" is defined implicitly through its consistent, narrow usage throughout the patent. Hochstein, on the other hand, emphasizes the Special Master's determination, also undisputed, that "nothing in the patent . . . explicitly excludes electromagnetic induction from the scope of "electrically connected," or . . . requires a conclusion that it should be so excluded," December 14, 2009, R&R at 18, since the disputed term is not explicitly defined in the patent. However, under Bell Atlantic, a claim term may be implicitly defined through consistent use. Thus, the Special Master's conclusion, and Hochstein's argument in favor of it, do not honor the Bell Atlantic holding.

Hochstein also contends that the manner in which the disputed term is used in the title of the patent is inconsistent with how it is used consistently elsewhere, thereby precluding a finding that the claim term is consistently used "throughout the entire patent specification." See Bell Atlantic, 262 F.3d at 1271. But that contention just emphasizes the reality that "electrically connected" is used consistently throughout the patent to describe a connection by an electrically conductive wire or line; it is not used more broadly to describe other kinds of connections, such as a connection by means of electromagnetic induction.

The title of the patent, which appears twice in the specification, reads: "Apparatus and Method for Electrically Connecting Remotely Located Video Games." In his December 14, 2009, R&R, the Special Master analyzed in great detail whether the manner in which "electrically connecting" is used in the title is inconsistent with the way it is used elsewhere. See December 14, 2009, R&R at 10-13. Although the Special Master ultimately accorded "limited weight" to the title in accordance with Pitney Bowes, he nevertheless found probate merit to Hochstein's argument that a claim construction that excludes electromagnetic induction from the scope of "electrically connected" would render the title of the patent inaccurate:

In my opinion, the context provided by the Background and Summary sections of the '125 Patent specification strongly favors Hochstein's interpretation of the patent's title. The second sentence of the Background section states that "the subject invention relates to the coordination of a computer game from more than one location" (1:9-11, emphasis added).

The Background goes on to say that:

A problem with the modern video games is that virtually all video games are designed to be played locally . . . . in order for a player to compete with someone other than the computer, that person must leave the home or have someone come into the game-owner's home.

1: 21-30. The Summary of the Invention section concludes:

The advantage of the subject invention is the ability of two or more players playing the same video game to compete with each other without using the same physical video game which alleviates the necessity of proximity of the players.

2:39-43 (emphasis added). In my opinion, that context removes any doubt as to the meaning of the title: it states that the disclosed invention concerns video games that are remote from each other but nevertheless "electrically connected" to each other. That was the solution to the stated problem that the inventors were trying to solve, and therefore the fact and method of connection of the games was a logical subject for the title of their patent.

December 14, 2009, R&R at 11. Simply put, the Special Master is concluding that the proper reading is that it was never intended that connection from one player to the other distant player would be through a long electrical cord that could extend miles, or even hundreds of miles.

Microsoft disagrees with the Special Master's analysis and conclusion regarding the title, and argues that "the title of the '125 patent is consistent with the patentees' use of 'electrically connected' in the rest of the patent exclusively to describe electrically conductive connections." Microsoft reasons, as the Special Master noted in his December 14, 2009, R&R, "that the title does not specifically say that the local and remote video games are "electrically connected" to each other; the title could mean, as in the first sentence of the Abstract, that each of the two games is "electrically connected" to the video game communicator." December 14, 2009, R&R at 10-11 (underlined emphasis retained).

The Special Master considered Microsoft's argument and rejected it, stating that "the context provided by the Background
and Summary sections of the '125 Patent specification strongly favors Hochstein's interpretation of the patent's title."

Id. at 11. Thus, the Special Master concluded that the manner in which "electrically connecting" is used in the title is likely inconsistent with how the term is used elsewhere in the patent. According to the Special Master and Hochstein, the disputed term is used more broadly in the title to describe a connection that does not involve an electrically conductive line or wire; elsewhere, it is used narrowly to describe only connections by means of electrically conductive lines or wires. Thus, Hochstein and the Special Master believe that the manner in which the disputed term is used in the title of the patent "destroys" the otherwise consistent manner in which the patentee used the term elsewhere in the patent.

The Court finds there to be genuine ambiguity with regard to how the disputed term is used in the title; the way in which the title is worded is ambiguous because it does not state to what the "remotely located video games" are being electrically connected. Given the entire context of the patent, the Special Master asserts that remotely located video games are being connected to each other, a connection that would involve electromagnetic induction. Microsoft argues that the title could mean that each remotely located game is "electrically connected" to the video game communicator, a connection that would not involve electromagnetic induction. It is impossible to conclude with ample certainty which interpretation was intended. Any effort to do so is, in the end, a guess. The title is simply ambiguous in its use of the disputed term.

In addition, the Court must reiterate that the Federal Circuit has explicitly stated that the title is "near[ly] irrelevan[tl] to claim construction and that it is "only aware of one case from [the Federal Circuit] in which the patent title was accorded any significance whatsoever in a claim construction." See Pitney Bowes, 182 F.3d at 1312. Based on the Court's reading of Pitney Bowes, it is improper to place any reliance on the title of the patent in this claim construction analysis. This Court ascribes no weight to the title in this claim construction analysis due to both its vagueness in its use of the disputed term, and in its near irrelevancy pursuant to Pitney Bowes. 8

8 In his April 4, 2010, Supplement to the December 14, 2009, R&R, the Special Master writes that he is "inclined to give [the title] a little more weight than [he] earlier stated [in his December 14, 2009, R&R]." April 4, 2010, Supplement to R&R of December 14, 2009, at 3. The Court rejects this approach to claim construction as inconsistent with the clearly established authority in Pitney Bowes.

In the end, the Court agrees with Microsoft that the '125 patent always uses the term "electrically connected" to describe electrically conductive connections that lack any inductive element interrupting the conductive connection. The '125 patent used different terms when it intends to include inductive connections.

Microsoft's Objections to April 4, 2010, Supplement to R&R of December 14, 2009, at 6 (docket entry 526). Stated differently,

when the patentees intended to permit the use of electromagnetic induction, they dropped the limiting modifier "electrically" and used different and broader terms - "connected" and couples" - to convey that different and broader meaning. That consistent usage in the claims and specification defines "electrically connected,"and none of the extrinsic evidence and arguments cited by the Special Master, even if they could properly be considered (and they cannot), can override that intrinsic evidence.

Id. at 1-2.

Once the Special Master made the correct and undisputed findings that the patentee (1) consistently used the term "electrically connected" to describe only electrically conductive connections, (2) never used the term "electrically connected" to describe connections utilizing electromagnetic induction, and (3) consistently used terms other than "electrically connected" to describe connections utilizing electromagnetic induction, the Court finds that he should have concluded his analysis utilizing intrinsic evidence alone. The Special Master erred when he proceeded to analyze how the broader term "connected" is used in the patent without the limiting modifier "electrically." It was this erroneous step that led
the Special Master to his conclusion that "the intrinsic evidence alone does not provide a compelling basis to conclude whether 'electrically connected' encompasses a connection created by means of electromagnetic induction." December 14, 2009, R&R at 19. In turn, it was the extrinsic evidencethat ultimately led the Special Master to his final claim construction recommendation. The Court believes that the Special Master's decision to continue his extrinsic analysis led him to reach an erroneous result. See Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002).

Hochstein points out that "Bell Atlantic is about 'redefining' a claim term to have an 'unconventional meaning' different from the term's ordinary meaning." Hochstein's Resp. to Microsoft's Objections to April 4, 2010, Supplement to R&R of December 14, 2009, at 5 (docket entry 527). This is a correct statement. It is also correct, as Hochstein asserts, that this case does not involve such a scenario. However, Bell Atlantic does not apply only to situations where a court is considering a deviation from the ordinary meaning of a claim term. The reach of Bell Atlantic is wider; it applies whenever a claim term, though not explicitly defined, is used "throughout the entire patent specification, in a manner consistent with only a single meaning." Bell Atlantic, 262 F.3d at 1271. For example, in Irdeto Access, discussed above, the Federal Circuit held that the disputed claim term, which had no ordinary and accepted meaning in the art, was implicitly defined through consistent use in accordance with Bell Atlantic. See 383 F.3d at 1301. Here, the patentee consistently used "electrically connected" only in a narrow sense to describe electrically conductive connections. Moreover, the patentee consistently used other terms, such as "connected" (without the "electrically" qualifier) and "coupled" to describe connections over a gap in a transformer. Pursuant to Bell Atlantic, the Court finds that this consistent usage (and non-usage) of the disputed term evinces the patentee's "clear intention[]" to exclude electromagnetic induction from the scope of "electrically connected." See Teleflex, 299 F.3d at 1327. See also Harmon, Patents & the Federal Circuit, supra, at § 6.2, pp. 352-353 ("[a]bsent . . . an accepted meaning, a claim term is construed only as broadly as provided for by the patent itself").

For all these reasons, the Court finds that the disputed term, "electrically connected," has been implicitly defined by consistent use in the patent pursuant to Bell Atlantic and its progeny, such that resort to extrinsic evidence is unnecessary. Notwithstanding this determination, however, the Court has closely examined the extrinsic evidence of record in this case and, for the reasons discussed in the next section of this Opinion and Order, finds all of it unhelpful. Thus, even if the Court were inclined to consider such evidence, the outcome of this claim construction dispute would remain unchanged.

G. The Extrinsic Evidence

As discussed above,

extrinsic evidence consists of all evidence external to the patent and prosecution history, including expert and inventor testimony, dictionaries, and learned treatises. This evidence may be helpful to explain scientific principles, the meaning of technical terms, and terms of art that appear in the patent and prosecution history.

Markman, 52 F.3d at 980. Moreover,

the use of extrinsic evidence as to the true meaning of the claim language is discretionary with the trial court. It can accept evidence it finds helpful, and reject other evidence as unhelpful, and resolve disputes en route to pronouncing the meaning of the claim language as a matter of law based on the patent documents themselves.

Harmon, Patents & the Federal Circuit, supra, at § 6.1, pp. 331-332 (footnote omitted). However, reliance on [extrinsic] evidence is unnecessary, and indeed improper, when the disputed terms can be understood from a careful reading of the public record. Nor may [extrinsic evidence] be used to vary claim terms from how they are defined, even implicitly, in the specification or file history.

Vitronics Corp., 90 F.3d at 1584-1585 (citations omitted). See also Markman, 52 F.3d at 981 ("[e]xtrinsic evidence is to be used for the court's understanding of the patent, not for the purpose of varying or contradicting the terms of the claims"); Harmon, Patents & the Federal Circuit, supra, at § 6.4, p. 386 ("[i]f the meaning of the claim limitations is apparent from the totality of the intrinsic evidence, then the claim has been construed").

In his R&R dated December 14, 2009, and his supplement dated April 4, 2010, the Special Master considered three types of purported extrinsic evidence: (1) the testimony of the parties' experts, Dr. Macedonia for Microsoft, and Dr. Matheson for
Hochstein; (2) dictionary definitions of the disputed term; and (3) the litigation conduct of Microsoft.

The Court addresses each, in turn.

1. Expert Testimony

Not surprisingly, Dr. Matheson, on behalf of Hochstein, and Dr. Macedonia, on behalf of Microsoft, disagree with regard to the ultimate question here - whether a person of ordinary skill in the art, at the time of the invention, would consider a connection by means of electromagnetic induction to be an "electrical connection." The Special Master urges the Court to give "enhanced credibility" and "additional weight" to the testimony of Microsoft's expert, Dr. Macedonia, elicited before the present dispute involving electromagnetic induction arose:

   I find particularly illuminating the opinions that Microsoft's expert, Dr. Macedonia, expressed (or failed to express) before the focus shifted from waves in wireless controllers to electromagnetic induction in isolation transformers. Because of that timing, it is my opinion that those original positions carry enhanced credibility and are entitled to additional weight.

December 14, 2009, R&R at 21. Before the focus of the parties' attention shifted from wireless connections (radio waves) to electromagnetic induction, Microsoft urged the Court to adopt one of the following constructions of "electrically connected":

   1. "[A] connection that allows an electrical current to flow between the connected components." Docket entry 507-2, ¶ 38.
   2. "[C]onnection in a way that allows for the flow of electricity between the two things being connected." Docket entry 469, p. 8.

All three of these proposed constructions say the same thing - that an "electrical connection" must involve the flow of current/electricity between the two items being connected.

The Special Master concludes that these [proposed constructions] are admissions by Microsoft that the criterion [for "electrically connected"] is whether electricity flows between two connected elements, notwithstanding that there may be an interposed gap in the conductors, such as the internal gap in an isolation transformer or capacitor, wherein electrical signals (but not literally current) cross the gap by the phenomenon of electromagnetic induction or capacitance, respectively.

The Court disagrees with the Special Master and Hochstein, and finds that Microsoft has never conceded or admitted that electromagnetic induction falls within the ambit of "electrically connected." It is true that, by offering the proposed constructions above, Microsoft admitted that an "electrical connection" is one that allows for current/electricity to flow between the two things being connected. However, the problem with the position of the Special Master and Hochstein is that Microsoft has never admitted that electricity or current flows between the gap in a transformer. In fact, Microsoft, through its expert, advances the exact opposite position:

   In the case of electromagnetic induction, there is no direct current path or electrically conductive connector across the related coils. Alternating current flowing in one coil can induce a current in the other, but no current flows between the coils and there is not an electrical connection.

Docket entry 488-2, ¶ 14 (emphasis added). Neither the Special Master nor Hochstein direct the Court's attention to anywhere in this record where Microsoft admitted that electricity or current flows between the gap in a transformer. 9 Thus, so far as the Court is aware, there is simply no support for the latter clause of the Special Master's statement (beginning with "notwithstanding") that Microsoft, by offering the three constructions above, admitted that "the criterion [for
"electrically connected"] is whether electricity flows between two connected elements, notwithstanding that there may be an interposed gap in the conductors." April 4, 2010, Supplement to R&R of December 14, 2009, at 1-2 (emphasis added). True, Microsoft has admitted that "the criterion [for "electrically connected"] is whether electricity flows between two connected elements," but it has never admitted that electricity or current flows over the gap in a transformer. Because Microsoft has never admitted that current/electricity flows over the gap in a transformer, the proffered three constructions, above, which were urged by Microsoft before the present dispute involving electromagnetic induction arose, do not constitute an "admission" that electromagnetic induction falls within the ambit of "electrically connected."

9 Microsoft has, however, admitted that current flows over the gap in a capacitor. See docket entry 516, October 23, 2009, Hr'g Tr. at 25, wherein Mr. Cederoth, on behalf of Microsoft, stated: "In electrical engineering, current flows through a capacitor." According to the Special Master, "isolation transformers . . . should be considered as providing no less of an electrical connection than the connection provided by a capacitor." December 14, 2009, R&R at 30. The Special Master explains this conclusion at pages 27-30 of his December 14, 2009, R&R and page 4, paragraph 10 of his April 4, 2010, Supplement. Hochstein agrees with it; Microsoft objects and urges the Court to disregard the Special Master's analysis regarding capacitors because the argument that transformers and capacitors are analogous was raised for the first time at oral argument on October 23, 2009, with no support in the record. Microsoft maintains that transformers and capacitors are materially different because, while they both have a gap, current flows over the gap in the case of a capacitor but not in the case of a transformer.

The Court agrees with Microsoft that the Special Master's analysis regarding capacitors should be disregarded because the record is undeveloped with regard to whether capacitors and transformers are analogous in the sense asserted by the Special Master and Hochstein.

2. Dictionary Definitions

At the onset, the Court notes, as did the Special Master in his December 14, 2009, R&R, that the Federal Circuit has cautioned against placing "heavy reliance" on dictionary definitions:

The main problem with elevating the dictionary to such prominence is that it focuses the inquiry on the abstract meaning of words rather than on the meaning of claim terms within the context of the patent. Properly viewed, the "ordinary meaning" of a claim term is its meaning to the ordinary artisan after reading the entire patent. Yet heavy reliance on the dictionary divorced from the intrinsic evidence risks transforming the meaning of the claim term to the artisan into the meaning of the term in the abstract, out of its particular context, which is the specification. The patent system is based on the proposition that claims cover only the invented subject matter. As the Supreme Court has stated, "[i]t seems to us that nothing can be more just and fair, both to the patentee and the public, than that the former should understand, and correctly describe, just what he has invented, and for what he claims a patent." Merrill v. Yeomans, 94 U.S. [568, 573-74, 24 L. Ed. 235, 1877 Dec. Comm'r Pat. 279 (1876)]. The use of a dictionary definition can conflict with that directive because the patent applicant did not create the dictionary to describe the invention. Thus, there may be a disconnect between the patentee's responsibility to describe and claim his invention, and the dictionary editors' objective of aggregating all possible definitions for particular words.

Phillips, 415 F.3d at 1321.

Regarding the "battle of the dictionaries," the Special Master concludes, after a thorough discussion in his December 14, 2009, R&R, that "it is inappropriate to place any reliance on [the dictionary definitions proffered by the parties] for claim construction guidance." December 14, 2009, R&R at 27.

Microsoft offers the following dictionary definition of "electrically connected":

Joined through a conducting path or a capacitor, as distinguished from being joined merely through electromagnetic induction. Modern Dictionary of Electronics, Robert F. Graf, 7th ed. (1999), at p. 235.
Everyone agrees that this definition, by its express terms, excludes electromagnetic induction from the scope of "electrically connected."

Hochstein, on the other hand, stresses Phillips' de-emphasis on dictionary definitions, but offers the following definition, which it contends contradicts Microsoft's proffered definition:

Connected via direct path, such as through a wire, resistance, inductance or capacitance. Illustrated Dictionary of Electronics, 5th ed. (1990).

Hochstein argues that its definition, unlike Microsoft's definition, encompasses electromagnetic induction within the meaning of "electrically connected." The Special Master, however, rejected Hochstein's argument, concluding that "there is no contradiction" between the two definitions since:

the two dictionaries are talking about different arrangements of elements. The first dictionary [Microsoft's] is technically accurate as to the absence of a direct path for electricity between paired inductors via electromagnetic induction (as in an isolation transformer); the second dictionary is more generic and does not specifically address electromagnetic induction or isolation transformers. However, the two dictionaries are in agreement to the extent they associate "electrically connected" with a "conducting path" or a "direct path."

December 14, 2009, R&R at 26-27 (underlined emphasis retained). Hochstein objects to the Special Master's conclusion that the two definitions are not inconsistent. Hochstein argues that the Special Master "misread" its proffered definition because he "apparently . . . read [the first two commas in the definition] as serial commas, believing that the definition of 'electrically connected' was merely 'connected via direct path'" and that "'a wire, resistance, inductance or capacitance' are merely examples of direct paths." Hochstein's Resp. to Microsoft's Objections to December 14, 2009, R&R at 11 (docket entry 522). Thus, Hochstein's proffered definition of "electrically connected" is "[c]onnected via direct path, such as through a wire, resistance, inductance or capacitance." Illustrated Dictionary of Electronics, 5th ed. (1990). Hochstein argues that this dictionary definition should be read as follows:

- connected via direct path, such as through a wire
- connected via resistance,
- connected via inductance or
- connected via capacitance

The Court does not agree, and finds Hochstein's rewriting of the dictionary definition to be flawed. The Court reads the terms "wire," "resistance," and "inductance or capacitance" as examples of direct paths, not as separate connections. However, even if Hochstein's reading is the correct/intended one, the definition remains ambiguous with regard whether electromagnetic induction is encompassed within the meaning of "electrically connected" since, as the Special Master found, Hochstein's definition "is more generic and does not specifically address electromagnetic induction or isolation transformers." December 14, 2009, R&R at 26.

The Court agrees with the Special Master's conclusions regarding the "battle of the dictionaries" in this case:

Summarizing this battle of the dictionaries: Hochstein asserts that its dictionary definition broadly encompasses electromagnetic induction and isolation transformers within the definition of "electrically connected," and that such definition contradicts Microsoft's dictionary definition; Microsoft asserts that the two definitions do not contradict because Hochstein's only refers to single inductors or coils, while Microsoft's is limited to paired inductors or coils, as in a transformer. Thus, the two experts do not even agree on what is meant by Hochstein's proffered dictionary definition. On the present contested state of the record concerning dictionary definitions, and particularly in view of Phillips' de-emphasis of this form of extrinsic evidence, it is inappropriate to place any reliance on such definitions for claim construction guidance.

December 14, 2009, R&R at 27.
3. Litigation Conduct of Microsoft

The Special Master considered the litigation conduct of Microsoft - specifically, the timing of its claim construction arguments, as extrinsic evidence in this matter. The Special Master believes that Microsoft's failure to raise the present non-infringement defense for several years is strongly suggestive of the conclusion that "the ordinary artisan after reading the entire patent" would conclude that "electrically connected" does encompass connections that indirectly transmit and couple signals and electrical energy through . . . isolation transformers.

December 14, 2009, R&R at 24 (citation omitted). Because of its importance to this discussion, the Court sets forth the Special Master's discussion of Microsoft's litigation conduct:

According to Hochstein's present motion papers, Hochstein has for more than four years asserted that Microsoft's wired connections between the modem and microprocessor satisfied the "electrically connected" limitation of claim 39. In three cited expert reports and interrogatory answers spanning March, 2005 to March, 2009, Hochstein explicitly identified as the infringing structure the wired Ethernet cable connection between the microprocessor-containing Xbox/Xbox360 consoles and the modem, using excerpts from Microsoft's written instructions and diagrams. Throughout this period, Microsoft has not denied knowledge that its accused consoles had an isolation transformer between the console's Ethernet port and the microprocessor.

During this period, Microsoft's technical expert, Dr. Macedonia, filed ten expert reports. Hochstein asserts that Dr. Macedonia never, in any of those Reports, contended that Microsoft's wired modem-to-microprocessor connections were not "electrically connected" or that an isolation transformer or electromagnetic induction was not a form of "electrical connection." Dr. Macedonia's silence on this point until July 6, 2009 is particularly telling for two reasons.

• First, four of Dr. Macedonia's earlier Reports were issued after a March 27, 2009 Expert Report from Hochstein's technical expert, Dr. Matheson, spelled out that an isolation transformer "couples a signal by converting the signal from an electrical signal on one circuit into a magnetic signal, and then back into an electrical signal on a different circuit." Thus, although (1) Microsoft was fully aware of the presence of an isolation transformer in the accused products;(2) its own expert and others on its litigation team must have read Dr. Matheson's description of how such common devices work to indirectly couple two conductors separated by a gap; and (3) the presence of such gap is undeniably inconsistent with Microsoft's originally proposed claim construction ("a connection that is in the form of electrically conductive connectors"), Microsoft failed for four years to raise this new-found non-infringement defense.

• Second, in the same Report where Dr. Macedonia's attention was focused on "electrically connected" as his basis for concluding (1) that wireless controllers are not covered by claim 39 because they use radio frequency waves to transmit data (Dkt. 507-2, ¶ 38), and (2) that wireless modem-to-microprocessor connections similarly did not infringe, he did not assert that "electrically connected" also did not cover the wired modem-to-microprocessor accused products that included an isolation transformer in that connection, although they, too, would avoid infringement under Microsoft's proposed claim construction, namely, a "connection that is in the form of electrically conductive connectors."

Dr. Macedonia holds three degrees in electrical engineering, telecommunications and computer science. It is not credible that he and the entire Microsoft litigation team, after repeatedly focusing on the meaning of "electrically connected" and other non-infringement defenses based on that claim limitation, would overlook this newly raised one if, as they now allege, the "the ordinary artisan after reading the entire patent" would conclude that "electrically connected" does not encompass a connection including an isolation transformer located inside the Xbox/Xbox360 consoles. In fact, on June 22, 2009, the day before Hochstein requested, and the Court ordered, a claim construction of "electrically connected," Microsoft asserted that it "is not a complicated term." So uncomplicated and apparent did Microsoft think this task that its original claim construction brief on this term asserted this to be one of those cases where "the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than application of the widely accepted meaning of commonly understood words." Yet it was not apparent to Dr. Macedonia and the Microsoft litigation team until July 6, 2009.
The history and context of Microsoft's positions on the construction of "electrically connected" are strongly suggestive of the conclusion that "the ordinary artisan after reading the entire patent" would conclude that "electrically connected" does encompass connections that indirectly transmit or couple signals and electrical energy through capacitors and isolation transformers, these components being commonly used in equipment of the type disclosed in the '125 Patent. Indeed, even Dr. Macedonia and the Microsoft litigation team, who undoubtedly had been repeatedly scrutinizing and dissecting the relevant language of this patent throughout this litigation, seem to have so concluded during this four-year period. It is not plausible that "the ordinary artisan" would have undertaken the highly sophisticated analysis of indirect connection or coupling versus direct connection that underlies Microsoft's new-found positions on this issue.

December 14, 2009, R&R at 21-24 (citations and footnotes omitted).

Microsoft objects to this entire discussion by the Special Master "as irrelevant and not proper extrinsic evidence at all." Microsoft's Objectionsto December 14, 2009, R&R at 15 (docket entry 520). As stated by Microsoft,

this is not a situation where an expert asserted one position and then reversed himself. Rather, . . . Dr. Macedonia did not say anything one way or the other. What an expert did not say is not evidence. The Special Master improperly relied on Dr. Macedonia's and Microsoft's

seeming "failure" as being "strongly suggestive of the conclusion that the ordinary artisan after reading the entire patent would conclude that "electrically connected" does encompass connections that indirectly transmit or couple signals and electrical energy through capacitors and isolation transformers."

Id. at 16. Microsoft continues:

the Special Master relied on this "silence," to in effect, declare, sua sponte, that Microsoft somehow waived its right to benefit from the Special Master's original claim construction simply because Microsoft's earlier expert reports were silent on that issue. The Special Master cites no authority for the novel proposition that a defendant's failure to articulate a particular claim construction argument to support a non-infringement defense at an earlier stage in the litigation can be taken as evidence, indeed, conclusive evidence, that the position is incorrect.

Id. at 17.

The Federal Circuit has stated that

extrinsic evidence consists of all evidence external to the patent and prosecution history, including expert and inventor testimony, dictionaries, and learned treatises.

Markman, 52 F.3d at 980.

True, the three forms of extrinsic evidence listed by the Markman court (testimony, dictionaries, and treatises) do not constitute an exhaustive list of allowable extrinsic evidence. However, neither the Special Master nor Hochstein cite any legal authority that would permit the Court to consider a party's litigation conduct—namely, a party's silence regarding a potential defense that it had no affirmative duty to raise previously—as extrinsic evidence against that party in a claim construction analysis. Subsequently, in Phillips, the Federal Circuit elaborated, that where the

claim term as understood by persons of skill in the art is often not immediately apparent, and because patentees frequently use terms idiosyncratically, the court looks to "those sources available to the public that show what a person of skill in the art would have understood disputed claim language to mean." Those sources include "the words of the claims themselves, the remainder of the specification, the prosecution history, and extrinsic evidence concerning relevant scientific principles, the meaning of technical terms, and the state of the art."

415 F.3d at 1314 (citations omitted). This list does not include litigation conduct.
The Court is unaware of any court that has considered a party's silence in this regard as evidence, nor does Harmon, in his treatise, mention litigation conduct in his discussion of allowable extrinsic evidence. See Harmon, Patents & the Federal Circuit, supra, at § 6.4, pp. 385-394 (discussing allowable extrinsic evidence). This is not a contracts case where the legal maxim "silence is acceptance," might apply. See Restatement (Second) of Contracts § 69 (1981).

Microsoft's failure to raise the present non-infringement defense earlier is not proper extrinsic evidence. The Court sustains Microsoft's third objection regarding its litigation conduct.

III. SUMMARY

The evidence in this case consists of intrinsic evidence, and extrinsic evidence in the form of expert testimony, dictionary definitions, and, purportedly, Microsoft's litigation conduct.

A. Intrinsic Evidence

With regard to the intrinsic evidence, the disputed term "electrically connected" is used seven times in the patent. In five of the seven uses, the term is used consistently in a narrow manner to describe a specific type of connection - one by an electrically conductive wire or line.

The two remaining uses of the term appear in the title of the patent, "Apparatus and Method for Electrically Connecting Remotely Located Video Games." Hochstein argues that the disputed term is used in the title to describe a connection utilizing electromagnetic induction, and therefore the title's use of the term is inconsistent with how the term is used elsewhere. Microsoft, on the other hand, argues that the title is not relevant to the definition, but in any event the term is not used in the title to describe a connection by means of electromagnetic induction; rather, the manner in which the term is used in the title is fully consistent with how it is used elsewhere. The Special Master "strongly favors" Hochstein's position, but concludes:

my own experience as a patent examiner and practitioner is that relatively little attention is directed to the title by the inventor, his attorney or the patent examiner. In my opinion, the subtlety of the technical question here (which will become more apparent as this analysis proceeds), and its probable insignificance to the examiner's evaluation of the patentability of the claims, make it unlikely that a busy patent examiner would have even noticed it, let alone be concerned about it. In view of the Pitney Bowes holding, I conclude that the patent's title, though supporting Hochstein's arguments concerning claim construction, is entitled to limited weight in this claim construction analysis, particularly as it concerns "electromagnetic induction."

In his April 4, 2010, Supplement to the December 14, 2009, R&R, the Special Master states that, "upon further reflection, [he is] inclined to give [the title] a little more weight." April 4, 2010, Supplement to December 14, 2009, R&R at 3. The Court is not so inclined. The way in which the title is worded is ambiguous because it does not say to what the "remotely located video games" are being electrically connected. Given the context of the patent, the Special Master asserts that remotely located video games are being connected to each other, a connection that must involve electromagnetic induction. Microsoft argues the title could mean that each remotely located game is "electrically connected" to the video game communicator, a connection that would not involve electromagnetic induction. It is not possible to conclude with ample certainty which interpretation was intended. The title is ambiguous in its use of the disputed term. In any event, the Court is not permitted to rest its claim construction analysis on the title. See Pitney Bowes, 182 F.3d at 1312-1313.

The Court reiterates that it need not look to extrinsic evidence, and that intrinsic evidence supports its conclusion.

B. Extrinsic Evidence

The extrinsic evidence consists of (1) the parties' technical experts, Dr. Macedonia for Microsoft, and Dr. Matheson for Hochstein, (2) dictionary definitions, and (3) the litigation conduct of Microsoft. Taking these three sources in reverse order, the Court does not give any weight to the litigation conduct of Microsoft because no one has cited any authority whatsoever that permits the Court to consider this.
The dictionary definitions are minimally helpful and, in any event, are not entitled to great weight in accordance with Phillips. One definition (Microsoft's) unequivocally excludes electromagnetic induction from the scope of "electrically connected." It is not clear from the other definition—the one offered by Hochstein—whether electromagnetic induction is encompassed within the meaning of "electrically connected" since the definition "is more generic and does not specifically address electromagnetic induction or isolation transformers." December 14, 2009, R&R at 26.

With regard to expert testimony, the Special Master and Hochstein assert that Dr. Macedonia admitted, before the dispute shifted from radio waves to electromagnetic induction, that "electrically connected" encompasses electromagnetic induction. For the reasons stated above, the Court does not agree. In the end, the Court is left with the rival opinions of two experts who stay true to the litigation positions of their respective clients.

IV. CONCLUSION AND ORDER

For the reasons stated above, the Court construes the term "electrically connected" to exclude "electromagnetic induction" from its scope. This is because, as the Special Master correctly found in his December 14, 2009, R&R, the patent consistently uses the term "electrically connected" in a narrow sense to describe a specific type of connection that does not involve a gap, the patent never uses the term "electrically connected" to describe a connection by means of electromagnetic induction, and the patent consistently uses terms other than "electrically connected," such as "connected" (without the "electrically" qualifier) or "coupled," to describe connections over a gap in a transformer. Moreover, the extrinsic evidence in this case, even if admissible, does not aid the Court in its understanding of the disputed term.

6) "Electrically Connected"

MKS contends that the term "electrically connected" in Claim 19 means "coupled to the primary winding such that power is transferred by electrical current flow." (D.I. 103 at 32). Advanced Energy contends that the term cannot "be construed so as to include the use of an impedance matching network," that is, the term must be construed to mean directly electrically connected to the primary winding, without intervening components. (D.I. 110 at 22).

Again, with regard to the term "electrically connected," the parties' dispute centers on the absence or presence of an impedance matching network. As previously discussed, based on the patent specification and prosecution, the Court concludes that the invention was not intended to encompass an impedance matching network. (D.I. 94 N.J.L. 480, 111 A9 col. 2 ln. 22-26, A12 col. 7 ln. 49-60, A13 col. 10 ln. 19-21, A121-22, 124, A169-70). Accordingly, the Court construes "electrically connected" to mean directly coupled to the primary winding, not through an impedance matching network, such that power is transferred by electrical current flow.

1. electrically controlled birefringence type ('028 patent); electrically controlled birefringence effect ('412 patent) 6

5 415 F.3d 1303 (Fed. Cir. 2005).6 At oral argument the parties agreed that these two terms should be given the same construction. See D.I. 1053 at 76-78.

CEA's proposed construction is: "a category of liquid crystal cells distinguished from the helical nematic type (i.e., the twisted nematic type) in which the molecules have a homeotropic direction when no voltage is applied between the electrodes."
Samsung's proposed construction is: "a type of liquid crystal cell wherein the liquid crystal molecules have a homeotropic structure in the absence of an electric field, and when the cell is excited the molecules are all inclined in the same direction to form an angle with the homeotropy direction."

The court adopts CEA's proposed construction.

The parties agree that the proper construction of this term includes reference to the state when no voltage is applied. Samsung's proposed construction also includes reference to the cell state when voltage is applied.

Samsung argues that CEA's proposed construction improperly excludes TN devices. CEA counters that in a French patent application, from which the '028 patent claims priority date, and in a October 28, 1985 Prior Art Statement submitted to the United States Patent and Trademark Office ("PTO") in connection with the prosecution of the '028 patent, the patent applicants specifically distinguished the claimed inventions from twisted helical nematic type cells. CEA also argues that Samsung's proposed construction includes the unwarranted limitation that "when the cell is excited the molecules are all inclined in the same direction to form an angle with the homeotropy direction."

The court agrees with CEA that during the prosecution of the French priority application, and during the prosecution of the '028 patent before the PTO, the inventors disavowed coverage of TN cells. 7

--- Footnotes ---
--- End Footnotes ---

The specifications also make clear that the liquid crystal cells addressed in the patents-in-suit are not TN cells. The '028 patent specification describes differences between known liquid crystal cells of the electronically controlled birefringence (ECB) type and those of the helical nematic, or twisted nematic, (TN) type. 8 That specification, however, states: "[m]ore specifically, according to the invention, the cell is of the electrically controlled birefringence type . . . ." 9

--- Footnotes ---
8 '028 patent, 1:13-53.9 '028 patent, 2:24-25. Similarly, the '412 patent begins with the statement that "[t]he present invention relates to a liquid crystal cell using the electricity controlled birefringence effect and to processes for producing the cell and a negative optical anisotropy uniaxial medium usable therein." '412 patent, 9-12.
--- End Footnotes ---

Therefore, the court agrees with CEA that the patents-in-suit do not include helical nematic type cells. The court also agrees with CEA that the additional limitation proposed by Samsung that "when the cell is excited the molecules are all inclined in the same direction to form an angle with the homeotropy direction" improperly imports a limitation from preferred embodiments described in the specification. 10

--- Footnotes ---
10 See Comark Communications v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998) ("[w]hile . . . claims are to be interpreted in light of the specification and with a view to ascertaining the invention, it does not follow that limitations from the specification may be read into the claims.").
--- End Footnotes ---

Therefore, the court adopts CEA's proposed construction: "a category of liquid crystal cells distinguished from the helical nematic type (i.e., the twisted nematic type) in which the molecules have a homeotropic direction when no voltage is applied between the electrodes."
1. "Electrically Coupled"

Defendants ask me to construe "electrically coupled" as "directly, electrically connected currents or circuits where each current or circuit always has equal electrical potential (voltage)." Plaintiffs seek a broader construction of the terms to mean "electrically connected," but not requiring a direct electrical connection or the same voltage. I agree with plaintiffs.

a. Intrinsic Evidence

Since this combined term is not defined in the specification, both parties point to the context in which the term is used in the claim in support of their arguments. According to defendants, the plain language in claim 1 and 8 must be taken together and requires that "electrical coupling" occur only through direct wire-to-wire connections in which each electrical current always has an equal potential. Specifically, defendants point to the language in claim 1 which states

wherein the second cable assembly is adapted to electrically couple the[sic] at least one of the plurality of electronic devices to the end of the first cable assembly, and

wherein the first cable assembly is configured to be electrically coupled to each of the plurality of cable assemblies via the modular connector.

Defendants read both references to the term together, arguing it requires that the second cable assembly and first cable assembly electrically couple by way of the modular connector of the first cable assembly. Defendants further argue that claim 8 has a similar structure as claim 1, but adapted to the two groups of cable assemblies instead of the two individual cable assemblies claimed in claim 1. Therefore, the same interpretation should apply.

Plaintiffs' construction of claim 1 is grounded on a different reading of the same text. Plaintiffs point out that "the second cable assembly is adapted to electrically couple the electronic device to the end of the first cable assembly . . . ." Accordingly, "electrically couple" cannot be limited to a direct wire to wire connection, as the electronic device and the first cable assembly are connected by the second cable assembly and are not in direct contact as described in the claim. As set forth in the claim and the specification, the second cable assembly physically separates the electronic device from the first cable assembly; therefore the electronic device is not directly coupled to the first cable assembly. Next, plaintiffs read "and wherein the first cable assembly is configured to be electrically coupled to each of the plurality of cable assemblies via the modular connector" as stating that the first cable assembly is electrically coupled to the second cable assembly, despite not being in direct physical contact.

Overall, the claims at issue do not contain language limiting the term to require direct wire-to-wire coupling or equal voltage. The claim language, setting forth the structure of the invention, is not compatible with defendants' construction. Furthermore, the fact that this is a combined term of the words "electrically" in addition to "couple" weighs in favor of plaintiffs' construction. The use of the word "electrically" suggests the combined term here has a meaning different than just "coupled." See, e.g., Phillips, 415 F.3d at 1314 (the term "steel baffles . . . strongly implies that the term "baffles" does not inherently mean objects made of steel") (citing Mars, Inc. v. H. J. Heinz Co., 377 F.3d 1369, 1374 (Fed. Cir. 2004) (claim term "ingredients" construed in light of the use of the term "mixture" in the same claim phrase); Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1356 (Fed. Cir. 1999) (claim term "discharge rate" construed in light of the use of the same term in another limitation of the same claim). The claim language here provides "a firm basis for construing the term." Id. at 1314. The nature of the electrical connection is not restricted by the claim language to direct physical coupling or with respect to voltage.

Defendants invoke the remainder of the specification in support of their proposed construction. They argue the preferred embodiments, illustrated in figures 1 and 2 of the '994 patent, describe examples of electrical coupling with wire-to-wire electrical connections with equal voltage on both sides of the connection. The weight to be afforded this argument is limited, however. The Federal Circuit has "repeatedly warned against confining claims to [the preferred] embodiments." Id. at 1323 (citing Nazomi Communications, Inc. v. ARM Holdings, PLC, 403 F.3d 1364, 1369 (Fed. Cir. 2005); Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906-08 (Fed. Cir. 2004); Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002).
2. Electrically Distinct Contacts

Contacts along the edge of a printed circuit board in which the contacts on the first side of the printed circuit board and the contacts on the second side of the printed circuit board are not connected across the printed circuit board edge but may be electrically connected away from the edge.
1. "electrically interconnected to the conductive gel layer"

Claims 1, 12, and 17 of the ’919 Patent describe an insulated lead wire that is "electrically interconnected to the conductive gel layer." Philips asserts that this phrase should be construed as "in direct contact with the gel layer, without the use of a conductive contact layer, such as a homogeneous thinly deposited metallic layer, a conductive ink material, or a flexible metal mesh." Philips renews its disclaimer arguments set forth in Section II.D.1, above. Cardiac Science contends that the term should be defined as "configured to enable electrical connection to the gel layer."

The Court finds that "electrically interconnected to the conductive gel layer" merely means that one end of the insulated lead wire enables electrical connection to the gel layer.

electrically separated from

Claim 1 contains the term "electrically separated from." Lonestar contends that the term means "the 'second layer of conducting strips' is separated from 'the first layer of conducting strips' by an insulating layer." Nintendo contends "electrically separated from" means "not electrically connected." The parties' dispute regards the extent of separation required by "electrically separated from."

The Court construes "electrically separated from" as "the 'second layer of conducting strips' is separated from the 'first layer of conducting strips' by a nonconducting layer." Nintendo's construction suggests an absolute electrical separation that is inconsistent with claim 1 and the specification. "Electrically separated from" is used in the context of the surrounding claim 1 language of "said second layer of conducting strips overlying, electrically separated from and substantially congruent to said first layer of conducting strips." Col. 7:2-4. Thus, the claim refers to the second layer conducting strips and the first layer conducting strips as being electrically separated. Claim 1 then continues by stating:

said first layer of conducting strips alternately connected to a first node and a second node, said second layer of conducting strips alternately connected to said first node and said second node in such a manner that each first layer conducting strip and a second layer conducting strip overlying said first layer conducting strip are connected to different nodes.

Col. 7:6-13. The claim states that both the first layer and second layer must be connected to the first node and second node. As a result, some strips in each layer are electrically connected. The strips in the first layer connected to the first node are electrically connected to the strips in the second layer that are also connected to the first node. The same is true for the strips in the first and second layers connected to the second node. These connections are also disclosed in the specification. The specification states, "All the strips 24A of the first layer and the strips 26A of the second layer are connected to form a common node. Likewise, the strips 24B of the first layer and the strips 26B of the second are connected to form a second common node." Col. 2:40-44. Thus, Nintendo's proposal that "electrically separated from" means "not electrically connected" is untenable in light of claim 1 and the specification.

The Court's construction includes that a nonconducting layer separates the first and second layers. The specification discloses a distance "d" between the first and second layers. Col. 3:9-10; Figure 3. The specification also discloses an insulating silicon dioxide layer separating the first and second layers. See Col. 5:50-57. An insulating layer is understood by those of ordinary skill in the art to be nonconducting. This is consistent with the specification and claims. The specification and claims define the first and second layers as "conducting" and by implication the separation layer is nonconducting. In the context of the terminology of the specification and claims, "nonconducting" is more appropriate than Lonestar's proposed term "insulating," which may need its own construction. The ’725 patent discloses examples of nonconducting materials, for instance, silicon dioxide and lantanium-modified lead zirconate tantalate. Col. 5:50-53, 58-61. Any of these...
materials may be used to separate the first and second layers. See Col. 5:39-61 (describing the process of forming a first layer of conducting strips and then depositing a layer of material over the first layer of conducting strips). Thus, the specification supports that the first and second layers are separated by nonconducting materials. Accordingly, the Court construes "electrically separated from" as "the second layer of conducting strips is separated from the first layer of conducting strips by a nonconducting layer.

1511

J. "Electro-Optical Conversion"

For the following reasons, this court construes the claim term "electro-optical conversion" found in claims 6, 7, 14, and 15 of patent '772 to mean:

The conversion of an electrical signal into an optical signal and/or the conversion of an optical signal into an electrical signal.

The parties presented nearly identical constructions as to the term "electro-optical conversion." Fujitsu proposed that "electro-optical conversion" be construed as "the conversion of an electrical signal into an optical signal, and/or an optical signal into an electrical signal." (Dkt. No. 90, Ex. C at 8-9.) Tellabs proposed: "the conversion of an electrical (optical) signal into an optical (electrical) signal." (Dkt. No. 91, Ex. C at 3.) Both constructions construe electro-optical conversion to be the conversion of an optical signal to an electrical signal, or an electrical signal to an optical signal. Consequently, this claim is not in dispute and needs no further construction by the court.

1512

C. Construction of "Electrode"

Claim construction is a matter of law and is reviewed de novo on appeal. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc).

1.

During the district court proceedings, the parties vigorously disputed the proper construction of the claim term "electrode." The district court construed this term in its Markman hearing approximately four months before trial, as "any conductive surface, including a metal chamber wall or other surface, coupled to the plasma." Opinion, slip op. at 6 (quoting the Markman order). The district court then defined "coupled" to mean "electrically connected or connected by a conductive path, capacitively, inductively, or by any other means of transferring energy." Id. at 6 (quoting the Markman order).

TEA argues that an "electrode" must participate in generating the electrical field that forms the plasma, and not merely be coupled to the plasma. TEA also asserts that Tegal made, and relied upon, such a distinction in the prosecution history to secure allowance of the '223 patent. TEA further argues that the district court improperly relied on extrinsic evidence in construing "electrode."

Tegal defends the district court's construction. Tegal also asserts that "coupling to the plasma" and "generating the electric field" have the same general result that the electrodes "act together to create AC electric fields that charge the gas." Tegal argues, however, that characterizing an electrode as being coupled to the plasma is "more faithful to the specification and the claim language."

2.

We need not address each of the parties' claim construction arguments directly. Rather, we construe the term "electrode" according to the normal rules of claim construction.
First, we look to the claim language. Then we look to the rest of the intrinsic evidence, beginning with the specification and concluding with the prosecution history, if in evidence.

If the claim language is clear on its face, then our consideration of the rest of the intrinsic evidence is restricted to determining if a deviation from the clear language of the claims is specified. . . .

. . . . Relying on extrinsic evidence to construe a claim is proper only when the claim language remains genuinely ambiguous after consideration of the intrinsic evidence. . . .

. . . But extrinsic evidence may never be used for the purpose of varying or contradicting the terms in the claims.

Throughout the construction process, it is important to bear in mind that the viewing glass through which the claims are construed is that of a person skilled in the art.

Looking first to the claims, we observe that the term "electrode" is used throughout the claims, particularly claims 1 and 7, and is used in a broad sense. It is also clear that "electrode" is a term of art susceptible to various meanings, and so we go to the specification, as indeed the parties direct us, to determine the scope of this term.

The specification also supports a broad construction, focusing primarily on the fact that electrodes are coupled to an electric potential or source. The specification introduces the term "electrode" in the summary section by merely describing the electric potential or the electrical, or electromagnetic, source to which a given electrode is "coupled." n6 '223 patent, col. 1, ll. 50-55 ("One of the electrodes is held at ground while the second is selectively coupled to a high frequency AC source and the third is selectively coupled to a low frequency AC source."). The specification then states that electric fields are established between the electrodes. Id. at col. 1, ll. 55-57.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n6 Regarding the term "coupled," we note that the parties do not dispute the district court's construction, and we accept it.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

A subsequent section of the specification, entitled Detailed Description of Preferred Embodiments, continues this focus on electric potential or source by noting that the electrodes must have "electrical isolation" between them. Id. at col. 2, l. 39. That section goes on to describe the electrodes of the preferred embodiment in terms of the electric potential or source to which they are coupled. Id. at col. 2, ll. 58-66 (stating that "a high frequency power supply 30 and a low frequency power supply 36 are coupled to the second and third electrodes" and "the top electrode 10 is coupled to ground"). The specification, therefore, broadly describes an "electrode," and imposes no limitations beyond its having an electric potential or source coupled to it, and the implicit requirement that it be a conductive surface so that electric fields can be established between electrodes.

Examining the prosecution history, we note that Tegal distinguished over the prior art by asserting that the '223 invention produced a single discharge among three electrodes. Tegal asserted, for example, that "there is nothing in [the cited prior art references] which would lead one of ordinary skill in the art to connect the AC sources to produce a single discharge[, that is, plasma,] from three electrodes." (Emphasis omitted). Accordingly, the word "electrode" must be read to reflect this position. However, the parties disagree as to how best to characterize this position. In essence, they debate whether "producing" the plasma "from three electrodes" requires that the three electrodes actually generate the plasma.

We conclude that the prosecution history is more accurately described as requiring the electrodes to be "coupled to the plasma," and not, as argued by TEA, as requiring the electrodes to generate the plasma. The inaccuracy of TEA's
characterization is revealed by the specification, which instructs us that a plasma is "generated by the high and/or low frequency electric fields established between the electrodes." '223 patent, col. 1, ll. 55-57. Thus, the electric fields, and not the electrodes, generate the plasma. However, it is undisputed that the electrodes will be coupled to the plasma due to the presence of ions, and a current, in the plasma.

In the prosecution history, Tegal also distinguished over the Cotton reference by stating that "the electrodes claimed in the present invention are not the same as those disclosed in Cotton," which Tegal described as being spiked electrodes. Accordingly, the term "electrode" must be construed so as not to cover a spiked electrode.

In sum, we construe an electrode as any conductive surface, including a metal chamber wall or other surface except a spike, coupled to the plasma, and having an electric potential or source coupled to it. Further, because claim 1 recites it, at least one of the electrodes must be "adapted for holding a workpiece." '223 Reexam. Cert., col. 1, ll. 36-37. Because the phrase "having an electric potential or source coupled to it" is duplicative of other limitations in the asserted claims, our construction diverges from the district court's only in explicitly excluding a spiked electrode.

E. "ELECTRODE"

Inverness disputes the breadth of the term "electrode" as it is used in the 268 patent. Inverness argues that the 268 patent does not disclose the use of carbon as a material for the reference electrode disclosed in the patent. Inverness Br., Addendum B, at 3-4. Specifically, Inverness avers that the specification merely teaches that the electrodes should be made from noble metals or metallized plastic. Id. at 4. Further, Inverness argues that prior art does not disclose the use of carbon as a reference electrode material for this type of chemical cell.

In contrast, Roche argues that there is no reason to vary the meaning of electrode from its ordinary meaning: "any piece of conductive material through which an electric current enters or leaves a medium such as a liquid solution." Roche's Reply Br. at 34. Roche avers that the 268 patent need not teach that which was well known in the art. Id. (citing Hybritech, Inc. v. Monoclonal Antibodies, Inc., 802 F.2d 1367, 1384 (Fed. Cir. 1986), cert. denied, 480 U.S. 947, 94 L. Ed. 2d 792, 107 S. Ct. 1606 (1987)). Specifically, the use of carbon electrodes in test strips was well known in the art prior to the 268 patented invention. Id. (citing Roche Reply App. Exh. 1, Exh. 313, C.R. Lowe, Biosensors: Concepts & Applications (University of Cambridge, U.K) (undated), at 27 & 34). See also Roche Resp. to Inverness' Surreply, at 16-17 (citing U.S. Patent No. 4,897,173, to Shiro Nankai et al., Jan. 30, 1990, at col. 7, ll. 50-53; col. 7, ll. 3-5 (the "Nankai patent")) (stating that the Nankai patent discloses in the claims and elsewhere a reference electrode made from carbon). Roche avers that U.S. Patent No. 4,897,173, to Shiro Nankai et al., Jan. 30, 1990 (the "Nankai patent"), discloses the use of carbon for a reference electrode in an electrochemical cell. The Nankai patent was listed as relevant prior art in the 268 patent. 268 Patent, at 2.

The Court finds that in the context of the 268 patent, electrode should be given its ordinary meaning: any piece of conductive material through which an electric current enters or leaves a medium such as a liquid solution. Starting with the language of the claims, there is nothing to suggest that the term "electrode" means anything extraordinary or requires special materials. See, e.g., id. col. 13, ll. 60-61; id. col. 14, ll. 62-63. The patent specification does state that the "disposable cells according to the present invention are preferably laminated layers of metallized plastic and nonconducting material. The metallized layers provide the working and reference electrodes . . . ." 268 Patent, col. 3, ll. 5-8. Further, the specification describes a process for metallizing the "polyimide Kapton" with silver-silver chloride for use as the reference electrode. Id. col. 5, ll. 52-67 to col. 6, ll. 10. The specification also teaches that "the reference electrode may also be of the type generally known as a 'pseudo' reference electrode which relies upon the large excess of the oxidizing species to establish a known potential at a noble metal electrode." Id. col. 6, ll. 11-15. But, none of the language in the patent suggests that these are the only materials that would work for the reference electrode. Moreover, the remaining descriptions of the reference electrode do not specify material. See id. col. 6, ll. 35-61.

As Roche suggests, the 268 patent need not teach what was well known at the time of the invention. Hybritech, 802 F.2d at 1384 (citing Lindemann Maschinenfabrik v. American Hoist & Derrick, 730 F.2d 1452, 1463 (Fed. Cir. 1984)). Claims 1 and 2 of the Nankai patent disclose:
1. A biosensor for electrochemically detecting concentration variations of a substrate in a liquid sample, comprising:

an insulating base;

an electrode system provided on said insulating base, said electrode system being primarily made of carbon and comprising, at least, a measuring electrode and a counter electrode . . .

* * *

2. A biosensor according to claim 1, wherein said electrode system includes the measuring electrode, the counter electrode and a reference electrode.

Nankai Patent, col. 6, ll. 46-53 to col. 7, ll. 3-5. These claims teach a reference electrode made from carbon used in a system designed to measure concentration electrochemically. There was no need for the 268 patent to teach carbon as a potential material for the reference electrode of its electrochemical cell; the Nankai patent had already taught it.

For these reasons, the Court finds that "electrode" in the context of the 268 patent has its ordinary meaning: any piece of conductive material through which an electric current enters or leaves a medium such as a liquid solution.

3. "electrode compartment"

Claim 1 of the '969 Patent describes an "electrode compartment." Philips asserts that this term should be defined as "a part of an enclosed space within the defibrillator case to hold the electrodes." Cardiac Science contends that the term "compartment" is commonly understood and need not be construed. Alternatively, Cardiac Science asserts that the term should be construed as "a defined space for containing electrodes."

The heart of the parties' dispute is whether the space of the compartment needs to be completely enclosed or not. Philips asserts that the defibrillator case lid 28 encloses the electrode compartment in the '969 Patent. ('969 Patent at c. 2, ll: 26-33.) However, Cardiac Science maintains that the space need not be enclosed. Specifically, Cardiac Science asserts that the electrode compartment is still referred to as a compartment even when the lid is open, thus demonstrating that Philips' construction is inappropriate. (Id. at c. 2, ll: 26-29.) The dictionary definition could support either party's construction. Merriam-Webster's defines "compartment" both as "a separate division or section" and "one of the parts into which an enclosed space is divided." Merriam-Webster's Collegiate Dictionary 252 (11th ed. 2003).

The Court finds that Philips' proposed construction is misguided. The "enclosed space" to which Philips refers, if anything, is that of the defibrillator case. Even following the dictionary definition of "compartment" that Philips advances, the electrode compartment would merely be a division of an enclosed space, that enclosed space being the defibrillator case. But the compartment itself need not be enclosed, as Cardiac Science is correct in asserting that the electrode compartment still remains a "compartment" even when the lid is open.

With these considerations in mind, the Court construes the term "electrode compartment" to mean "a section within the defibrillator case that contains the electrodes."

a. Construction of "electrode means"

The first term in dispute concerns the "electrode means" for connecting one of the capacitor plates to the circuit. The full claim limitation reads: "electrode means comprising a source/drain in said substrate contiguous with said doped region and electrically connecting said doped region of said MOS capacitor to the other of said busses." '830 at 6:32-35. Despite use of
the term of art "means," this limitation is not a means-plus-function limitation subject to interpretation under 35 U.S.C. section 112, P 6 because the language thereafter provides a sufficient substantive description of the electrode structure. Micro Chem. Inc. v. Great Plains Chem. Co., 194 F.3d 1250, 1257 (Fed. Cir. 1999) (the presumption that section 112, P 6 applies "collapses, however, if the claim itself recites sufficient structure, material, or acts to perform the claimed function").

The plain meaning of "source/drain" is not fully apparent from the claim itself, but its location and function is readily understood from the whole of the claim. The "source/drain" is understood to be embedded in the substrate. The "doped region," whose antecedent basis is found in element (b) of claim 1, likewise is embedded in the substrate, being formed in the substrate at a location beneath a gate electrode. The limitation that the source/drain is contiguous with the doped region introduces the notion that not only are they both within the substrate, but the two regions meet at an interface. Furthermore, this interface provides electrical communication between the two regions because the claim also requires that the doped region be electrically connected to one of the busses via the source/drain.

Claim 1 marks the only recitation of "source/drain" in the entire patent, but the phrase is readily understood to refer to, in the aggregate, the source and drain "regions" described in the specification. The terminology of source and drain is borrowed from transistor technology, and the analogy is further strengthened by the choice of a capacitor in the form of a "MOS capacitor" to illustrate the invention. The figures used to illustrate an embodiment of the invention show what would be the source, drain, channel, insulating oxide layer and gate of an MOS transistor, but used in the invention to function as a capacitor.

The analogy between the capacitor of the invention and a transistor, however, has its limits. In another embodiment, an additional region is embedded in the substrate that interconnects the source and drain regions-a feature that would render a transistor nonfunctional. This embodiment is said to offer the additional advantages of lowered resistance in the pathway between the lower capacitor plate and the bus, as well as alternate locations at which to form the connection to the bus. Thus, one skilled in the art would understand that the terms source and drain do not impart the limitations appurtenant to transistors, but instead loosely indicate the method of formation (doping), and the general location (within the substrate contacting a channel--here called the "doped region"), of these regions. The term "source/drain," coined specifically in claim 1, reflects the teaching of the specification that the otherwise distinct regions may be connected and function as one aggregate.

Based on the foregoing, the Court construed the phrase "electrode means comprising a source/drain" to mean a region or regions embedded in a semiconductor substrate that forms an interface with the lower capacitor plate, which is the doped region embedded in the substrate that lies beneath the gate electrode, and the region or regions electrically connect the lower plate to one of the busses.

C. '472 Claim 1: "delivery electrode means for discharging"

The third disputed phrase in Claim 1 identifies "delivery electrode means for discharging the stored energy into the heart of a wearer of the device." '472 Patent, col. 8, ll. 67-68. CPI asserts that 35 U.S.C. § 112 P 6 does not apply to "delivery electrode means for discharging," while St. Jude contends that the phrase is a means-plus-function statement and that the disclosed structure is "an electrode that is implanted in the atrium of the patient's heart." Def. Prop. Conc. of Law at 2.

The claim element is stated in means-plus-function form with "means for" language, so the presumption is that 35 U.S.C. § 112 P 6 applies. CPI argues that there is a basis for departing from the presumption in his instance because one skilled in the art would understand the term "delivery electrode" to connote sufficiently definite structure (i.e., an electrode) to perform the stated function. See, e.g., Personalized Media, 161 F.3d at 703-05 (holding that the term "digital detector" recited sufficient structure to avoid 35 U.S.C. § 112 P 6; claim did not use word "means"); MediaCom Corp. v. Rates Technology, Inc., 4 F. Supp. 2d 17, 27 (D. Mass. 1998) (holding that "switch means operatively connected to said first jack means for disconnecting said first telephone from said network" was not a 35 U.S.C. § 112 P 6 means-plus-function statement "because it describes the structure that supports the disconnecting function (i.e. a switch or switches).").

The court disagrees that the "delivery electrode means" element recites sufficient structural detail to overcome the
presumption that 35 U.S.C. § 112 P 6 controls. In cases where the Federal Circuit has departed from the presumption established by the use of "means for," the court has emphasized that the claim language provided detail beyond some minimal statement of structure. See, e.g., Environ Corp. v. Clestra Cleanroom, Inc., 209 F.3d 1360, 1365 (Fed. Cir. 2000) (finding that "second baffle means" rebuts the presumption that 35 U.S.C. § 112 P 6 applies because the term "baffle" itself imparted structure and because the claim gave further location and formational details); Rodime PLC v. Seagate Technology, Inc., 174 F.3d 1294, 1303-04 (Fed. Cir. 1999) ("The claim also recites the specific location and interconnection of each of these structural sub-elements. . . . This detailed recitation of structure for performing the moving function takes this claim element out of the scope of 35 U.S.C. § 112, P 6."); Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996) (finding that the claim language described definite structure as well as the location and extent of the structure).

Further, in Unidynamics Corp. v. Automatic Products Int'l, Ltd., the Federal Circuit adhered to the presumption established by use of the term "means" and found that the claim element "spring means tending to keep the door closed" invoked 35 U.S.C. § 112 P 6. 157 F.3d 1311, 1319 (Fed. Cir. 1998). The court distinguished Cole v. Kimberly-Clark on the basis that the claim in Cole had not only described definite structure but also described the location and extent of the structure. See id.

St. Jude's proposed construction, which requires the electrode to be implanted in the atrium of the patient's heart, is also faulty. The function to be performed -- "discharging the stored energy into the heart of a wearer of the device" -- is stated in terms broad enough to include both atrial and ventricular therapies. A limitation requiring the discharging end of the electrode to be implanted in the atrium would import structural detail of the disclosed devices beyond what is required to perform the recited function. See Chiuminatta Concrete Concepts, Inc. v. Cardinal Industries, Inc., 145 F.3d 1303, 1308 (Fed. Cir. 1998) (claim construction properly omitted details of the embodiment that defined structure unrelated to the recited function).

The use of an atrial catheter electrode is necessary to the disclosed embodiments, but not necessary to the function recited in the claim. The claim element is concerned more broadly with a means by which to transfer energy from the device to any point in the heart where the electrical therapy is to be delivered. See '472 Patent, col. 7, ll. 39-43 ("AND gate 82 switches the discharge switch 84 to its conductive state, thereby discharging the storage and discharge capacitor 78 through the heart 76 by way of a catheter 72 implanted in or about the heart, as in the right atrium 74.").

The court intends to define "delivery electrode means" as "structure identical or equivalent to a catheter-type electrode extending from the implanted device to the heart, such that the point of discharge is located at the point where the electrical therapy is to be delivered."

The element "delivery electrodes for discharging said stored energy into the heart of the wearer" in Claim 18 recites another structural element that must be included in the implanted "electronic package." As was the case for the term "delivery electrode means" in Claim 1, St. Jude contends that the "delivery electrodes" element in Claim 18 is a means-plus-function element and that the specification limits the scope of the claim to electrodes implanted in the atrium.

Although the phrase in Claim 18 omits the word "means," the element is otherwise not different from the "delivery electrode means" element in Claim 1. The phrase in Claim 18 also identifies a function, and it provides no more illumination than the parallel element of Claim 1. The court sees no valid basis for finding that "delivery electrode means" discloses less structure than the phrase "delivery electrodes." The court finds that the element is subject to 35 U.S.C. § 112 P 6 and intends to define "delivery electrodes" as "structure identical or equivalent to a catheter-type electrode extending from the implanted device.
to the heart, such that the point of discharge is located at the point where the electrical therapy is to be delivered."

D. "electronic access"

Plaintiff, citing The Computer Glossary 129 (9th Ed. 2001) and the Dictionary of Computer and Internet Words at page 1, argues that the term "electronic access" should be construed as "the ability to gain entry to or use a computer or other devices." (Dkt. 86 at Ex. 1, p. 2). Plaintiff also relies on the Shames declaration. n5 Defendants have not proposed an alternate construction.

n5 Shames opines that "[a] Skilled Person would understand that the term 'electronic access' means 'the ability to gain entry to or use a computer or other devices' in the '229 patent." (Dkt. 73 at p.9).

The plain language of the claim provides that browser-based subscribers have electronic access to a home page via a modem and the ISP. ('229 patent, col. 5, ll. 57-59). The Court finds that Plaintiff's use of the phrase "or other devices" unnecessarily expands the scope of the plain language of the claim itself. The claim only requires a computer for access to the billing system. Accordingly, the Court finds that a person skilled in the art would understand the phrase "electronic access" as used in Claim 1 to be "the ability to gain entry to or use a computer."

As an initial matter, we find that construction of the preamble is necessary. The preamble describes the components of "an electronic auction system". The components are used in the steps that comprise the "electronic auctioning process." The entire claim must be read as a whole.

TERM # 1: "electronic auction system" - Defendants reiterate the temporal limitation argument that they lost on summary judgment. We need not address it again. This term means: "The equipment and procedure used to sell fixed income financial instruments to the highest bidder using computers."  

TERM # 9: "an electronic auctioning process for auctioning fixed income financial instruments" - Defendants' proposed construction is an admitted restatement of the argument they lost on summary judgment. We will not revisit that issue. Based on our earlier constructions, this phrase means: "a process for selling fixed income financial instruments to the highest bidder using computers."

3. "Electronic Chip"

The district court provided the jury with the following construction of "electronic chip" (emphasis added):

"Chip" is not used in whatever technical sense it may have; here, it means the same thing as an electrical component, whether it is a complex integrated circuit of several subparts or a single resistor. A resistor itself is made of two leads, case,
and resistant core, at a minimum, making it a packaged electronic component.

Although we do not agree with the district court's construction, for it appears from the definition given to the jury that the district court was confusing a "packaged electronic component" (i.e., the claimed invention as a whole) with an "electronic chip" (i.e., an element of the claimed invention), this aspect does not appear to have been material to the result, and any error appears to have been harmless.

II. Interpretation of the Term "Electronic Circuit"

The parties vigorously disagree as to whether the relevant claim language is written in means-plus-function format. Claim 1 of the 855 Patent is representative of a disputed claim in which the term "electronic circuit" appears. That claim provides in part:

A window covering with actuator, comprising: . . . an electronic circuit electrically connected to the control signal generator and the battery for processing the control signal to cause the battery to energize the motor to move the rod.

Finally, claims 1, 71, 83, and 97 of the 855 Patent and claims 1, 22, 31, 35, and 42 of the 480 Patent identify the physical location of the electronic circuit as "electrically connected to the control signal generator and the battery." Claim 1 of the 958 Patent indicates that the electronic circuit is electrically connected to the light sensor and the battery. Language identifying physical location suggests that a patentee intended to recite a structural element. See Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996). While claims 18 and 28 of the 480 Patent do not indicate the physical location of the electronic circuit, the Court is persuaded for the reasons above that the language of these two claims is not written in means-plus-function format.

Accordingly, the Court finds that the term "electronic circuit" does not invoke 35 U.S.C. § 112, P 6. Furthermore, the Court finds that a person of ordinary skill in the art of electronic circuits would understand the term "electronic circuit" to mean "an arrangement of interconnected electronic components that can perform specific functions upon application of proper voltages and signals." 2

Footnotes

2 Hunter Douglas argues that the term "electronic circuit" does not connote sufficiently definite structure because it is a generic term that refers to a multitude of structures. The test, however, is not whether a claim term connotes a precise physical structure. On the contrary, 35 U.S.C. § 112, P 6 is inapplicable even where the claim term denotes a variety of structures to one knowledgeable in the art. See Personalized Media Communications, 161 F.3d at 705.
B. A Microprocessor Is a Type of Electronic Circuit

The parties disagree over whether a microprocessor is an example of an electronic circuit as that term is used in the disputed claims. Hunter Douglas appears to agree that, in general, a microprocessor is a type of electronic circuit. But it argues that Harmonic Design is not entitled to a broad claim scope because the specifications and the prosecution history of the patents at issue teach "a very narrow solution to the problem of saving battery power" that is at odds with the use of microprocessors. See Def.’s Construction Brief, at 20.

Harmonic Design used the term "non-logical CMOS component" in dependent claim 18 of U.S. Patent No. 5,444,339, an older patent related to the patents at issue here. To overcome an obviousness rejection to that particular claim by the U.S. Patent Office, Harmonic Design had distinguished the term "non-logical CMOS component" from a microprocessor taught by the prior art. Harmonic Design argued that a microprocessor, unlike a non-logical CMOS component, consumes a relatively large amount of power. Because a stated object of the patents at issue here is to provide a window covering device that "consumes relatively little power," Hunter Douglas argues that the Court should interpret the term "electronic circuit" to exclude microprocessors.

Harmonic Design limited its comments to the U.S. Patent Office regarding microprocessors to a single, dependent claim. Harmonic Design did not argue that the broad term "electronic circuit" does not include microprocessors. Moreover, no claim in the patents at issue refer to a non-logical CMOS component. Finally, none of the disputed claims appear to require battery-conserving features. This fact is significant since other claims appear to provide for battery-conserving features. See, e.g., 855 Patent, claims 14, 99; 480 Patent, claims 40, 43. For the above reasons, it appears that Harmonic Design never intended to exclude microprocessors from the scope of term "electronic circuit."

The ultimate issue, therefore, is whether the term "electronic circuit" includes microprocessors. As mentioned above, Hunter Douglas apparently agrees that it does. In any event, the Court notes that one of ordinary skill in the art of electronic circuits would understand that a microprocessor is a type of electronic circuit. The term "microprocessor" is defined as "an integrated circuit that contains the logic elements for manipulating data and for making decisions." IEEE Standard Dictionary, p. 653. And the term "integrated circuit" is defined as a "combination of connected circuit elements (such as transistors, diodes, resistors, and capacitors) inseparably associated on or within a continuous substrate." IEEE Standard Dictionary, p. 536. It follows from these definitions that a microprocessor is a type of electronic circuit. See also Decl. of Lawrence J. Kamm, P 12.

For the above reasons, the Court finds that the term "electronic circuit" includes microprocessors.

E. "electronic commerce" or "electronic commerce transaction"

The magistrate judge rejected the parties' suggestions that the terms "electronic commerce" and "electronic commerce transaction" should have separate definitions, finding that "they should be construed applying a single definition[.]" First Report at 4. The magistrate judge recommended that "electronic commerce" and "electronic commerce transaction" should be construed as "a sequence of one or more related electronic transmissions that facilitate the purchase of and payment for goods and services between an originator and a recipient." Id. at 4, 11. No objections have been filed with respect to the magistrate judge's proposed construction. After careful review of the magistrate judge's findings and conclusions, record, legal briefing, and applicable law, the court determines that the magistrate judge's proposed construction of "electronic commerce" and "electronic commerce transaction" in patent '878 is correct, and it is hereby accepted as the court's construction of "electronic commerce" and "electronic commerce transaction."

a. "electronic commerce"

Claims 1, 7, 11, and 14 refer to computers and systems for conducting and coordinating "electronic commerce." Microsoft argues that "electronic commerce" should be limited to the "purchase and download" of electronic data over an electronic network. This interpretation is based entirely on one description in the patent specification of buying selling software over the internet, this being known as "digital commerce." '124 Patent, 1:30-37; 1:21-25.

NCI correctly responds that this definition is not in the part of the specification that describes the invention, but rather is part of a preamble describing the prior art. Instead, NCI proposes a construction that includes any commercial activity conducted by means of computer through a network.

The Court adopts NCI's interpretation. Microsoft's interpretation would not only be contrary to the ordinary meaning of the phrase, it would also improperly import a limitation from the specification. Electronic commerce is commercial activity - including, for example, licensing and purchasing transactions - conducted over an electronic network, such as the Internet. This interpretation is consistent with the ordinary meaning of the phrase and is supported by the specification. '124 Patent, 1:45-51, 4:23-27, 5:62-64, 15: 40-43, 24: 38-28:2.

1526

15. "Electronic Communications Network"

The plaintiff argues that this term does not need further construction. In the alternative, the plaintiff proposes "a network in which data or information is communicated electronically." The defendant proposes "a system of electronic circuits, electronic components, electronic devices, electronic equipment, computers, transmission channels, and related sources which are interconnected together to exchange information."

After considering the parties' positions, the court concludes that this term does not have a technical definition and no construction is necessary.

F. "electronic display means" / "electronic display"

The final limitation of claim 1 reads, "electronic display means for displaying information, by the teacher to the students." The defendants contend that "electronic display means" is a means plus function term; the term's function is "displaying information by the teacher to the students" and its corresponding structure is "a liquid crystal display (LCD), a video projector, a student terminal display, a television, a television projector, a monochrome display, and their equivalents." In contrast, the plaintiff argues that "electronic display" should be construed, and this term is not a means plus function term. Because this term is commonly understood, Better Education believes that "electronic display" requires no construction.

When the word "means" is used in a claim term, there is a presumption that § 112, ¶ 6 applies. Personalized Media
4. "Electronic element for suppressing noise"

The parties dispute the meaning of the terms "electronic element" and "suppressing" as they are used in the phrase "electronic element for suppressing noise." These terms appear in claims 1, 2, and 4 of the ’641 patent as follows:

1. A modular jack to be mounted on a circuit board, said modular jack comprising:

   a printed board containing an electronic element for suppressing noise:

   a contactor for contacting with a plug, said contactor being electrically connected with the electronic element by a wire on the printed board;

   a terminal for contacting with the circuit board, said terminal being electrically connected with the electronic element by a wire on the printed board; and

   An insulating housing for encasing the printed board.

2. A modular jack as claimed in claim 1, wherein the noise suppressing electronic element is an array of common mode choke coils.

4. A modular jack as claimed in claim 1, wherein the noise suppressing electronic element is a chip capacitor.

a. "Electronic element"

Murata argues that "electronic element" should be construed simply as "an electronic component." Murata's Opening Brief, at 25. Bel Fuse argues that "electronic element" should be limited to "an electronic component (not including wound toroidal cores) such as a chip-type element." Bel Fuse's Responsive Brief, at 18. To support this limitation, Bel Fuse argues that one of the objects of the invention of the '641 Patent is to make the jack "compact," and if wound toroidal cores are used as the electronic element for suppressing noise, the jack cannot be compact. Bel Fuse also argues that since the specification discloses only embodiments that contain chip-type elements (an array of common mode choke coils, a chip inductor, and a chip capacitor), wound toroidal cores are not considered part of the invention.

In the background of the invention, the '641 Patent describes U.S. Patent No. 5,015,204 ("the '204 Patent") as prior art. '641 Patent, col. 1, 11. 33-56. The '204 Patent discloses a modular jack which contains a common-mode choke coil. See Ex. 3 to Bel Fuse's Responsive Brief. One end of the wire wound on the coil is the contactor which contacts with the plug, and the other end acts as a lead to connect with a printed board external to the modular jack. The '641 Patent states that the design of the '204 Patent has the following disadvantages: (1) since the contactor, terminal and coil are a single unit, they must be plated together which can result in unnecessary plating of the coil; (2) additional common mode choke coils are needed to increase the number of signal circuits, resulting in the jack not being compact; and (3) the pitch among the terminals is more than the 1.02 mm pitch of an ordinary circuit board, requiring a newly designed circuit board. '641 Patent, col. 1, ll. 33-56. The '641 Patent teaches that it has several advantages when compared to the prior art: (1) it is compact and economical; (2) the pitch among terminals can be set to the ordinary pitch of 1.02 mm or another value; (3) the contactor and terminal can
be plated separately and with different metals; and (4) a change in wire patterns on the printed board can accommodate an increase in the number of signal circuits. Id. at col. 1, 1.59-col. 2, 1.21.

Murata argues that these advantages are realized by the insertion of the printed board, rather than the elimination of wound toroidal cores. The court agrees. While the specification of the '641 Patent criticizes the configuration of the '204 Patent, that configuration is different from the disclosure of the '641 patent, not merely because the '204 Patent teaches use of a wound core but more importantly because it does not teach the inclusion of a printed board within the modular jack.

Additionally, there is no reason to limit the scope of "electronic element" to the embodiments disclosed in the '641 Patent. The '641 Patent discloses three preferred embodiments, each using a different electronic element for suppressing noise. The first embodiment teaches use of a common mode choke coil array. '641 Patent, col. 3, 11. 15-22. This array is placed on a base plate of ceramic material, thus making it a chip type element. Id. at col. 3, 11. 15-19. The second embodiment teaches a chip inductor, and the third embodiment teaches a chip capacitor. Id. at col. 4,11. 20-22, 35-37. The three disclosed embodiments teach the specific electronic elements for suppressing noise that are claimed in dependent claims 2 (array of common mode choke coils), 3 (chip inductor), and 4 (chip capacitor). Therefore, the electronic element for suppressing noise of independent claim 1 must be broader than merely those three examples. Phillips, 415 F.3d at 1315 ("[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim.") (citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004)). However, the application of this maxim to this case does not support Murata's construction because it does not necessarily follow that claim 1 must be broad enough to include all electronic elements for suppressing noise. For example, claim 1 would be broader than dependent claims 2, 3, and 4 if claim 1 included all chip type elements beyond the three claimed in the dependent claims.

That being said, there is nothing in the specification or description of the prior art to indicate that the "electronic element" is limited to chip type elements or excludes wound toroidal cores. While the specification suggests that chip-type elements might be preferred, as discussed above, the specification speaks inclusively of other embodiments:

Although the present invention has been described in conjunction with the embodiments above, it is to be noted that various changes and modifications are apparent to those who are skilled in the art. Such changes and modification are to be understood as included within the scope of the present invention defined by the appended claims. . . . [T]he method of providing an electronic element such as the common mode choke coil array 20, the chip inductors 40, the chip capacitors 50 or the like for the printed board 30, 41 and 51 . . . may be determined arbitrarily.

Additionally, even if using wound cores would make the modular jack somewhat less compact than using other noise suppressing elements, the other objects of the invention could still be satisfied, such as allowing the pitch among the terminals to be set to the ordinary pitch of 1.02 mm or another value and allowing the contactor and terminal to be plated separately and with different metals. Phillips, 415 F.3d at 1327 ("We have held that '[t]he fact that a patent asserts that an invention achieves several objectives does not require that each of the claims be construed as limited to structures that are capable of achieving all of the objectives.'").

For these reasons, the court finds that one of ordinary skill in the art would not have interpreted "electronic element" as used in the claims of the '641 patent, in light of the specification, as excluding wound toroidal cores or being limited to chip-type elements. Thus, the court construes "electronic element" as an "electronic component."

1. "Electronic Element"

This term will be defined as "a device or thing that has (1) distinct characteristics related to electricity; together with (2) terminals at which it may be connected to other distinctly electrical devices or things in order to form a circuit (3) in which electrons move through devices called semiconductors."
The phrase "electronic element" appears in claim 1 of each of the four Patents: "A process for incorporating at least one electronic element in the manufacture of a plastic card . . . positioning said at least one electronic element in the absence of a non-electronic carrier directly between said first and second plastic core sheets to form a plastic core. . . ." '207 Patent, Claim 1; '155 Patent, Claim 1; '099 Patent, Claim 1; '367 Patent, Claim 1; '367 Patent, Claim 20. (See also Cohen Decl., Exh. L.)

It also appears in the following language of the '207 and '155 patents: "Positioning at least one electronic element in the absence of a non-electronic carrier directly between said first and second plastic core sheets. . . ." '207 Patent, claim 16 and '155 Patent, Claim 15. (See also Cohen Decl., Exh. L.) "Electronic element may take a wide variety of forms and perform a wide variety of functions. As shown . . . electronic element may be provided by a micro-chip and a circuit board antenna, a read/write micro-chip and a wire coil antenna, or any other suitable electronic element." '207 Patent, Specification, col. 3:46-52 (internal references omitted).

The specification of the '099 patent states that the "electronic element may take a wide variety of forms (microprocessor chip, circuit board, transponder, etc. )." (Pl. Br. at 15-16, quoting the '099 Patent at col. 4:35-37.)

Plaintiff urges that an "electronic element" in all of the patents in suit should be construed to mean "a device having distinct electrical characteristics and having terminals at which it may be connected to other elements to form a circuit that utilizes a semiconductor device." (Pl. Br. at 14).

Defendant urges that the term be construed to mean "A microchip and an antenna" in the '207 and '155 patents. Defendant further contends that the term is ambiguous in the context of the '099 and '367 patents, and thus cannot be defined at all.

Because this is the most hotly contested term, and its definition is critical to the construction of the patents, I will summarize the parties' arguments in some detail.

Definitional Sources:

Plain Meaning: Both parties place great reliance on dictionary definitions. Yet while using the same dictionary, they come up with two different "plain" meanings for this key phrase.

Plaintiff notes that the Dictionary of Scientific and Technical Terms (McGraw Hill 5th ed. 1994) ("McGraw Hill") does not contain a definition for the phrase "electronic element." But it does define both the word "electronic" and the word "element." 2 So Plaintiff puts those two definitions together and argues that the "definitions of the words that make up this term provide a clear ordinary meaning." (Pl. Br. at 14).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

- - - - - - - - End Footnotes- - - - - - - - - - - - - -

Plaintiff cites to the definition the word "element," as "component," which in turn is defined as, "any electric device . . . having distinct electrical characteristics and having terminals at which it may be connected to other components to form a circuit." Id. at 424. McGraw Hill defines "electronic" as "pertaining . . . to circuits . . . utilizing electron devices . . ." id. at 661, and defines "electron device" as "a device in which conduction is principally by electrons moving through a vacuum, gas, or semiconductor." Id. at 660. Observing that vacuum and gas conduction are irrelevant to the patents in suit, Plaintiff notes that McGraw Hill defines the term "semiconductor device" as an "electronic device in which the characteristic distinguishing electronic conduction takes place within a semiconductor." Id. at 1790. (McGraw Hill (6th ed. 2003), p. 1895 also defines "semiconductor" to mean, "A solid crystalline material whose electrical conductivity is intermediate between that of a conductor and an insulator, ranging from about 10^<5> mhos to 10^<7> mho per meter, and is usually strongly temperature-dependent." Plaintiff makes no reference to this definition.)

Defendants agree with Plaintiff's definition of the word "electronic" and also with Plaintiff's observation that the word "element" is synonymous with "component." But taking off from that, they observe that McGraw Hill -- while lacking a definition for the phrase "electronic element" -- does contain a definition for the phrase "electronic component." And it is
not the same as the combined definition of the words "electronic" and "element" crafted by Plaintiff. Rather, "electronic component" means, "A component which is able to amplify or control voltages or current without mechanical or other non-electrical command, or to switch currents or voltages without mechanical switches; examples include electron tubes, transistors, and other solid-state devices." McGraw Hill at 701. Defendant argues that this is superior to a definition that combines the separate definitions for the terms "electronic" and "component" because, inter alia, the term "component" as defined by McGraw Hill relates to the wrong field -- Electricity as opposed to Electronics -- and is therefore not apt. 3

--- Footnotes ---

3 I find it interesting that McGraw Hill contains no definition for the term "element" -- the admitted synonym for "component" (and the word Leighton actually uses in the patent) - that falls within the field of Electronics, either. Indeed, the "element-component" synonym that Defendant invokes in order to turn my attention to the phrase "electronic component" (which is not the phrase used in the patent) is found under the heading Electricity, not Electronics, which turns Defendant's argument back on itself!

--- End Footnotes ---

It is important to Defendant that I prefer the definition of "electronic component" over Plaintiff's combined definition of the separate terms "electronic" plus "component" because the definition of "electronic component" incorporates (and, according to Defendant, is limited to) "solid-state devices." That term is defined by McGraw Hill to mean, "A device, other than a conductor, which uses magnetic, electrical and other properties of solid materials, as opposed to vacuum or gaseous devices." The italicized language (which appears to limit "electronic components" to solid-state devices, such as micro-chips) is critical to Defendant for two reasons. First, Defendant argues that the only solid state device that satisfies the criteria of the patent is a micro-chip. Second, in the '099 and '367 patents, a bare antenna, which is a conductor (and thus not a solid state device), is embedded. It is that, Defendant argues, which renders the term "electronic element" indefinable in connection with those two patents.

The fact that both parties agree that the word "component" is synonymous with the patentee's chosen word "element," and that there is a definition for the phrase "electronic component" in McGraw Hill, might be thought to solve the definitional conundrum. Indeed, there is a certain Occam's Razor kind of elegance to Defendant's point.

However, there are two serious flaws with this argument. First, defining "electronic element" to exclude a conductor, like an antenna, reads a disclosed embodiment (in the case of the '099 patent, the preferred embodiment) out of the patent. Adopting that definition is thus inconsistent with the rules that claims are to be construed so as to (1) make sense and (2) be consistent with the specifications.

Second, as is so often the case with scientific and technical definitions, Defendant's proposed definition is tautological -- that is, it contains the very word ("component") that it purports to define. To be useful to a jury, the construction of the phrase "electronic component" cannot define the word "component" as "a component." 4 Since there is no clue within the definition of "electronic component" to what a "component" might be (other than a non-exhaustive list of examples, about which more in a moment), one could only craft a workable definition of "electronic component" by incorporating into it the definition of the undefined word -- "component" -- that appears elsewhere in the McGraw Hill Dictionary. Of course, Defendant does not want me to do that, because then we would end up with Plaintiff's definition (or its functional equivalent)!

--- Footnotes ---

4 Since Defendant insists (and Plaintiff agrees) that "component" is synonymous with "element," I could turn to yet another dictionary -- the Oxford English Dictionary, which is used by persons not skilled in any art except the art of looking up words -- and find a definition of "element" that fits quite nicely into the language of the patent: "a constituent part." However, that definition would be far too broad to fit within Plaintiff's claimed invention (see below at 23).

--- End Footnotes ---

What should be obvious from all of the above is that I cannot fashion a so-called "ordinary meaning" definition of the term
"electronic element" by using a dictionary alone. Nor should I. When interpreting terms used in a patent, one is required to look at how the term is used in the patent itself and in its prosecution history, to see if that use is consistent or inconsistent with any dictionary definition. It is to that exercise that we now turn.

Specifications: The specifications for the '207 patent certainly do not suggest that the term "electronic element" should be defined as narrowly as Defendant urges. For example, it says:

Electronic element 20 may take a wide variety of forms and perform a wide variety of functions…[It may include] a micro-chip 22 including a wire antenna 24 connected thereto, a micro-chip 22' and a circuit board antenna 24', a read/write micro-chip 22" and a wire coil antenna 24", or any other suitable electronic element.

Similarly, in the related '099 patent, "Electronic element 20 may take a wide variety of forms (microprocessor chip, circuit board, transponder, etc.)." And as noted above, Fig. 4, one of the disclosed embodiments of the '099 patent, shows the electronic element to be a bare antenna.

Plaintiff has specifically disclaimed to the court any effort to invoke patent rights in whatever the "electronic element" might be. However, Plaintiff's use of broad language in the specifications clearly evinces an attempt to include any sort of electronic element that presently can or might in the future be usefully implanted in a smart card -- not just micro-chips and antennas, which appear to be the preferred embodiment given today's technology.

Defendant correctly notes that all of the disclosed embodiments in the '207 and '155 patents are variations on the "micro-chip plus antenna" theme, and all the disclosed embodiments in the '099 and '367 patents are variations on the "micro-chip or antenna" theme. But it is hornbook law that a patent is not limited to its disclosed embodiments. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (unless patentee specifically indicates such a limitation, claims should not be construed as limited to embodiments of invention having a particular feature simply because all embodiments disclosed in the specifications share that feature). A review of the file wrapper does not disclose anything suggesting that Leighton ever disclaimed the use of any type of electronic device in connection with its process during the prosecution of the patent, so Oberthur cannot invoke any patent estoppel to limit the patent's scope to the disclosed embodiments.

Plaintiff further argues that construing "electronic element" to mean "micro-chip and antenna" with respect to the '207 and '155 patents would violate the doctrine of claim differentiation. Under this doctrine, each claim in a patent is presumed to have a different scope. See, e.g., Versa Corp. v. Ag-Bag Int'l Ltd., 392 F.3d 1325, 1329-30 (Fed. Cir. 2004). "The difference in meaning and scope between claims is presumed to be significant 'to the extent that the absence of such difference in meaning and scope would make a claim superfluous.'" Id. (quoting Tandon Corp. v. U.S. International Trade Com., 831 F.2d 1017, 1023 (Fed. Cir. 1987)). Therefore, limitations of dependent claims are not read onto independent claims, because to do so would render the independent claims superfluous as duplicative of the dependent claims.

In the '207 patent, dependent claims 13 and 14 of the '207 patent narrow the scope of the term "electronic element" as it appears in independent claim 1 by specifying that the "electronic element" must be "a micro-chip and an associated wire antenna" (claim 13) or "a micro-chip and an associated circuit board antenna" (claim 14). Defining "electronic element" to mean only "a micro-chip and an antenna" would improperly impose the limitations of dependent claims 13 and 14 onto independent claim 1. Defendant fails to refute this argument.

Prosecution History: Plaintiff also argues that the prosecution history of these patents demonstrates that the term "electronic element" as used in the patents in suit should be read as broadly as Plaintiffs urge -- and, moreover, that a person of ordinary skill in the art would so read it.

One of the critical prior art patents is U.S. Patent No. 5,519,201, a prior art patent that is cited in the prosecution history of the '367 patent. This patent relates relate to "smart card" technology. Persons skilled in the art would be expected to be familiar with this patent.

The '201 patent contains the following language concerning the electronics that make smart cards work:

Some identification cards include an integrated circuit and are known as 'integrated circuit cards' or 'Smart Cards.' More generally, herein, 'Smart Card' refers to any portable card-like device which includes one or more electronic components,
i.e., active components such as integrated circuits, transistors and diodes, and passive components such as resistors, capacitors and inductors.

Col. 1:32-38.

Elsewhere in the '201 Patent, the inventor states that electronic elements (or components, as he calls them) can include:

- integrated circuit modules, transistors, diodes, and passive components such as resistors, inductors and capacitors.
- Further, an integrated circuit module for use with the invention can be a printed circuit board to which is attached one or more integrated circuit chips, a printed circuit board without an integrated circuit chip attached, or just an integrated circuit chip.

(Pl. Br. at 16, quoting the '201 patent at col. 2:55-64.) This language is extremely broad and does not at all suggest that "electronic elements" in "smart cards" are limited to micro-chips and their antennas. Nor does it support Defendant's argument that the term "electronic element" as used in the '367 and '099 patents is indefinable because an antenna -- which all parties agree is a "passive component" or an "inductor" -- falls outside the ambit of "electronic elements." Defendant urges the Court to read these passages (in particular the former passage) such that only "active components" are encompassed within the reach of the term "electronic components," but such a reading defies logic as well as basic principles of English grammar.

--- Footnotes ---

5 Similarly, the prior art U.S. Patent No. 5,412,192, cited in the provisional application for the '207 patent and teaching a system for changing the activation status of a data card, such as a charge card, uses the phrase "internal electronics" to refer to the "wire coil antenna and micro chip" of the '207 provisional application and defines that phrase in an extremely broad manner to include "battery, fuses, crystal display, and photocell." ('207 Provisional Application at 19).

6 The quoted language in the '201 patent also indicates that Defendant's proposed use of the McGraw Hill definition of "electronic component" for the patents in suit is misplaced since it would read out the "passive components" included within the category of "electronic component" used in the '201 patent.

--- End Footnotes ---

Defendant argues that an antenna cannot possibly be an electronic device because it is an electromagnetic device (according to McGraw Hill), which is something entirely different. However, as noted above, the word "electronic" mean "pertaining to electron devices." Antennas "pertain" or relate to "electron devices" by functioning with them to complete the circuitry that embodies the "smart card" technology.

Moreover, the prior art patents draw a distinction between active and passive electronic devices, with the latter plainly including devices that function using electromagnetic action. For example, the '201 patent notes that "electronic components" can include "passive components" such as "inductors," which would encompass antennas. '201 patent, col. 1:32-38.

Result

It is easy to reject Defendant's proposed definition of "electronic element" as "a combination of a microchip and an antenna" with regard to the '207 and '155 patents. Such a construction, as Plaintiff correctly observes, would violate almost every rule of claim construction. It is inconsistent with the broad language used in the specifications. It is inconsistent with prior art patents that use the same term. And it is far narrower than even the dictionary definition of the phrase "electronic component" that Defendant advances.

It is equally easy to reject Defendant's argument that the term "electronic element" is used differently in the '376 and '099 patents, and cannot be defined at all as used in those patents because one disclosed embodiment identifies something (an antenna) that is not, in fact, an electronic element. Defendant's thesis that this term is used differently in the latter two patents is entirely dependent on acceptance of its extremely narrow construction of the term "electronic element," which
limits that term to a combination of a microchip and an antenna." Since I have rejected that narrow construction, I must reject the argument based thereon. And the preceding discussion highlights the flaws in Defendant's claim that the term cannot be defined.

7 Specifically, Oberthur claims that because the '099 patent and '367 patents indicate that the embedded "electronic element" is only an antenna--not a micro-chip and antenna--this distinction renders the term ambiguous. (Def. Br. at 51.) Unless the definition of "electronic element" is confined to "microchip and antenna" -- an argument I decline to accept -- this argument makes no sense.

This leaves me with the task of deciding whether Plaintiff's proposed definition (or some variant on it) is the correct construction of the term, based solely on intrinsic evidence. As I make this decision, I must keep in mind that claim construction is essentially the crafting of a jury instruction, so the term definition must be comprehensible by a lay juror as well as one skilled in the art.

Leighton's proposed definition is "a device having distinct electrical characteristics and having terminals at which it may be connected to other elements to form a circuit that utilizes a semiconductor device." This combines the following definitions (from McGraw Hill):

Electronic: pertaining…to circuits….utilizing electronic devices

Electron devices: a device in which conduction is principally be electrons moving through a….semiconductor

Semiconductor Device: an electronic device in which the distinguishing electronic conduction takes place within a semiconductor

Component: any electric device…having distinct electrical characteristics and having terminals at which it may be connected to other components to form a circuit.

Plaintiff's invocation of the McGraw Hill definition of "component" rules out the use of a broader, less technical definition for the word element, such as "a constituent part." This is consistent with the argument made in Plaintiff's brief that, because the word "electronic" modifies "element," the patentee claims use of just one specific type of circuit -- one that uses a semiconductor device.

Coupling this with the broad wording of the specification ("Electronic element 20 may take a wide variety of forms….") and the equally broad use of the term electronic element and the analogous term electronic component in critical prior art patents, I conclude that to construe this term with reference solely to intrinsic evidence we must define additional terms (from McGraw Hill):

Semiconductor: a solid crystalline material whose electrical conductivity is intermediate between that of a conductor and an insulator…

Conductor: a wire, cable or other body or medium that is suitable for carrying electric current.

Insulator: a device having high electrical resistance and used for supporting or separating conductors to prevent undesired flow of current from them to other objects.

Electrical: related to or associated with electricity, but not containing or having its properties or characteristics.

I craft the following instruction to give to the jury concerning the phrase "electronic element":

Ladies and gentlemen, the first term that I must define for you is "Electronic element." That is a technical term. The word
"electronic" means "pertaining to circuits that use something called electron devices." An electron device, for the purposes of this patent, is a device or thing in which electrical current is carried ("conducted" is the technical term) principally by electrons moving through something called a semiconductor. So electronic means "pertaining to circuits utilizing a semiconductor device." An "element" is the same thing as a "component," and a "component" is an electrical device (something that has distinct characteristics related to or associated with electricity) and that has terminals, or end points, at which it can be connected to other components to form a "circuit," which is a combination of electrically interconnected components. So "electronic element" means "a device or thing that has distinct characteristics related to electricity, and that also has terminals at which it may be connected to other distinctly electrical devices or things in order to form a circuit, in which electrons move through devices called semiconductors."

B "Electronic Mail Message"

I adopt the following definition: "A digital text message that is sent over a communications network from one device to another."

Plaintiffs offer, "A message sent and received electronically." Defendants offer, "A letter or memo or other text message sent through a communication network from one computer to another."

Both parties use the word "message" in their definition of "electronic mail message," and neither defines it. I assume from this that the parties take the position that "message" need not be construed. I agree, and so decline to construe that word.

Electronic mail is one of the many forms of communication that may be used to transmit a signal from the central processing unit to the holder of the account, notifying the holder of the transaction and seeking authorization. The patentee clearly intended that the invention be compatible with any and every sort of device through which a message could be conveyed to the holder, and with every medium for the transmission of information. Indeed, the patentee lists "electronic mail message" among a number of types of information transmissions:

The signal utilized could be in the form of a communication transmission, depending on the communication medium utilized, a telephone call, a voice message, a beeper and/or a pager message, an electronic mail message, a fax transmission, and/or any other mode of communcation which may be utilized with any of the apparatuses, devices and/or components described herein…"

"725 Patent, col. 10: 45-52 (Emphasis added). The apparatuses, devices and components described herein included in the patentee's definition of "cardholder (or account holder) communications device" include landline and cellular telephones, beepers, pagers, fax machines, personal computers, answering machines, PDAs or handheld devices, and any other apparatus that communicates via "telecommunication systems, satellite communications systems, radio communications systems, digital satellite communications systems, personal communications services communications systems" and "any other appropriate communications system." ("725 Patent, col. 4:39-44).

The list of communications devices is intended to be exhaustive and anticipatory. The patentee obviously understood that rapid advances in the electronics industry had the potential to render existing means of communications obsolete and drafted the patent so that the invention was not dependent on the use of any particular type of communications device. it

The term "electronic mail message" (or e-mail message) has a common non-technical meaning to the user of these various communications device. The term as used colloquially means a readable (text) message that is sent to a communications device. E-mail messages are commonly understood to be "electronic letters" -- that is, they deliver the message in readable form, rather than via sound or video. And they are sent from device to device. These devices are generally computers, but these days they can also be PDAs (Blackberry being the obvious example) or cellular telephones that have a text messaging feature. They are sent and received digitally, rather than in analog form. Electronic mail messages are not beeps or pages; they are not voicemails or messages left on telephone machines; they are not faxes. You know them when you see them.

The breadth of the patentee's definition of "communications system" and "communications transmission" suggests that
"electronic mail message" as used in the claims in suit ought to be understood in its colloquial sense, as opposed to some technical sense.

That being so, I see no reason why I should not define "electronic mail messages," in accordance with its commonly-understood meaning: "A digital text message that is sent over an communications network from one device to another."

There is absolutely no indication that the patentee intended any particular technical meaning for the term "electronic mail message" in the patent, or that he did not intend the term to have its ordinary, colloquial meaning. I see no need to resort to technical dictionaries to define this term, since its meaning it readily apparent from the language used in the patent to describe the invention.

Plaintiffs' proposed definition, "a message sent and received electronically," is far too broad, since it would encompass messages sent via pagers and voice mail as well as electronic text messages.

4. Electronic Mail Message: A formatted text message that is transmitted over a communication system. As originally inputted to an electronic mail system by the sender, the electronic mail message includes the following characteristics: (a) a destination address identifying the person(s), place(s) or object(s) to which the message is directed; (b) an indication of the sender (which may be added automatically by the electronic mail programming); (c) a subject field (which maybe blank); and (d) the inputted message text. The term "electronic mail message" encompasses all forms of the message as it moves through the communication system (information may be added or deleted to facilitate further transmission as it proceeds through the system).

5. Electronic Mail Programming: An application program specially designed to create, send, access and manage electronic mail messages. Electronic mail programming may operate on a variety of different types of processors (e.g., desktop computer, email server, handheld device, mainframe computer).

A. "Electronic Mail System"

The term "electronic mail system" appears in all of the asserted claims of the '960, '670, and '172 patents. For simplicity, we will use system claim 1 (from which disputed claim 15 depends) and method claim 18 (from which disputed claims 32 and 34 depend) of the '960 patent as exemplars. Claim 1 of the '960 patent reads as follows:

1. A system for transmitting originated information from one of a plurality of originating processors in an electronic mail system to at least one of a plurality of destination processors in the electronic mail system comprising:

   at least one gateway switch in the electronic mail system, one of the at least one gateway switch receiving the originated information and storing the originated information prior to transmission of the originated information to the at least one of the plurality of destination processors;

   a RF information transmission network for transmitting the originated information to at least one RF receiver which transfers the originated information to the at least one of the plurality of destination processors;

   at least one interface switch, one of the at least one interface switch connecting at least one of the at least one gateway switch to the RF information transmission network and transmitting the originated information received from the gateway switch to the RF information transmission network; and wherein
the originated information is transmitted to the one interface switch by the one gateway switch in response to an address of the one interface switch added to the originated information at the one of the plurality of originating processors or by the electronic mail system and the originated information is transmitted from the one interface switch to the RF information transmission network with an address of the at least one of the plurality of destination processors to receive the originated information added at the originating processor, or by either the electronic mail system or the one interface switch; and

the electronic mail system transmits other originated information from one of the plurality of originating processors in the electronic mail system to at least one of the plurality of destination processors in the electronic mail system through a wireline without transmission using the RF information transmission network.

960 patent, col. 49, ll. 2-45 (emphases added). Claim 18 of the '960 patent reads as follows:

18. A method for transmitting originated information from one of a plurality of originating processors in an electronic mail system to at least one of a plurality of destination processors in the electronic mail system comprising:

transmitting the originated information originating from the one of the plurality of originating processors to a gateway switch within the electronic mail system;

transmitting the originated information from the gateway switch to an interface switch;

transmitting the originated information received from the gateway switch from the interface switch to a RF information transmission network;

transmitting the originated information by using the RF information transmission network to at least one RF receiver which transfers the originated information to the at least one of the plurality of destination processors; and

transmitting other originated information with the electronic mail system from one of the plurality originating processors in the electronic mail system to at least one of the plurality of destination processors in the electronic mail system through a wireline without transmission using the RF information transmission network; and wherein

the originated information is transmitted to the interface switch by the gateway switch in response to an address of the interface switch which has been added to the originated information at the one of the plurality of originating processors or by the electronic mail system and the originated information is transmitted from the interface switch to the RF information transmission network with an address of the at least one of the plurality of destination processors to receive the originated information which has been added at the originating processor or by either the electronic mail system or the interface switch.

960 patent, col. 52, ll. 11-49 (emphases added).

The district court construed "electronic mail system" as:

A type of communication system which includes a plurality of processors running electronic mail programming wherein the processors and the electronic mail programming are configured to permit communication by way of electronic mail messages among recognized users of the electronic mail system. The various constituent processors in the electronic mail system typically function as both "originating processors" and "destination processors.["]

Claim Construction Order, slip op. at 4.

RIM argues there are two ordinary meanings of "electronic mail system": a broad definition that encompasses "communicating word processors, PCs, telex, facsimile, videotex, voicemail and radio paging systems (beepers)" and a narrow definition that defines the term in the context of "pull" technology. Asserting that Campana endorsed the pull technology definition during prosecution, RIM argues that "electronic mail system" includes a pull technology requirement. RIM also argues that during prosecution Campana characterized an "electronic mail system" as a wireline system to
distinguish over the Zabarsky reference. Thus, RIM argues that "electronic mail system" requires a processor interconnected with other processors to serve the common purpose of providing electronic mail services to end users through pull technology while utilizing wireline, point-to-point connections.

NTP responds that the district court's claim construction of "electronic mail system" is correct and is consistent with the written description. NTP contends that RIM's proposed construction of "electronic mail system" as requiring pull technology contravenes the plain language of the claim and is inconsistent with Campana's disclosure. Further, NTP argues that RIM never raised its pull technology claim construction at the Markman hearing, but in fact argued the opposite. Finally, NTP argues that RIM's requirement that "electronic mail system" be limited to a wireline only system simply cites the prior art description of those terms, and not Campana's use of the term as including wireless connections.

At the outset, we note that NTP correctly points out that RIM did not argue its pull technology construction before the district court, instead arguing that an electronic mail system is limited to a wireline only system. See J.A. at 2821-22 (arguing that "electronic mail system" should be construed as "a system of single processors or groups of processors linked by a wire line system, such as the PSTN ("Public Switch Telephone Network"), that provides a system for transmitting information between at least two computers"). We have previously held that presenting proposed claim constructions which alter claim scope for the first time on appeal invokes the doctrine of waiver as to the new claim constructions. See CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1370 (Fed. Cir. 2002) ("[A] waiver may occur if a party raises a new issue on appeal, as by, e.g., presenting a new question of claim scope ...." (internal quotation marks omitted)); Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1346 (Fed. Cir. 2001) ("As it relates to claim construction, the doctrine [of waiver] has been applied to preclude a party from adopting a new claim construction position on appeal."). For the first time on appeal, RIM is attempting to add a pull technology limitation to the claim that it did not raise before the district court. Because RIM failed to raise before the district court the argument that the claim should be limited to pull technology, the argument was waived, and we decline to address it on the merits.

The district court's claim construction, which includes various architectures of single processors and groups of processors, is correct. The claims themselves recite that an "electronic mail system" includes various configurations of originating processors and destination processors that communicate via wireline connections or over an RF transmission network. See, e.g., '960 patent, claim 1. Moreover, the written description recognizes that electronic mail systems may have various processor architectures. See, e.g., id. at col. 1, l. 60 - col. 2, l. 22; id. at col. 2, ll. 13-17 ("It should be understood that the illustrated architecture of the single and associated groups of processors is only representative of the state of the art with numerous variations being utilized."); see also '670 patent, col. 1, l. 64 - col. 2, l. 25; '172 patent, col.1, l. 65 - col. 2, l. 25.

RIM's premise that the "electronic mail system" is limited to a wireline only system is flawed. The plain language of the claim 1 preamble recites that the claimed system transmits originated information "from one of a plurality of originating processors and destination processors that communicate via wireline connections or over an RF transmission network. See, e.g., '960 patent, claim 1. Thus, all of the originating and destination processors are recited in the claims as being contained in the "electronic mail system." This language, however, is not helpful in determining whether the "electronic mail system" may include wireless connections. Accordingly, we turn to the written description.

The written description expressly indicates that the "electronic mail system" in the patent claims may include wireless connections. Campana described prior art "electronic mail services" as "basically a wire line-to-wire line, point-to-point type of communications" system. Id. at col. 1, ll. 52-54 (emphasis added). The use of the term "basically" suggests that an electronic mail system may include other types of connections, including wireless connections. Moreover, Campana provided an example of one prior art electronic mail system in commercial use, stating "FIG. 1 illustrates a block diagram of a typical electronic mail system in commercial use such as by AT&T Corporation." Id. at col. 1, ll. 60-62. In this prior art electronic mail system, "groups of processors ...may be distributed at locations which are linked by the [PSTN]. The individual processors may be portable computers with a modem which are linked to the [PSTN] through wired or RF communications as indicated by a dotted line." Id. at col. 1, l. 66 - col. 2, l. 4 (emphasis added). Figure 1 depicts various processors that are all connected to the PSTN via either wired or wireless links. The prior art electronic mail system depicted in Figure 1 is incorporated into Figure 8, which Campana describes as a "block diagram of an electronic mail system in accordance with the present invention." n5 Id. at col. 22, ll. 60-61. Accordingly, because RIM's argument that the term "electronic mail system" cannot include wireless connections contradicts the text and figures of the written description, it must be rejected.
Importantly, when a retail customer decides to participate in the system, the retail customer, after browsing and searching, customer. Id., col. 16, ll. 41-42. retail price and a wholesale price into the system. Id., col. 16, ll. 40-41. The retail price may then be displayed to the retail an item, he may choose to sell to other retail dealers or to retail customers. In that situation, the retail dealer may enter a reserve price indicator" that is not accessible to retail purchasers. Id., col. 16, ll. 31-33. However, if a retail dealer purchases provides that "[a] dealer may be provided with special logon identifications and passwords to view the reserve price ... and may be used to structure the two-tiered market of dealer-to-dealer and retail markets." '176 patent, col. 16, ll. 27-29. It further reserve to a local store customer." Id., col. 1, ll. 49-51. The specification provides that "the price and reserve price fields dealer price[,] and an authorized dealer has pre-approved access to the dealer-to-dealer price and may charge and display the '176 patent is designed in part to provide a system that allows participants to speculate, i.e., to buy an item and then promptly sell it at a higher price. That is the purpose to which Half.com alludes in contending that the patent requires the electronic market to be able to handle not only buying but also selling. The specification makes clear, however, that speculation is not the only use for the system, and that there are other purposes for the system in the context of "the two-tiered market of dealer-to-dealer and retail markets."'176 patent, col. 16, ll. 28-29. One of the main purposes of the patented system is to create a double-tiered market for goods, "where the first tier is a retail price and the second tier is a wholesale or dealer to dealer price[,] and an authorized dealer has pre-approved access to the dealer-to-dealer price and may charge and display the retail price to a local store customer." Id., col. 1, ll. 49-51. The specification provides that "the price and reserve price fields may be used to structure the two-tiered market of dealer-to-dealer and retail markets." Id., col. 16, ll. 27-29. It further provides that "[a] dealer may be provided with special logon identifications and passwords to view the reserve price ... and reserve price indicator" that is not accessible to retail purchasers. Id., col. 16, ll. 31-33. However, if a retail dealer purchases an item, he may choose to sell to other retail dealers or to retail customers. In that situation, the retail dealer may enter a retail price and a wholesale price into the system. Id., col. 16, ll. 40-41. The retail price may then be displayed to the retail customer. Id., col. 16, ll. 41-42. Importantly, when a retail customer decides to participate in the system, the retail customer, after browsing and searching,
has only the option of purchasing goods. The customer is not allowed to sell goods to the retail dealer. That is, while dealers
are able to act as participants in the dealer-to-dealer market by buying from and selling to other dealers, customers in the
retailer-to-customer market are not allowed the same freedom. The description of the retail-to-retail market discloses two
types of electronic markets--those in which a participant can buy, browse, and search, and those in which a participant can
sell, browse, and search. The description of the use of the invention for speculation discloses a third type of electronic
market—one in which a participant can buy and sell as well as browse and search. Accordingly, we agree with the district
court's definition of electronic markets as markets in which the participants, in addition to browsing and searching, may
either buy or sell or do both.

4. "Electronic Marketplace"

Liquidnet defines "electronic marketplace" broadly as "any combination of computer hardware and/or software for
receiving and processing, for potential execution, data representative of orders received from an OMS database." ITG/Pulse proposes a narrow definition that defines the term as "an electronic destination where non-binding indications are matched and negotiated." Because the intrinsic evidence supports elements found in both definitions, I construe "electronic marketplace" to have a different meaning than that provided by either of the parties. An "electronic marketplace" is an electronic destination that (1) receives and processes non-binding indications, (2) allows for the matching of non-binding indications with their contra interests and for the negotiation and execution of trades, and (3) has the capacity to record trades if and when they are executed.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

107 Liquidnet Br. at 25.
108 ITG/Pulse Br. at 20.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

Each element of this definition is supported by intrinsic evidence. The specification states: that "[t]he ETM includes an
OMS data integration module (ODIM) for receiving and processing data representative of orders received from the OIMs";
109 that "[t]raders can communicate with the ETM to anonymously negotiate trades of securities"; 110 and that "[a] transaction history module records transactions performed by the ETM in the ETM database." 111 As for the capacity to allow matching, claim two contemplates the "matching [of] at least one non-binding indication sent to the electronic marketplace with a contra interest[.]" 112 Because claim two expressly adds this limitation to the method described in claim one, 113 claim two evidences that the ETM described in claim one has the capacity to match non-binding indications.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

109 Patent '834 col. 2 ll. 61-63.
110 Id. col. 2 ll. 52-53 (emphasis added).
111 Id. col. 3 ll. 13-15.
112 Id. col. 13 ll. 16-18.
113 See id. col. 13 ll. 16-19 (beginning claim two by incorporating "[t]he method of claim 1" and then adding the "further" limitation of "matching at least one non-binding indication sent to the electronic marketplace with a contra interest and providing an indication of the match"). In the vernacular of patent law, claim two is dependent on claim one.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -
Within the securities trading context, the term "electronic marketplace" suggests an electronic destination where trades are executed. The specification clarifies how these trades occur: the ETM receives and processes non-binding indications; it allows for the matching of non-binding indications and for the negotiation and execution of trades; and it records those trades if and when executed.

Liquidnet objects to the incorporation of a "negotiation requirement" in this definition on the grounds that the specification "discloses a host of other modules and features that may optionally be incorporated into the electronic marketplace, and the negotiations module is not described as being any more fundamental to the operation of the electronic marketplace than any of these features." 114 However, the sections of the specification that I have cited are from the "Disclosure of the Invention" section of the patent. The other modules mentioned by Liquidnet are either from the "Detailed Description of the Preferred Embodiments" section, which expressly states that "the present invention can lack one or more of the modules described herein," 115 or are described as preferable aspects of the invention. 116 Thus, the specification's disclosure of the patented method's negotiation aspect is properly distinguished from these other possible aspects of the patented method.

Accordingly, I construe the term "electronic marketplace" to mean "an electronic destination that (1) receives and processes non-binding indications, (2) allows for the matching of non-binding indications with their contra interests and for the negotiation and execution of trades; and it records those trades if and when executed.

--- Footnotes ---

114 Liquidnet Reply at 18.

115 Patent '834 col. 6 ll.62-63. Liquidnet suggests that this statement within the "Detailed Descriptions of the Preferred Embodiments" section means that all modules described throughout the entire specification are not required elements of the patented method. See Liquidnet Reply at 17. However, it is far from obvious that this statement applies to the entire specification. Moreover, the main aspect of my construction to which Liquidnet objects is the inclusion of language referring to negotiation. The specification does not just say that the claimed method includes a negotiation module. It flatly states that "[t]raders can communicate with the ETM to anonymously negotiate traders of securities." Patent '834 col. 2 ll. 52-53 (emphasis added).

116 See, e.g., Patent '834 col. 3 ll.15-18 ("The transaction history module also preferably records other data processed by the ETM including, for example, the orders received from and sent to the trading systems and the conducted negotiations." (emphasis added)).

--- End Footnotes ---

Liquidnet has one other objection that must be addressed. 117 It asserts that ITG/Pulse's construction is precluded by the claim differentiation doctrine because "dependent claim 2 of the '834 Patent depends directly from claim 1 and adds the additional step of 'matching at least one non-binding indication sent to the electronic marketplace with a contra interest and providing an indication of the match.'" 118 While claim two is dependent on claim one -- and this is an appropriate context to apply the claim differentiation doctrine -- 119 Liquidnet's argument fails. My construction only states that the "electronic marketplace" allows for the matching of non-binding indications; it does not require that an instance of such matching must occur.

--- Footnotes ---

117 Liquidnet also points to evidence in the prosecution history suggesting that an "electronic marketplace" does not have to allow for negotiation. See Liquidnet Reply at 19. However, this evidence is insufficient to overcome statements in the specification showing that the capacity to permit negotiation is a necessary feature of an "electronic marketplace" as the term is used in claim one of Patent '834.

118 Liquidnet Br. at 27 (quoting Patent '834 col. 13 ll. 16-19).

119 See Curtiss-Wright Flow Control Corp., 438 F.3d at 1380.

--- End Footnotes ---

Accordingly, I construe the term "electronic marketplace" to mean "an electronic destination that (1) receives and processes non-binding indications, (2) allows for the matching of non-binding indications with their contra interests and for the
negotiation and execution of trades, and (3) has the capacity to record trades if and when they are executed."

1537

The next term for construction is "an electronic medium" which also is used in Claim 1, Element (a); "said RAM of said microcontroller being updateable via an electronic medium. . . ." SuperGuide contends the term includes any electronically generated signal regardless of its source. Gemstar and Defendants agree that the phrase means any electronic medium that can be used to update the up-dateable memory of the microcontroller, including, as the specification discloses, digital information for the storage of programming information in the RAM. SuperGuide's construction appears to agree with that of the Defendants and Gemstar.

The specification provides:

As indicated in FIG. 2, the random access memory or updateable memory of microcontroller 60 is subject to updating via electronic media. The particular medium chosen could be radio or television subcarrier 67a (via antenna 22 and RF section 64 if desired), telephone link 67b, magnetic cards or floppy disks 67c, or equivalents to any or all of the above. Regardless of the method of updating the RAM of microcontroller 60, the system 10 must additionally include suitable hardware and/or software for the updating task, such as a modem if telephone link 67b is utilized.

Reiter '578, at Col. 4, ll. 29-39. The Court therefore construes the term "electronic medium" as an electronic medium that can be used to update the up-dateable memory of the microcontroller.

1538

4. Electronic navigational aid device

Claims 1 and 10 describe the components of an "electronic navigational aid device." Although plaintiff maintains that the term "electronic navigational aid device" requires no construction, defendant asks the court to define it as "any electronic device designed to provide information used for navigation, including an in-vehicle system, hand-held system, etc."

Although the term is not particularly ambiguous, I construe it for clarity as, "any electronic device designed to provide information used for in-vehicle navigation." Neither the claim language or the specification limits the device to a "hand-held system" or any other system, so there is no need to add any such limitations to the claim.

1539

TERM # 7: "said computers being coupled to at least one electronic network for communicating data messages between said computers" - The real dispute regarding the meaning of this term is whether the "electronic network" can be a closed, or direct-dial, network, or is limited only to public networks, such as the Internet. Again, defendants have not supported their proposal to require use of the Internet for all steps of the auction process. In fact, the patent explicitly states that it requires that only one step be performed via the Internet. This allows other electronic networks to perform the remaining steps. This phrase means: "said computers being connected to at least one network for communicating data messages between said computers, such connection being at least partially via the Internet."

1540

11. "electronic postcard"

Claim Language FotoMedia's Proposed Defendants' Proposed
The defendants argue that the patent specification teaches only how the individual image elements of a postcard can be compressed together into two fixed image files, each representing the front and back of an electronic postcard. The defendants argue that because there is no other formatting disclosed, the claimed postcard should be limited to this format. As Fotomedia points out, the specification discloses that the post card is at least composed of HTML pages. See '936 patent, at col.6, ll.19-22. Therefore, the Court finds that an electronic postcard should not be limited to images. The Court construes "electronic postcard" as an "electronic display that contains graphics and/or text representing a postcard."

1541

7. Electronic Sourcing System

'683 Patent, Claims 3, 6

'516 Patent, Claims 1, 2, 6, 9, 21, 22, 29

'172 Patent, Claim 1

ePlus asserts that "electronic sourcing system" means: an electronic system for use by a prospective buyer to locate and find items to purchase from sources, suppliers or vendors. Lawson argues that the term does not need to be construed because it is a preamble statement of purpose or intended use that is not a limitation on the scope of the claim. However, if the Court should interpret the phrase, Lawson argues that it should mean: a system for determining what inventory will be used to fulfill requests for items.

A preamble "limits the invention if it recites essential structure or steps, or if it is necessary to give life, meaning, and vitality to the claim." Catalina Mktg Int'l, Inc. v. Coolsavings. com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002). "Electronic sourcing system" limits the invention because it gives meaning to the claim. Thus, the Court must construe the disputed claim term.

a. Words of the Claims

"Electronic sourcing system" is included in the preamble of numerous claims in the Patents-in-Suit. The majority of the claims describe the system is relation to selecting the catalogs to search, searching the catalogs, and generating a requisition and purchase order. Significantly, the claims at issue never mention "inventory."

b. Specification

The specification provides that the electronic sourcing system provides "a user with the capability of searching a database containing data…relating to items available from at least two vendor product catalogs." '683 Patent at 2:47-52; ‘516 Patent at 2:51-56. This supports ePlus' proposed construction because it demonstrates that the system is used to locate items to purchase from vendors.

The specification also provides support for Lawson's definition. For example, it describes the use of the Fisher RIMS system to determine what inventory will be used to fill requests for orders. See '683 Patent at 14:6-15:19. This demonstrates that part of the electronic sourcing system involves the process of determining what inventory will fill a request for an item.

c. Proper Construction
Lawson's proposed construction is simply too limiting, describing only one part of the electronic sourcing system, which significantly, does not even appear in the words of the claims. Thus, "electronic sourcing system" means: an electronic system for use by a prospective buyer to locate and find items to purchase from sources, suppliers or vendors. That construction is consistent with the words of the claim and the specification. It is also consistent with construction of the term in ePlus, Inc. v. SAP America, Inc., Civil Action No. 3:05cv281 (E.D. Va. 2006).

1542

C. "Electronic Storage Media" is "Memory Configured to Store Information in a Format that an Electronic Device Can Read" and "Storing, in Electronic Form, Information" Means "Storing Information in a Format that An Electronic Device Can Read."

The terms "electronic storage media" and "storing, in electronic form, information" appear in asserted claims 1,3,6, and 19. In each of these claims, the unit in communication with the central information bank contains a "memory for storing, in electronic form, information transmitted to" the unit from the central information bank.

The unit in turn is configured to transfer information to the "electronic storage media" of system users. The parties' proposed definitions are equivalent -- both agree that the terms refer to the storage of information in an electronic format. The parties disagree sharply, however, over the meaning of "electronic." Digeo contends that "electronic" is a generic term that covers a wide variety of storage media, including but not limited to computer hard drives, floppy disks, magnetic tapes, and compact disks. Audible contends that "electronic," as it is used in the claims, covers only memory that stores information in the form of "electrical signals," and excludes all other memory, including magnetic memories (such as hard disks, floppy disks, and magnetic tapes) and optical memories (such as compact disks).

Digeo's interpretation of the term "electronic" seems to the court to be consistent with the ordinary meaning of the term and its use in the claim language. Audible's interpretation seems strained, but as the court is not of skill in the art of networked information systems, the court looks to the specification to illuminate the ordinary meaning.

The court finds the specification inconsistent with Audible's narrow interpretation. The patentees were aware of a broad range of storage mediums, including "tapes, diskettes, cartridges, laser disk[s]," and "compact disk[s]." 823 Patent at 1:22-23. In a list of storage mediums on which publishers might provide content for the invention, the patentees mentioned "magnetic or electronic disks, cartridges, or tape reels or compact disks, laser disks, tape cassettes, etc." Id. at 3:62-63. Audible seizes upon the first "or" in the phrase, insisting that the patentees drew a distinction between "magnetic" media and "electronic" media. In Audible's view, because the patentees only claimed "electronic" media, they surrendered all else.

In its briefs, Digeo contended that Audible's interpretation of "electronic storage media . . . would exclude any known computer-readable storage device." Digeo Reply Br. at 11. When the court echoed that concern at oral argument, Audible responded with a 12-page supplemental brief (Dkt. # 41) with extrinsic evidence showing that there is a species of media that is electronic, but not magnetic or optical, and that this species was known in the art during the prosecution of the 823 Patent. With apologies to Shakespeare, the court finds that Audible doth protest too much. The question is not whether specialized "electronic" media existed, but whether the patentees intended to limit the practice of their invention solely to such media. If they had so intended, one would expect the specification to indicate this choice with something other than a single ambiguous use of the word "or." If the patentees had so intended, one would expect the intrinsic evidence to contain a reference to the specialized "electronic" media. If the inventors intended to exclude the most common storage mediums (i.e., hard disks, floppy disks, and compact disks), the court expects that the inventors would have said so.

Moreover, the claims themselves suggest that the patentees were not concerned with specialized "electronic" media. Although several claims refer to the end user's media as "electronic storage media," e.g., Claims 1-5, several others refer simply to "storage media," e.g., Claims 11-14, 17-18, whereas others use the term "memory unit," e.g., Claims 6-10, 27, 29-30. In Claim 19, the inventors simultaneously claimed the more general "storage media" with the supposedly more specific "electronic storage media." In claims depending from Claim 19, the patentees continued to switch between the two terms without explanation. If the court were to follow Audible's logic, it would be forced to conclude patentees sometimes chose to exclude a vast array of media, and sometimes did not, and did so with no explanation whatsoever. The court finds this implausible.
Audible also points to the prosecution history in support of its proposed construction, but again asks the court to read too much into the inventors' choice of words. In a preliminary amendment at the outset of the 292 Application, the patentees inserted the word "electronic" to modify "storage media" in the claims. PH at 500-618-23. Nowhere in the history, however, is there a suggestion that the patentees were making a distinction between "electronic" media in the sense that Audible uses the term and other forms of media. n5 The patentees did not make the distinction in their remarks accompanying the preliminary amendment. PH at 500-628-33. The PTO did not acknowledge the distinction in rejecting the preliminary amendment. PH at 500-638-42. The patentees did not make the distinction in their response to the rejection. PH at 500-645-653. The PTO did not note any distinction when it allowed the claims as drafted in the preliminary amendment. PH at 500-655-56. As the court has already noted, there can be no prosecution disclaimer absent a clear and unambiguous disavowal of claim scope. The court finds no disavowal of claim scope inherent in the patentee's use of the word "electronic."

n5 Although Audible does not acknowledge it, the patentees used the phrase "storing, in electronic form" in their claims since they filed the 056 Application. PH at 500-435. This casts more doubt on Audible's assertion that they surrendered claim scope when they later added the word "electronic" to the claim phrase "storage media."

For the reasons stated above, the court concludes that "electronic storage media" means "memory configured to store information in a format that an electronic device can read," and that "storing, in electronic form, information" means "storing information in a format that an electronic device can read." The term "electronic" does not exclude magnetic or optical media such as hard drives, floppy disks, or compact disks.

D. "Electronic Tax Return"

Simplification's Construction Block's Construction
A statement of tax liability A completed computerized tax
or tax-related information in return ready for submission to
a form prescribed by a taxing authority, in an electronic a governmental tax agency.

The parties main dispute is whether the term "electronic tax return" should be understood to refer to a "completed" document. Block contends that the essential utility of the patents-in-suit is that they "automatically complete one's tax return." (D.I. 84 at 14.) Construing the claims in a manner that does not clearly require this, Block contends, would allow the claims to "drift" into the partially automated systems that Simplification distinguished during prosecution. Block also raises the same arguments it raised in support of its position that the term "preparing" should, in the context of the patents-in-suit, be equated with "completing." See supra Part II.C.4. Simplification's proposed construction does not include a "completeness" requirement. Rather, Simplification focuses on the meaning of "tax return," and proposes a construction based on definitions contained in U.S. Treasury Regulations. (See D.I. 80 at 31.)

For the reasons set forth above, the Court agrees with Block that, given the intrinsic evidence, the term "electronic tax return" should be construed to refer to a "complete" document. However, Block's construction fails to elucidate the meaning of "tax return." Though it is unclear whether the parties have genuine differences over the definition of "tax return," the Court will nevertheless adopt Simplification's proposed construction, which Block does not appear to dispute. Because a general definition of "tax return" is not provided in the intrinsic record, the Court concludes that it is not inappropriate to, as Simplification contends, look to U.S. Treasury Regulations for assistance in construing certain terms of the patents-in-suit. Indeed, with regard to "electronic tax returns," the specification explains that they are prepared with "respect to the particular taxing authorities," and lists the IRS From 1040 and Form 1040EZ as examples. Thus, adopting a general definition of "tax return" based on a description provided by a key "taxing authority" is, in the Court's view, in line with the
specification. Accordingly, the Court will construe "electronic tax return" to mean "a completed computerized statement of tax liability or tax-related information ready for submission to a governmental tax agency."

B. "Electronically"

<table>
<thead>
<tr>
<th>Simplification's Construction</th>
<th>Block's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>By way of devices, circuits, or systems utilizing electron devices, intervention from the user.</td>
<td>Performed on a computer automatically without manual intervention from the user.</td>
</tr>
</tbody>
</table>

The dispute between the parties boils down to whether the term "electronically" should be construed in a manner similar to "automatic tax reporting." Based on statements Simplification made during the BPAI hearing, Block contends that it should. Simplification, on the other hand, asks for a broader construction based on a definition from the IEEE Standard Dictionary of Electrical and Electronics Terms.

The Court concludes, as Block contends, that the prosecution history mandates that the term "electronically" be understood in a manner similar to "automatic tax reporting." Indeed, during the BPAI hearing, the Board explained to counsel for Simplification that "when I look through your arguments, it seems like you're equating electronic, automatic, and no manual input all to be the same. I could put equal signs in between." (D.I. 79, Exh. F at 24:15-18.) Simplification did not dispute this assertion, but unequivocally confirmed it as follows:

JUDGE MEDLEY: But you don't claim automatic everywhere.

MR. SARTORI: We do not claim- that's right. We do not claim - I'm sorry. I'm sorry.

JUDGE MEDLEY: So electronic - see, that's why I'm kind of having a problem. Because I read your brief -

MR. SARTORI: I thought you were on the '052 for a second. You're on the '787. I'm sorry,

JUDGE MEDLEY: But you do. You sort of mix the issues. I read what you say, and it seems like you're saying automatic is electronic, is not entering manually information. You're equating all three.

MR. SARTORI: That's right. In the context of the '052 patent, which recites "automatic" in all the claims, "automatic" needs to be given its ordinary meaning and weight. In those ones, I think it's clear with regard to the Beamer reference.

In the '787 we have two independent claims, 1 and 10, which do not recite "automatic." The rest of the independent claims recite "automatic." And so those ones, I think it's clear that the Beamer doesn't teach it. We're focusing on claims 1 and 10.

And there are two reasons that I said previously that the Beamer article does not teach it. One is they're connecting electronically. And yes, we are saying electronically means that there's no manual input. You have to - we're saying you need to read it in light of the specification.

(Id. at 28:9-29:5 (emphasis added.) ) Thus, during the BPAI hearing Simplification expressly stated that "electronically means that there's no manual input" and that this followed from a reading of the claims "in light of the specification." As above, the Court finds this to be a clear and unmistakable disavowal of claim scope, which, rather than being taken out of context, is buttressed by subsequent statements that Simplification made to the BPAI. Specifically, the transcript of the BPAI hearing reveals that the Board was, in fact, reluctant to accept Simplification's assertion that "electronically means that there's no manual input." Thus, following the exchange above, the, Board continued to question Simplification on the issue:

JUDGE LEE: Isn't the way you're interpreting it contrary to just logic or common sense? You know, simply saying this is made of wool doesn't mean it doesn't have other components.
MR. SARTORI: I'm sorry. You lost me, sir.

JUDGE LEE: Saying something is electronic doesn't necessarily exclude any kind of manual contribution.

MR. SARTORI: The claim recites connecting electronically to a tax data provider, and then collecting electronically from a tax data provider. And that needs to be done electronically. The -

JUDGE LEE: Yeah. But why does that exclude any kind of manual input? I mean, that's crux to the issue.

MR. SARTORI: Yes, for Claims 1 and 10 of the '787 patent.

JUDGE LEE: You just say that it does, but I don't get it.

MR. SARTORI: In the context of the step which refers to - that recitation of collecting electronically refers to step 12 of the patent. And there it talks about, as I said before, the invention eliminates the current requirement that a taxpayer manually collect the tax data, and that the taxpayer - it eliminates the current requirement that the taxpayer manually enter the tax data onto the tax return or into the computer. And by collecting electronically, you're eliminating those requirements. And to the extent that Beamer makes you do those things, or the system requires you do those things, it doesn't anticipate the claim.

(Id. at 29:9-30:3).

Understanding the Board's motivation behind these lines of questions is helpful to capture the significance of these exchanges. Specifically, from the outset of the hearing, the Board's questions reveal that it was concerned because, although Simplification had distinguished its invention from the prior art on the basis of the prior art requiring manual entry, Simplification had nevertheless pursued claims that recited only an "electronically" limitation and not an "automatic" limitation. (See id. at 5:22-23 ("But not all of your claims require automatic collecting. I see quite a few that don't require automatic collection.").) Faced with these questions, Simplification took the position, set forth above, that "electronically" should be understood similarly to "automatic." The Court concurs with that position. Indeed, the evidence set forth above in support of the Court's construction for "automatic tax reporting" is relevant to and informs the construction of "electronically" also. (See supra Part II.A.) Accordingly, the Court concludes, as Block contends, that the term "electronically" means "performed on a computer without manual intervention from the user."

In support of their proposed construction, Simplification points to a dictionary definition from The IEEE Standard Dictionary of Electrical and Electronics Terms, which defines "electronic" to mean "[o]f or pertaining to devices, circuits, or systems utilizing electron devices." (D.I. 80, Exh. D.) This dictionary, in turn, defines "electron device" to be "[a] device in which conduction is principally by electrons moving through a vacuum, gas, or semiconductor." (Id.) In the Court's view, these definitions are vague, overbroad, and poorly suited to the context of the patents-in-suit. Indeed, the patent defines the "electronic intermediary" that carries out the steps of the claimed invention to be, in part, a "general purpose computer and a computer program." ('052 patent at 4:39-42.) If anything, this suggests that the term "electronic" is connected to the use of a computer. The Court finds nothing in the specification or prosecution history supporting an expansive construction based on the term "electron device."

Simplification further relies on the doctrine of claim differentiation for the position that the term "electronically" must be understood differently than the term "automatically." (See D.I. 85 at 17-18.) However, claim construction positions based on claim differentiation are rebuttable, taking a secondary role if an alternate construction is dictated by the written description or prosecution history. See Regents of the Univ. of Cal. v. DakoCytomation Cal., Inc., 517 F.3d 1364, 1375 (Fed. Cir. 2008). For the reasons set forth above, the Court concludes that, in this case, the prosecution history and specification trump claim differentiation.

Finally, Simplification notes that the specification explains that certain steps of the claimed method could be performed

- 1961 -
using certain prior art software that does not provide a fully automated tax preparation system, such as TurboTax. (See D.I. 85 at 15-16, 23-24.) Based on this, Simplification contends, one of skill in the art would understand that the invention of the patents-in-suit, like the prior art, requires "manual intervention and input at several points," such that Block's construction of "electronically" should be rejected. (Id. at 15.) The full portion of the specification relied upon by Simplification is as follows:

In the present invention, step 13 can be implemented using a computer program similar to the computer programs currently available in the market place, such as TurboTax, which is a registered trademark of Intuit, Inc. Although step 13 can be implemented with current technology, the current technology requires that the tax data and other information relevant to the taxpayer be inputted manually. With the present invention, this information is obtained as described above in steps 11 and 12.

('052 patent at 6:33-41.) In the Court's view, this passage does not embrace the use of prior art methods that required manual input. On the contrary, this passage disparages prior art software specifically on the basis of it requiring manual input and explains that this is overcome in the "present invention." To the extent this passage suggests that certain steps of the claimed method could be done using software "similar" to prior art software, such statements appear to be only for the purpose of setting the stage for distinguishing such art. Accordingly, after reviewing the portion of the specification relied upon by Simplification, the Court is reluctant to place much weight on references to prior art software in the specification.

Electronically communicate with each other as desired and communication between the connected devices as desired

Lantronix argues these terms should be construed to mean "transmission and/or receipt of electronic information between linked devices in a manner that the information can be utilized by the receiving device." Lantronix contends "communication . . . as desired" requires transmission of information and the receiver's understanding of the information received. If the recipient lacks understanding or is unable to use the information, then the information has not been effectively communicated. Alternatively, Lantronix contends the terms should not be construed and the jury should apply the terms' plain meanings.

Digi proposes the terms be construed to mean "electronically communicate using pre-arranged and mutually agreeable protocol, parameters, and pin-outs." Digi argues that when the invented automatic configuration process is completed, the connector is reconfigured by a simple instruction for changing protocol, parameters, and pin-outs. Digi contends the specification uses "different interface functions," "changing protocol, parameters, and pin-outs," "requisite interface function," and "nature of the connection interface" interchangeably to describe the result of the physical connection being modified such that the communication between the devices can take place as desired. See 470 patent, 2:2-22.

Lantronix criticizes Digi's proposed construction on several grounds. First, Lantronix contends the concept of "protocol, parameters or pin outs" will be unfamiliar to the jury. Second, Lantronix contends Digi has imported the limitation of "protocol, parameters or pin outs" from the specification without any basis for doing so. Finally, Lantronix argues that Digi's proposed language is inappropriate. The specification describes four methods for configuring the connector: (1) a microprocessor with EPROM (1:67-2:7); (2) a programmable logic array (2:7-14); (3) an external input device (2:14-19); and (4) self-programming of the connector (2:19-24). Changing protocol, parameters, and pin-outs relates only to a programmable logic array. This is a specific embodiment recited in claim 9. Therefore, according to claim differentiation principles, claim 1 should not be construed to contain this limitation.

The Court adopts Lantronix's proposed construction and construes this term to mean "transmission and/or receipt of electronic information between linked devices in a manner that the information can be utilized by the receiving device." This construction comports with the plain meaning of the claim language and is in concert with the description contained in the specification. Lantronix is correct that Digi's limitation of "protocol, parameters, and pin-outs" impermissibly limits the claim to only one of the disclosed embodiments. Further, as claim 9 is limited to the programmable logic array, which utilizes changing the protocol, parameters, and pin-outs, claim differentiation principles do not support Digi's limitation.
K. "electrical communication/electronically connected"

These terms are used in several claims in the '734 patent and claims 13-15 of the '440 patent, such as in claim 4 of the '734 patent referring to a "first party control unit" which has "a sales random access memory chip electronically connected to the first party hard disk . . ." (Docket # 69, Exhibit I, Column 9, lines 44-48). Claim 5 describes "the second memory" which includes "a playback random access memory chip electronically connected to the second party hard disk . . ." (Id., Column 10, lines 7, 10-12). Claim 11 discloses a "means or a mechanism for connecting electronically via the telecommunications lines the first memory with the second memory such that the desired digital video or digital audio signals can pass therebetween, said connecting means or mechanism in electrical connection with the transferring means or mechanism. . . ."

Defendants assert that the ordinary and accustomed meaning of "electrical communication" is a connection through "a hard-wired conduction path." Defendants further point out that Figure 1 of the patents illustrates a hard-wired conduction path between all of the elements.

Sightsound responds, first, that even if a hard-wired conduction path is necessary, there is no basis in the claims or specification for requiring that it be "single," as opposed to multiple, hard-wired conduction paths. The court agrees. The term "single" cannot be part of the definition.

Second, Sightsound notes that defendants' definition would require that the parties' respective control units be in a hard-wired conduction path with one another. The court has already analyzed the term "connecting through telecommunications lines," and the court agrees, for the reasons set forth above, that the control units need not be in a hard-wired conduction path while "electronically connected over telecommunications lines."

What remains, however, is a determination of whether the individual components of the first party memory must be connected by a hard-wired conduction path, and whether the same is true for the components of the second party memory. Sightsound states that, as to invention elements at the same site, "the language of the claims specifically uses these terms to link related elements and it does so by clear and express recitations." (Docket # 74, at 30). Thus, the parties are in agreement that, as to invention elements at the same location, "electronically connected" and "electrical communication" each require a hard-wired conduction path.

8. "Electronically Providing"

The plaintiff argues that this term does not need further construction. In the alternative, the plaintiff proposes "furnishing or providing data or information using an electronic system or device." The defendant argues that the term means "electronically transmitting."

According to the defendant, in the context of the patent, information is transmitted to a central system. The plaintiff argues that nothing in the intrinsic evidence requires that "providing" necessarily includes "transmitting." The plaintiff also argues, that under the doctrine of claim differentiation, "electronically providing" cannot mean "electronically transmitting" because "electronically transmitted" is used in a different claim. See '116 patent, claim 16.

The plaintiff has the better argument. Accordingly, the court declines to construe this term, other than to reject the defendant's construction that "providing" requires "transmission."

- 1963 -
Electronically specifying information identifying a plurality of parts and specifications for the parts

The Staples Defendants originally submitted this term for construction, but they withdrew the term during the hearing. Orion contended the term did not, and does not, require construction. Thus, the Court did not construe the term.

Hyundai argues that the claim term "electronically specifying information identifying a plurality of parts and specifications for the parts" in the '627 patent is "undefined, insolubly ambiguous, and not amenable to construction." Hyundai argues that "electronically specifying" (1) lacks an ordinary meaning in the art, as evidenced by the inventor's testimony, (2) does not appear in the text of the specification, and (3) could cover a number of different functions disclosed in the specification. The ultimate question, however, is "whether a person experienced in the field of the invention would understand the scope of the claim when read in light of the specification." That is satisfied here.

The specification explains that "computer system 100 incorporates a display apparatus 102, a data storage device 104, a part selection device 106 and a user interface mechanism 108." '627 patent, col. 6:19-21. The specification further explains, in conjunction with Fig. 1A that "data storage device 104 electronically stores both graphic and textual part-related information 112 including specifications 124, features 132 and customer benefits 134. The specifications 124 may further include a manufacturers part number 126, a particular part's attributes 128 and a product description 130." '627 patent, col. 6:30-35.

The Staples Defendants pointed out that the prosecution history indicated that method claim 1 of the '627 patent was in some respects similar to apparatus claim 1 of parent U.S. Patent No. 5,283,865. Claim 1 of the '865 patent calls for "storage means for electronically specifying information identifying a plurality of parts and specifications for parts." According to the Staples Defendants, "claim 1 in the parent patent made clear that it was the 'storage means' that provided the 'electronically specifying' function." The Staples Defendants suggested that the specification disclosed a "data storage device" that "might be" the "storage means" of claim 1 of the '865 patent, but supposed that "the idea of a storage device 'specifying' something . . . seems different from the idea of a storage device "stor[ing]' something . . . ," and suggested that the difference was "not clear."

The Staples Defendants, although also contending that "electronically specifying" rendered the claim indefinite, proposed construing the limitation to mean "electronically providing information identifying a plurality of parts and specifications for parts." The Staples Defendants arrived at that conclusion based on the foregoing prosecution history and dictionary definitions for "specify." The Staples Defendants, however, withdrew that term from the list of disputed terms during the prior Markman hearing, and the Court, as a result, concluded that because there was no longer any dispute among the parties, the term did not require construction.

Hyundai now argues that, in the progression of the claim language from the parent application (now patent) to the current patent, deleting "storage means for" rendered the scope of claim 1 of the '627 patent "indefinite because the functional language used to define the purpose of a structural element does not translate into a comprehensible, free-standing step in a method claim." Hyundai argues that "[t]he term 'electronically specifying' loses all clarity of definition when it is divorced from the term 'storage means for' and arguably remains in Claim 1 of the '627 patent due to careless claim-drafting." Hyundai Opening Brief at 42.

Hyundai acknowledges that the Staples Defendants had proposed that the disputed limitation meant "electronically specifying information identifying a plurality of parts and specifications for parts," but, apparently, does not agree with that proposed construction. Specifically, Hyundai argues that the problem with the Staples Defendants' proposed construction is that the subject limitation could, according to Hyundai, refer to a number of other functions disclosed in the specification. In particular, Hyundai argues that "[b]ecause the step of 'electronically specifying information identifying a plurality of parts . . . falls between the steps of 'receiving information' and 'associating at least one of the parts . . . ', it is unclear exactly what is being electronically specified, how such specification is performed, and why it is being performed." Hyundai Opening Brief at 41.

Hyundai's argument is based on the faulty premise that step b) must come after step a) and before step c). "Unless the steps of a method actually recite an order, the steps are not ordinarily construed to require one." Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1343 (Fed. Cir. 2001). "[S]uch a result can ensue when the method steps implicitly require that they be performed in the order written." Id. The Federal Circuit has adopted "a two-part test for determining if the steps
of a method claim that do not otherwise recite an order, must nonetheless be performed in the order in which they are written." Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1369-70 (Fed. Cir. 2003). First, the court "look[s] to the claim language to determine if, as a matter of logic or grammar, they must be performed in the order written." Id. If not, the court secondly "look[s] to the rest of the specification to determine whether it 'directly or implicitly requires such a narrow construction.'" Id. "If not, the sequence in which such steps are written is not a requirement." Id.

In the context of claim 1 of the '627 patent nothing in terms of logic or grammar requires that step b) be performed between steps a) and c) or after step a). Further, nothing in the specification directly or implicitly requires the same. Although step c) refers to "the plurality of parts" referenced in step b) and "customer's requirements" referenced in step a), and therefore suggests that step c) occur after steps a) and b), there is no similar language in step b) requiring performance of that step after step a). As noted above, the Staples Defendants drew a parallel between claim 1 of the '865 patent and claim 1 of the '627 patent, and noted that the "storage means" may refer to the "data storage device" disclosed in the specification. The specification suggests that parts-related information may be stored in the "data storage device" before the step of "receiving information" in step a). See e.g., the abstract.

Hyundai also contends that the deposition of the sole inventor of the '627 patent indicated that he was not aware of an ordinary meaning for "electronically specifying." However, Hyundai overlooks his immediately preceding testimony:

Q. What does "electronically specify" mean, sir?

... 
A. Electronically specify information. So the key words you are asking is electronically specify?

Q. Yes. What does that mean?

... 
A. Electronic format.

Q. But what is an example of an electronic format?

... 
A. It is not on paper.

Dep. Jerome Johnson, July 1, 2005, p. 219:10-24. Thus, although Mr. Johnson may not have been aware of an "ordinary meaning" for "electronically specify," he knew what the term meant.

Hyundai argues that the claim "is unclear exactly what is being electronically specified, how such specification is performed, and why it is being performed," but those things are not required by § 112(2). The claims are not required to "describe the invention, which is the role of the disclosure portion of the specification, not the role of the claims," and § 112's 'full, clear, concise, and exact' requirement applies only to the disclosure portion of the specification, not to the claims. Orthokinetics, Inc. v. Safety Travel Chairs, Inc., 806 F.2d 1565, 1575 Cir. 1986). And, in actuality, contrary to Hyundai's argument, the claim actually does set out "what is being electronically specified"--namely, "information identifying a plurality of parts and specifications for the parts.

Moreover, contrary to Hyundai's further arguments, "electronically specifying information identifying a plurality of parts and specifications for the parts" is not analogous to "aesthetically pleasing look and feel" found to have rendered the claims indefinite in Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342 (Fed Cir. 2005). The problem in Datamize was that "aesthetically pleasing' does not just include a subjective element, it is completely dependent on a person's subjective opinion." Id. at 1350. Whether or not one is practicing the method step of "electronically specifying information identifying a plurality of parts and specifications for the parts" does not depend on "a person's subjective opinion."

Nor is "electronically specifying information identifying a plurality of parts and specifications for the parts" analogous to "comparing . . . characterizing information" found to have rendered the claims indefinite in Union Pacific Resources Co. v. Chesapeake Energy Corp., 236 F.3d 684 (Fed. Cir. 2001), another case that Hyundai relies on. In Union Pacific, it was not clear whether "comparing" was being used as a technical or scientific term to refer to a complex process of "stretching and squeezing" a data log in a method related to drilling for oil and natural gas, or whether it was being used in a colloquial sense to mean "to examine in order to note the similarities or differences of." Id. at 692. Hyundai posits no analogous question here.
"Only claims 'not amenable to construction' or 'insolubly ambiguous' are indefinite." Datamize, 417 F.3d at 1347; see also Marley Mouldings, Ltd. v. Mikron Indus., 417 F.3d 1356, 1361 (Fed. Cir. 2005)(when a claim "is not insolubly ambiguous, it is not invalid for indefiniteness"); Bancorp Servs., L.L.C. v Hartford Life Ins. Co., 359 F.3d 1367, 1371 (Fed. Cir. 2004) ("We have held that a claim is not indefinite merely because it poses a difficult issue of claim construction; if the claim is subject to construction, i.e., it is not insolubly ambiguous, it is not invalid for indefiniteness."). "By finding claims indefinite only if reasonable efforts at claim construction prove futile, we accord respect to the statutory presumption of patent validity, see 35 U.S.C. § 282, and 'we protect the inventive contribution of patentees, even when the drafting of their patents has been less than ideal.' . . . Thus, 'close questions of indefiniteness in litigation involving issued patents are properly resolved in favor of the patentee.'": Bancorp, 359 F.3d at 1372 (quoting Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375, 1380 (Fed. Cir. 2001)). Also "[c]laim definiteness is analyzed 'not in a vacuum, but always in light of the teachings of the prior art and of the particular application disclosure as it would be interpreted by one possessing the ordinary level of skill in the pertinent art.'" Energizer Holdings v. US. Intl Trade Comm'n, 435 F.3d 1366, 1370 (Fed. Cir. 2006) (quoting In re Moore, 439 F.2d 1232, 1235, 58 C.C.P.A. 1042 (CCPA 1971)).

Here it is clear that in the context of the '627 patent, as well as claim 1, "information identifying a plurality of parts and specifications for the parts" is in an electronic form that permits practice of the claimed "computerized method of selling parts for particular equipment." Indeed, that is what the claim says, i.e., "electronically specifying."

The Court concludes that one of ordinary skill in the art would understand that "electronically specifying information identifying a plurality of parts and specifications for the parts" means "information identifying a plurality of parts and specifications for the parts that is in an electronic form."

D. "Electronically Updating."

This term was used at least once in each independent claim of the '381 patent. For example, claim 34 recited (col. 15:34-55):

34. A computer-implemented method for renting movies to customers, the method comprising:

establishing over the Internet a rental agreement with a customer that provides for charging the customer a periodic fee;

providing electronic digital information that causes one or more attributes of movies to be displayed;

establishing, in electronic digital form, from electronic digital information received over the Internet, a movie rental queue associated with a customer comprising an ordered list indicating two or more movies for renting to the customer;

causing to be delivered to the customer up to a specified number of movies based on the list;

in response to one or more delivery criteria being satisfied, if the customer is current on the periodic fee, selecting another movie based upon the order of the list and causing the selected movie to be delivered to the customer; and

in response to other electronic digital information received from the customer over the Internet, electronically updating the movie rental queue.

The same final limitation appeared in each of the independent claims of the '381 patent. Netflix and Blockbuster seem to agree that "updating" means "changing." They part company on the meaning of "electronically." Specifically, Netflix contends that "electronically," when read in the context of the claims and the specification, requires that the provider's computer perform the updating function. Blockbuster argues that the updating function can be performed by "any device that uses a flow of electrons in a vacuum, in gaseous media, or in a semiconductor."

Here, the independent claims of the '381 patent are instructive because the phrase was not used in the specification. The claims indicated that information is received from the customer. This indicates that the device doing the updating receives
information; it does not address exactly which device performs the updating function.

The specification and claims of the '381 patent simply do not teach the requirement that only the provider's computer can be used to update the information. In fact, the specification goes to great lengths to state that (col. 10:12-19):

[t]he approach described herein for renting items to customers is applicable to any type of rental application and (without limitation) is particularly well suited for Internet-based rental applications for renting movies and music to customers. The invention may be implemented in hardware circuitry, in computer software, or a combination of hardware circuitry and computer software and is not limited to a particular hardware or software implementation.

Other portions of the specification teach a variety of computer hardware and software systems and specifically do not confine the system itself to a computer in any particular location or under any particular entity's control. For instance, the specification contemplates the use of software that could operate on the customer's computer or in some other remote setting.

The use of the term in the claims does limit the term "electronically updating" further than what Blockbuster would propose. The claim itself required that the updating be done "in response to other electronic digital information received from the customer over the Internet." Clearly, the device that performs the function must be able to receive information in this manner. This limitation does not, however, mean that the only device capable of doing so is the provider's computer. Netflix is attempting to confine this phrase to the embodiment of the invention that it practices which is expressly not allowed in claim construction. On the other hand, "electronic" is a commonly-understood word which needs no clarification. Blockbuster's proposed definition's discussion of electrons and vacuums would likely cause more confusion than leaving the term to its common meaning.

Accordingly, this order holds that "electronically updating" means changing based on information received from the customer via the Internet using an electronic device. "Electronic" is given its plain-language meaning.

Anascape contends that these limitations are not means-plus-function limitations under § 112, P 6. Anascape states that if the court considers these limitations to be a means-plus-function limitation, it agrees with Microsoft that the corresponding function is the function listed after the "means for" language and that the corresponding structure is an "ASIC or micro-controller integrated circuitry, and equivalents thereof."

Each of the seven phrases incorporates the "means for" language that gives rise to a presumption that the patentee used the
term advisedly to invoke §112 P6. Rodime PLC v. Seagate Tech. Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999), cert. denied, 528 U.S. 1115, 120 S. Ct. 933, 145 L. Ed. 2d 812 (2000). If a claim term recites no function this presumption disappears. Id. In each of these claims the phrase "means for" is followed by a verb describing what the "means" does - a function of the invention.

The court must next determine whether the claim language recites sufficient structure for performing the function. Id. Anascape argues that "electronics" preceding "means" in four of the claims, and "active electronic" preceding "means" in the other three terms sufficiently recite the structure.

In Rodime, the "means for" language was followed by a list of structural items, which together performed the function. See Rodime 175 F.3d at 1303. In the present case none of the seven claims at issue recite such a list. Similarly, "a pair of rotatable shafts projecting downwardly from said frame means and defining a biaxial plane" sufficiently describes "gearbox means for rotating said blade means." Allen Engineering Corp. V. Bartell Indus., 299 F.3d 1336, 1348 (Fed. Cir. 2002). The seven claims at issue do not have such a description.

The term "second baffle means" was held to recite sufficient structure because the word "baffle" is a structural term. Envirco Corp. v. Clestra Cleanroom, Inc., 209 F.3d 1360, 1364-65 (Fed. Cir. 2000). Anascape argues that the word "electronics," used in four of the claim terms, recites sufficient structure to overcome the means-plus-function presumption. The word "electronics" is a generic word that could refer to technology ranging from a vacuum tube to semiconductors. See McGraw-Hill Dictionary of Scientific and Technical Terms 627 (4th ed. 1989)(defining "electronics" as "study, control, and application of the conduction of electricity through gasses or vacuum or through semiconducting or conducting materials").

Anascape points to claim 70 of the '991 patent in support of its argument that "electronics" recites sufficient structure. The means-plus-function presumption can be overcome only if the "claim itself" recites sufficient structure "to perform entirely the recited function." Sage Prods., Inc. v. Devon Indus., 126 F.3d 1420, 1427-28 (Fed. Cir. 1997). Claim 70 is a different claim that does not contain the "means for" language. Whether Claim 70 describes sufficient structure is irrelevant.

Because the four terms that begin with "electronics means . . ." do not recite limited and definable structure, the court concludes that they are means-plus-function limitations. Given this finding, Anascape agrees with Microsoft that the structure is "ASIC or micro-controller integrated circuitry, and equivalents thereof."

The other three terms claims use "active electronic means for interpreting . . ." Anascape states that this discloses sufficient structure to overcome the means-plus-function presumption. The specification defines the term: "Active electronics 46 (i.e., ASIC or microcontroller integrated circuitry, etc.) which in addition to having normal circuitry of a typical game controller such as a prior art controller also has circuitry for interpreting the analog output of sensor material 36 and converting it into a digital signal. . . ." '991 patent, col. 11, ll. 10-15.

Microsoft argues that it is improper to look to the specification to determine whether a term in a phrase using "means" recites structure. A patentee can be his own lexicographer. There seems little difference between the Enviroco Court's discerning structure from a word with a common structural definition, such as "baffle," and making the same use of a phrase defined in the specification. Phillips could be used to argue that looking to the specification for a definition is preferable to consulting a general use dictionary.

As with "baffle" in Enviroco, "active electronic" imparts structure. The three claims that include "active electronic means" are not means-plus-function clauses. Evidently recognizing the definition in the specification, neither party argues for an alternative construction of "active electronic."

1. "the electrotherapy device can provide at least six [nine] electrical [therapeutic electrical] shocks to the [a] patient before the battery is depleted"

Claims 69, 70, 81, and 82, the only claims asserted in the '961 Patent, state that "the electrotherapy device can provide at least six [nine] electrical [therapeutical electrical] shocks to the [a] patient before the battery is depleted." The parties dispute the meaning of this term. Philips asserts that the term should be construed as "a defibrillator battery has enough
charge to delivery to a patient, six [nine] defibrillation shocks across the normal operating temperature range." Cardiac Science proposes that the term be defined as "when the battery low warning is given, the battery is able to deliver at least six [nine] therapeutic electrical shocks to the patient." Thus, the dispute centers on whether the six [or nine] shocks remaining must be provided "across the normal operating temperature range" of the defibrillator.

Neither the claim language nor the specification supports a construction that includes the phrase "across the normal operating temperature range" of the defibrillator. Philips' attempts to rely upon extrinsic evidence to support its construction are unavailing. The Court construes "the electrotherapy device can provide at least six [nine] electrical [therapeutical electrical] shocks to the [a] patient before the battery is depleted" as "when the battery low warning is given, the battery is able to deliver at least six [nine] therapeutic electrical shocks to the patient."

GO BACK

1552

Image Element means "the smallest element of an image that can be assigned independent characteristics."

GO BACK

1553

A. "an element substrate having / an element substrate . . . having"

Defendants propose that the phrase "element substrate" should be construed to mean "a single piece of material on which the matrix and peripheral drive circuits are integrally formed." Plaintiff proposes that the phrase should be construed to mean "the substrate with thin-film transistors." The parties' constructions differ in two relevant respects. First, defendants' construction requires that the matrix and peripheral drive circuits be "integrally formed" on the substrate. Second, defendants' construction requires that the element substrate be made of a "single piece of material."

1. Integrally Formed

Although the parties dispute whether the matrix and peripheral drive circuits must be "integrally" formed on the element substrate, it is not clear from the intrinsic record what the term "integrally" means. The patent appears to use the word and its variants in two senses. Claims 11 and 20 illustrate the first sense, which suggests that two elements are formed at the same time or as part of the same fabrication step. Claim 11 requires that the external wiring elements be "formed integrally with said first conductive layer"—in other words, that the external wiring be formed as part of the same fabrication step during which the first conductive layer is formed. 189 patent at 17:66-67. The first sense does not appear to apply to defendants' proposed construction, which relates to the peripheral circuit as a whole and not to any single circuit element.

The word "integral" and its variants are used in a second, broader sense in several places in the specification. The "Field of the Invention" section describes the patented invention as relating to "a peripheral circuit integral type liquid-crystal display device." Id. at 1:9-10 (emphasis added). The description of related art describes the prior art giving rise to the need for the patented invention as having "a peripheral drive circuit and a display section [which] are integrated on a panel." Id. at 1:65-66 (emphasis added). The prior art is also described as follows: "the peripheral drive circuit integral type active matrix liquid-crystal display device in accordance with the second conventional example shown in FIG. 17 has a peripheral drive circuit disposed inside the sealing material region 17." Id. at 2:35-39. The Summary of Invention states that "an object of the present invention is to provide a peripheral drive circuit integral type liquid-crystal display device which is excellent in image quality and high in reliability." Id. at 3:19-21. Also, the beginning of the detailed description states as follows: "FIG. 1 is a front view showing an outline of an element substrate of an active matrix type liquid-crystal display device in accordance with embodiments 1 to 5 of the present invention, in which a peripheral drive circuit is integral with a display section." Id. at 5:25-29. In contrast, the specification describes an alternate prior art configuration in which "the peripheral drive circuit which is made up of a semiconductor integrated circuit is attached externally to a liquid-crystal panel through the tape automatic bonding (TAB) technique or the chip on glass (COG) technique." Id. at 1:27-30.

Based on the preceding examples, "integral type" LCD suggests at least two separate meanings. The first suggests that the peripheral circuits are deposited directly on the glass, rather than attached through the "tape automatic bonding" or "chip on
glass" techniques. The second suggests that the peripheral circuit is located inside the sealing material—thus "integrated" within the LCD rather than connected externally via wiring the extends out through the sealing region.

At oral argument, defendants clarified that their proposed construction seeks to impose the first requirement—that the peripheral drive circuits be "integratedly formed" (directly deposited) on the same transparent material that underlies the matrix of pixel electrodes. Neither party took a position on whether the peripheral circuit must be located inside the sealing material. The court will therefore limit its discussion to whether the peripheral circuit must be directly deposited on the same material that underlies the electrodes.

The full claim element in dispute, including sub-elements, reads as follows: "an element substrate having: a matrix circuit; a peripheral drive circuit driving said matrix circuit." Id. at 50-52. This language, without any further construction, indicates that the element substrate must "have" both a matrix circuit and a peripheral drive circuit—in other words, that the peripheral drive circuit and matrix circuits are included within the element substrate. See, e.g., Crystal Semiconductor Corp. v. TriTech Microelectronics Int'l, 246 F.3d 1336, 1348 (Fed. Cir. 2001) (noting that "having" is a transitional term of art, denoting inclusion, which may be either open-or closed-ended). The claim does not, however, expressly require that the peripheral drive circuit or matrix circuit be incorporated into the substrate in any particular way.

Turning to the specification, although several passages characterize the claimed device as an "integral-type" LCD, nothing in the specification limits the claims to that type of device. The invention, rather, is limited to displays with asymmetrical wiring crossing the sealing region; without an asymmetry, there is nothing to "correct." Although defendants argue that the asymmetry only exists when "the drive and matrix circuits are integral to the same substrate," nothing in the specification supports such a broad assertion. See Defs.' Brief in Opposition at 20.

Defendants also argue that the prosecution history supports their construction. In the Notice of Allowance, the examiner distinguished a piece of prior art, U.S. Patent No. 5,396,356 ("Fukuchi") on the grounds that "either of Fukuchi's LCD substrates -- alone—does not appear to contain a matrix circuit (rather, the electrodes on both substrates in combination form a matrix circuit), a peripheral drive circuit (i.e., such circuit must be formed on the same substrate that the matrix circuit is formed)." Mosko Dec., Exh. S at 3. In the quoted passage, the examiner does not appear to have been considering the precise question currently before the court—exactly how the drive circuit is incorporated into the substrate—but the separate question of whether the drive circuit is part of the TFT substrate at all, or is located on the opposing substrate. Based on the claim language, as the examiner correctly noted, both the matrix circuit and the peripheral circuit must be incorporated into the element (TFT) substrate.

In sum, nothing in the intrinsic record before the court supports defendants' contention that the drive circuit be "integratedly formed" on the substrate.

2. Single Piece of Material

Based on the papers submitted in connection with the claim construction hearing, defendants' contention that the substrate must be made of a "single piece of material" is ambiguous. The court can conceive of two possible meanings. First, defendants may be contending that "substrate" refers only to the transparent sheet on which the circuitry for the LCD is formed, and not to the final panel that is assembled into the LCD (which includes circuit elements, including the peripheral drive circuit and the matrix circuit). Second, defendants may be contending that the transparent sheet must in all cases be made from a single piece of material, as opposed to a composite or laminate, or multiple pieces of material arranged horizontally like floor tiles or squares on a chessboard.

With respect to the first meaning, as just discussed, the claims require that the element substrate "have"—that is, incorporate—the peripheral drive circuit and the matrix circuit. Defendants do not suggest that the matrix circuit and peripheral drive circuit are made of a single material; indeed, as discussed in connection with the 258 patent, the circuitry typically consists of many layers of conductive and insulating material. The "substrate" contemplated by the claim thus consists of multiple pieces of material.

It is true that some language in the specification appears to equate "substrate" with the transparent material on which the circuit elements are formed. See, e.g., 189 patent at 7:22-23 ("a substrate 201 such as a quartz substrate or a glass substrate"). As with the 995 patent, discussed infra, the word "substrate" is used to refer interchangeably to the clear
material on which circuit elements are formed and to the final component of the LCD panel that consists of the clear material and any circuitry attached or deposited thereon.

With respect to the second meaning, at oral argument defendants clarified that their proposed construction focuses on the question of whether the substrate can be made of multiple pieces of material arranged horizontally, like tiles. The only evidence provided by defendants in support of this construction are the portions of the specification describing the type of material from which the substrate is made, such as quartz or glass, and a dictionary entry which defines substrate as "[t]he underlying material upon which a device, circuit, or epitaxial layer is fabricated." Mosko Dec., Exh. R at 515. None of these references makes any mention of the number of pieces of material that may make up a substrate. The court therefore declines to limit the phrase "element substrate" to a "single piece of material."

Neither party offers a convincing argument why the claim language would benefit from further definition. The court therefore adopts a construction based on the claim language. The court construes the phrase "element substrate" to mean "the substrate having a matrix circuit and a peripheral drive circuit driving said matrix circuit." See 189 patent at 16:51-53.

b. "Elements"

Macromedia contends that the term "elements" should be construed to mean "a representation of a shape, including attributes such as color, line width, and fill properties, that could be displayed on a computer screen." (D.I. 470 at 6). Adobe contends that the term "elements" should be construed in accordance with the definition expressly provided in the specification, namely "a shape together with its graphical attributes, such as color, line width, fill properties, and line properties." (D.I. 479 at 12).

In construing the term "elements," the Court has considered the specification of the '443 Patent. ('443 Patent, Col. 2, lines 32-34). Because the specification expressly defines the term "elements" as Adobe contends, the Court construes the term "elements" to mean "a shape together with its graphical attributes, such as color, line width, fill properties, and line properties."

7. Embedded.

Intel defines "embedded" or "embedding" by reference to the word "encapsulating." However, Intel offers no argument or support for its position that "embedded" means "encapsulated," despite being asked directly about this matter at the claim construction hearing. In the Joint Claim Construction Statement, Intel attempts to define "embedded" by reference to what it believes is embedded within an instruction. Contending the term carries no special meaning, Intergraph offers a dictionary definition of "embedded." The Court construes "embedded" as introduced as or made an integral part thereof. '028 patent 7:9-45; Fig. 6 & 7 (defining by way of description); Webster's II New College Dictionary 366-67 (1995).

In the '404 patent, the parties dispute the district court's interpretation of two limitations: (1) embedded in a series of interrelated screens (the embedded limitation); and (2) operatively connected (the operatively connected limitation). The embedded limitation appears in all three of the '404 patent's independent claims. Claim 1 is representative:

1. An interactive computer software system permitting a user to take a pre-selected computer course or access a pictorial data base, comprising:

(c) a graphics computer sub-system operatively connected to said host computer sub-system, said graphics computer sub-
system executing said course upon interrogation by said host computer sub-system wherein said course includes a series of interrelated pictures displayed by said graphics computer sub-system, said series of pictures defining a course responsive to input data from the user and interactively dialoguing with the user as the user progresses through said pre-selected course or data base; and

(d) wherein said pre-selected computer course comprises a distributed program embedded in said series of interrelated pictures.

'404 patent, col. 8, l. 49-col. 9, l. 3 (emphasis added). The district concluded:

In claims 1, 11, and 14 of the '404 Patent, "embedded in a series of interrelated screens" means:

The patent covers a program whose graphic elements include their instructions in a single file for each screen with all of the control codes being directly accessible on the consumer screen.

Amended Claim Construction Order, slip op. at 1 (emphasis added).

The specification supports the district court's interpretation. Turning first to the background section, prior art systems suffered from a saving format that was unalterable during the use of the program. '404 patent, col. 1, ll. 11-15. Specifically, "references to pictures [in prior art systems] are embedded in the control program along with all the other programming codes necessary to create a functional course." Id., col. 1, ll. 40-43 (emphasis added). In contrast:

The present invention inverts the normal construction of a course. Where prior art systems embed picture references into a control program, thus, producing a large executable file containing thousands of programming language command lines, the present invention embeds the control commands necessary to run the course into the graphic pictures the author and operator see. These control commands are called microscripts, and may be visible or invisible graphical elements of the complete picture presented to the human operator.

Id., col. 1, ll. 51-60 (emphasis added). Thus, "the invention. . . executes the distributed 'program' that is embedded into the numerous pictures or screens, as opposed to the more universal 'compiled' program[of prior art systems]." Id., col. 5, ll. 40-50 (emphasis added). These pictures or screens may, in turn, be stored on a disk as individual ASCII coded files, though each picture file is to be totally self-contained such that modification of one does not affect the others. Id., col. 1, l. 68-col. 2, l. 3; col. 2, ll. 28-29.

Thus, the inventor specified that "the invention" requires an association of command codes with individual pictures or screens. Moreover the invention permits alteration of each picture or screen (e.g., by changing the associated command codes) without affecting the other pictures or screens. The district court properly articulated that the invention's graphic elements (i.e., pictures and screens) must include their own instructions, which allows independent modification of each graphic element.

In addition, the district court also properly determined that the instructions (i.e., command codes) for a given picture or screen must be stored in a single file. IP Innovation concedes that the specification only discloses a "single file" embodiment, see id., col. 1, l. 68-col. 2, l. 3, but argues against importing this limitation into the language of the claims. The '404 patent, however, repeatedly uses the phrase "the present invention" or "the invention of the present disclosure" in describing its inventive features (including the embedded limitation), rather than the phrase "in the present embodiment" or "in one embodiment." See, e.g., id., col. 1, ll. 51-52; col. 2, ll. 16-20, 53-59, 62-64; col. 3, ll. 11, 45-47, 56-60; col. 5, ll. 47-50, 57-58; col. 7, ll. 17-25. In contrast, the '404 patent uses the term "embodiment" in reference to non-inventive features, such as the graphic monitor and memory components. See, e.g., id., col. 4, ll. 63-66. The only other reference to "embodiments" in the '404 patent is common boilerplate language that does not specifically address the inventive features in any detail. Id., col. 4, ll. 17-28; col. 8, ll. 43-47.

Thus, the '404 patent does not disclose multiple embodiments having different implementations of the embedded limitation as suggested by IP Innovation. Rather, the 404 patent's narrow characterization of what "the invention" covers in reference to the embedded limitation supports a construction requiring location of all of the command codes for a given picture or screen within a single file.
Finally, the district court also properly determined that the command codes for a given picture or screen must be directly accessible from the computer screen. IP Innovation contends that this feature has absolutely no relation to the term "embedded." To the contrary, the '404 patent states: "the microscript may be embedded anywhere in the pixel pattern of the screen." Id., col. 2, ll. 30-31 (emphasis added). Embedding the microscript in the pixel pattern of the screen means that it must be directly accessible without reference to another file. In other words, a user need not access another file to obtain the command code when it is already present in the pixel pattern of the screen. This discussion in the specification supports the district court's requirement that the code be directly assessable on the screen.

The prosecution history confirms the district court's interpretation. During prosecution, the '404 patent applicant amended the claims to incorporate the "embedded" limitation to traverse a prior art rejection. The applicant also included remarks that distinguished the claimed invention over prior art touch screen displays, which allegedly did not disclose the "MicroScript principle as disclosed and claimed by the Applicant[.]"] Contrasting the claimed invention from these prior art displays, the '404 patent applicant explained: "this invention visibly, physically, and electronically connects the button to its command, embodied as a MicroScript" by embedding the MicroScript code in each picture or screen. This explanation reaffirms the district court's construction requiring direct accessibility of the command code.

In brief, the district court properly construed the embedded limitation to mean providing graphical elements (i.e., individual pictures or screens) with corresponding instructions (i.e., command code) in a single file for each graphical element, such that all of the control codes for a given graphical element are directly accessible on the consumer screen. The narrow characterization of the invention in the specification and file wrapper do not permit IP Innovation's broader interpretation.

Disputed Claim Term 2: First Code Module Embedded [as in a web page]

The parties agree that a "code module" is a bundle of code that a computer can read -- or, more simply, a computer program. And in the context of this patent, where two separate code modules are needed for the invention to function, the "first" code module is the first of the two computer programs to download onto the end user's platform (computer) and to "execute" -- that is, to run, or to carry out its programming instructions.

Where the parties disagree is over the meaning of the word "embedded." I conclude that Tacoda has the upper hand in this argument.

There are times when "the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words." Phillips v. AWH Corporation, 415 F. 3d 1303, 1314 (Fed. Cir. 2005), citing Brown v. 3M, 265 F. 3d 1349, 1354 (Fed. Cir. 2001). Such is the case with the word "embedded." One need not refer to a dictionary to know the common meaning of that common English word: something is "embedded" in something else when it is planted inside, and so is physically contained within, that something else. Neither party suggests that "embedded" is some sort of technical term. Therefore, the word's plain meaning should control.

Tacoda adopts that plain English meaning of the word "embedded" when it defines "first code module embedded" as "a computer-readable program that is contained within the HTML code of a web page." (HTML -- HyperText Markup Language -- is the predominant markup language for Web pages on the World Wide Web)

Modavox urges that "embedded" refers either to a code module that is physically planted and contained within the web page or to a code module that, while not physically present, is referenced in the web page for future insertion.

I reject Modavox's effort to broaden the scope of the language it used in its patents. Computer code is not "embedded" within a web page when it is merely referenced for future insertion into the web page. Rather, an embedded code is a code that has already been placed into the architecture of the web page. Every principle of claim construction supports such an interpretation.
1. Tacoda's interpretation conforms to the ordinary meaning of the word "embedded," Phillips, supra, 415 F. 3d at 1321 (Fed. Cir. 2005).

2. It also makes sense in the immediate context of the claim term. It is axiomatic that the immediate context is highly instructive to a person skilled in the art in construing the claim term. Phillips, supra., 415 F. 3d at 1312. Therefore, one must look closely at how the word is used in its context. While "embedded" functions as an adjective in the patents (i.e., it describes the first code module), that adjective derives from a verb that is in the past tense, thereby suggesting that the act of embedding the code module has already occurred. Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F. 3d 1547, 1553 (Fed. Cir. 1997). This becomes clearer when one reads the entire clause in which the word "embedded" appears; its says: "When said Web page is downloaded, automatically executing a first code module embedded in said Web page." Nothing in that language suggests that the first code module could be referenced in some link that is embedded in the Web page, called up and then incorporated into the already-downloaded Web page. It is the code module itself, not a link to the code module, that must be embedded, so that it can execute AUTOMATICALLY (i.e., without any further action by anyone) when the Web page is downloaded. Modavox's suggested reading of the language would read the "embedded" out of the patent. Chef. Am. Inc., v. Lamb-Weston, Inc., 358 F. 3d 1371, 1374 (Fed. Cir. 2004) READ.

3. Tacoda's proposed meaning conforms to the specification. The specification is the best source of the meaning of a disputed term, and provides the primary basis for construing the claim. Phillips, supra., 415 F. 3d at 1315-17. Here, the specification contains a Figure that shows the first code module as entirely contained within the architecture of the web page (Fig. 1, Items 34, 36). Furthermore, the language of the specification reveals that the first code module is "embedded in the HTML of the web page when a Web page developer designs the Web page (Emphasis added) and "may be copies and pasted into a web page during Web page development" (5:3-5). Modavox has not cited, and the court has not located, anything in the patent that discloses any other concept of embeddedness, or suggests that the code can be "embedded" by being linked into the Web page well after the page has been designed by its developer. In a case decided only two months ago, the Federal Circuit ruled that where nothing in the specification suggested any that any alternative embodiment fell within the scope of the claim, construction of a claim term should be limited by what was disclosed in the specification. Netcraft Corp. v. Ebay, Inc., 549 F. 3d 1394, 1399 (Fed. Cir. 2008).

Modavox's rejoinder to Tacoda's argument is that "embedded" need not mean "entirely contained within" because such an interpretation would violate the doctrine of claim differentiation. This doctrine stems from the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope. Seachange Int'l, Inc. v. C-COR, Inc., 413 F. 3d 1361, 1368 (Fed. Cir. 2005). The presumption is, however, rebuttable, and can be overcome by a contrary construction dictated by the written description [contained in the specification] or prosecution history." Id. at 1369. While two claims of a patent are presumptively of different scope, the doctrine of claim differentiation cannot broaden claims beyond their permissible scope, or supplant other canons of construction that compel a narrower construction. Tate Access Floors, Inc., v. Maxxess Technologies, Inc., 222 F. 3d 958, 967-68 (Fed. Cir. 2000); Bristol-Myers Squibb Co., v. Ben Venue Labs., Inc., 246 F. 3d 1368, 1376 (Fed. Cir. 2001).

Modavox argues that Dependent Claim 2 in the '636 patent would be redundant of Independent Claim 1 if the meaning of "embedded" were limited in the way suggested by Tacoda. To be precise, it notes that this dependent claim describes a method where the first code module "issues said first command" to retrieve a second code module "from a server via the network connection." 15:1-3. Plaintiff argues that this demonstrates that the embedded code module claimed in Independent Claim 1 "can issue a command that retrieves a code module from a server system using the Internet." (Modavox's Opening Claim Construction Brief at 8)

However, as Tacoda points out in its responsive brief, Independent Claim 1 of the '636 patent, which recites that the first code module "issues a first command to retrieve a second code module," is silent about where that second code module might be found. Dependent Claim 2 of the same patent specifies that the second code module be retrieved "from a server system via a network connection." The reference to the server system and the internet adds a new and different requirement that is not found in Independent Claim 1, where the word "embedded" appears. Thus, there is no risk of redundancy between the two claims if the word "embedded" is given its common sense meaning. That, as the Federal Circuit has recently instructed, renders the doctrine of claim differentiation inapplicable. Netcraft, supra., 549 F. 3d at 1400.

Finally, Modavox's contention that the first code module would be "embedded" if it included code referenced or loaded via a link in the Web page also renders the claim language ambiguous. Tacoda offers an excellent example. If the first code
module consisted of a reference to a link to the second code module, then the second code module would be part of the first code module. That, of course, would render it superfluous to "retrieve" the second code module -- because the second code module would already be "embedded" in the web page by virtue of its being referenced via link to the first code module! Such a construction is nonsensical.

Accordingly, I accept Tacoda's interpretation of the word "embedded" and I will define for the jury the phrase "Web page including a first code module embedded therein" as follows:

"Embedded means contained within the programming architecture (technically known as its "HTML code") of a computer-readable program (the technical name for which is "code module").
Therefore, nothing in the '306 patent restricts the bit signals in the empty payload field to ones that serve no purpose other than place-holding. The specification includes the explanatory phrase "i.e. garbage bits," which, according to the parties, limits the "bit signals of some kind" to bits that serve no purpose other than place-holding.

For the reasons discussed above, "emitter module," for purposes of the '756 patent, means "a self-contained assembly of electronic components and circuitry that contains at least one electrical ionizer and that gives or sends out ions." This construction shall govern construction of the term throughout the patent.

For the reasons discussed above, "emitter module," for purposes of the '756 patent, means "a self-contained assembly of electronic components and circuitry that contains at least one electrical ionizer and that gives or sends out ions." This construction shall govern construction of the term throughout the patent.

B.

As noted, claims 1, 3, and 4 of the '306 patent claim "a transmission overhead field containing frame timing information and an empty payload field." The district court construed the term "empty payload field" to mean "a payload field that is empty of source data, but including bit signals of some kind, i.e. garbage bits." Telcordia Techs., Inc. v. Cisco Sys., Inc., No. 04-cv-876, slip. op. at 6 (D. Del. June 22, 2006) ("Claim Construction Order"). The parties dispute whether the claim construction includes the explanatory phrase "i.e. garbage bits," which, according to the parties, limits the "bit signals of some kind" to "bits that serve no purpose other than place-holding."

The empty payload fields are "empty" of data packets and therefore have non-source bit signals only. The specification explains that "a train of DTDM frames with empty payload fields . . . has a bit rate which defines a basic backbone transmission rate for the DTDM system." '306 patent col.7 ll.27-30. Therefore, the bit signals help the DTDM system maintain a bit stream even when it is not transmitting data from an information source. The specification does not specify where in the frame the "bit rate" is stored nor does it specify the type of non-source bits used to maintain the bit rate. Therefore, nothing in the '306 patent restricts the bit signals in the empty payload field to ones that serve no purpose other
The district court apparently took the explanatory phrase from an ad lib comment made during an oral hearing at the Federal Circuit. In Bell Communications Research, Inc. v. FORE Systems, Inc., 62 Fed. Appx. 951, 2003 WL 1720080 (Fed. Cir. 2003), Bell Communications Research, Inc., now known as Telcordia, asserted the '306 patent against another defendant. This court reviewed a district court's construction of the term "empty payload field" in the '306 patent. In that case, the district court had explained that "a frame's payload has zero data in it." 62 Fed. Appx. 951, Id. at *6. During oral hearing, Bell Communications agreed with Circuit Judge Bryson's characterization of bits in the "empty payload fields" as "garbage:"

Judge Clevenger: Can we come back to the empty payload field? "Empty" seems to me . . . the common meaning of the word "empty" means there is nothing there. So, you are saying that there is something in the written description that tells me what empty means?

Bell Communications's Counsel: I am saying . . .

Judge Clevenger: Where in the written description?

Bell Communications' Counsel: A144, column 7, lines 29-35. And, what you will see there at that point . . .

Judge Clevenger: There is a bit rate.

Bell Communications's Counsel: It says, "this train." It is talking about empty payload field. "This train 10 has a bit rate." In other words, it's empty, but it has a bit rate. Because in order to have . . . sometimes there won't be a packet ready. The stream must continue. There must be a bit in the stream. It just won't be a data bit, it won't be a source data bit. It will be a bit. And it will have information in it, but it won't be source information.

Judge Bryson: It would just be garbage, I take it. I mean it will just be 1's and 0's that have no relationship to the stream of any information that's coming in from the source.

Bell Communications's Counsel: Exactly, Your Honor.

The issue on appeal, at least initially, seemed to be whether the district court actually meant "no bit signals of any kind" when it said "zero data." Id. At oral hearing, however, Fore Systems, Inc. stated its understanding that "'zero data' encompassed various bit signals that might maintain the stated transmission rate of a bit stream, including 'placeholders' or 'garbage bits.'" Bell Commc'n's, 62 Fed. Appx. 951, 2003 WL 1720080, at *6. Because the parties' agreement on this broader interpretation of "zero data" rendered the claim construction issue moot, this court declined to refine the district court's construction. Id.

The claim construction issue on appeal in the present case--whether the empty payload field only has bits that act as placeholders--is different from the one in Bell Communications--whether the empty payload field has any bits at all. Circuit Judge Bryson's comments, therefore, are not directly relevant to the specific issue in the present case. The district court erred by limiting the claim scope based on the ad lib comment from the bench.

In addition, contrary to Cisco's assertion, Telcordia has not changed its proposed claim construction of "empty payload field." In Bell Communications, Telcordia agreed that the empty payload fields only have "garbage bits" because it understood the phrase "garbage bits" to mean bits with "no relationship to the stream of any information that's coming in from the source." In the present case, Telcordia disputes the claim construction with the phrase "garbage bits" because the district court apparently meant "non-source bit signals that serve no purpose other than place-holding." Thus, Telcordia is not precluded from making the claim construction arguments that it makes now.

Accordingly, "empty payload field" means "a payload field that is empty of source data, but includes bit signals of some kind."
I. Claim Construction

While the parties dispute the court's construction of many of the claim terms at issue before the district court, we address the construction of only those terms essential for disposition of this appeal.

The independent claims of the '927 patent recite a method or computer for "emulating" target instructions of the instruction set of a target computer using, inter alia, "emulation registers" capable of corresponding to registers in the target computer. The written description defines the term "emulation" generally as "a process in which one computer X behaves identically to another computer Y, as X executes the instructions of Y, where the internal architectures of computers X and Y are different." '927 patent, col. 2, ll. 30-33. We adopt this construction and conclude that the district court correctly interpreted this term.

Claims 4 and 14 define the particular manner in which the claimed processor emulates. Specifically, both claims require a "M+N bit expanded RISC instruction" with N bits defining the "native instruction . . . configured for emulating target instructions from the instruction set of a target computer." Consistently, the claims require an expanded instruction decoder that uses "M bits from each said expanded RISC instruction to redefine the RISC architecture computer in terms of the target computer." The written description of the '927 patent defines N bits of an expanded RISC instruction, also referred to as the LHS (left-hand side) of the instruction, as the number of bits of the instruction that the microprocessor uses "in its native mode." '927 patent, col. 5, ll. 1-2. With regard to the M bits of the expanded RISC instruction, also referred to as the RHS (right-hand side) of the instruction, the '927 patent states that "contained within the additional M bits [of the expanded RISC instruction] and used in conjunction with the N bits are directions on the use of resources within the RISC computer, peculiar to each emulated instruction." '927 patent, col. 5, ll. 6-9. The written description of the '927 patent explains that the M bits, or RHS, of the expanded RISC instruction are used "to redefine, during emulation of a target processor operation, the register data paths . . . of the LHS [or N bits of the expanded RISC instruction] to correspond to the target processor instruction being emulated, permitting the host processor to mirror, without physical changes, the target processor architecture being emulated." '927 patent, col. 8, ll. 31-37. Consistently, TechSearch's expert, Dr. Hoevel, recognizes that to emulate, "the host computer has to interpret and execute the target instruction set used in the target computer . . . and claims 1 through 3 of the '927 patent reveal the advantages of the special kind of emulation and backwards compatibility found in the '927 patent."

We conclude, as the district court did, that the M+N bit expanded RISC instruction recited in claims 4 and 14 includes N bits corresponding to an instruction of the host microprocessor's instruction set, and M bits which work with the N bits to "redefine" or "translate" the expanded RISC instruction to "emulate" the instructions of the microprocessor of the target computer. We further conclude that the claimed "expanded instruction decoder" is a decoder that "redefines" or "translates" the native instruction identified as N bits of the expanded RISC instruction, using M bits of the expanded RISC instruction, thereby enabling the instruction set of the microprocessor of the computer to emulate the instructions of a target computer.

C. Construction of "a UART emulation which"

Next the parties dispute the meaning of "a UART emulation which", appearing in Claim 1 of the 305 patent as follows:

a UART emulation which in response to an access by the procedure for accessing the register set of a UART, converts the access as required for the register set and address assignment of the device;

PCTEL contends that the term means "software that responds to the operating system as a hardware UART would respond in that it." Agere counters with the construction, "a software mimicking of the data and control registers of a UART, and not simply accessing a non-UART device by bypassing the communications driver that handles UART devices, which."
PCTEL argues the context of the term explains the meaning of "UART emulation." According to PCTEL, the remainder of the claim teaches that UART emulation consists of responding to requests by the operating system for the UART register set data. The requests are then converted to contend with the non-UART devices that may actually be present according. PCTEL contends that their construction represents the functionality described in the 305 patent.

Agere's reading of "UART emulation" focuses on access to the data and control registers of the UART. Agere argues that to the extent to which the 305 patent teaches UART emulation, it only teaches the "mimicking" of the data and control registers of a hardware UART. Agere points to portions of the specification detailing the manner in which data is structured and formatted to emulate the UART standard. n8 Agere also points out that PCTEL disclaimed certain characteristics of UART emulation during the prosecution history and reexamination of the patent. The patent examiner noted that UART emulation was already disclosed in prior art Patent Number 5,678,059 ("Ramaswamy patent"). In distinguishing the 305 patent from the prior art, PCTEL asserted that the Ramaswamy patent taught away from 305's UART emulation because Ramaswamy bypassed the COM driver when it accessed non-UART devices. Malz Declaration, Ex. 15 at 26008-09. Therefore, according to Agere, PCTEL disclaimer implies that the 305 patent includes a limitation requiring that the system access the COM driver. Agere urges the Court to adopt a construction of "UART emulation" in line with this requirement.

--- Footnotes ---

n8 "The data and control values are formatted for a standard UART device so that whether software modem 223 is a standard modem containing a hardware UART or a software modem is completely transparent to application 140 and operating environment 130." 305 Patent, 7:17-22; Also, Agere cites the appendix in which the structures of the control register are detailed. 305 Patent, Appendix A, 1:1-20.

--- End Footnotes ---

PCTEL's construction is closer to the plain meaning of the term "UART emulation." However, as currently presented, PCTEL's proposed construction would broaden the scope of the claim beyond what was actually understood in light of PCTEL's disclaimers throughout the prosecution history and reexamination record. The Court agrees with Agere's contention that the UART emulation, as actually taught by the 305 patent, is narrower than that which is asserted by PCTEL. However, the Court does not agree with Agere's argument that the COM driver limitation was necessarily adopted by PCTEL during prosecution. Accordingly, the clearest reading of "a UART emulation which" is "software that responds to the operating system as a hardware UART would respond, with respect to UART control and register data, which."

1565

"When enabled," "To enable" and "Disable"

For "when enabled" and "to enable," Plaintiff proposes "when activated" and "to activate," respectively. Defendants suggest "when power is supplied, i.e., when the device is turned on." On the flip side, Plaintiff argues that "disable" should be defined as "to deactivate." Defendants submit that the construction of "disable" should be "to switch off power, i.e., to turn off."

Claim 3 uses the terms "enabled," "to enable" and "disabled," but the specification includes no special definition of these terms. Plaintiff argues first that no definition is needed, and that the "plain and ordinary" meaning of the terms should suffice. As with so many patents involving electronic devices, "plain and ordinary" is not so easy to discern.

Defendants correctly argue that these terms are used in the specification in connection with a power management feature of the invention. At times, the described devices (the location signal generating device and the telemetry transmitter) use no power, i.e. they are turned off: When a signal is received, power is turned on, and they are able to operated. In other words, according to Defendants, the claim merely describes devices similar to a common electric lamp. When the switch is in the "on" position, the light bulb is illuminated. When in the "off" position, the bulb is dark.

LunarEye asserts that the claim language should not be so limited. LunarEye would interpret the claim to also describe devices which continuously receive power, although they might be in a "low" power condition, so that power consumption
is minimized. This would be similar to the "hibernation" state observed in some computers and cell phones, which have a blank screen when not used for a certain period of time, although they are still using some power.

Defendants argue that because the specification and prosecution history do not disclose any embodiment that does not involve power being turned off and on, the claim must be so defined. See Wang Laboratories, Inc. V. America Online, Inc., 197 F.3d 1377 (Fed. Cir. 1999). Plaintiff naturally reminds the court that limitations may not be imported into the claim from the specification. See Teleflex, Inc., 299 F.3d 1313, 1327-28 (Fed. Cir. 2002)

But review of contradictory axioms is not analysis. Liebel-Flarsheim Co. V. Medrad, Inc., 358 F3d 898, 904 (Fed. Cir. 2004). The court must determine if there is either a limitation in the claim language itself, or a clear intent to limit the claim expressed in the specification or prosecution history.

The claim simply refers to devices being "enabled" and "an enable controller" configured "to disable" devices. This could mean, as Defendants argue, that the devices have all power supply turned off. But anyone who owns a computer or a cell phone, let alone someone skilled in the art, would be aware that such devices can be in a "hibernation" or "sleep" mode, in which they receive a small amount of power.

The question then becomes whether the applicant expressed a clear intent to limit the claim scope. According to the specification, the invention's operational sequence may begin "[u]pon receipt of a page or the occurrence of another triggering action . . . ." Col. 1, L. 63-64. This does not indicate whether the device is already using some low level of power. The "method may include applying power to a GPS receiver and a cellular transmitter upon receipt of the page, and disconnecting power from the GPS receiver and the cellular telemetry transmitter upon transmission of the location of the object." Col. 2, L. 39-43. "Disconnecting power" implies that all power is shut off. But, this is just a description of one variation of the invention.

A flow chart of the power management system is provided by Figure 3 of the patent. The verbal description of the flow chart states that the "[t]he controller wakes up the GPS receiver . . . .," which then "wakes up" the cellular network transmitter. Col. 6, L. 26-28. The prosecution history contains a communication from the Patent Examiner with the following references:

"a controller 25 (enable controller) configured to wake-up (enable) the LDS . . . ."

"to put back to sleep (disable) the LDS receiver/processor . . . ."

See Independent Witness' Brief, Ex. 2, [Doc. # 84-3] p. 7. There seems to be little dispute that "enable," as used by the inventor, and as understood by the Examiner, is synonymous with "wake up." Similarly, "disable" can be used interchangeably with "put to sleep."

Together, these references indicate that "to enable" and "when enabled" (or "waking up") requires the application of power. Conversely, "to disable" (or "put to sleep"), involves the removal or reduction of power.

The question still remains: Does the claim describe only a device which receives no power until it is "enabled?" In an Office Action (Date Mailed: 07/12/01) the Examiner compared Claim 26 of Allen's application, (which later became the Claim 3 now in dispute) with language in an earlier, related, patent, U.S. Patent No. 5,777,580 (Janky) Col. 11, L. 26-40. As a basis for rejecting Claim 26 of Allen's application, the Examiner states that "Janky et. al. clearly show and disclose a vehicle location system (triggerable location-reporting apparatus)" with the same features disclosed in Allen's Claim 26. See Independent Witness Brief, DX 2 [Doc. # 84-3] p. 7 of 15.

The Examiner noted that Janky already taught an enable controller configured to "wake-up (enable)" the LDS n2 receiver/processor (location signal generating device) and the telemetry transmitter when it receives a trigger signal, and, inherently, to "put back to sleep (disable)" the location signal generating device and the telemetry transmitter. See DX 2, [Doc. # 84-3] p. 7 of 15. (Emphasis added)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
On the next page of the Office Action, the Examiner stated: "Janky et al. further disclose that the GPS processor is in a 'sleeper' mode (power is not applied) until the system receives a page (column 11 lines 35-40)." (Emphasis added). Nothing in the record indicates that Allen ever tried to contradict or correct the Examiner's obvious understanding that "disable" meant "put back to sleep" and "sleeper mode" meant "power is not applied." On the other hand, whether or not power was being turned off, or merely reduced, was not the focus of the interchange between the Examiner and Allen.

The "Response To Final Office Action" states that "the enable controller in Janky does not necessarily disable the location-signal generating device and the telemetry transmitter after the telemetry transmitter transmits the location signal, as required by claim 26 [now claim 3 in the patent before the court], and Janky does not inherently include this limitation." (Emphasis in the original) [IW's Brief, EX. 4, Doc. # 84-4, p. 10 of 18]. The Response explained to the Examiner that Claim 26 [now claim 3] can be distinguished from Janky because the system in Janky "may leave the system enabled" until it is "unenabled" sic by a person performing an action such as removing power, rather than by the enabler itself. In other words, Allen distinguished his patent by asserting that the controller would accomplish a task performed by a person. But there was no clear statement that the task could not be a reduction of power.

The argument that "sleep" or "sleeper mode" means "no power" could be supported by the specification's description of the power management flow chart, Figure 3.

The controller then goes back to sleep. 72 With this power management approach, significant power is being used only when position information is being transmitted over the cellular network. The rest of the time the only drain on system power is the page receiver, which has a very low power requirement . . .

Col. 6, L. 33-38. (Emphasis added). If the "only drain" is the page receiver, then the GPS and the transmitter must be using no power at all. This conclusion is supported by the following at Col. 5, L. 62-64: "When the page receiver 34 receives a page over antenna 44 that is addressed to the page receiver 34, the page receiver 34 transmits a "power-on" signal 46 to the controller 36." (Emphasis added).

The foregoing are the strongest arguments for defining "enabled" as meaning that power is supplied or "tuned on." But none is a "clear disclaimer" of other possibilities. There is no statement that the GPS (location signal generating device) or the telemetry transmitter could not be, or would not be in a low power state. The single statement by the patent examiner about a GPS processor in a "sleeper mode (power is not applied)" referred specifically to Janky and how much power was being applied or removed was not the focus of debate. The court can not merely assume or infer a "clear disclaimer."

The claim language is broad enough to encompass an enable controller which turns the devices completely on and off, or a system in which at least some power is continuously 9 applied to the devices. While only one embodiment (the preferred embodiment) is described in the specification, there is no clear statement disclaiming other embodiments or limiting the devices. The court therefore defines these terms as follows:

"Enabled" means "fully operational and performing its function."

"To enable" means "to place into a condition which is fully operational and performing its function."

"To disable" means "to place into a condition which is not fully operational and performing its function."

For this term, Plaintiff proposes, "a microprocessor or other computing device." Defendants suggest, "a microprocessor or
other computing device that is configured to perform and actually performs specified tasks."

The parties do not dispute that the term "enable controller" means "a microprocessor or other computing device." The parties also agree that the enable controller must be configured to perform specified tasks, but Plaintiff argues that additional claim language already defines what the enable controller is required to do.

If the court inserts Defendants' proposed construction, an "enable controller" would be defined as "a microprocessor or other computing device that is configured to perform and actually performs specific tasks configured to enable the location-signal generating device and the telemetry transmitter when it receives a trigger signal . . .." This proposed definition is both confusing and unnecessary. It is clear that the functionality required by the enable controller is already defined by the remainder of the claim limitation. Therefore, those limitations do not need to be imported into the construction of "enable controller" itself.

The court will define the term as follows:

"Enable controller" means "a microprocessor or other computing device."

GO BACK

1567

6. "to enable the second end to be interconnected to a defibrillator"

Likewise, Claim 1 of the '919 Patent describes an insulated lead wire that extends from the package "to enable the second end to be interconnected to a defibrillator prior to the opening of the package and use of the first electrode." Claims 2, 12, and 17 contain similar language. Philips construes this language to mean "such that the connector on the end of the lead wire is outside the package, allowing it to be plugged into a defibrillator." Cardiac Science, on the other hand, asserts that the term "interconnect" means "connect" and that this clause "provides a functional definition of 'extending from the package,' the preceding term."

Similar to the Court's discussion of the previous term, the Court finds no support in Philips' argument that this term should be construed to include some kind of "plugging in" requirement. The clause in which the phrase appears already recognizes that the second lead wire extends from the package. The term otherwise requires that the lead wire extends from the package in a manner that allows for interconnection to the defibrillator prior to use of the electrode. No further construction is required.

"When enabled," "To enable" and "Disable"

For "when enabled" and "to enable," Plaintiff proposes "when activated" and "to activate," respectively. Defendants suggest "when power is supplied, i.e., when the device is turned on." On the flip side, Plaintiff argues that "disable" should be defined as "to deactivate." Defendants submit that the construction of "disable" should be "to switch off power, i.e., to turn off."

Claim 3 uses the terms "enabled," "to enable" and "disabled," but the specification includes no special definition of these terms. Plaintiff argues first that no definition is needed, and that the "plain and ordinary" meaning of the terms should suffice. As with so many patents involving electronic devices, "plain and ordinary" is not so easy to discern.

Defendants correctly argue that these terms are used in the specification in connection with a power management feature of the invention. At times, the described devices (the location signal generating device and the telemetry transmitter) use no power, i.e. they are turned off. When a signal is received, power is turned on, and they are able to operated. In other words, according to Defendants, the claim merely describes devices similar to a common electric lamp. When the switch is in the "on" position, the light bulb is illuminated. When in the "off" position, the bulb is dark.
LunarEye asserts that the claim language should not be so limited. LunarEye would interpret the claim to also describe devices which continuously receive power, although they might be in a "low" power condition, so that power consumption is minimized. This would be similar to the "hibernation" state observed in some computers and cell phones, which have a blank screen when not used for a certain period of time, although they are still using some power.

Defendants argue that because the specification and prosecution history do not disclose any embodiment that does not involve power being turned off and on, the claim must be so defined. See Wang Laboratories, Inc. V. America Online, Inc., 197 F.3d 1377 (Fed. Cir. 1999). Plaintiff naturally reminds the court that limitations may not be imported into the claim from the specification. See Teleflex, Inc., 299 F.3d 1313, 1327-28 (Fed. Cir. 2002)

But review of contradictory axioms is not analysis. Liebel-Flarsheim Co. V. Medrad, Inc., 358 F3d 898, 904 (Fed. Cir. 2004). The court must determine if there is either a limitation in the claim language itself, or a clear intent to limit the claim expressed in the specification or prosecution history.

The claim simply refers to devices being "enabled" and "an enable controller" configured "to disable" devices. This could mean, as Defendants argue, that the devices have all power supply turned off. But anyone who owns a computer or a cell phone, let alone someone skilled in the art, would be aware that such devices can be in a "hibernation" or "sleep" mode, in which they receive a small amount of power.

The question then becomes whether the applicant expressed a clear intent to limit the claim scope. According to the specification, the invention's operational sequence may begin "[u]pon receipt of a page or the occurrence of another triggering action . . . ." Col. 1, L. 63-64. This does not indicate whether the device is already using some low level of power. The "method may include applying power to a GPS receiver and a cellular transmitter upon receipt of the page, and disconnecting power from the GPS receiver and the cellular telemetry transmitter upon transmission of the location of the object." Col. 2, L. 39-43. "Disconnecting power" implies that all power is shut off. But, this is just a description of one variation of the invention.

A flow chart of the power management system is provided by Figure 3 of the patent. The verbal description of the flow chart states that the "[t]he controller wakes up the GPS receiver . . . .", which then "wakes up" the cellular network transmitter. Col. 6, L. 26-28. The prosecution history contains a communication from the Patent Examiner with the following references:

"a controller 25 (enable controller) configured to wake-up (enable) the LDS . . . . "

"to put back to sleep (disable) the LDS receiver/processor . . . . "

See Independent Witness' Brief, Ex. 2, [Doc. # 84-3] p. 7. There seems to be little dispute that "enable," as used by the inventor, and as understood by the Examiner, is synonymous with "wake up." Similarly, "disable" can be used interchangeably with "put to sleep."

Together, these references indicate that "to enable" and "when enabled" (or "waking up") requires the application of power. Conversely, "to disable" (or "put to sleep"), involves the removal or reduction of power.

The question still remains: Does the claim describe only a device which receives no power until it is "enabled?" In an Office Action (Date Mailed: 07/12/01) the Examiner compared Claim 26 of Allen's application, (which later became the Claim 3 now in dispute) with language in an earlier, related, patent, U.S. Patent No. 5,777,580 (Janky) Col. 11, L. 26-40. As a basis for rejecting Claim 26 of Allen's application, the Examiner states that "Janky et. al. clearly show and disclose a vehicle location system (triggerable location-reporting apparatus)" with the same features disclosed in Allen's Claim 26. See Independent Witness Brief, DX 2 [Doc. # 84-3] p. 7 of 15.

The Examiner noted that Janky already taught an enable controller configured to "wake-up (enable)" the LDS n2 receiver/processor (location signal generating device) and the telemetry transmitter when it receives a trigger signal, and, inherently, to "put back to sleep (disable)" the location signal generating device and the telemetry transmitter. See DX 2, [Doc. # 84-3] p. 7 of 15. (Emphasis added)
On the next page of the Office Action, the Examiner stated: "Janky et. al. further disclose that the GPS processor is in a 'sleeper' mode (power is not applied) until the system receives a page (column 11 lines 35-40)." (Emphasis added). Nothing in the record indicates that Allen ever tried to contradict or correct the Examiner's obvious understanding that "disable" meant "put back to sleep" and "sleeper mode" meant "power is not applied." On the other hand, whether or not power was being turned off, or merely reduced, was not the focus of the interchange between the Examiner and Allen.

The "Response To Final Office Action" states that "the enable controller in Janky does not necessarily disable the location-signal generating device and the telemetry transmitter after the telemetry transmitter transmits the location signal, as required by claim 26 [now claim 3 in the patent before the court], and Janky does not inherently include this limitation." (Emphasis in the original) [IW's Brief, EX. 4, Doc. # 84-4, p. 10 of 18]. The Response explained to the Examiner that Claim 26 [now claim 3] can be distinguished from Janky because the system in Janky "may leave the system enabled" until it is "unenabled" sic by a person performing an action such as removing power, rather than by the enabler itself. In other words, Allen distinguished his patent by asserting that the controller would accomplish a task performed by a person. But there was no clear statement that the task could not be a reduction of power.

The argument that "sleep" or "sleeper mode" means "no power" could be supported by the specification's description of the power management flow chart, Figure 3.

The controller then goes back to sleep. 72 With this power management approach, significant power is being used only when position information is being transmitted over the cellular network. The rest of the time the only drain on system power is the page receiver, which has a very low power requirement . . .

Col. 6, L. 33-38. (Emphasis added). If the "only drain" is the page receiver, then the GPS and the transmitter must be using no power at all. This conclusion is supported by the following at Col. 5, L. 62-64: "When the page receiver 34 receives a page over antenna 44 that is addressed to the page receiver 34, the page receiver 34 transmits a "power-on" signal 46 to the controller 36." (Emphasis added).

The foregoing are the strongest arguments for defining "enabled" as meaning that power is supplied or "tuned on." But none is a "clear disclaimer" of other possibilities. There is no statement that the GPS the (location signal generating device) or the telemetry transmitter could not be, or would not be in a low power state. The single statement by the patent examiner about a GPS processor in a "sleeper mode (power is not applied)" referred specifically to Janky and how much power was being applied or removed was not the focus of debate. The court can not merely assume or infer a "clear disclaimer."

The claim language is broad enough to encompass an enable controller which turns the devices completely on and off, or a system in which in which at least some power is continuously applied to the devices. While only one embodiment (the preferred embodiment) is described in the specification, there is no clear statement disclaiming other embodiments or limiting the devices. The court therefore defines these terms as follows:

"Enabled" means "fully operational and performing its function."

"To enable" means "to place into a condition which is fully operational and performing its function."

"To disable" means "to place into a condition which is not fully operational and performing its function."
The terms "disabling cache operations" and "enabling caching operations" are found in Claim 1 of the '136 Patent. The terms do not appear in the contested claims of the '226 or '244 Patents. Claim 1 of the '136 Patent describes "[a] method for coherently caching I/O devices available for shared access on a network comprising . . . disabling cache operations upon finding that a new computer joined the network; and enabling caching operations at each computer after each computer has connections in place with the cache software of every other computer on the network." (Id. at FIG. 5C) (emphasis added). The parties agree that "enabling caching operations" is the opposite of "disabling cache operations" and that the two terms should be construed together. (Instrument No. 69, at 28; Instrument No. 77, at 15). There is also no dispute that "cache operations" and "caching operations" are the same. (Id.).

The parties also agree that the term "disable" means "prohibit," and the term "enable" means "permit." (Instrument No. 69, at 29; Instrument No. 77, at 15). In order to assist the Court, both parties refer to the IEEE DICTIONARY definition of "disable" and "enable." (Id.). The IEEE DICTIONARY defines "disable" as "[a] command or condition that prohibits some specific event from occurring." (IEEE DICTIONARY at 299) (emphasis added). As a corollary, the IEEE DICTIONARY defines "enable" as "[a] command or condition that permits some specific event to occur [or] to proceed." (Instrument No. 69, at 29) (emphasis added). In this case the specific event is "cache operations" or "caching operations." The parties have agreed that the term "cache" means "a portion of system main memory (e.g., RAM) used for temporary storage of data." (Instrument No. 69, at 9-10). The parties have further argued that the term "caching" means "storing in cache." (Id.). The parties dispute whether the term "caching" is the same as "cache operations," or whether "caching" is just one of several different "cache operations." The parties further dispute whether the duration of the prohibited or permitted cache operations should be reflected in the construction of the terms "disabling cache operations" and "enabling caching operations."

With regard to the duration of prohibited or permitted cache operations, Claim 1 of the '136 Patent implies that the disabling of cache operations is only temporary, because cache operations are only disabled "upon finding that a new computer joined the network." (Id. at FIG. 5C) (emphasis added). Thus, Superspeed argues that the term "disabling cache operations" means "temporarily prohibiting (i.e., suspending) cache operations" and "enabling caching operations" is "continuing or resuming those caching operations." (Id.). Although the terms "suspending" and "resuming" may constitute a convenient short-form to reflect the temporary nature of prohibiting or permitting cache operations, the Court finds that it is unnecessary to use these specific terms in the construction. Because the specifications specifically provide for operations to be "temporarily disabled," the Court finds that the term "temporarily prohibiting" cache operations is a preferable construction. Because the specifications do not specifically state that "enabling caching operations" is temporary in nature, the Court finds that the term "permitting" caching operations is a preferable construction. However, the Court must also determine what specific cache operations are temporarily prohibited or permitted.

Superspeed contends that the specifications and flow chart figures of the '136 Patent indicate that "if cache operations are disabled . . . data cannot be read from the cache nor placed into the cache from the disk." (Instrument No. 69, at 31). Specifically, the specifications provide:

"Referring to FIG. 5C, the "read data" (440) program flow will now be described. . . . The program checks whether the cache status flag 'disable' is set (452), if so, the program exits. . . . The cache status flag 'disable' indicates that some Open VMS system in the VMScluster . . . does not have the cache driver . . . of the invention loaded. This normally would indicate that some Open VMS system is currently joining the VMScluster . . . and has not yet successfully loaded the cache software of the invention. . . . [T]he cache status flag 'disable' indicates an inconsistent view of the cache for the invention across the VMScluster and VAXcluster, preventing active cache operations (and possible subsequent corruption) of the data contained in a disk I/O device."

(136 Patent, at 17:46-18:9) (emphasis added). Figure 5C of the '136 Patent further indicates that the "read data" program flow checks whether the cache status flag "disable" is set. (Id. at FIG. 5C).
The specifications do not specifically define the term "active cache operations." However, the parties appear to agree that the active cache operations that are disabled include: the reading of data from the cache, and the storing of data into the cache. Superspeed admits that "placing data into the cache for rapid access and then accessing it from the processor" are operations that are prohibited while caching operations are disabled. (Instrument No. 69, at 31). Oracle agrees that the "plain meaning of 'cache operations' exceeds just storing data in a cache and includes reading data from a cache (a prerequisite to using the cached data), and writing data to the cache." (Instrument No. 77, at 16). According to the demonstrative exhibit that Oracle presented in oral argument, Oracle uses the term "writing data" from the disk to cache synonymously with "caching" or "storing data" in cache. (DX 1, at 60). Accordingly, the parties agree that disabling cache operations prohibits reading data from the cache, and storing data in a cache.

However, disabling cache operations does not prohibit all cache operations. Superspeed argues that even while caching operations are disabled, some operations on the cache may still be undertaken. Specifically, Superspeed contends that "the software continues to check the free memory and can release cache if the memory used in the cache is needed elsewhere." (Instrument No. 69, at 30). This allows the program to modify the size of the cache for small, medium, or large cache data buckets. (Instrument No. 69, Exh C, at 8:61-65). Superspeed further contends that the system can "unload" or clear cache data in the system when cache operations are "disabled." (Instrument No. 69, at 30; Exh C, at 17:31-36, FIG. 5B). Finally, Superspeed contends that the software can invalidate cache data when writing to an I/O device. (Id.; Exh C, at 17:40-45, 21:58-22:27, FIG. 5K). Oracle does not dispute that the program can modify the size of cache, clear the cache, and invalidate cache data while caching operations are disabled. (Instrument No. 77, at 20). This interpretation appears to be consistent with the specifications and flow chart figures described in the '136 Patent.

Because "disabling cache operations" does not prohibit the use of all cache operations, a construction that the term "disabling cache operations" means "prohibiting use of data in the cache" would be too broad. However, a construction of the term "disabling cache operations" to mean "suspending caching" does not indicate that reading data from the cache is also prohibited, and would thus be too narrow. Taking into consideration the duration of prohibited cache operations and the specific cache operations that are prohibited by "disabling cache operations," the Court finds that the term "disabling cache operations" means "temporarily prohibiting the storing and reading of data on the cache," and that the term "enabling caching operations" means "permitting the storing and reading of data on the cache."
2. Enabling Said EFM Decoder (Claims 1 and 6)

Mediatek argues "enabling said EFM decoder" should be construed as "restarting the flow of EFM decoded audio data." Matsushita argues "enabling said EFM encoder" should be construed as "activating the EFM decoder."

The Court finds, for the reasons stated by Mediatek, that "enabling said EFM decoder" is properly construed as "restarting the flow of EFM decoded audio data."

"Encapsulates the Point-To-Point Link Level Session in a Forwarding Protocol Header"

"Encapsulates the Point-To-Point Protocol Session in the Layer 2 Forwarding Protocol Header"

Alcatel contends that these terms do not comply with the requirements of 35 U.S.C. § 112 P 2, and thus are unable to be construed. Cisco argues that these terms are plain on their face, with no special or uncommon meaning, and thus should not be construed by the Court.

As Alcatel points out, and Cisco does not refute, it is nonsensical for a point-to-point link level session and a point-to-point protocol session to be encapsulated in a header. A header, as discussed above, is "the first part of the message, which contains controlling data, such as originating and destination stations, message type and priority level." 69 The Computer Desktop Encyclopedia, at 395; see also The New IEEE Standard Dictionary (5th ed. 1992), at 589 (defining "header" as "Identification or control information placed at the beginning of a file or message."). The parties also agree that the "point-to-point protocol sessions" means "a communication connection between a source and destination pair using the point to point protocol." Revised Joint Statement, Ex. F, at 78. Therefore, according to this claim term, a communication between a source and destination would be encapsulated solely in the first part of the packet. However, as can be seen from the patent, a packet contains more than simply the header, and thus it appears illogical that an entire communication would be placed in the initial portion of the packet containing only the identifying or control information. See, e.g., Valencia, Figs. 5, 9.

69 The Court has previously construed the terms "layer 2 forwarding protocol header" and "forwarding protocol header" as "initial information fields of a packet operating according to a layer 2 forwarding protocol."

Nevertheless, Cisco argues that, since the parties agree that one of ordinary skill in the art would understand "encapsulating the link level protocol in the forwarding protocol" to be "placing a packet formatted according to the link level protocol in the layer 2 forwarding protocol packet," 70 then one would understand the above terms to mean placing the packets comprising a point-to-point (link level) protocol session in the header of a (layer 2) forwarding protocol packet. See Cisco's '019 Opening Brief, at 24.

Even if this interpretation is essentially illogical, as Alcatel contends, the Court need not concern itself at this stage with whether the processes identified by the claim terms are capable of being achieved (i.e. enablement); during claim construction, under 35 U.S.C. § 112 P 2, the Court must determined whether the terms are capable of being understood (i.e. definiteness).

[D]efiniteness and enablement are analytically distinct requirements, even though both concepts are contained in 35
U.S.C. § 112. The definiteness requirement of 35 U.S.C. § 112, P 2 is a legal requirement, based on the court's role as construer of patent claims. Definiteness requires the language of the claim to set forth clearly the domain over which the applicant seeks exclusive rights. The test for whether a claim meets the definiteness requirement is 'whether one skilled in the art would understand the bounds of the claim when read in light of the specification.'

Process Control Corp. v. Hydreclaim Corp., 190 F.3d at 1358 n.2; see also 3 Donald S. Chisum, Chisum on Patents, § 8.03 at 8-14 (2001) (noting the difference between the requirements of "definiteness, which claims must meet, from the requirements of enablement, which the disclosures of the specification must meet").

Therefore, the Court does not find the above claim terms indefinite. Instead, the Court construes the term "encapsulates the point-to-point link level session in a forwarding protocol header" as "placing a communication connection between a source and destination pair using the point to point link level protocol in the initial information fields of a packet operating according to a layer 2 forwarding protocol." Similarly, the Court construes the term "encapsulates the point-to-point protocol session in the layer 2 forwarding protocol header" as "placing a communication connection between a source and destination pair using the point to point protocol in the initial information fields of a packet operating according to a layer 2 forwarding protocol."

The parties dispute the meaning of two key limitations in the '805 patent claims: "enciphered" and "unenciphered." The court construes enciphered as follows:

Transmission of information in a secure mode; i.e., the transmitted output is encoded (as by logically scrambling the signal).

('805 patent, col. 2, Ins. 30-46, 54-58; col. 3, Ins. 20-24; col. 5, Ins. 9-11; D.I. 435 at Tab B, pp. 68, 78, 79-80) The court construes unenciphered as follows:

Transmission of information in a clear, not secure mode; i.e., the transmitted output is uncoded.

('805 patent, col. 1, Ins. 28-29; col. 3, Ins. 18-19; D.I. 435 at Tab B, pp. 68, 78, 209)

The claims, written description, and prosecution history, when read together, clearly show Harris equated unenciphered transmissions with being "clear" and uncoded and equated enciphered transmissions with being encoded. The patent specification explicitly defines "clear" with the term "unenciphered." ('805 patent, col. 3, 18-19) In addition, Harris used the term "encoded" in place of "unenciphered" when describing signaling transmissions during patent prosecution. Harris did this to distinguish the invention from prior art in which signaling transmissions were "encoded." (D.I. 435 at Tab B, pp. 68, 209)

In the '805 patent specification, the term enciphered is equated with being encoded, whether by a unique code assigned to each mobile or by a common code. (See '805 patent, col. 2, Ins. 30-46, 54-58; col. 3, Ins. 20-24) Harris also used the term "coded" in place of the term "enciphered" during patent prosecution. (D.I. 435 at Tab B, pp. 68, 78, 79-80)

Plaintiff argues that the construction of unenciphered and enciphered should reflect the level of security that a transmission provides, such that the difference between the two terms depends on how "readily detected and monitored" a transmission is. (D.I. 433 at 3) Plaintiff claims that enciphered transmissions necessarily include "some significant attribute of security or privacy" and that, to provide significant security, transmissions "cannot easily be detected and monitored by others." (Id. at 21-2)(emphasis added)

The court disagrees. Plaintiff's suggested constructions of the limitations are subjective and do not comport with Harris' own use of the terms in the patent and during patent prosecution. Harris recognized that different types of codes provided differing levels of security, but Harris never suggested that this defined the difference between the terms "unenciphered" or "enciphered." Rather, Harris drew the line between "unenciphered" and "enciphered" as being either insecure or secure, not at some subjective level of security that would vary with the sophistication of potential eavesdroppers.
5. "enciphering/deciphering algorithm"

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;enciphering algorithm&quot;</td>
<td>a prescribed set of well-defined rules or processes for the solution of a problem in a finite number of steps</td>
</tr>
<tr>
<td>Claims 10, 26, 45, 51</td>
<td></td>
</tr>
<tr>
<td>&quot;deciphering algorithm&quot;</td>
<td>a prescribed set of well-defined rules or processes for the solution of a problem in a finite number of steps</td>
</tr>
<tr>
<td>Claim 46</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Defendants' Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;enciphering algorithm&quot;</td>
<td>a series of steps for encrypting signals</td>
</tr>
<tr>
<td>Claims 10, 26, 45, 51</td>
<td></td>
</tr>
<tr>
<td>&quot;deciphering algorithm&quot;</td>
<td>a series of steps for decrypting signals</td>
</tr>
<tr>
<td>Claim 46</td>
<td></td>
</tr>
</tbody>
</table>

The primary dispute with regard to this term is the meaning of the word "algorithm." At the hearing, Saxon proposed that the construction of this word be based on the dictionary definitions cited by Defendants. See Markman Hr'g Tr. at 106:4-15; Newton's Telecom Dictionary (10th ed. 1996)) (defining algorithm as "[a] prescribed finite set of well defined rules or processes for the solution of a problem in a finite number of steps."); IEEE Standard Dictionary of Electrical and Electronic Terms (1988) (defining algorithm as "[a] prescribed set of well-defined rules or processes for the solution of a problem in a finite number of steps"). Defendants argued that their proposal would be easier for a jury to understand.

3 The only evidence cited by Defendants to support their proposals are the dictionary definitions cited above. The Court finds these definitions to be inconsistent with Defendants' proposals.

The Court finds that the dictionary definition offered by Defendants may be easily understood by a jury. However, the Court's construction need not include the general purpose of an algorithm, e.g., "for the solution of a problem in a finite number of steps," because the claim terms specify specific purposes. Accordingly, the Court construes "enciphering algorithm" as "a prescribed set of well defined rules or processes for encrypting signals." The Court construes "deciphering algorithm" as "a prescribed set of well defined rules or processes for decrypting signals."

D. "an enclosed lamp envelope"

TLI asserts that the term "an enclosed lamp envelope" simply means an enclosure and should be given its ordinary and customary meaning. See TLI's Br. at 13. Sylvania, however, contends that the term envelope should be construed to require that the envelope be either elliptical or spherical in shape. In support of this construction, Sylvania argues that the only
envelope shapes disclosed in the '017 patent are spherical or elliptical, and therefore the patent should be limited to those restrictions. See Sylvania's Br. at 11.

The description of the preferred embodiment or the invention provides that the "lamp envelope … preferably has a substantially elliptical shape." '017 patent, col. 18, lines 57-59. (Emphasis added). The description of the preferred embodiment further states that "[a]s will be apparent to those skilled in the art, regardless of whether the elliptical or spherical shape is used, the geometry of [the] lamp envelope … provides the maximum amount of reflectance back to [the] light-emitting element … and thus provides more heat to [the] element … to, in turn, generate more light." '017 patent col. 19 lines 19-25. (Emphasis added). Notably, the specification simply indicates a preference for an elliptical or spherical shaped lamp envelope, but does not specifically limit the envelope to those two shapes. The specification describes only one or two preferred or potential embodiments of the patented invention. See Northern Telecom Ltd. v. Samsung Electronics Co., Ltd., 215 F.3d 1281, 1293 (Fed. Cir. 2000)(indicating that the Federal Circuit Court of Appeals "consistently declines to construe claim terms according to the preferred embodiment.") Unless there is limiting language in the specification suggesting that the patented invention would not work absent a sphere or ellipses, or that the sphere or ellipses is an improvement over the prior art that warranted issuance of the patent, then any "enclosure," with its broadest ordinary meaning supported by the specification, is acceptable. Because the specification and prosecution history of the '017 patent do not exclude or limit the shape of the lamp envelope in any way, I find that the term "an enclosed lamp envelope" means "an enclosure."

1577

Encoded; encoders; configured to encode; encoding

The Court adopts Ciena's proposed construction and construes the terms respectively as "adding coding bits; component(s) for adding coding bits; configured to add coding bits; having coding bits added."

Nortel argues that the terms should be construed such that "the coding referred to in each of the terms involves appending a bit stream containing coding bits."

Nortel argues that the '176 patent teaches a method for encoding FEC bits in an optical signal that increases the bit rate of the optical signal. Nortel contends that the patent requires that FEC bits are encoded into an overhead bit stream. Nortel claims that the specification supports its construction by offering the sole explanation of how to encode FEC bits through adding them to individual optical channels. See Col. 6:28-32. Nortel argues that Column 6, Lines 47 through 52 of the specification further "explains that the addition of FEC ‘enables’ a channel trace function that also ‘encodes’ channel identification, source, and destination into a ‘small overhead bit stream.’" Nortel contends that the term “appended” more accurately describes the addition of FEC bits to the existing data signal in this context than the term “added.” Ciena argues that the term encoding has a well understood meaning in the art, which is “adding coding bits.”

The specification of the '176 patent indicates that: “Optionally, remodulators 30 include forward error correction (FEC) encoders 45. The addition of forward error correction to a wavelength division multiplexing optical communication system advantageously decreases the bit error rate by adding redundancy, e.g., coding bits, to the individual optical channels which comprise the [wavelength division multiplexing] signal.” Col. 6:26-32. This language from the specification indicates that the “encoding” performed by encoders refers to adding coding bits. Although this example appears in a preferred embodiment, the term “append” or “appending” is not found anywhere in the '176 patent. Furthermore, the term “appending” potentially introduces unnecessary ambiguity to the claim term. The parties do not dispute that the addition of the bits required by the claim is not location specific. However, the word “append” tends to connote location, specifically adding to the posterior portion of that which is being appended. Accordingly, the Court construes the terms respectively as “adding coding bits; components for adding coding bits; configured to add coding bits; having coding bits added.”

1578

2. encoded information (claim 1)

Plaintiff's construction: "information provided by the encoder of the optical disc drive to be sent to the recording circuit of the optical disc drive"
Defendants' construction: No construction needed

Defendants object to plaintiff's proposed construction because they say it imposes a limitation that encoded information must be in the encoder; once it is transferred to the recording circuit, it becomes something else. Plaintiff says that defendants have misread their proposal; "[w]hat matters is that the information has been encoded for writing to the disc (as contrasted with, e.g., information in a different format as sent from a host computer)." Dkt. # 181, at 28.

I agree with defendants that plaintiff's use of the phrase "to be sent" suggests that the data cannot be "encoded information" once it is sent. Further, plaintiff provides no support for its construction. Accordingly, I conclude that this claim cannot be construed at this time.

Court's construction: No construction needed

GO BACK

1579

1. "Encrypt"

The 823 Patent elaborates the meaning of "encrypt" in its discussion of the three levels of encryption it provides. 823 Patent at 15:18-20. The first is "pre-transport" encryption of information by publishers before it is placed into the network system. Id. at 15:19-23. The second level is encryption by the network before transmitting data to the "book bank" or other local units. Id. at 15:23-24. The third level is an encryption process that occurs when information is transferred from the book bank or local unit onto a user's storage media. Id. at 15:29-31.

The patent devotes little discussion to the first two levels of encryption. Pre-transport encryption receives no attention. The second level of encryption, which is the initial encryption that the patented system performs, is intended to "make the data ready for being transmitted with less risk of unauthorized use while being transmitted through a communications network." Id. at 5:64-66. The inventors note that "standard available encryption protocols" are available to perform this level of encryption. Id. at 6:1-3. The discussion of these "well-known encryption algorithms" shows that encryption is not merely protecting data from access with a password or authorization code. Id. at 15:59-6:9. Encryption requires enciphering the information.

The patentees often described the third-level encryption process as "dynamic encryption." Dynamic encryption is a process that combines disparate sources of authorization into an encryption format that one can only decipher by reproducing the same combination of sources. The patent describes this concept in several ways:

A "dynamic" encryption process is utilized so that only the electronic reader associated with the user card used to access the information from the Book Bank and download the information to the user storage cartridge can be utilized to display the information in an understandable text format.

Id. at 4:11-16.

Dynamic encryption refers to the process in which the Book Bank works together with the storage media to perform a proprietary encryption of downloaded data.

Id. at 15:18-20.

Specifically, [dynamic encryption ensures that] data storage medium accessible from one reader/computer will not be accessible using another reader/computer unless such access has been prearranged. . . .

Id. at 15:53-58.

The patent provides a single example of how to implement a dynamic encryption system, although it notes that many other methods are available. Id. at 16:10-12. The example provides for numbering the letters of the alphabet from 1 to 26, and
then "shifting" each number a fixed number of spaces based on the last digit of a serial number electronically embedded in the user's storage media. Id. at 16:12-43. The user's password is then converted to a number that dictates intervals at which the code is re-shifted. Id. at 16:43-67. No one could decode the resulting data without both the user's password and the last digit of the electronic serial number from the user's storage media.

The court notes that although the asserted claims of the patent are focused on the final level of encryption, that encryption process need not be the dynamic encryption process described above. Under the doctrine of claim differentiation, the court must construe an independent claim to avoid nullifying claims that depend from it, unless there is compelling evidence for a nullifying construction. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004) ("[T]he presence of a dependent claim that adds a particular limitation raises a presumption that the limitation in question is not found in the independent claim."). Claim 1 requires a local unit "configured to encrypt" information at time of transfer to a user, whereas Claim 3, which depends from Claim 1, requires that the local unit be "further configured to utilize information stored on the electronic storage media to encrypt," which is the defining feature of the "dynamic encryption" illustrated in the patent. 823 Patent at 15:14-16 ("Dynamic encryption refers to the process in which the Book Bank works together with the storage media to perform a proprietary encryption of the downloaded data."). Thus, if Claim 1 required the dynamic encryption method exemplified in the written description, then Claim 3 would be at least partially redundant. The court concludes that the bare term "encrypt" is not coextensive with "dynamic encryption."

The patent's discussion of encryption reveals that while an encryption process can employ a password, it must ultimately encode information, not merely create a barrier to accessing the information. A process that merely required a password without altering information would not encrypt information. The patent claims do not, however, specify a particular type of "information" to be encoded, see supra Part III.D, and the court finds no basis in the intrinsic evidence for imposing such a limitation. The court therefore construes the term "encrypt" to mean "to encipher or encode by altering information."

F. "to encrypt the payload portion of the packet data" and its variants

<table>
<thead>
<tr>
<th>Term</th>
<th>Widevine Construction</th>
<th>Verimatrix Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>to encrypt the payload</td>
<td>Plain and ordinary meaning based on construction of &quot;encrypt&quot; and &quot;payload portion.&quot; Insertion of &quot;only&quot; is extraneous and contrary to the plain language of the claim.</td>
<td>to encrypt only the examined payload portion of the packet data</td>
</tr>
<tr>
<td>portion of the packet data</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The parties dispute how much of a packet the invention encrypts. Verimatrix seeks to add "only the examined" to every limitation that recites encryption of the payload portion. Under Widevine's proposal, on the other hand, the encryption bridge is capable of encrypting the entire packet.

The common specification of the '175 and '831 patents criticizes the prior art for encrypting an entire packet and explains the benefits of the invention's ability to encrypt only the payload portion of the packet:

With current encryption solutions that encrypt data less discriminately, the data is unable to be delivered across unmodified firewalls, proxy servers and NATs. For instance, when a user requests data from a streaming server, that data stream is organized into packets that have specific data for identifying the target use. Without accurately parsing the data into payload and non-payload parts, the user specific data is readily damaged or scrambled during the encryption process, making it impossible for the firewall, proxy server or NAT to deliver the data to the requesting user. In contrast, the present invention accurately separates the payload and non-payload parts, encrypting only the payload part.

- 1992 -
'175 patent, 18:65-67. Similar language appears in the abstract, as well: "encrypting only the first portion of the data . . . wherein the second portion of the data is not encrypted." '175 patent, Abstract. As a solution to the problem created by encrypting an entire packet, the invention uses "selective encryption" to leave the non-payload portion of a packet intact. See '175 patent, 5:18-24. Yet another excerpt from the specification unambiguously describes the invention as encrypting only the payload portion of a packet:

[T]he invention provides a software bridge that examines network data passing through, parses the network data and only encrypts the relevant payload part, leaving the non-payload part that may include data such as routing, size and other header data surrounding the payload part entirely untouched.

'T175 patent, 8:18-25.

This is one of those cases where the "specification makes clear that the invention does not include a particular feature." SciMed Life Sys. V. Advanced Cardiovascular Sys., 242 F.3d 1337, 1341 (Fed. Cir. 2001). Here, the invention does not include the feature of encrypting anything more than the payload portion of a packet and permits the Court to interpret the claim term more narrowly than it otherwise would. See Honeywell Int'l, Inc. v. ITT Indus., Inc., 452 F.3d 1312, 1319-20 (Fed. Cir. 2006). The Court construes the phrase "to encrypt the payload portion of the packet," and its variants, to mean "to encrypt only the payload portion of the packet."

2. "encrypting"

The parties dispute the meaning of the term "encrypting" in the phrase "encrypting said television signal in accordance with said pseudo-random signal" of claim 21. IPPV argues that "encrypting" includes any and all forms of encryption, while Echostar argues that "encrypting" is limited to a certain form of encryption and does not include a method of encryption called inversion.

In support of its position, Echostar contends that because "encrypting" is sometimes used interchangeably with the terms scrambling and encoding, the plain meaning of "encrypting" is unclear. Thus, the court must look to the specification to determine the proper meaning. Echostar argues that the specification makes clear that "encryption" does not include encrypted event data

Claim 1 contains the term "encrypted event data." Accolade contends that "encrypted event data" means "information representing an action or occurrence coded to be unintelligible without decoding information, commonly a key or a password." Citrix contends that the term means "the event data that was encrypted by the client program."

The Court construes "encrypted event data" as "event data coded to be unintelligible without decoding information, commonly a key or a password." The parties' main dispute is whether the client program encrypts the encrypted event data. Claim 1 itself states, "said client program encrypting event data and transmitting said encrypted event data over said TCP/IP protocol network." Col. 13:53-55 (emphasis added). Thus, claim 1 expressly requires that the client program encrypts event data. Because it is not necessary to repeat in the claim construction what is already clarified in the claims, the Court accordingly constructs "encrypted event data" without reference to a client performing the encryption. Furthermore, the Court applies Accolade's language "unintelligible without decoding information, commonly a key or a password," which will help the jury to understand what is meant by "encrypted." "Event data" does not require further construction because lay jurors would understand the plain meaning of "event data" as simply information regarding an event. The intrinsic evidence does contradict this plain meaning. Accordingly, the Court construes "encrypted event data" as "event data coded to be unintelligible without decoding information, commonly a key or a password."
More specifically, as noted in the introductory portion of the specification, the present invention is based upon an

the differences between analog and digital types of delays, as might be implied from the rejection. Rather the rejected

Claims 1, 13 and 23 were rejected under 35 U.S.C. § 102 as being anticipated by the Block et al. patent. The rejection

as follows:

other parts. In the March 15, 1984 amendment reference by Echostar, the inventors distinguished their application by stating

"encryption," it cannot be applied to the term as used in the 1980s or before. The court, therefore, will look to the

Sherwood went on to testify, "I think encryption was used to make it sound a little more high tech than it really was. But,

deposition that encryption is a component of scrambling, but "the term ["encryption"] was used rather loosely in the '80s."

IPPV responds by arguing that "encrypting" should be construed in accordance with its plain meaning, which is to encode or

scramble information to prevent unauthorized access. It contends that particular embodiments appearing in the specification

should not be read into the claims, and that the specification does not explicitly provide a definition that is contrary to the

plain meaning of the term "encrypting." According to IPPV, the specification describes a preferred embodiment, which
describes encryption of a television signal by rearranging portions thereof with a cyclic encoder, and an alternative

embodiment, which describes encryption of a program signal by randomly rearranging portions thereof with a non-cyclic
encoder. The specification further states that "any type of encoder that is capable of operating in two or more modes under
control of the . . . signal can be successfully employed."

IPPV also argues that the prosecution history does not limit "encrypting." It contends that the inventors' statements
distinguishing the prior art do not refer to claim 21, but rather to claims 1, 13 and 23. Moreover, IPPV contends that claims
1, 13 and 23 contain terminology that expressly or implicitly limits the process of encrypting to rearranging portions of the
television program signal. Specifically, claim 1 refers to a "plurality of delay elements," claim 13 refers to "an encoding
device for rearranging parts of the video signal" and claim 23 refers to "a plurality of analog delay elements." IPPV argues
that these claims are directed at the "cost savings" aspect of the invention, whereas claim 21 is directed at the security aspect
of the invention, which is not concerned with a specific encryption technique.

The essence of the dispute over "encryption" is whether the term includes inversion, a specific method of encryption. As a
preliminary matter, the court concludes that there was no established plain meaning for the term "encryption" when the '942
patent was issued. In distinguishing encrypting from scrambling, Robert A. Sherwood, an expert for IPPV, testified at his
deposition that encryption is a component of scrambling, but "the term ["encryption"] was used rather loosely in the '80s." Sherwood went on to testify, "I think encryption was used to make it sound a little more high tech than it really was. But, generally, they were used interchangeably in the industry." Thus, even if there is currently an accepted plain meaning for "encryption," it cannot be applied to the term as used in the 1980s or before. The court, therefore, will look to the

specification and prosecution history to construe "encryption."

The prosecution history reveals that "encryption" describes a method by which parts of a signal are rearranged relative to
other parts. In the March 15, 1984 amendment reference by Echostar, the inventors distinguished their application by stating
as follows:

Claims 1, 13 and 23 were rejected under 35 U.S.C. § 102 as being anticipated by the Block et al. patent. The rejection
states that the Block patent teaches the delay of a video signal in analog form and the encryption of an encode signal. It is
respectfully submitted, however, that the distinctions between the rejected claims and the Block patent do not lie merely in
the differences between analog and digital types of delays, as might be implied from the rejection. Rather the rejected
claims are directed to a different type of encoding technique than that which is disclosed in the Block patent.

More specifically, as noted in the introductory portion of the specification, the present invention is based upon an

- 1994 -
improvement to the system disclosed in the Block patent. Both the system of the Block patent and that of the present invention operate in the same general fashion to encode a television program signal, i.e. by rearranging parts of the signal relative to other parts thereof.

(emphasis added). IPPV argues that this entire passage refers to claims 1, 13 and 23, and not to claim 21. The court, however, finds that in the second paragraph, the inventors are referring to the invention as a whole and not specific claims. Thus, the court further finds that the inventors defined "encryption" in the present invention as involving the rearranging of parts of the signal relative to other parts.

The specification also reveals that the method of inversion is not included in "encryption." The specification reads as follows:

Other approaches to television signal scrambling have proven to be more secure . . . . One such approach is to invert lines or fields of video information on some basis that can be reproduced at a subscriber location . . . .

Security tends to be adequate in approaches to video scrambling in which the video information is randomly inverted and a secure code is transmitted with the video so that the decoder can properly reinvert, but difficulties arise with respect to picture quality . . . .

Various measures have been employed to eliminate or at least reduce this problem with varying degrees of success . . . .

It is accordingly a general object of the present invention to provide a novel method and system for scrambling or encoding television signals wherein the difficulties of the prior art systems above are obviated.

From this, the court determines that the inventors intended the invention to be a new method of encryption that obviated the drawbacks of inversion. The court therefore concludes that "encryption" does not include the method of inversion. Thus, the term "encryption" of claim 21 describes a method wherein parts of the signal are rearranged relative to other parts. "Encryption" does not include the method of inversion.

The term "end of access control signal" means a signal generated by the requesting agent and transmitted over the system bus to indicate completion of memory access. It need not occur at the end of the memory access as long as it indicates when the memory access is to be complete.

The term "end of access system bus control signal" means a signal transmitted over the system bus to indicate completion of memory access. It need not occur at the end of the memory access as long as it indicates when the memory access is to be complete.

The parties dispute the meaning of the term, "said end user inquiries being the retrieving and viewing of text and/or graphic data from a database" which appears in Claim 1(e) and Claim 3(f) of the '025 Patent. The claim term reads as follows:

accessing data files by said first end users, said accessing data files by said first end users being a plurality of inquiries from individual first end users, said end user inquiries being the retrieving and viewing of text and/or graphic data from a
Plaintiffs contend that the proper construction of the term is "said end user inquiries being requests for information that are passively monitored." Defendants propose that the proper construction of the term is "said end user inquiries being the opening and viewing data received by an end user in response to one or more requests for data from a database." Both parties' proposed constructions restate the initial claim language, "said end user inquiries being." Accordingly, putting aside this restated initial claim language, the parties' dispute centers on the meaning of the remaining claim phrase, "the retrieving and viewing of text and/or graphic data from a database." As discussed more fully below, the Court finds that the available evidence supports Plaintiffs' proposed construction of the term at issue.

In support of their construction, Plaintiffs initially argue that Defendants' proposed construction is not a construction at all, but is only a slightly revised restatement of the claim language that adds an unnecessary limitation. Specifically, Plaintiffs state that Defendants' proposed construction unnecessarily adds a limitation that the "end user inquiries" must consist of data "received by an end user in response to one or more requests for data." Plaintiffs insist that reading such a limitation into the claim construction is improper.

Next, Plaintiffs rely on the '025 Patent prosecution reexamination history. Specifically, Plaintiffs point to Keithley's March 2005 and April 2005 representations to the PTO, made during reexamination of the '025 Patent. (Herbst Decl. P 7, Ex. 5, Response to Office Action in Ex Parte Reexamination and Request for Continued Examination, submitted March 14, 2005 at P. 28-30; P 8, Ex. 6, Response to Office Action in Ex Parte Reexamination and Request for Continued Examination, submitted April 14, 2005 at P. 30-32.) In Keithley's March 2005 representation to the PTO, in an attempt to differentiate the '025 Patent from other prior art, he explained the difference between "actively" collecting data--as taught by prior art, and "passively" collecting data--as taught by the '025 Patent. (Herbst Decl. P 7, Ex. 5 at P. 28-30.) There, Keithley conceded that claim elements 1(c) and 1(d) include an initial form of collecting data that is similar to the "active" data collection feature found in the prior art because the data is collected by having the end user answer specific questions. (Id.) However, Keithley further explained that claim element 1(e) teaches a second form of collecting data, not found in the prior art. (Id.) In particular, Keithley stated that claim element 1(e) relates only to the system "passively" collecting data by watching the end user, rather than requiring the end user to respond to questions. (Id.) In his March 2005 reexamination representation, Keithley stated, "Claim 1 [ ] claims a second form of collecting data, which is a relatively PASSIVE collection . . . Thus, a second set of data may be collected by PASSIVELY watching the inquiries of the first end user as they 'retrieve and view text and/or graphic data.' . . . It is the collection of data by watching the actions of the end user." (Id. P. 29-30.) Keithley made an nearly identical reexamination representation to the PTO in April 2005. (Id. P 8, Ex. 6 at P. 30-32.)

Conversely, in support of their construction, Defendants similarly point to the '025 Patent prosecution reexamination history. (Pleune Decl. P 25, Ex. X, Response to Office Action in Ex Parte Reexamination and Request for Continued Examination, submitted April 14, 2005 at P. 30-33.) 1 Defendants accord significance to Keithley's distinction between "active" and "passive" data collection by focusing on the term, "inquiries," and argue that Plaintiffs' election to focus on the second form of data collection, at the exclusion of the first form of data collection, is somehow improper. However, Defendants fail to adequately explain how Plaintiffs' data collection distinction supports Defendants' proposed construction over Plaintiffs'.

1 In their joint claims construction statement, the parties generally cite to the same portions of the specification in support of their respective constructions. (Jt. Claims Construction Statement 3-7) (containing parallel citations to: col. 1, ll. 12-45; col. 4, ll. 23-26; col. 7, ll. 17-30; col. 11, ll. 16-20.) As noted above, the parties also generally cite to the same portions of the '025 Patent prosecution history and re-examination history. (Id. 5-12) (containing parallel citations to: '025 Patent Prosecution History: Second Preliminary Amendment, filed 7/20/95, p. 10; Reexam History: Response filed 3/14/05 and Response filed 4/14/05.) However, with the exception of the '025 Patent prosecution reexamination history explained above, neither party provides analysis as to how their citations support their respective construction of the term at issue.
express clarification that the claim term at issue focuses on "watching the actions of the end user" and monitoring "the behavior of the first end user as they surf through the database." (Herbst Decl. Ex. 5, P. 30, 32.) Accordingly, the Court finds Defendants' reliance on the '025 Patent prosecution reexamination history to be unsupportive of their proposed construction.

Lastly, without citing legal authority, Defendants argue against Plaintiffs' proposed construction on grounds that it would require the Court to further interpret the phrase, "passively monitored." However, because "courts construe claim terms in order to assign a fixed, unambiguous, legally operative meaning to the claim," the Court finds Defendants' argument unconvincing. Chimie v. PPG Indus., 402 F.3d 1371, 1377 (Fed. Cir. 2005).

In reviewing the current record, the Court finds Keithley's statements during the '025 Patent prosecution reexamination history to be compelling evidence in support of Plaintiffs' proposed construction. Plaintiffs' proposed construction incorporates the term "passively monitored." To that end, it is undisputed that Keithley consistently explained in March 2005, and again in April 2005, that Claim 1(e) relates only to the system "passively" collecting data by watching the end user, rather than requiring the end user to respond to questions. Because the prosecution history is compelling and because Defendants' arguments to the contrary lack merit, the Court finds that the prosecution history weighs heavily in favor of Plaintiffs' proposed construction.

Additionally, although not specifically addressed by the parties in their claims construction briefs, the Court notes that the other claims in the '025 Patent also tend to support Plaintiffs' proposed construction of the term at issue. As to the other claims, claims 1(c) explicitly refers to obtaining "end user information from a first end user . . . ." (Herbst Decl. P 5, Ex. 3, '025 Patent at col. 14, ll. 46-47) (emphasis added.) Claim 1(d) explicitly refers to the act of the "end user" "providing" "digital electronic end user information. (Id. at col. 14, ll. 49-53) (emphasis added.) Thus, in comparing the volitional nature of the contemplated conduct in the claim terms, it is apparent that Claim 1(c) and Claim 1(d) envision more affirmative conduct than does Claim 1(e). Both Claim 1(c) and Claim 1(d) indicate that information will be taken "from," or "provided" by, the end user. In contrast, Claim 1(e) indicates no such requirement on the part of the end user.

Finally, although the specification does not conclusively resolve the construction of the term at issue, the Court finds that it tends to weigh in favor of Plaintiffs' proposed construction. Although not specifically addressed by the parties in their claims construction briefs, the Court notes that the specification states that "the instant invention provides detailed data on all aspects of viewership and response." (Id. at col. 1, ll. 37-38.) Accordingly, the specification contemplates both the passive act of observing the end user's viewership, along with the more active conduct of eliciting a response. This reasoning in consistent with Plaintiffs' repeated explanation between the passive conduct associated with Claim 1(e), and the more active conduct associated with Claim 1(c) and Claim 1(d).

Taking into account the claims, the specification, and the relevant patent prosecution history, the Court construes "said end user inquiries being the retrieving and viewing of test and/or graphic data from a database" as "said end user inquiries being requests for information that are passively monitored."

1585

(2) endpoint, hub, physical layer device

N-Data seeks to give these terms their plain and ordinary meaning. Dell seeks to limit "endpoint" and "hub" to a "network" and "physical device," and it seeks to limit "physical layer device" to a "physical medium." The term "endpoint" appears in only the '216 patent and patent application titled "Network Link Endpoint Capability Detection," incorporated into the patent by reference. '216 Patent, col. 9, ll. 7-10; '261 Patent, col. 13, ll. 17-20. For the reasons discussed above, the court adopts "network" as a part of the definition. The intrinsic record, however, does not support Dell's limitation of the terms to require "physical."

As such, the court defines "endpoint" as a "device at the termination of a network link."

"Hub" is defined to mean "circuitry that connects multiple nodes over data links."

A "physical layer device" is defined as "a device for transmitting or receiving data over a medium."
In construing patent claims, a court should give the terms their plain, ordinary, and accustomed meaning to one of ordinary skill in the relevant art. Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001). A term's ordinary meaning, however, must be considered in the context of all intrinsic evidence, namely the claims, the specification, and the prosecution history. See id. at 1342-43; Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). The specification is "the single best guide to the meaning of a disputed term." Vitronics Corp., 90 F.3d at 1582.

Claim 1 recites:

1. A treatment apparatus, comprising: an energy delivery device including at least a light energy member an RF energy member, and at least one energy delivery surface, the at least one energy delivery surface configured to deliver energy from the light energy member and the RF energy member to and through a skin surface and create a tissue effect at the skin surface or at a site below the skin surface; and a cooling member coupled to the energy delivery device.

Col. 23, 11. 1-10.

The claim requires that both light and RF energy must be delivered through the same energy delivery surface. However, the patent does not define the term "energy delivery surface." At oral argument, plaintiff defined "energy delivery surface" as the outer surface of the energy delivery device through which energy is delivered toward the patient. Relying on the American Heritage definition of surface, defendants define an energy delivery surface as the "layer forming the outer boundary of an object that is designed to deliver both RF and light energy through a single surface to and through the skin." The differences between the definitions are apparent when applied to the Polaris WR system.

The Polaris WR system consists of a console, hand piece (or applicator), and software. The applicator includes a light energy source (diode laser) and an RF energy source (pair of electrodes). See Kreindel Decl. P 12. The two RF electrodes are located at the distal end of the applicator and are spaced apart to deliver RF energy at a depth of 2.5 mm. See id. Between the RF electrodes is a sapphire crystal light guide which delivers laser energy. Id. The tips of the two electrodes extend slightly beyond the end of the light guide. Id., fig. 1; Grundfest Decl. P 45.

Plaintiff argues that the tips of the RF electrodes and light guide jointly form one energy delivery surface. Reitman Decl. PP 23-24. In the words of plaintiff's expert, "the energy delivery surface (c) is arranged with the light energy member (a) positioned between the RF electrodes (b)." Id. The RF electrodes create an electrical current through which light energy passes.

In contrast, defendants argue that the RF electrodes and light guide each have their own energy delivery surfaces. Thus, the Polaris WR system is comprised of three distinct energy delivery surfaces: the end of the light guide and the tips of each of the RF electrodes. Grundfest Decl. PP 44-46. In other words, the applicator end is made up of three different objects, each with their own energy delivery surface. Under defendants' narrower construction, the Polaris WR system does not infringe plaintiff's patent because each energy delivery surface transmits only type of energy: the RF electrodes transmit RF energy and the light guide transmits light energy. See Kreindel Decl. P 12.

The patent specification supports plaintiff's construction. For example, the specification directly contradicts defendants' position that the RF electrodes each form their own energy delivery surface. The specification states, "energy delivery devices suited to this purpose include one or more RF electrodes. Accordingly, energy delivery device 18 can include a plurality of electrodes with or without insulation. The non-insulated sections of the RF electrodes collectively form template energy delivery surface 20." Col. 15, 11. 14-19 (emphasis added). Further, the specification states that "one or more energy delivery devices 18 can form an energy delivery surface 20 in template 12." Col. 6, ll. 64-65.

Additionally, dependent claims support plaintiff's interpretation. For example, dependent claims 8-10 describe an apparatus in which the energy delivery surface is divided into multiple sections. Col. 23, 11. 29-36. The surface of an RF energy
member (electrode) and the surface of a light energy member comprise sections 1 and 2, respectively of the energy delivery surface. Id. The dependent claims lend further support that an "energy delivery surface" can be composed of both RF electrodes and a light guide. Claim 1 must be broad enough to encompass these dependent claims.

The Court accepts plaintiff's definition of energy delivery surface as the outer surface of the energy delivery device through which energy is delivered toward the patient. Defendants' Polaris WR system literally infringes this element of claim 1 because both light energy (from the light guide) and RF energy (from the electrodes) pass through the outer surface or boundary of the energy delivery device (tip of the Polaris WR applicator).

1587

1. "Energy Signal."

Consistent with the intrinsic evidence of the '508 patent, "energy signal" means "a signal representative of the electrical energy determination made by the first processor, such as watthour delivered/received, volt amp reactive hour delivered/received, or volt amp hour delivered/received."

1588
d. "Energy source"

Where the term "energy source" appears in a claim in the shock delivery patents, the patent invariably describes it as connected to the defibrillator electrodes and/or discharged across the electrodes. Thus, whatever the energy source is, it must be a source that is capable of delivering a therapeutic shock to a patient. The court therefore construes "energy source" to mean "a source of energy that is capable of delivering a therapeutic shock to a patient." The parties' main dispute seems to be whether a battery is such an energy source. The patent indicates that a battery can be part of such an energy source. E.g., 454 Patent Claim 23 ("the energy source comprises a battery"). However, if a battery is incapable of delivering a therapeutic shock, it is also incapable of serving as an "energy source" on its own. At oral argument, Defibtech claimed (without evidence) that a battery is incapable of delivering enough shock in a short enough period of time to have therapeutic use, and that only a capacitor or set of capacitors could accomplish the task. The court need not resolve this issue. The claimed "energy source" is one capable of delivering a therapeutic shock. Determining which sources of energy meet this requirement is a question for another day.

1589

2. "enhanced drift region"

Claim 1 of the '046 Patent claims, in pertinent part:

a first region formed completely within said semiconductor material of said first conductivity type, said first region being self-aligned with said conductive gate when forming said first region, and said first region being of first conductivity type and having a second dopant concentration to form an enhanced drift region of said DMOS transistor, wherein said second dopant concentration is greater than said first dopant concentration;

wherein said first region acts to reduce an ON-resistance of said DMOS transistor as compared to said DMOS transistor lacking said first region.

(See '046 Patent at 7:26-58.) Micrel contends that "enhanced drift region" is a label for the region defined by the claim limitations and therefore needs no further construction. MPS proposes that this term be construed as: "region, distinct from the second region, which is more highly doped than the drift region formed by the semiconductor material and substantially reduces on-resistance (e.g. 20-30%)."
The crux of the dispute between the parties is whether the '046 Patent requires the enhanced drift region to reduce the on-resistance by a certain degree, e.g. "significantly" or "substantially," or whether it merely requires some reduction. The claim language at issue does specify that the enhanced drift region "significantly reduce" or "substantially reduce" the on-resistance, but rather, merely provides that it "reduce" the on-resistance. (See '046 Patent at 7:56-58.) Although a court may limit the claim language if the specification clearly sets forth a definition of the disputed term, see CCS Fitness, 288 F.3d at 1366, the specification here does not do so. In most places where the function or purpose of the "enhanced drift region" is discussed, the specification of the '046 Patent teaches that it "significantly" or "substantially" reduces on-resistance. (See '046 Patent at Abstract, 1:64-65, 3:22-24, 5:24-25.) However, in discussing the implantation of phosphorus ions to create the enhanced drift region, the specification also teaches that the dosage may be as low as 5E11 "for advantageous results to occur." (See id. at 3:29-30.) Thus, the Court concludes that the specification does not provide sufficient support to read a limitation into the claim language to require that the enhanced drift region reduce on-resistance to a significant or substantial degree.

In addition to construing "enhanced drift region" to reduce on-resistance substantially, MPS argues that this term should be construed as a "region, distinct from the second region, which is more highly doped than the drift region formed by the semiconductor material." Micrel does not dispute that the enhanced drift region is distinct from the second region and that the second region is more highly doped than the enhanced drift region. Rather, Micrel argues that construing the enhanced drift region in this manner would be redundant because the claim language already make clear that the second region is distinct from and more highly doped than the enhanced drift region (the first region). (See '046 Patent at 7:26-37.) The Court agrees. Therefore, the Court will not define "enhanced drift region" beyond how it is already described in Claim 1.

1590

F. "entering a clerk authorization code for initiating a debit purchase transaction"

CAT construes the term "entering a clerk authorization code for initiating a debit purchase transaction" to mean "the clerk enters a series of numbers and/or letters, or a combination thereof, which permits the initiation of a debit purchase transaction." (D.I. 44 at 24) SVS agrees that the code "permits the initiation of a debit purchase transaction" but construes the phrase "entering a clerk authorization code" to mean "the clerk enters via the keypad a code." (D.I. 47 at 27) Notably, CAT does not dispute that the clerk must enter the authorization code, and SVS does not dispute the format of the code. See, e.g., D.I. 60 at 156 (CAT's attorney: "I think . . . logic would tell me that the clerk has to enter the codes."). Thus, the only disputed issue is whether the clerk must enter the code "via the keypad." I agree with CAT that the clerk does not have to enter the clerk authorization code via the keypad.

SVS repeats the same arguments for the "via a keypad" limitation that I already rejected in connection with the "entering a customer authorization code" term above. (D.I. 43 at 17-18) SVS also contends that the preferred embodiment relating to cell phone activation -- which describes the clerk "entering an authorization 206 code on the remote keypad" -- mandates adoption of its proposed construction. (D.I. 43 at 18) However, as already explained, claim terms are not necessarily limited to a single preferred embodiment. (D.I. 47 at 27) Also, in the prosecution history, the "clerk authorization code" element never contained the "keypad" limitation, nor were the applicants obliged to insert it into the amended claims.

Therefore, I recommend that the Court construe the term "entering a clerk authorization code for initiating a debit purchase transaction" to mean "the clerk enters a series of numbers and/or letters, or a combination thereof, which permits the initiation of a debit purchase transaction."

1591

5. "entering said secret code into the multi-function card to activate the same.

Step 4 of Claim 1 provides for "entering said secret code into the multi-function card to activate the same." 311 patent, col. 10, Ins. 65-66. Plaintiff argues that this term should be construed as
a step of the method recited in claim 1 that means manipulating the multi-function card in some manner to put the secret code assigned in the previous step into the multi-function card in order to activate it. The activation of the multi-function card enables access to the data set of a particular single purpose card, document, key or the like in order to convert the multi-function card in form and function to that particular single purpose card, document, key or the like.

Joint Stmt. at App. A, p. 5. Defendants argue that the Court should construe this term as "entering a code before the electronic multi-function card is turned on, and thus before the electronic multi-function card displays any information." Id. Thus, the primary dispute arises out of what "activated" means and at what point the user enters the secret code.

The terms "to activate", "activated" or "activation" are used throughout the patent, but they are not specifically defined. The first mention states that the multi-function card will be "capable of differentiating between an activated and a non-activated, i.e. neutral, state." 311 patent, col. 2, lns. 12-14. "Neutral" is also a term which is not defined in the patent.

The term "activated" is also used to show that the card is activated when the card holder has entered a secret code. Id., col. 2, lns. 46-48. Perhaps the most specific definition of "activated" provided in the patent is the following:

when not activated, [the card] is a neutral electronic card and, when activated in a particular way, [it] will display the logo of the issuing institute, the holder's photo, his signature and other relevant data in a visible matter. . . . In the non-activated state, which is illustrated in Fig. 1a [sic, 1b] 1, such a card may be regarded as a blank page . . . .

311 patent, col. 4, lns. 39-40. The patent also provides that the user "has to activate the electronic multi-function card . . . by entering his secret code and to decide thereafter which of the available individual cards is to be used." 311 patent, col. 7, lns. 10-13.

Moreover, the patent provides that the "first activation process" is during the initial loading of the multi-function card when the signature and photo become visible for the first time. Id., col. 8, lns. 17-22. Because the patent links the term "activation" to being able to see the signature and photo, and loading single cards onto the multi-function card, "activation," as the term is used in reference to the secret code, requires the state of being able to see, and therefore "access" these things. Simply put, data sets can not be accessed until the user enters in the secret code.

Defendants contend that the user enters the secret code before the multi-function card is turned on. In contrast, plaintiff argues that the secret code is entered to access the data, but the code is not entered before the user turns on the card's power. The patent does not speak to the issue of when the card's power is turned on and off. Instead, it simply provides that the card is not "activated" until the secret code is entered.

Thus, the Court adopts the following definition of "Entering said secret code into the multi-function card to activate the same": "The user activates the electronic multi-function-card by entering the secret code. 'Activated' means the point at which the user has entered in the secret code so that she is able to access a data set."

Defendants contend that the user enters the secret code before the multi-function card is turned on. In contrast, plaintiff argues that the secret code is entered to access the data, but the code is not entered before the user turns on the card's power. The patent does not speak to the issue of when the card's power is turned on and off. Instead, it simply provides that the card is not "activated" until the secret code is entered.

Thus, the Court adopts the following definition of "Entering said secret code into the multi-function card to activate the same": "The user activates the electronic multi-function-card by entering the secret code. 'Activated' means the point at which the user has entered in the secret code so that she is able to access a data set."

Plaintiff contends that this phrase means "causing the information concerning the FCC unit to go into or be received into a programmed computer in order to settle or decide by a choice of alternatives. . . ." 55 Defendants contend that it means "the
act of inputting the data obtained previously in Step I into a computer that contains a sequence of coded instructions for the purpose of fixing, by way of calculating, the recited parameters of the injection schedule." 56 The Court will examine several words and phrases in turn.

56 (Defs.' Opening Claim Construction Br. at 25.)

--- End Footnotes ---

A. "entering"

Plaintiff defines "enter" as "to cause to go into or be received into something" as in "<. .a boy at a school>." 57 Defendants define "enter" as "put in: insert" as in "<. .the new data into the computer>" and ultimately propose "inputting." 58 "Input" is defined by Webster's Third New International Dictionary (1986) as, among other things, "data or similar information fed into a computer or accounting machine." Id. at 1167. It is clear from the claim's context that Defendants' definition is most consistent with the patentee's use of the word and the intrinsic record. See Ferguson, 350 F.3d at 1338 ("The words used in the claims must be considered in context. . . ."). The claim speaks of "entering the data . . . into a programmed computer." '236 patent, col. 15, ll. 62-63. And the specification teaches that "by inserting [certain] known values into the following equations [as provided], an individual or computer program can determine an initial or primary schedule for the introduction of catalyst X." '236 patent, col. 10, ll. 20-23 (emphasis added). Given this context, the Court finds that "entering" means "inputting."

--- End Footnotes ---

B. "data"

The Court has previously found that "data" requires no construction. See supra Analysis Part I.B. Because this word is used consistently throughout the claim, no construction is needed here. See Phonometrics, Inc., 133 F.3d at 1465.

C. "concerning the FCC unit"

The Court has previously found that "concerning" carries its ordinary meaning of "relating to." See supra Analysis Part I.E. Because this word is used consistently throughout the claim, the Court gives it the same construction here. See Phonometrics, Inc., 133 F.3d at 1465.

D. "programmed computer"

The parties have agreed that "computer" means "a programmable electronic device that can store, retrieve, and process data." 59 The Court has no quarrel with this definition, but finds it unnecessarily cumbersome and will provide no construction here.

--- Footnotes ---

59 (Joint Claim Construction Br. at 1.)

--- End Footnotes ---

E. "in order to"
The Court has previously construed "in order to" to mean "for the purpose of." See supra Analysis Part I.C. Because this phrase is used consistently throughout the claim, the Court gives it the same construction here. See Phonometrics, Inc., 133 F.3d at 1465.

F. "determine"

Plaintiff defines "determine" as, among other things, "to settle or decide by choice of alternatives or possibilities" and "to fix the form or character of beforehand." 60 Defendants define "determine" as "to fix the form, position, or character of beforehand: ordain" and "to find out or come to a decision about by . . . calculation." 61 They ultimately propose that "determine" be construed as "fixing, by way of calculating, the recited parameters of the injection schedule." 62

Because "determine" has multiple dictionary definitions, "some having no relation to the claimed invention, the intrinsic record must . . . be consulted to identify which of the different possible dictionary meanings . . . is most consistent with the use of the words by the inventor." Texas Digital, 308 F.3d at 1203 (citations omitted). "[A] common meaning, such as one expressed in a relevant dictionary, that flies in the face of the patent disclosure is undeserving of fealty." Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998). Consulting the intrinsic record, it is clear that Plaintiff's first proposed definition--"to settle or decide by choice of alternatives or possibilities"--is inadequate. It is too broad and it fails to consider the involvement of a computer. See Ferguson, 350 F.3d at 1338 ("The words used in the claims must be considered in context. . ."). Considering that the stipulated definition of "computer" is "a programmable electronic device that can store, retrieve, and process data," 63 expanding the definition to encompass "settle[ing] or deciding" would be inappropriate. In contrast, Plaintiff's second proposed definition, which is nearly identical to Defendants' first proposed definition--"to fix the form or character of beforehand"--is more consistent with the patentee's intended use. Thus, the Court concludes that "determine" means "to fix."

The parties also disagree over whether the "determination" requires a computer calculation. Defendants argue that a computer calculation is required. 64 Plaintiff is not so categorical. It argues that the "determination can come by way of a "computer calculation of raw data" or by way of a "computer implementation of [an individual's] mental assessment" of the data. 65

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -
The Court agrees with Plaintiff's view. The claim states that data concerning the FCC unit is inputted into a computer "in order to determine" an injection schedule composed of "a basic cycle time," "a first period of the basic cycle time," "a second period of the basic cycle time," and "an addition amount of the catalyst." '236 patent, col. 15, ll. 64, 66, col. 16, ll. 1, 3. The claim does not state, however, that a computer calculation or a computer implementation of an individual's mental assessment is necessary to achieve this result. But the specification teaches that either may be performed. For instance, the specification states that the "basic cycle time is used to establish (by engineering calculations and/or computer programs) a regular schedule of introduction for a particular catalyst ingredient in a FCC unit being used for a given FCC task." '236 patent, col. 8, l. 65-col. 9, l. 1 (emphasis added). It also states that "by inserting the[ ] known values into . . . equations, an individual or computer program can determine an initial or primary schedule for the introduction of catalyst X." Id., col. 10, ll. 20-24 (emphasis added). In both instances, the specification contemplates that a computer or an individual will perform certain calculations to determine the injection cycle. Thus, a "determination" may be carried out by way of a computer calculation of the data or a computer implementation of an individual's calculation of the data.

G. Summary

Accordingly, the Court concludes that the phrase "entering the data concerning the FCC unit into a programmed computer in order to determine . . ." means "inputting the data relating to the FCC unit into a programmed computer for the purpose of fixing, by way of a computer calculation of the data or a computer implementation of an individual's calculation of the data . . .".

3. "entering the recording device to said conference call as an additional participant"

NICE's Construction | Witness's Construction
--- | ---
Plain meaning. | Joining the recording device to the conference call as an additional participant after the conference call has been established between the first and second participants.

The parties dispute the meaning of "entering the recording device to said conference call as an additional participant," as used in claim 1. NICE contends that, following the Court's construction of "recording device" and "conference call," the disputed term has plain meaning that does not require construction. Witness's timing limitation, NICE contends, has no basis in the claim language or specification. Witness contends that the text and structure of the claims require the recording device to be entered after the conference call has already been established between the original participants, citing claim 1 ("entering the recording device to said conference call as an additional participant." (emphasis added)). NICE responds that claim 2, which is dependent on claim 1, makes clear that the recording device is entered at the same time as the data session is initiated:

"[T]he method of claim 1, wherein the step of selectively entering the recording device to said conference call includes the step of directing the recording device to enter said conference call as the additional participant when a data session has been initiated.

(col. 7:27-31 (emphasis added).)

The Court concludes that "entering the recording device to said conference call as an additional participant" does not require construction. Though claim 1 might be read to reveal a sequential ordering of activities by the method, with the recording device entered last, claim 2 clearly shows that this sequential ordering is not required.
8. "Enterprise monitor": an A network monitor that receives and analyzes data from domain monitors.

n8 '203, '212 and '615 patents, multiple claims.

12. "Enters"

Defendants argue that "enters" means "inputting the DTMF digits of the called party number by the subscriber using the keypad of the telephone handset," while Cygnus argues that "enters" means "dials" or "calls." "Enters" appears in claims 1, 6, and 11 of the '027 patent as part of the phrase "the subscriber enters the [telephone] number of the called party." "Enters" appears in the specification once, in the description of the preferred embodiment: "When the subscriber enters a called party number, CRU 20 seizes a second outbound circuit 25. DTMF Generator 26 recognizes the called party number DTMF digits entered by the subscriber and outpulses those digits over the second seized circuit." '027 patent, col. 7, 11. 50-54. While in the preferred embodiment, the "called party number" is clearly sent by the subscriber as "DTMF digits," the claim is not so restricted.

"Enters" means "dials."

d. "an entire ring oscillator variable speed system clock in said integrated circuit"

The plaintiffs argue that this term means "a ring oscillator that generates the signal(s) used for timing the operation of the CPU, capable of operating at speeds that can change, where the ring oscillator is located entirely on the same semiconductor substrate as the CPU." The defendants' proposed construction is "a [ring oscillator variable speed system clock] that is completely on-chip and does not rely on a control signal or an external crystal/clock generator." The dispute is whether the ring oscillator may rely on a control signal or an external crystal/clock generator.

In support of their construction, the defendants argue that the applicant disclaimed use of a control signal and an external crystal/clock generator in order to distinguish over prior art. The plaintiffs contend that it did not disclaim all types of control signals, such as voltage and current controlled oscillators; there was only a disclaimer of the more narrow "command input." In addition, the plaintiffs argue that, although an external crystal is not directly used to generate a system clock signal, the external crystal can be used as a reference signal to account for delay across certain circuit elements.

The Court agrees with the defendants that the applicant disclaimed the use of an input control signal and an external crystal/clock generator to generate a clock signal. See Response to Office Action, April 11, 1996, at 8; Response to Office Action, January 13, 1997, at 4; Response to Office Action, July 7, 1997, at 3-4. Accordingly, the Court construes the term to mean "a ring oscillator variable speed system clock that is located entirely on the same semiconductor substrate as the CPU and does not directly rely on a command input control signal or an external crystal/clock generator to generate a clock signal."
N. "entries"

Claim 1 contains the term "entries": "a database with entries correlating each of a plurality of user IDs with an individualized rule set." The specification states that "[t]he present invention allows for creating and implementing dynamically changing rules, to allow the redirection, blocking, or allowing, of specific data traffic for specific users, as a function of database entries and the user's activity." Linksmart states that no construction is necessary, or alternatively, proposes "records in a database." BWI asserts the following construction: "records in a database, each record including a user ID and a unique rule set individualized for the user ID."

According to BWI, the rule set must be unique and individualized for each user ID. But claim 7, which depends from claim 1, explains that the entries correlate a plurality of users' IDs with a common individualized rule set. As such, the term "entries" does not require the entries to correlate a unique rule set to each user ID. BWI also asserts that each record must include a user ID and a rule set. BWI relies on a portion of the specification that illustrates a record containing a user ID and rule set. (‘118 patent, 6:11-22). This portion of the specification describes an embodiment, however. The claim language states that the entries correlate, not include, the user IDs and rule sets. Nothing in the patent excludes a database with user IDs and rule sets stored in separate tables. Finally, the remainder of BWI's construction merely restates what is required in the claim language--the correlation of user IDs with rule sets. As such, the court construes "entries" to mean "records in a database."

2 At the May 25, 2010 claim construction hearing, counsel for BWI appeared to argue that the court should not consider claim 7 when construing "entries" because "claim 7 hasn't been asserted in this lawsuit." A person of ordinary skill reading the '118 patent would discern, however, that claim 7 is intrinsic evidence regardless of whether Linksmart would later decline to assert that claim. See also Phillips, 415 F.3d at 1315 ("Other claims of the patent in question, both asserted and unasserted, can also be valuable sources of enlightenment as to the meaning of a claim term.").

2. The '562 patent

As for the phrases "an entry initiate key" and "entry initiate signal," the district court acknowledged that an indefinite article normally means "one or more" in open-ended claims, but found sufficient evidence in the specification of the '562 patent and the prosecution history to limit "an" to the singular. We agree that "a" or "an" normally carries the meaning of "one or more" in claims containing the transitional phrase "comprising." KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000). Here, however, the patentee clearly intended the use of only one entry initiate key.

Looking first to the language of Claim 9 itself, the phrase "user activation of an entry initiate key" is immediately followed by a reference to "said entry initiate key," which reinforces the singular meaning. See Abtox, Inc. v. Exitron Corp., 122 F.3d 1019, 1023-24 (Fed. Cir. 1997). Likewise, Claim 1 refers to a "keyboard means having a plurality of keys for providing respective keyboard output signals upon user activation of respective one of said keys . . . said keyboard output signals further comprising an entry initiate signal." The patent thus contemplates pressing only one key at a time to provide keyboard output signals, including the entry initiate signal. Significantly, during prosecution, the claim language was amended from "ones of said keys" to "one of said keys," a disclaimer of the plural.

The specification further confirms that the patented invention only uses one entry initiate key. In describing how a particular embodiment could incorporate the inventions described by the '359 patent as well as the '562 patent, the specification states that pressing more than one key simultaneously would initiate a routine "which is irrelevant to an understanding of the
present invention," i.e., the "learn" or "scan" method which is described in the '359 patent. ’562 Patent, col. 5, ll. 7-21.

In any case, if the number of keys pressed exceeds one, the routine is not part of the present invention and will not be described in detail herein.

If the number of keys pressed is equal to one, the microprocessor first tests whether this is the record key. If the user has pressed the record key (herein also referred to as the enter initiate key), he has taken the initial step for implementing the present invention, i.e., for entering the necessary data for identifying a particular manufacturer and model number directly on the keyboard.

Id. at col. 5, ll. 21-31 (emphasis added). We thus agree with the district court that "an entry initiate key" means "one entry initiate key" and "entry initiate signal" means "the keyboard output signal generated by the entry initiate key."

Because it is undisputed that the accused device required a user to press two keys simultaneously to initiate the code entry programming sequence, a routine that was expressly disclaimed by the '562 patent, we must affirm the summary judgment of non-infringement.

D. "Alert Envelope"

Honeywell appeals the district court's claim construction of the term "alert envelope." Claim 1 of the '080 patent calls for a "first alert envelope" and a "second alert envelope." According to the claim, these indicate a first and second terrain threat. The district court construed "first alert envelope" as a "term of art in avionics and means an at least 2-dimensional region in the vertical plane surrounded by a continuous boundary." Claim Construction Decision, 264 F. Supp. 2d at 148. For the term "second alert envelope," the district court required "two distinct alert zones, the boundaries of which are independently determined by distinct first and second functions of the same variables; specifically flight path angle, look ahead distance, and terrain floor boundary." Id. The district court construed the terms according to its reading of "the language set forth in the claim." Id.

Claim 1 of the '080 patent describes the "first alert envelope" as a determination of the "first function of the flight path angle, said look ahead distance and said terrain floor boundary." Claim 1 of the '080 patent describes the "second alert envelope" as "indicative of a second severity of terrain threat, wherein boundaries of said second alert envelope are determined as a second function of the flight path angle, said look ahead distance and said terrain floor boundary" and "outputting an alert signal when a subset of the stored terrain information is located within the boundaries of at least one of said first and second alert envelopes."

Once again, the claim itself provides considerable information about its meaning. In part, the district court correctly defined the "alert envelope" as a two dimensional region of space with some detail about the way to determine the boundaries of each envelope. The district court, however, incorrectly added the limitations not found in the specific language of the claim. Specifically, the trial court read in requirements that the alert envelope appear "in the vertical plane" and "surrounded by a continuous boundary." The claim itself explains that "alert envelope" encompasses "an at least two dimensional region whose boundaries are determined as a function of the flight path angle, look ahead distance and terrain floor boundary." In sum, one of skill in this art would agree that the claim defines this term adequately without additional limitations.
encompasses a system that uses distance as an operative warning parameter; that is, the court's construction allowed claim 1 of the '436 patent to cover a system that uses the distance of an airplane from an airport not just as a trigger to enable the warning system, but as one of the operative warning parameters in the warning system itself. Universal characterizes the warning system of its accused device as being "always on" and therefore not being "enabled" based on the distance of the airplane from an airport. Universal contends that its system does not fall within the scope of claim 1, as properly construed, because the claim should have been construed to encompass only the use of "an enclosed boundary for activating or turning on a warning system as a function of distance of the aircraft with respect to the airport and wherein the warning system does not itself use that distance as an operative warning parameter."

The language of claim 1 is broad enough to cover any system that creates an area within a particular distance from an airport in which a ground proximity warning system will operate to give a warning when another parameter is triggered, such as the aircraft's height above the ground. Moreover, nothing in the specification requires that the term "enabling envelope" be given a narrower construction. Universal notes that the specification describes a system that uses some indicator other than flap position to enable a warning system and that distance was not used as a parameter in the prior art warning systems described in the specification. While that is true, the specification is not at odds with the court's construction of the term "enabling envelope," which referred to "activating or turning on" a set of limitations for safe operation of the aircraft.

Relying on a passage from the prosecution history, Universal contends that during prosecution the applicants disclaimed a ground proximity warning system that uses airport distance in determining whether to issue a ground proximity warning, as the warning system of the accused device does. The purported disclaimer came in the course of one of the applicants' responses to the examiner's rejection of several claims as obvious in light of an article by Jeffrey Parnau about aircraft systems that warn pilots that they are about to enter restricted airspace. The Parnau reference disclosed a system that would give a warning based on an aircraft's distance from a specific point. The examiner found it obvious from that reference to make that point the center of an airport runway and to use the aircraft's distance from that point to determine when the airplane is on final approach to the runway.

In response, the applicants distinguished their final-approach detection system from the Parnau warning system as follows:

While the applicants agree with the Examiner's characterization of the Parnau reference, it is equally clear that the warning system referred to in the Parnau reference relies on distance as an operative warning parameter. . . However, such a warning is based solely on the distance of the aircraft from the restricted airspace. In contradistinction, the warning system recited in the claims at issue recites a 'warning of a hazardous flight condition' enabled 'as a function of the distance between the aircraft and a reference point.' Thus, it should be clear that contrary to the teachings of Parnau, the warning system recited in the claims at issue does not utilize distance as an operative warning parameter, but merely to enable the warning system.

Focusing on the applicants' use of the indefinite article "an" in referring to the term "operative warning parameter," Universal argues that the applicants disclaimed any system in which distance was used as one factor in determining whether to issue a warning.

Honeywell argues that the passage in question distinguishes Parnau on the ground that it issues a warning based "solely on the distance of the aircraft from the restricted airspace." Thus, according to Honeywell, the warning in Parnau is triggered solely by distance, whereas in the applicants' claims, distance both enables the warning system and may be used, in conjunction with some additional factor or factors such as aircraft altitude, to trigger a warning.

The passage in question can be read either way. The reference to Parnau's warning as based "solely on . . . distance" supports Honeywell's interpretation of the passage, while the reference to the application claims as "not utiliz[ing] distance as an operative warning parameter" supports Universal's interpretation. In context, however, it is plausible to read the phrase "an operative warning parameter" as referring to the sole parameter that triggers a warning, particularly in light of the fact that in Parnau itself distance is the sole operative warning parameter. The quoted passage can thus be understood to distinguish Parnau as a system in which distance is used not to enable the system, but to trigger a warning; read that way, the passage would not exclude a system in which distance is used to enable and also as a parameter in determining whether a warning should issue. Because the passage is ambiguous, we conclude that it does not constitute a sufficiently clear and deliberate statement to meet the high standard for finding a disclaimer of claim scope. See, e.g., N. Am. Container, Inc. v. N. Am. Container, Inc. v.
Plastipak Packaging, Inc., 415 F.3d 1335, 1345--46 (Fed. Cir. 2005). We therefore reject Universal's argument that the trial court's construction of the claim term "enabling envelope" was impermissibly broad. 1

1 Universal also argues that the claim term "envelope" should be construed to have its plain meaning of "a boundary that encloses." Although the district court defined "enabling envelope" for the jury as "activating or turning on a set of limitations within which an aircraft can perform safely and effectively," that construction more accurately defines the claim term "enabling the warning system." It is not clear that Universal preserved an objection to that aspect of the jury instruction, but in any event because nothing turns on the precise definition of "enabling envelope," that minor semantic issue is not a basis for overturning the verdict.

Datapoint next contends that it was error for the Master to construe the claim term "equal peers" in claim 31 of the 732 patent to mean that nodes must have direct access to all other nodes in the network so that all data frames transmitted by each node are "heard" by all other nodes. It contends that this claim construction is incorrect because it (1) excludes the preferred embodiment, insofar as the basic nodes in Figure 1 above, cannot "hear" the communication between the enhanced nodes, and (2) improperly limits the invention to the preferred embodiment, insofar as it requires direct access to all other nodes in the network through a single logical point. Alternatively, Datapoint asserts that it was error for the Master to define "equal peers" when that term already had been defined in the patent specification.

The phrase "equal peers," appearing first in the 732 patent specification as a part of the amendment referred to above, explains the method by which the various nodes communicate:

Each node of a bus-type LAN may directly address and communicate with all of the other nodes as equal peers through the single logical point . . . The nodes are equal peers because none of them have a higher hierarchical status than the others for purposes of communicating in accordance with the predetermined logical connectivity pattern over the single network configuration.

732 patent, col. 4, lines 54-65. This amendatory language was accompanied by Datapoint's remarks distinguishing two prior art patents, Beierle and Coden. Datapoint distinguished Beierle by noting that some nodes, particularly in Beierle's disclosed star configuration, existed at a higher hierarchy:

The Beierle reference discloses a network in which all of the nodes are connected in a plurality of different network configurations and in which communications occur in accordance with different logical connectivity patterns . . . . [A] 'master' node in the star network has a higher hierarchy than the other nodes in order to effect the star logical connectivity pattern, and indeed some of Beierle's network configurations themselves appear to have greater hierarchy than other network configurations, even though the same nodes appear to be involved. The nodes do not, therefore, appear to be equal peers.

Similarly, Datapoint distinguished the Coden reference in a manner that sheds light on the intended meaning of "equal peers":

[Coden] appears to be a network [that] uses a bus in order to also effectuate a ring. In order to do so, the ring nodes appear to communicate with the bus nodes through an interface [that] resembles a bridge. Thus, it would appear that the ring nodes and bus nodes have different hierarchical levels and are not peers, because a ring node cannot directly communicate with another ring node, except by passing communications through bus nodes.

In effect, Datapoint urges that we determine the meaning of "equal peers" from only the amendatory language that appears
in the specification. Although one may begin to glean some meaning of the term from the specification, it was entirely appropriate for the Special Master (and now for us) to look also to the prosecution history to aid in our interpretation of "equal peers." Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995) ("Arguments and amendments made during the prosecution of a patent application and other aspects of the prosecution history, as well as the specification and other claims, must be examined to determine the meaning of terms in the claims."). This presents the classic example of why reference to the prosecution history is not only appropriate but often is necessary. To suggest in this instance, as Datapoint does, that the definition in the specification is sufficient -- "The nodes are equal peers because none of them have a higher hierarchical status than the others" -- simply begs the question of what is meant by the phrase "higher hierarchical status." We therefore do not agree that the Master erred by refusing to limit his construction of "equal peers" to the "definition" in the specification.

Considering the above-excerpted quotes distinguishing Beierle and Coden, in light of the specification, we are satisfied that the Master's construction of "equal peers" was correct. Nevertheless, Datapoint argues that it was error to require all nodes to "hear" each communication, because "the claim language does not require a communication to traverse the entire medium." App. Br. at 32 (quoting 879 patent, col. 22, lines 45-50 ("New hubs capable of transmitting data at the enhanced rate must be presenting those segments of the network where enhanced frames are communicated, but basic hubs may continue to be used on branches of the network which contain basic nodes."). Read in context, this excerpt does not support the proposition for which it is cited.

To the contrary, the 732 patent specification makes quite clear that (1) all data being sent over the network have a source and destination address, and (2) all nodes review the data to determine whether they are the intended recipient of the transmitted message. See, e.g., 732 patent, col. 5, lines 12-17 ("Since all of the other nodes on the LAN also receive the signals transmitted by the source node, the address of the destination node is utilized by each node on the network to recognize and accept only those transmissions addressed to it, while discarding or not recognizing the other transmissions not addressed to it.") (emphases added). Thus, the Master's construction requiring that each node "hear" (as opposed to process or otherwise manipulate) every communication, simply reflects the inherent fact that each node must "hear" a communication before it can "recognize and accept only those transmissions addressed to it." Viewed through this prism, we agree with the Master's construction.

GO BACK

1602

MStar also argues that the Commission erred in construing the "equality" limitation. Claim 1 requires that "said second clock signal is generated to have a clock period such that the time to provide said plurality of destination pixel data is equal to a period to receive said source pixel data in said source image frame." '867 patent, col. 22, ll. 15-18. In the 481 Investigation, the Commission determined that this required an "equality of the periods to receive the source image frame and to provide the destination image frame." 481 Commission Decision, slip. op. at 9. The ALJ adopted the same construction for the 491 Investigation, although the parties disputed the meaning of "image frame." However, both the ALJ and the Commission agreed with Genesis that this construction "mean[t] an equality of full frame periods," i.e., there must be equality of the periods of time to input and output active pixel data, horizontal blanking pixel data and vertical blanking pixel data.

On appeal, MStar argues that the "period to provide said plurality of destination pixel data" (which is "representative of said destination image frame") should not include the time to provide vertical blanking pixel data. First of all, MStar notes that the ALJ had construed the phrase "pixel data" as used elsewhere in the claim language to include only active pixel data, and not blanking pixel data. Thus, MStar argues that the "period to provide said plurality of destination pixel data" only includes the time to provide active pixel data. However, MStar concedes that because horizontal blanking pixel data is interspersed between active pixel data, the "period to provide said plurality of destination pixel data" must include the time period to provide both active pixel data and horizontal blanking pixel data. In other words, it is impossible to determine the period to input or output the active pixel data of an image frame without including the time to provide the horizontal blanking pixel data. However, because vertical blanking pixel data is at the end of an image frame, after all the active pixels, it is possible to time the input or output of active pixel data and horizontal blanking pixel data without including vertical blanking pixel data. Thus, MStar proposes a construction that would include the time to provide active pixel data and horizontal blanking pixel data, but not vertical blanking pixel data.
Not only is such a construction strained, but it also ignores the fact that the claim language refers to the "period to provide said plurality of destination pixel data," which is "representative of said destination image frame." MStar argues that because "pixel data" as used elsewhere refers only to active pixel data, the "destination pixel data . . . representative of said destination image frame" must include only active pixel data. However, while the blanking pixel data is not visible on the monitors, it is part of the "destination image frame" as it affects the timing of the pixel data flow. Indeed, MStar concedes that "upscalers must recognize the fact of vertical blanking lines." Appellant's Reply Br. at 21. In response to the charge that its construction of the claim is "technologically implausible," MStar argues to no avail "that upscalers must operate in a given way does not mean that the claim language must cover that [necessary] operation." Id. Finally, we note that the whole specification refers to equal frame rates (i.e., frames per second in versus frames per second out). The specification does not teach that the inventor or one skilled in the art would seek to measure the strained subset advanced by MStar. Thus, because vertical blanking pixel data is necessary to make an image appear on the screen properly, the "destination pixel data" which is "representative of said destination image frame" must include active pixel data, horizontal blanking pixel data and vertical blanking pixel data. MStar has failed to show any error in the Commission's claim construction.

GO BACK

1603
Equipment

Defendants argue "equipment" should be construed as "implements such as machinery or tools used in an operation or activity." Again, the Court agrees with Orion that this term does not require construction. "Equipment" is not used in a manner inconsistent with its ordinary lay meaning. Like "parts," "equipment" is a common word that any jury will understand. Further, Defendants' construction is again likely to be misleading. As Defendants point out, Figure 29 lists "industrial, road & misc. equipment, farm equipment, light trucks & vans, passenger cars, trucks, buses & coaches" as examples of equipment. It may not be obvious to a jury that they are to consider light trucks and vans, passenger cars, trucks, and buses to be "implements."

GO BACK

1604
G. "Erasing Said Video Product"

Plaintiff's Construction

To remove or obliterate the downloaded and stored video data from the storage locations where the video data is stored, such as to clear, overwrite or designate as deleted such storage locations.

Defendant's Construction

At the user site, deleting the video product from memory entirely; this does not include scrambling or other methods of limiting access to the video product.

Defendant agrees with Plaintiff that this claim term refers, at least, to removing or obliterating the downloaded and stored video data. (See D.I. 65 at 13.) Furthermore, Plaintiff does not appear to take issue with Defendant's position that the erasing must take place at the "user site." Thus, the dispute between the parties is whether this claim term also refers to "scrambling" or "designating as deleted" (Plaintiff's position) or not (Defendant's position).

Plaintiff draws its proposed construction largely from the Federal Standard 1037C Glossary of Telecommunications Terms, which defines "erase" as "[t]o obliterate information from a storage medium, such as to clear or to overwrite." (D.I. 64, Exh. L.) Plaintiff further points to the Merriam-Webster OnLine Dictionary, which sets forth a quaternary definition for "erase" as "to delete from a computer storage device." (Id., Exh. M.) Based on this, Plaintiff apparently contends that the claim term should be defined to also encompass designating storage locations as being deleted. Notably, both of Plaintiff's dictionary
definitions postdate the filing of the '402 patent.

In response, Defendant points to the following excerpts from the specification:

. "In one embodiment, the control system erases or scrambles the stored program after it has been viewed a predetermined number of times (e.g., once), and in other embodiment the program is erased or scrambled after a predetermined interval (e.g., 24 hours)." ('402 patent at 2:21-26 (emphasis added).)

. "Control unit 22 also erases or otherwise (e.g., scrambles) limits access to the stored data after a use limit specified by the central station or fixed at the customer site have been met or exceeded . . . " (Id. at 3:22-25 (emphasis added).)

. "If the result of the comparison step at block 54 is affirmative, the microprocessor 30 issues a command to controller 44 to erase the video data stored in memory 20 or to otherwise block access to the data by the television set 18." (Id. at 4:44-49 (emphasis added).)

Based on these excerpts, Defendant contends that the specification distinguishes erasing of the data from other methods of limiting access, such as scrambling.

The Court agrees with Defendant that the specification clearly distinguishes "erasing" from scrambling and other methods of blocking access. In light of this intrinsic evidence, which speaks directly to the dispute between the parties, the Court is reluctant to rely on Plaintiff's dictionary definitions. Indeed, both dictionary definitions postdate the filing of the patent. Furthermore, in the Court's view, neither of the definitions legitimately support the notion that "erasing" should include designating storage locations as being deleted. Because the parties agree that this claim term refers to "removing or obliterating the downloaded and stored video data," the Court will define it as such. In addition, the Court will clarify that this term does not refer to scrambling or other methods of blocking access. Finally, the Court notes that Defendant's proposed construction requires that the "erasing" take place at the "user site." In reviewing Plaintiff's briefing on this term, the Court does not detect any opposition to this position. Furthermore, as explained above, because the claims explicitly call for the video product to be transmitted to the "user site," it must be that the "video product" is also ultimately erased at the "user site." Accordingly, the Court will construe "erasing said video product" to mean "at the user site, removing or obliterating the downloaded and stored video data; this does not include scrambling or other methods of limiting access to the video product."

E. "Error Code Correction And Detection (ECC) Subsystem"

1. Proposed Constructions

Plaintiffs' proposed construction of "an error code correction and detection subsystem" or "ECC subsystem" is "a portion of a larger system that performs error correction and detection." Plaintiffs' '736 Br. at 14. Defendants, however, propose that "error code correction and detection subsystem" should be construed according to its ordinary meaning, which they contend is: "one subsystem that performs all error correction and detection on two different formats of processed data, such as CD and DVD format processed data, according to applicable standards or specifications, to produce corrected data which is to be transferred to a MPEG decoder." Defendants' '736 Br. at 12. Thus, the main dispute between the parties is whether there is one subsystem that utilizes the same circuitry to perform all error correction and detection on two different formats of processed data, or whether the claim supports multiple error correction and detection subsystems.

2. Claim Language 8

The parties do not contest that claims 1 and 7 use the phrase "error code correction and detection subsystem" even though the process carried out by that subsystem is generally described as "error correction and detection." Plaintiffs' '736 Br. at 14; Defendants' '736 Br. at 12-14. The parties further agree that "error code correction and detection" is abbreviated as "ECC" in
the patent and that this abbreviation is common for systems that perform error correction and detection. Id. at 14-15, n. 7.

Defendants contend that the claims require that the ECC subsystem perform error correction and detection on the processed data to produce corrected data, which is transferred by the parallel interface to the MPEG decoder. Defendants' '736 Br. at 12. Furthermore, as mentioned earlier, defendants assert that the ordinary meaning of the claims requires their proposed construction of "ECC subsystem" as "one subsystem that performs all error correction and detection on two different formats of processed data, such as CD and DVD format processed data, according to applicable standards or specifications, to produce corrected data which is to be transferred to a MPEG decoder." Id.; '736 patent at Figs. 4 & 5, 3:62-4:15, 4:30-35, 8:15-26. 9

9 Plaintiffs argue that the '736 patent at 3:66-4:15 contradicts defendant's narrow construction because that embodiment's error code correction and detection operations are not associated with any standards although that embodiment's sync detection and demodulation for CD and DVD data are described with reference to standards. Reply at 6. Plaintiffs also contend that Figure 4 does not limit the invention because the specification states that Figure 4 depicts "an embodiment of DVD/CD controller 62." Id.; see '736 patent at 6:40-41. Lastly, plaintiffs assert that the '736 patent at Figure 5, 7:38-8:1, and 8:15-18 relate to the embodiment of Figure 4 as signified by the reference numeral "96" used for the ECC subsystem. Reply at 6.

On the other hand, plaintiffs assert that because the claims use the transitional term "comprising" with the indefinite article "an," the article "an" is an open-ended claim limitation meaning "at least one." Scanner Techs. Corp. v. ICOS Vision Sys. Corp. N.V., 365 F.3d 1299, 1304 (Fed. Cir. 2004); Crystal Semiconductor v. Tri Tech Microelectronics Int'l, Inc., 246 F.3d 1336 (Fed. Cir. 2001). To rebut plaintiff's claim that "an" is an open-ended claim limitation, defendants contend that their construction is not based on the term "an." Defendants' '736 Br. at 13, n.12.

d. Specification

Citing to '736 patent specification at 3:8-23 and 3:50-58, defendants argue that there can only be one ECC subsystem because the claimed benefit of the patent in reducing the number of subsystems would not be accomplished under plaintiffs' assertion that the claims allow for multiple ECC subsystems. Id. Plaintiffs, however, assert that neither of the passages cited by defendants nor any other passage in the specification attributes the claimed benefit in reducing the number of subsystems to the ECC subsystem. Reply at 6. According to plaintiffs, the patent instead identifies the shared memory and parallel interface as permitting a reduction in number of subsystems. Id.; see '736 patent at 4:30-39, 8:47-56, 9:7-11; 10:12-16

According to defendants, the specification further supports their construction of "ECC subsystem" because it requires one ECC subsystem that is responsible for performing error detection and correction for both CD and DVD data. Defendants' '736 Br. at 12; see '736 patent at 7:38-39 ("ECC subsystem 96 is responsible for performing error detection and correction for both CD and DVD data"). Plaintiffs, on the other hand, argue that the specification does not support defendants' construction. Plaintiffs' '736 Reply Br. at 6; see '736 patent at 3:66-4:15, 6:40-41, 7:38-8:1, 8:15-18, Figs. 4 & 5.

e. Extrinsic Evidence

Defendants contend that inventor testimony supports their contention that the ordinary meaning of error code correction and detection subsystem requires one subsystem that performs all error correction and detection on two different formats of processed data. Inventor Hsu, who was responsible for the error code correction and detection subsystem, testified that his invention combined the error correction for CD data and DVD data into a single subsystem implemented in a single circuit block. Deposition of Wen Hsu, O'Callaghan Decl., Ex. 12 at 147:15-19, 157:9-25, 53:24-54:11, 56:10-15, 56:23-25.

f. Conclusion
Defendants' argument that a single subsystem wherein the identical circuitry within the subsystem must be capable of performing error correction and detection on all formats of data is rejected. The claims do not specify that the identical circuitry has to be used for all processing, independent of data format. Nor does Hsu's testimony support this asserted limitation, as he established only that his invention combined error correction for CD and DVD data into a single subsystem. However, the specification and Hsu's consistent testimony, do support defendants' argument that the ECC subsystem must be capable of performing error correction and detection on at least two data formats. Thus, the court construes "an error code correction and detection subsystem" as "a subsystem capable of performing error correction and detection on two different data formats." The circuitry within the subsystem for performing the correction and detection functions on the different data formats may be different and there may be multiple ECC subsystems.

V. Claim Five: "The repeater management device of claim 1 wherein the media access controller further comprises means for generating preambles and error correcting codes, means for detecting error correcting codes, means for handling deferrals and collisions, means for controlling and handling backoff conditions, and means for retrying data transmission." Claim 5 is dependent on claim 1. Claim 5 requires a MAC that generates and detects error correcting codes. One skilled in the art would perceive "error correction coding [as] 'an encoding of data and redundant check bits that enables decoding hardware to reconstruct the original data in the presence of a data-bit or check-bit error.'" (Witness Statement of Howard Frazier at 23 (quoting IEEE Dictionary 395 (7th ed. 2000)).) Altima's expert Mr. Frazier explained:

An error correcting code adds additional information to data that is being transmitted. You transmit the data that you want to send and then you generally append some redundant bits, some additional bits, to that data which would enable hardware at the receiving or decoding end to recreate, reconstruct the original data, and correct it in the presence of noise or byte errors. So, if error had been introduced in the data during transmission, the error correcting code information can be used to reconstruct the data and restore it.

(Intel argues that the patentees acted as their own lexicographers in Claim 5 and the phrase "generating . . . error correcting codes" refers to CRC generation. (Level One's Reply at 39.) As such, the claim specifies a MAC that uses "a particular cyclic redundancy code designed for error detection and not error correction." (Id.) However, this construction is not supported by the prosecution history. Application claim 6 required the MAC to comprise "means for generating preambles and error correcting codes, means for detecting error correcting codes . . . ." Application claim 13, which was expressly canceled, required the MAC to comprise "means for generating preambles and cyclic redundancy checks (CRCs) for the data packets. . . ." These two claims used different terms to require different functions. The prosecution history reveals that the patentees did not mean CRC generation when they used the phrase "generating . . . error correcting codes." Although one skilled in the art may view the reference to "correcting" instead of "detecting" as an obvious error, the claim cannot be rewritten by the Court to correct this error. Cf. Allen Eng'g Corp. v. Bartell Indus., Inc., 299 F.3d 1336, 1349 (Fed. Cir. 2002) ("It is not [the court's] function to rewrite claims to preserve their validity."). Therefore, claim 5 requires a MAC to generate and detect error correcting codes.

1. Principles of claim construction

Claim construction of a patent, including terms of art within claims, is exclusively within the province of the court, not the

It is well-settled that, in interpreting an asserted claim, the court should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history. See Markman, 52 F.3d at 979, 34 U.S.P.Q. 2d at 1329. Such intrinsic evidence is the most significant source of the legally operative meaning of disputed claim language.

The first step is to look to the words of the claims themselves, both asserted and nonasserted, to define the scope of the patented invention. Id. Second, it is necessary to review the specification to determine whether the inventor has used any terms in a manner inconsistent with their ordinary meaning. Id.

The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication. Id. "Claims must be read in view of the specification, of which they are a part." Id. (citing Markman, 52 F.3d at 979). The specification is always highly relevant to the claim construction analysis, and usually, it is dispositive; it is the single best guide to the meaning of a disputed term. Id. The drawings or figures of the patent are considered with the specification in interpreting claim language. Wright Medical Tech., Inc. v. Osteonics Corp., 122 F.3d 1440, 1443 (Fed. Cir. 1997).

Third, the court may also consider the prosecution history of the patent, if in evidence. Vitronics Corp., 90 F.3d at 1582.

In addition, the Court should not read into a patent limitations that do not exist in the claims. As the Federal Circuit recently held, "[t]he danger of improperly importing a limitation is even greater when the purported limitation is based upon a term not appearing in the claim." Amgen, Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1325 (Fed Cir. 2003) (internal citations omitted).

Moreover, like contract interpretation, the Court should first give claim terms their ordinary and accustomed meanings.

Claim terms take on their ordinary and accustomed meanings unless the patentee demonstrated an intent to deviate from the ordinary and accustomed meaning of a claim term by redefining the term or by characterizing the invention in the intrinsic evidence using words or expressions of manifest exclusion or restriction, representing clear, disavowal of claim scope.

Apex, Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1377 (Fed. Cir. 2003) (emphasis added) (citation omitted).

In fact, the Federal Circuit has issued a ruling instructive on this issue. In Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1343-44 (Fed. Cir. 2001) the Federal Circuit overruled the district court's holding that the claim term "portion" was to be accorded a meaning narrower than its customary meaning, by finding that the district court had improperly relied on the preferred embodiment, the drawings, and one passage in the prosecution history to "overcome the presumption.

Finally, if an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term, it is improper to rely on extrinsic evidence. Id. at 1583. Extrinsic evidence is that evidence which is external to the patent and its file history, such as expert testimony, inventor testimony, dictionaries, and technical treatises and articles. Id. at 1584. Extrinsic evidence in general, and expert testimony in particular, may be used only to help the court come to the proper understanding of the claims; it may not be used to vary or contradict the claim language. Id.

This approach was affirmed in the Federal Circuit's most en banc decision, Phillips v. AWH Corp., 415 F.3d 1303, 1317 (Fed. Cir. 2005). In that case, the Court reiterated that "[w]e have viewed extrinsic evidence in general as less reliable than the patent and its prosecution history in determining how to read claim terms." Id.

Following this guidance and framework, this Court finds that the '252 Patent's Claim and the specification establish that the "error correcting means" refers to a circuit or portion of the computer chip geared towards error correction: Reading the Claim 1 and the patent language as a whole it is clear that the terms using the "means" language are used in their ordinary and customary meaning throughout the patent to mean "circuit" or "portion" of the chip. As such Claim 1 provides sufficient
structure and section 112, paragraph 6 does not apply to the analysis.

This Court rejects Mediatek's argument that Claim 1 requires a specific sequential order. Nothing in the claim language, the specification, or the patent prosecution gives rise to the limitation that the "error correction means" must happen in a specific sequential order. Rather, the circuit or portion must simply be able to "read, detect, correct, and write." While Claim 1's language demonstrates the processes that will take place, it does not require a specific order. Most importantly, it does not specify when detection of errors must take place or when correction must take place - arguably either could come first. Claim 1's specifications simply provide an example of how this could work. Defendant Mediatek's argument impermissibly would limit Claim 1's "error correcting means" to a sequential order requirement not included in the patent's claim. This is just the type of limitation the Federal Circuit has warned against.

1608

4. "Scan processing error flags" (claims 1, 3)

TriPath defines "scan processing error flags as "an indication by the system (i.e. an issued flag or signal) that an error has occurred during scan processing." Cyttyc agrees with this definition, except that it would strike the words "or signal." Cyttyc argues that "scan processing error flags" are not generic signals, but specific computer software mechanisms. TriPath responds that its definition is more clear and precise because a flag is an electronic signal.

TriPath is correct that an error flag is an electronic signal. However, adding the word "signal" into the definition of "scan processing error flag" unduly expands the scope of the claims.

Beginning with the claim language, the words "scan processing" modify "error flags." This indicates that the error flags are related to the image processing process. Claim 3 explains how they are related: the "scan processing error flags are generated by checking if the at least one machine processing effectiveness parameter is within a range." 327 patent at col. 8, 11. 58-61. In other words, when the invention detects that a slide is not suitable for processing or has been processed improperly, it generates an error flag.

The specification, in the preferred embodiment, describes two types of error flags. Id. at col. 5, 11. 48-48; col. 6, 11. 53-61; Table 2. These flags are numerical values issued when errors are found at two different magnifications, 20X and 40X. Id. These two "algorithm processing error flags" are the only two of the thirteen suitability measures explicitly labelled "error flags." Id.

However, this alone does not support a narrow reading of "scan processing error flags." The Abstract refers to other types of flags: magnification error flags, staining flags, main optical density flags. Id. at Abstract. The specification also appears to use "flag", "measure", and "test" as related and sometimes interchangeable nouns. See, e.g., id. at col. 1, 11. 35-37 ("The [suitability] tests include machine processing error flags, staining measures . . . "); col. 5, 11. 58-59 ("Table 2[, which lists the 20X and 40X error flags mentioned above,] provides a short description of each measure used to test slide suitability").

These flags, measures, and tests mentioned in the written description are indeed signals. However, they are particular types of signals used for a particular purpose. A computer conducts the image processing and slide suitability scoring, so the signals must be electronic. The thirteen suitability tests are, at their essence, computer software mechanisms that indicate when an error has been detected. To construe "scan processing error flags" to include any other type of signal, is inconsistent with the specification and the claims.

1609

B. "Error Indicator"

Plaintiffs propose the following construction of "error indicator":

- 2016 -
An "error indicator" is a device that indicates if a compartment has not been placed in a location, or if the compartment has not been placed in a location within a predetermined amount of time.

(Docket Entry No. 40, p. 21). Universal also contends that the claim term "error indicator" is in means-plus-function format because it lacks sufficient structure and impermissibly covers each and every device for indicating error.

Like the disputed claim term "location indicator," the term "indicator" has a well-known meaning connotative of structure to those of skill in the art. Plaintiffs' construction of the term "error indicator" is consistent with the term's use in the specification. The ordinary meaning of the term "error" is undisputed. In this invention, an "error" occurs when a compartment is placed in an incorrect location. The term "error" is an adjectival qualification placing an additional functional constraint on the term "indicator," which connotes structure. The addition of this functional constraint does not reduce the definiteness of the structure connoted by the term "indicator," such that section 112, P 6 applies. See Personalized Media, 161 F.3d at 705; Apex, 325 F.3d 1364, 2003 WL at *7. In the context of the invention covered by the '943 Patent, the possible errors include placing components or component compartments in an incorrect location, or failing to load compartments within a certain time. ('943 Patent, col. 6, 1.58-col. 7, 1.2). This court adopts plaintiffs' construction of the term "error indicator."

1610

Thomcast's lead argument is that the claims of the '944 patent, when properly construed, do not require any sort of fine modulation of the amplifier output. Thomcast thus asserts that the district court's conclusion of invalidity for failure to disclose the best mode of fine modulation cannot stand. We agree with Thomcast. Claim 7 lacks any explicit requirement for fine modulation and contains no explicitly recited structure for achieving such modulation. The parties, however, focus on the following claim language: "having an output providing an amplified signal that has essentially the same wave shape as the input signal." The parties dispute whether this functional language necessarily requires that the claims only cover devices that achieve fine modulation of the output signal or whether the language merely states the normal function of any amplifier, i.e., creating an output signal that is similar to, but larger than, an input signal. We conclude that it is the latter.

From the language, "essentially the same," it is not clear the extent to which the patent requires the output signal to match the input signal. On the one hand, the quoted claim language undoubtedly refers to the quality of the amplifier output. On the other hand, the term "essentially" broadens the requirement that the signals be "the same." To determine what the patent means by "essentially the same," we must look outside the claims. See, e.g., Slimfold Mfg. Co. v. Kinkead Indus. Inc., 810 F.2d 1113, 1116 (Fed. Cir. 1987) ("Claims are not interpreted in a vacuum, but are part of and are read in light of the specification.").

When read in the context of the entire patent, it becomes apparent that the quoted phrase cannot support the interpretation the defendants would place on it. The written description does not indicate that there is any signal smoothing circuitry required to make the input and output signals have "essentially the same waveform." As the district court specifically noted: "Nowhere in the application was mention made of fine modulation or pulse width modulation." Indeed, the defendants recognize in their brief that the patent does not mention any type of smoothing circuitry for filling in between the steps of the raw amplifier output.

The written description merely describes, in extensive detail, the electrical circuitry required for the "first-on, first-off" switching scheme. When speaking of switching amplifiers in general, the Description of the Prior Art states: "An essential feature of the known amplifier is the fixed association between the voltage steps of the input signal range and the corresponding switching stages on the output side." Col. 1, lines 29-32. In this statement, Furrer defines an amplifier as the circuitry between an input side and an output side, with the output side defined by switching stages without further smoothing circuitry. He also indicates how the input steps are related to the output steps. With respect to these features, Furrer did not distinguish his invention from the prior art.

The detailed description of the invention also indicates that any contemplated smoothing circuitry is separate from the claimed amplifier. Referring to Figure 1, the patent states: "A block diagram of an embodiment of the switching amplifier according to the invention and an additional monitoring unit is represented." Col. 3, lines 26-28. Figure 1 indicates a "Load," which is shown external to the amplifier and which "can be constructed as the RF output stage of a broadcast
transmitter and can additionally be provided with a low-pass filter for smoothing purposes." Col. 3, lines 51-54. This passage confirms that any contemplated smoothing hardware is not part of the claimed amplifier, but instead is part of a broader transmitter that includes the amplifier and other components. Nor does the written description indicate that the switching stages that make up the claimed amplifier must be modified to produce smoothed output, such as by remainder processing PWM. 2

2 The written description does state, in a single instance, that the switching stages produce a "staircase voltage which, after a smoothing process, corresponds to the amplified input signal." Col. 7, lines 43-45. This language describing the relationship between the input signal and the output signal differs from the claim language on which the district court relied, i.e., "having essentially the same wave shape." Furthermore, we cannot say that this single citation can transform the claims' tangential reference to signal shape into a structural claim limitation, especially in light of the patent's otherwise singular focus on the "first-on, first-off" switching scheme.

The prosecution history also supports this conclusion. The claims in Furrer's original application were all denied by the Examiner. Furrer then added the claims which ultimately became claims 7 through 9 of the '944 patent. In the "Remarks" accompanying his amendment, Furrer cited the "first-on, first-off" switching scheme as the patentable aspect of his claimed invention, distinguishable from the prior art. He never mentioned fine modulation. The patent was granted after the amendment. Thus, the prosecution history does not indicate that Furrer limited his claims to an amplifier that includes fine modulation circuitry.

In light of the written description's almost universal focus on the "first-on, first-off" switching scheme and on that scheme's ability to generate a stepped output that corresponds to the input signal, we conclude that the claims are directed to an amplifier with the structure explicitly recited and that no further smoothing circuitry is required. Signal fidelity is a very real concern for a designer of broadcast transmitters, and the evidence seems to indicate that signal fidelity was also one of Furrer's concerns during his engineering work. Nonetheless, Furrer's claimed invention, which we look to in our analysis, is directed toward a switching amplifier that is but a component of a larger broadcast transmitter. The amplifier, as claimed, does not require fine modulation or circuitry to achieve fine modulation.

1611

(c) Establishing a charge for paying lifetime payments after the account value reaches zero in accordance with the guarantee.

The first step of Claim 1 speaks of "establishing a charge for paying lifetime payments after the account value reaches zero in accordance with the guarantee." The parties disagree on what "establishing a charge" means. The Plaintiff proposes to "define 'establishing a charge' as the 'creation or establishment' of a charge, which is the 'cost or fee paid to the entity offering the annuity to guarantee periodic payments after such payment and/or charges have exhausted the account value . . . '" (Pl. Br. at 21; DE 34.) The Defendant contends that "establishing" means calculating a fee in one of three ways set forth in the patent, said fee to be paid by the owner for the contract guarantee of lifetime payments." (Df. Br. at 25; De 39-2.) The Defendant cites the specification (815 Patent 10:33-35) in support of its interpretation. In addition, the Defendant asserts that the word "charge" "as used in the '815 Patent means a fee paid by the owner thereby making the account value available in the post-annuitization phase." (Df. Br. at 25; DE 39-2.)

The '815 Patent does not limit the establishment of charge to only the three methods listed in column 10 of the specification. Column 10 states:

In certain embodiments of the present invention, the cost of the lifetime guarantee may be charged by one or more of three methods. The first method is a front-end charge, or 'premium load' . . . . The second method is a charge which is deducted from each benefit payment as it is paid. . . . The third method is an asset charge which is deducted daily from the account value. . . .
('815 Patent, 10:33-48.) At first glance, this may appear as a complete list of available methods to impose a charge for the guarantee of lifetime benefits. However, an earlier reference to the cost of the lifetime guarantee makes clear that the three methods are not exclusive:

The charge for the guarantee of lifetime payments may be established in various ways, including determining a front end charge and deducting the front end charge from an initial deposit, determining a charge to be deducted from each periodic benefit payment, or determining an asset charge and periodically deducting the asset charge from the account value.

('815 Patent, 6:8-15 (emphasis added.).) But most importantly, as discussed above, the term of art used in Claim 1--"comprising the steps of"--signifies that the claim is open-ended. In light of this evidence, the Court construes the term "establishing a charge" not to be limited to the three methods noted in column 10:33-55.

The Defendant's argument regarding the meaning of the word "charge" need not be addressed. The Defendant does argue that a charge is not what the Plaintiff claims it to be, that is, a cost or fee for the benefit provided. Rather, the Defendant merely reiterates its position that the account value is limited to the post-annuitization phase of the contract. Since the Court has already addressed the scope of the account value, and the parties agree what a charge is, no further discussion is necessary.

D. "establish a communication link between said remote home base and said plurality of various job sites"

The term "establish a communication link between said remote home base and said plurality of various job sites" is found in claim 1 of the '490 patent: "said modem adapted to link said memory to a remote home base to establish a communication link between said remote home base and said plurality of various job sites at which said retractable and self-contained mobile repair unit is working." The exact term is not found in the specification. But the specification does describe the following: "Monitor 48 converts signal 94 to a digital value, stores it in a memory 96, associates it with a real time stamp, and eventually communicates the data to a remote home base 100 by way of a modem 98. . . . An operator at a home base 100 remote from the work site at which repair unit 20 is operating accesses the data stored in circuit 124 by way of a PC-based modem 98 and a cellular phone 136." ('490 patent, 3:52-55, 4:28-31). Key argues that "establish a communication link between said remote home base and said plurality of various job sites" requires no construction. On the other hand, the defendants contend that this term means "to create a tie or bond that allows the exchange of information between the location where the operator of the mobile repair unit receives data related to the repair unit, and such location is removed from the multiple diverse kinds of work sites at which the repair unit is operating."

The defendants argue that the claim language requires a single communication link that connects the remote home base to each of the plurality of job sites. Forbes and Petron emphasize that the plurality of job sites necessarily requires more than one job site. The claim is not limited to a single communications link, however; when used with an open-ended transition, the indefinite article "a" means "one or more" except in rare circumstances where the patentee clearly intended to limit the term to a single item. Baldwin Graphic Sys., Inc. v. Siebert, Inc., 512 F.3d 1338, 1342 (Fed. Cir. 2008). Nothing in the patent indicates that the inventor intended to limit the claimed system to a single communications link. Thus, there may be more than one communications link connecting the remote home base and plurality of job sites. This reading of the claim language is reinforced by the use of the word "between." If the patentee had intended for a single communications link to connect the remote home base to each of the plurality of job sites, presumably he would have used the word "among" instead of "between."

In further support of their proposed single communication link construction, the defendants contend that each mobile repair unit could have a modem that communicates to a single central memory, which in turn communicates to the remote home base. This configuration would not satisfy the claim language, however. The claim requires a "self-contained mobile repair unit . . . comprising: . . . a memory . . . and a modem electrically coupleable to said memory." The defendants' depiction of three mobile repair units at three job sites sharing a single memory would not satisfy the requirements of claim 1; each mobile repair unit must have its own memory. As such, the court is persuaded that each communication link is required to connect only one job site to the remote home base. Therefore, the term "establish a communication link between said remote
home base and said plurality of various job sites” is construed to mean “establish communication connections between the remote base and each of the various job sites.”

1613

11. "establish[ing] patient-specific rules associated with each of the geographically dispersed hospitalized patients"

The parties agree on plaintiff’s proposed language: "establish[ing] patient-specific rules for each of the individual, geographically dispersed hospitalized patients." Plaintiff proposes this language as the entirety of the construction. Defendants seek to add three additional components to this phrase: "at the remote center," at the beginning of the construction; the word "customized" to modify "patient specific rules;" and "who are being monitored" at the end of the phrase. Thus, defendants' complete proposed construction would read: "establish[ing] at the remote command center customized patient-specific rules for each of the individual, geographically dispersed hospitalized patients who are being monitored." We address each in turn.

First, defendants seek to insert a limitation requiring that the establish[ing] patient-specific rules step occur at the remote command center. The claims in question specifically identifies which step occurs at the remote command center and that step relates to the determination of whether a rule has been contravened. This appears to be inconsistent with defendants' proposal. Additionally, the remote command center language defendants propose to add appears nowhere in the phrase at issue which pertains to "rules." The remote command center language was available to the inventors regarding the "establishing rules" step and they chose not to insert this limitation. Thus, we find from the context of the claims that the absence of the "at the remote command center" limitation in the claim terms requires its absence in the construction at issue.

The Court also rejects defendants' request to insert the word "customized," because it is redundant. Defendants agree that "customized" is interchangeable with "tailored." "Patient-specific rules" has already been construed as "a rule tailored to the medical condition of a patient." (See § III.B.10.) Adding the word "customized" would only confuse a jury.

Finally, defendants propose to add "who are being monitored" to the end of the construction. For the reasons set forth below (see § III.B.12) we decline to add this additional language. Thus, "establish[ing] patient-specific rules associated with each of the geographically dispersed hospitalized patients" is construed as: "establish[ing] patient-specific rules for each of the individual, geographically dispersed hospitalized patients."

1614

The relevant issue on appeal with respect to the second disputed term, "establishing the spatial relationship," is whether the district court properly excluded "the use of an optical reference system" from its construction. Claim Construction Op. at 7. Referencing the specification, the district court noted that the specification describes "an acoustic or ultrasonic range finding system" as well as "an electromagnetic position and orientation system" to track the movement of an object. Id. at 6 (citing '056 patent, col.6 l.48-col.11 l.18, col.11 l.18-col.12 l.32). The court further noted that although the specification mentions the use of an optical system, the statements were "too general in nature" to support Medtronic's broad proposed construction. Id.

We agree with the district court's reasoning. Similar to the '454 patent, the specification of the '056 patent discloses that the spatial relationship is established by using an acoustic tracking system or an "ultrasonic range finder or reference system" that uses spark gaps that emit "energy in the form of sound pulses which are received by (at least) three microphones." Id. col.6 ll.48-58. The specification also describes in detail the use of "an electromagnetic position and orientation system." Id. col.11 ll.18-20. Medtronic's argument for inclusion of an optical tracking system is largely premised on a single statement that appears in the specification, i.e., that "[a]n optical system can be used as an alternative to the acoustic system described earlier." Id. col.12 ll.33-34.

We agree with the district court that this passing reference to an optical tracking system fails to support an interpretation broader than that adopted by the court. A claim is to be construed in light of the written description that supports it. Phillips
v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 2005) (en banc). And it is true that the minimal one sentence reference to an optical tracking system is a mention of an optical tracking system. However, the remainder of the specification describes acoustic systems. There is no enabling description of how to make and use an optical tracking system, and claims are best construed to preserve their validity. Tate Access Floors, Inc. v. Interface Architectural, 279 F.3d 1357, 1369 (Fed. Cir. 2002); see also Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1557 (Fed. Cir. 1996) (overruled on other grounds); Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1581 (Fed. Cir. 1996). Because this case is one in which ambiguity as to the scope of the claim language can be "resolved in a manner that would preserve the patent's validity," Phillips, 415 F.3d at 1327, that principle can properly be applied here. Moreover, the inventor himself stated, in answer to a series of questions regarding whether an optical tracking unit was available to him at the time of his invention of the acoustic system that "[w]e weren't aware of any commercial optical tracking system that was available" and "[i]t seemed at the time that this would be an obvious development, that it would be coming in time. It was just that at this time that we were writing this, that such a system wasn't available to us." J.A. at 6562 (emphasis added). Thus, rather than being a disclosure of an optical system sufficient to support an interpretation of a claim as including an optical system, it was merely "an attempt to preempt the future before it has arrived." Fiers v. Revel, 984 F.2d 1164, 1171 (Fed. Cir. 1993). Such a minimal dropping of an unenabled reference to an undeveloped system does not support a claim to it.

We accordingly conclude that the court did not err by excluding an optical tracking system from its claim construction.

GO BACK

4. "subcarrier-indexed estimates of transmission quality"

The next disputed term appears in both the preamble and body of Claim 1. The issue presented with respect to this term is whether the "subcarrier-indexed estimates of transmission quality" must be measured by the four factors appearing in the preamble, namely channel gains, channel noises, desired carrier bit-error-rates, and the programmed power mask. (See Tr. at 24:1-19, 28:8-20).

Plaintiff contends that this term is a claim limitation because the antecedent basis for the term appearing in the body of the claim, specifically in step (a), is derived from the term in the preamble. '447 Patent, col. 13, 11. 2-6. At the hearing, Plaintiff introduced the prosecution history for the '447 Patent in support of its proposition. 8 The prosecution history shows that Claims 1 through 15 of the '447 Patent were initially rejected by the PTO under 35 U.S.C. § 112. The PTO indicated that the original term that appeared in the body of the claim, namely "the measured subscriber channel quality estimates," lacked a clear antecedent basis. See Office Action dated June 21, 1994 at 2. In response to the Office Action, the patentees amended the claim by adding "subcarrier-indexed estimates of the transmission quality" to both the preamble and body of the claim.

8 The Court notes that this evidence was not contained in the record prior to the Markman hearing. Neither Plaintiff nor Defendants relied on any prosecution history evidence to support their claim construction arguments, despite having been given an opportunity to revise their written submissions prior to the hearing. Although Globespan submits this evidence at a late stage, the Court will nonetheless consider it, particularly since Defendants did not object at the hearing. (See Tr. 29:1-31:10).

Unfortunately, what the PTO's reaction was to that amendment remains a mystery. Did the PTO allow the claims, recognizing that the amendment added sufficient specificity to the claims? Or, did the PTO require more? Because Plaintiff failed to submit the complete prosecution history, the Court does not know the answer to these simple, but potentially dispositive questions. Nonetheless, assuming arguendo the answer to the first question is in the affirmative, Plaintiff then argues that the method encompassed by Claim 1 incorporates the limitations associated with the term as set forth in the preamble. Plaintiff characterizes this as a "clear prescribed method [] for determining sub-carrier quality estimates." (Tr. at 28:8-10). Thus, Plaintiff argues that the claim requires the estimates of transmission quality be determined "by reference to channel gains, channel noises, desired carrier bit-error-rates, and the programmed power mask." (Tr. at 28:17-20; see also Chart at 2).
Conversely, Defendants argue that the claim does not require the estimates to be based on these four factors. Rather, Defendants assert that the subcarrier-indexed estimates may be measured using a variety of methods, some of which may include all or none of the factors listed in the preamble. According to Defendants, estimates may be measured simply by SNRs. Defendants contend that the specification clearly supports their argument. It states the following:

When given a set of initial SNR estimates of the orthogonal carriers of a multicarrier communication system, a set of target bit error rates for the carriers, and an arbitrary transmit power mask together with an overall transmit power constraint, the present invention provides a method of determining the initial bit and energy allocations, and therefore the corresponding transmission bandwidth.

'447 Patent, col. 7, 11. 10-17 (emphasis added). Defendants argue that nothing in the specification suggests that the "set of initial SNR estimates" must be measured by channel gains, channel noises, desired carrier bit-error-rates, and the programmed power mask - factors which only appear in the preamble.

This Court agrees with Defendants. Generally, a preamble is a limitation of the invention if it "recites essential structure or steps, or if it is necessary to give life, meaning, and vitality to the claim." Catalina Mktg. Int'l v. Coolsavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002) (quotations omitted). However, if the patentee's use of the preamble merely states an intended purpose or use, and the patentee defined a structurally complete invention in the body of the claim, the preamble is not limiting. Id. Furthermore, although claim scope may be limited if a particular disputed term derives antecedent basis from the preamble, the Court's determination must be based on an examination of the patent as a whole, "to gain an understanding of what the inventors actually invented and intended to encompass by the claim." Id. (citing Corning Glass Works v. Sumitomo Elec. U.S.A., Inc., 868 F.2d 1251, 1257 (Fed. Cir. 1989).

This Court concludes that "subcarrier-indexed estimates of transmission quality" need not be measured by any of the four factors listed in the preamble. Although the prosecution history suggests that the claim was amended to include an antecedent basis in the preamble for the disputed term, this alone does not support Plaintiff's contention that the claim should be read to require the four factors. Simply because the term appears in the preamble, the Court is not required to import all the words surrounding the term. Plaintiff has not cited any case law that would suggest otherwise. Additionally, and perhaps more importantly, the claim language itself, specifically the language contained in Claims 5 and 6, indicate that subcarrier quality estimates may be made "through the computation of an average signal-to-noise measure on a subcarrier . . . [or] . . . the computation of an average signal-to-noise ratio multiplied by a subcarrier dependent programmed reliability factor . . . ." '447 Patent, col. 13, 1.65 - col. 14, 1.10. Thus, the claims themselves demonstrate that subcarrier-indexed estimates of transmission quality need not be measured by four factors, but may be measured, for example, through the computation of SNRs. This comports with Defendants' assertion.

Furthermore, one of the preferred embodiments described in the specification shows why Plaintiff's argument is incorrect. The preferred embodiment describes an algorithm consisting of several steps involved in the initialization procedure. '447 Patent, col. 7, 1.35 - col. 8, 1.56. The first step involves computing SNR estimates, or estimates of transmission quality. The fifth step involves the maximum energy allowable in the carrier as defined by the power mask. Plaintiff's requirement that the estimates be measured based on, among other things, the power mask would effectively exclude this preferred embodiment from the claim scope, since it is not until after the calculation of estimates that the power mask comes into play.

As the Federal Circuit has articulated, "a claim construction that would exclude the preferred embodiment 'is rarely, if ever, correct and would require highly persuasive evidentiary support.'" Rexnord Corp. v. Laitram Corp, 274 F.3d 1336, 1342 (Fed. Cir. 2001) (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996)). Plaintiff has not shown sufficient evidence to support its narrow construction. Accordingly, it must be rejected. Therefore, this Court concludes that disputed term [4] "subcarrier-indexed estimates of transmission quality" does not require that the measurements of the estimates be determined by any of the four factors enumerated in the preamble.
The Court agrees with Samsung and construes the term "etch" in claim 11 of the '339 patent and claim 3 of the '442 patent as "a process or processes for removing one or more materials using chemical and/or physical means." MEI's proposed construction--"a chemical or plasma used to remove material from the claimed insulating layer and the claimed first soft mask or second soft mask in one step"--adds the limitations that an etch must be done in one step, includes only a chemical or plasma mechanism, and is used to remove material from an insulating layer. MEI's proposed construction is overly narrow. The specification discloses that an "etch" step may be done with various chemical and physical processes, may combine more than one process as part of a single etch "step," and may be used to remove soft masks and insulating materials. See '339 Pat. col. 4:36-50 (disclosing chemical and physical etch methods); col. 4:30-32; col. 8:9-21 (disclosing multiple etch processes used as part of a single etch step).

Whether Chemical Mechanical Polishing is Vertical Anisotropic Etching.

In the claims construction, the Court ruled that etching is defined as removing material. Boning's position is that the process used by Tower and UMC is chemical-mechanical polishing. He explains that this is a method for removing elevated portions of the exposed surface of a wafer. It is used primarily for the purposes of planarizing the wafer surface of defining structures. The mechanization process operates to chemically soften (often through oxidation) a shallow layer of the exposed surfaces of the wafer and then remove the softened layer by making sub-microscopic scratches across the oxidized surface using the abrasive particles of the slurry. The chemical agent in the slurry modifies only the exposed surfaces of the wafer surface. Only after the abrasive particles have removed the top exposed layer can the oxidizing agent modify the newly exposed wafer material, and the next layer can then be "scratched" away. In essence, he defines this process as a horizontal process rather than a vertical process.

Boning contends that the CMP process is not an "etch" process. Only the top layer of material is removed in this process. The court has already defined "etch" as "removing material." Therefore, the process Boning defines is one that removes material. However, the key issue is whether it removes said material by vertical anisotropic etching which is defined as "etching which removes material significantly faster in the vertical direction than in the horizontal direction." Boning states that CMP is not a vertical anisotropic process. He states that the process actually removes material faster in the horizontal direction than in the vertical direction. CMP continues to remove material across the wafer surface until the process is terminated, as the CMP pad encounters a material that resists removal (a polish stop) which in the case of tungsten is commonly a silicon dioxide layer. He states that there nevertheless may be a residual shallow removal from areas not covered by the polish stop -- dishing.

Unless CMP can also remove the adjacent material, CMP cannot effectively remove material from a given point on the wafer surface, which confirms the horizontal nature of CMP. He also states that, in contrast to CMP, vertical anisotropic etching is predominantly carried out in the presence of resistant material. In contrast to CMP, he claims that vertical anisotropic etching also attacks all exposed surfaces regardless of their relative height. Boning also points out that in the accused processes there is an additional step not found in the '802 patent. He states that a silicon dioxide insulating layer must be planarized using CMP prior to the etch step in which the contact (or via) openings are formed.

Boning further contends that the accused processes use sputtering as opposed to vacuum evaporation in depositing the interconnection metal. Vacuum evaporation is a method for depositing a thin film by applying heat to the source of film material, thereby causing evaporation. Sputtering, in contrast, uses a plasma to generate ions which mechanically dislodge particles from the source of the film material. The dislodged particles fly in a line-of-sight fashion to strike and adhere to the wafer surface, in time forming a thin film of the sputtered material. He claims that the two processes are distinct and that the sputtering process cannot infringe Claims 1 and 2. Boning acknowledges that the Court's construction of sputtering would fall within the definition of vacuum evaporation.

Gwozdz states that CMP in a wafer fab is usually arranged as a vertical anisotropic etch, removing material significantly faster in the vertical direction than in the horizontal direction. His assertion that the Tower and UMC processes infringe is primarily based on the testimony of two witnesses, Buchbinder for Tower and Chien for UMC. From this testimony, he constructs charts which he claims support his contention of infringement (Buchbinder at A-2, I, J). Citing Buckbinder's deposition, he claims that the tungsten etching process is done by CMP, which is vertical anisotropic etching. However,
Buchbinder merely states that the process is done by CMP.

No question is ever asked of the witness as to whether the process is isotropic or anisotropic. The questioning of the witness sheds no light on the question of vertical or horizontal etching. Apparently Gwozdz is able to make this synapse in reasoning based on his unwavering assertion that half of all fab labs employ CMP, which is, in his opinion, vertical anisotropic etching. STM also states that any "horizontal process" "is really a vertical process" since layering is really etching vertically. Such simplistic reasoning would also mean that any vertical process is also a horizontal process since etching vertically has a layering effect.

Gwozdz apparently discredits the results of the CMP process as demonstrating that there is not literal infringement. The patent teaches that, on vertical anisotropic etching, there is a uniform etching process with the result that the insulating layer is laid bare while the contact opening is left practically filled with the conductive material. Claim 1 teaches that the conductive material is removed outside the opening. Boning maintains that CMP does not remove all of the material. He argues that recess regions of the wafer are not affected by CMP and hence there is not a uniform removal process across the wafer (Boning at 20).

Gwozdz's Puzzling Statement

Gwozdz steadfastly maintains that CMP is vertical anisotropic etching. However, in his deposition, Gwozdz states that CMP cannot etch the narrow contact opening mentioned in Claim 1 by the preferred method, vertical anisotropic etching. The Court assumes that the question is directed to etching of the insulating layer and not etching of the conductive plug. The patent states that vertical anisotropic etching is the preferred method of etching the contact hole in the insulating layer. Gwozdz's comment that CMP is vertical anisotropic etching leaves the Court with the impression that it is not a true etching process called for by the patent or only an etching process with limited parameters. He does state that CMP can be used for removing the overburdened tungsten. The critical distinction is whether the material is removed significantly faster in the vertical rather than the horizontal direction. Although Gwozdz states that such is the case, he does not give any support to his conclusion. "Significant" means "having meaning" or "distinctive." The New Britannica-Webster Dictionary and Reference Guide, 856 (1981). STM has belatedly furnished deposition excerpts of Buchbinder's deposition demonstrating that tungsten is removed from the contact hole in the tungsten etch. However, this still does not resolve the issue of whether STM has produced any evidence that CMP removes material significantly faster vertically as opposed to horizontally.

Chien was the designated representative for UMC. The questions and answers given are no model of clarity. When asked whether the tungsten CMP process removed material from within the contact opening, Chien replied: "We hope not, yeah." When later questioned, he stated that it removes material as small as possible. Chien also testified about another process called plasma etch back, which appears to apply to older products. In any event, the depositions of the two witnesses demonstrate that there are still some "holes" in the final analysis of whether CMP is vertical anisotropic etching. If it is not, there is no literal infringement. As to the questioning of both Buchbinder and Chien, the Court is sympathetic to the plight of the court reporter taking Chien's deposition: "What I've got doesn't quite make sense because I'm missing words here and there." The Court is in total agreement. Much of the testimony presented is not helpful on the key issue before the Court.

The Court is left with the task of determining whether there are fact issues as to infringement. The testimony of the various witnesses, as well as Boning and even Gwozdz, indicates that the CMP process produces voids or seams in the conductive material in the contact holes. Sandisk claims that this is contrary to the teaching of the '802 patent. The patent does not mention voids or seams or even indicate that the process is undertaken to avoid such a result. However, the patent does indicate that the entire volume of the narrow contact openings is filled. Figure 4 of the patent also indicates that the entire volume of the narrow contact opening has been filled with conductive material. The witnesses for Tower and UMC also indicate that this appears to be an expected consequence of the tungsten process. Gwozdz's assessment is that nothing in claim 1 or 2 of the patent excludes a process that produces seams or voids. The Court finds that, as to voids, there is a fact issue presented.

More troubling is whether STM has sufficiently shown that CMP, as that process is practiced by Tower and UMC, is vertical anisotropic etching. Other than Gwozdz's assertion, the Court can find no support for STM's position. STM maintains that this single unsubstantiated assertion is enough to create a fact issue. Gwozdz states that Buchbinder's deposition by itself explicitly documents all the elements of Claims 1 and 2 demonstrating infringement. Yet, as noted, Buchbinder admits that CMP is used and that a small portion of material is removed from the contact hole in the process. According to STM's
lawyers, this is an unintended consequence of the etching process. Yet, no witness confirms that CMP etches significantly faster vertically. Only Gwozdz makes this statement with no support to his assertion. As Boning points out, not all material is removed in the tungsten etch. He states that the process known as dishing demonstrates that the process is not vertical anisotropic etching.

The question for the Court is whether STM has produced any evidence that the CMP process, as practiced by Tower and UMC, fits within the definition of vertical anisotropic etching. To do so, the Court must undertake an analysis of Gwozdz's reasoning. STM attached excerpts of his report. First, he states that probably more than 50% of fabrication processes practice the '802 patent with excess tungsten removed by CMP. Second, he states that CMP parameters are adjusted so that the etch rate, in addition to being sensitive to surface orientation, is also sensitive to local topography, in such a manner that the etch rate at the bottom of small depressions is very slow. He states that although conductive material is necessarily removed from the opening due to a rapid vertical etch rate, only a small portion of the conductive material is removed from the opening. This "explanation" adds little to the inquiry of whether CMP actually removes material significantly faster vertically. In fact, his explanation of the slow etch rate at the bottom of small depressions would seem to detract from a concept of a significantly faster vertical etch rate in CMP.

Boning brings out two differences in CMP and vertical anisotropic etch not addressed by Gwozdz. First, Boning states that vertical anisotropic etch enables engineers to remove material from select portions of the wafer while leaving other portions, those covered by resist, unaffected. As Boning explains, this allows the contact hole to be etched in the first etching process, a process that even Gwozdz admits CMP cannot perform. Second, in contrast to CMP, the vertical anisotropic process attacks all the exposed horizontal wafer surfaces, regardless of their relative height. The process removes both raised and recessed exposed regions of a given material at the same rate and, thus, conserves the differences in height between raised and recessed regions of the wafer surface. Boning points out that Gwozdz's testimony regarding the slow etch rate at bottom of the depressions in CMP demonstrates that the action of CMP is not uniform across all regions of the wafer surface.

Sandisk has also attached articles outlining the Tungsten CMP process (Exh. D to Motion). One article notes that, in the lower areas of the wafer surface, etching is inhibited by the surface film and removal is slow, while in the high areas, etching occurs due to the absence of the surface film and the removal rate is high.

The Court notes that Gwozdz's rebuttal report does not address any of Boning's opinions or conclusions. Buchbinder and Chien's deposition testimony provides no grounds for Gwozdz's apparent naked assertion that CMP is actually vertical anisotropic etching. Whether material is removed faster vertically or horizontally is never asked. The removal rate features of the process are simply not addressed. The Court has also reviewed Gwozdz's deposition excerpts. Gwozdz gives no underlying rationale to support his conclusion. He claims to have some expertise in CMP as it relates to tungsten plugs. Other than a couple of conclusory statements, he states no facts to support his position that CMP is vertical anisotropic etching.

STM contends that Gwozdz's statement is enough to preserve a fact issue for resolution in this case. In the end analysis, the void created is in Gwozdz's testimony. There are no substantive facts to back up his conclusory opinion and, as such, STM cannot carry its burden on infringement. Shaboon v. Duncan, 252 F.3d 722, 736 (5th Cir. 2001); Orthopedic & Sports Injury Clinic v. Wang Labs., Inc., 922 F.2d 220, 225 (5th Cir. 1991). The Court finds that Sandisk's Motion for Summary Judgment on Noninfringement should be granted.

6. "etching"

Agere argues that the term "etching" should be construed as "removing material through chemical reaction and/or physical action." Atmel presently argues that the term "etching" should be construed as "the process for removing material in a specified area through a wet or dry chemical reaction, or by physical removal, such as by sputter etch." The Court notes that Atmel's present proposed construction provides that "etching" can include removing material by physical action, see Def.'s Post-Hearing Brief at 9, whereas Atmel's proposed construction prior to the Markman hearing provided that etching only applied to removing material through chemical reaction and not through physical action, see Atmel Corporation's Claim Construction Brief Filed Pursuant to the Court's Order of October 18, 2002 ("Def.'s Second Brief") at 32. Prior to the
Markman hearing, this was the only significant difference between the parties' proposed constructions. There now appears to be no significant difference between the proposed constructions. The Court finds that either construction would be acceptable, but concludes that Atmel's present proposed construction is slightly preferable as it appears to be precisely the definition provided in the treatise Microchip Fabrication, see Peter Van Zant, Microchip Fabrication 507 (2d ed. 1990), which treatise was relied upon as authoritative by Agere's expert witnesses, see Tr. 12/05/02 at 53-54. Accordingly, the Court construes the term "etching" as "the process for removing material in a specified area through a wet or dry chemical reaction, or by physical removal, such as by sputter etch."

Etching

Etching is the removal of material.

Ethernet

The Court agrees with Ciena and construes the term as "data communications protocol available in 10 Mbits/s, 100 Mbits/s and 1 GigaBits/s versions." Nortel argues that the term should be construed as "a network protocol defined by the IEEE 802.3 standard." Nortel relies on several dictionary definitions for its construction and further contends that its construction is consistent with how the term is used in the specification. Arguing that the specification supports its construction, Nortel cites Column 2, Lines 8 through 13 of the specification, which discuss the different protocols used in the data communications industry and state that the industry "developed using a completely different set of interfaces and protocols, for example carrier sense multiple access collision detection CSMA/CD systems, subject of IEEE standard 802.3, and Ethernet which is available in 10 M/Bits/s, 100 M/Bits/s and 1 GigaBits/s versions." However, this excerpt from the specification draws a distinction between the CSMA/CD protocol, which it states is subject to IEEE standard 802.3, and Ethernet, which it does not connect to the IEEE standard.

Furthermore, Nortel cites Column 7, Lines 52 through 54 of the specification, which state, "Ethernet ports operating at 10 MBit/s; and 100 MBit/s in accordance with IEEE standard 802.3" arguing that it supports Nortel's definition of “Ethernet.” However, the fact that the ports are in accordance with the IEEE standard does not indicate that the patentee meant to define “Ethernet” as “a network protocol defined by the IEEE 802.3 standard.”

Ciena's construction is supported by the specification. The specification indicates that Ethernet is a protocol used in the data communications industry, as opposed to the telecommunications industry. See Col. 1:66-2:16. The specification also references bit rates of 10 MBit/s, 100 MBit/s and 1 GigaBit/s in reference to the Ethernet protocol. See Col. 2:12-13. “[T]he specification ‘is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.’” Phillips, 415 F.3d at 1315. Accordingly, the Court construes the term in accordance with the specification.
The preamble of claim 1 of the '196 Patent discloses 'a currency counting and evaluation device for receiving a stack of currency bills, rapidly counting and evaluating all the bills in the stack and then re-stacking the bills . . .' '196 Patent, Col. 31, ll. 41-46. Cummins argues that as a word in the preamble, the word "evaluating" should not be given any specific limiting meaning. To the extent it requires limitation, however, Cummins argues that the dictionary meaning of "evaluating" is synonymous with "denominating." Glory argues that this word means both the evaluation of the value of the bill and the evaluation of the genuine vs. counterfeit bills. The parties agree that any construction of "evaluating" applies to both the '196 Patent and the '806 Patent.

While the word "evaluation" appears only in the preamble of claim 1 of the '196 Patent, the claims of the '806 Patent provide more guidance. The '806 Patent use both "evaluate" and "denominating" in the same independent claim, claim 16. When two terms are used together in the same claim, they are presumed to have different meanings. Bancorp Services, L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367, 1373 (Fed. Cir. 2004) (use of two terms in "close proximity in the same claim gives rise to an inference that a different meaning should be assigned to each"). Glory's position is consistent with this principle. Additionally, Cummins has claimed a patent for a machine that both (i) determines whether a bill is genuine or spurious, and (ii) attaches a denomination to those bills that the machine finds to be genuine. Given the presence of these two functions, the Court agrees with Glory that "evaluating" encompasses determining for each bill whether that bill's value can be determined.

Claim construction is a legal determination that we review de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1455-56 (Fed. Cir. 1998) (en banc). The words of a claim are generally given their ordinary and customary meaning as understood by a person of ordinary skill in the art in question at the time of the invention when read in the context of the specification and prosecution history. See Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) (en banc).

Lucky Litter argues that the Commission erroneously construed claim 33 as having a "cat exit" limitation and that without this added limitation, claim 33 is invalid as anticipated or obvious. Claim 33 reads:

33. A self-cleaning cat litter box comprising:
   a pan-shaped housing defining an upwardly open litter chamber to be filled to a given fill level with cat litter;
   a comb drive coupled to the housing;
   a comb extending between two opposed sidewalls and being coupled to the comb drive and movable between a storage position and a discharge position, the comb projecting down into the litter chamber to a level below the fill level so that the comb engages clumps in the litter and moves such clumps toward the discharge position; and
   a mode selector switch operatively connected to said comb drive, the switch being moveable between a manual operation position wherein an operator causes the comb to move toward the discharge position and an automatic operation position wherein the comb moves toward the discharge position automatically upon the occurrence of a predetermined event.

'847 patent, claim 33 (emphasis added). The Administrative Law Judge (ALJ) construed the "automatic operation position" of claim 33 as "a position of the mode selector switch where combing is initiated in response to a cat exit," ALJ Decision at 48, and the Commission declined to review this decision, Commission Decision at 5.
The appellants argue that this construction conflicts with the plain language of the claim, which refers to a predetermined event, not to a cat exit. The appellants explain that in Applica's request for reissue, Applica stated that claim 1 contained "recitations regarding a cat exit sensor and a delay means which are too limiting of the invention." J.A. 37238-39. The appellants point out that claim 33 was added during reissue and does not contain the "cat exit" language of claim 1.

The Commission responds that the specification distinguishes the invention over the prior art in terms of cat exit: "The present invention provides effective improvement for the rake drive of the Carlisi [U.S. Patent No. 5,048,665] device so that movement of the comb or rake through the litter can be made responsive to entry and exit of the cat from the litter box." '847 patent col.1 ll.47-50. The Commission argues that the broader plain language interpretation of the "predetermined event" would jeopardize the validity of claim 33 by encompassing the periodic combing described in Carlisi. The Commission asserts that the specification emphasizes that the litterbox is "directly responsive to the exit of a cat from the litter box." Id. col.1. l.62. The Commission argues that the patent clearly disavows automatic operation on a timed basis because the specification discloses that an object of the invention is to provide an improved rake or comb drive that "does not operate on a periodical basis so that there is no substantial possibility that the comb mechanism will carry out a cleaning operation while a cat is present in the box." Id. col.1 l.63-col.2 l.2.

We conclude that the "automatic operation position" of claim 33 must be construed in accordance with its plain meaning. Claim 33 requires "an automatic operation position wherein the comb moves toward the discharge position automatically upon the occurrence of a predetermined event." On its face, the claim does not limit the predetermined event to a cat exit. The words of a claim are generally given their ordinary and customary meaning, absent a clear indication otherwise from the specification or prosecution history, as where the patentee acts as his own lexicographer or clearly disavows claim scope. Here, the specification does not support limiting the term to a cat exit. This is not a case where the patentee acted as his own lexicographer and defined the term "predetermined event"; in fact, the words "predetermined event" appear nowhere in the specification. Thus, the specification does not clearly indicate the patentee's intent to impart a unique meaning to "predetermined event." See Helmsdorfer v. Bobrick Washroom Equip., Inc., 527 F.3d 1379, 1381 (Fed. Cir. 2008) ("A patentee may act as its own lexicographer and assign to a term a unique definition that is different from its ordinary and customary meaning; however, a patentee must clearly express that intent in the written description."). In addition, nothing in the specification clearly and unmistakably disavows predetermined events other than cat exit. The Commission asserted that the specification disavowed periodic cleaning, such that claim 33 should require a cat exit, by the statement: "Another object of the invention is to provide a new and improved comb drive for a self-cleaning cat litter box that is capable of remaining in[] operation for extended periods of time without attention from the cat owner and that does not operate on a periodical basis so that there is no substantial possibility that the comb mechanism will carry out a cleaning operation while a cat is present in the box." '847 patent col.1 l.63-col.2 l.2. This statement falls short of the type of clear and unmistakable disavowal required to limit the ordinary meaning of a claim term.

Moreover, the prosecution history shows that the patentee viewed his invention more broadly and sought reissue to remove "cat exit sensor and delay means which are too limiting of the invention." J.A. 37238. Although the original claim set included claims requiring "a cat exit sensor" for actuating the self-cleaning operation after "sensing exit of a cat from the litter chamber," claim 33, which was added during reissue, does not contain this limitation. Claim 33 makes no mention of a cat exiting the litter box. We will not read in a cat exit limitation into this claim. In short, nothing in the claim language, specification, or prosecution history requires a cat exit limitation. The "automatic operation position" of claim 33 requires only that the "comb move[] toward the discharge position automatically upon the occurrence of a predetermined event." '847 patent, claim 33.
The last disputed phrase we address is "event timer." Based on the same reasoning it relied upon in construing the disputed phrase discussed above, the district court construed "event timer" to mean "nonvolatile memory for storing the event timer information sequences used to control directly the recording of the selected television program. It does not include multiple memories." SuperGuide Corp., 169 F. Supp. 2d at 525, 529-30.

According to Gemstar, this phrase means "at least nonvolatile memory and logic for storing 'event timer information sequences' that are used to control the recording of a television program. It may include additional information and memories as well, including volatile memory." Gemstar contends that the court erred in holding that the claimed "event timer" may store only "event timer information sequences" because claim 1 is a "comprising" claim. In support of its proffered construction, Gemstar first argues that the plain language of claim 1 does not limit the type or number of memories used by the event timer. Gemstar also points out that claim 1 is a "comprising" claim. With respect to the specification, Gemstar contends that the district court inserted the requirement of a single, nonvolatile memory by relying solely on one embodiment while ignoring another embodiment, Figure 2, which discloses an event timer with two memories.

According to Thomson, the "event timer" element requires non-volatile memory for storing the event timer information sequences which directly control the recording device. Thus, Thomson maintains that the court's construction does not exclude multiple event timers, but the particular event timer that controls recording must be nonvolatile. In support,
Thomson relies on the specification and prosecution history to point out that one of the primary objectives of the '357 patent is to store VCR control information in the nonvolatile memory of the event timer so that it is not lost in the event of a power failure. Lastly, in response to Gemstar's argument about Figure 2, Thomson explains that it is an embodiment of claim 4, which depends on claim 1, and covers a second event timer located externally to the recording device.

As with the previous phrase, the disputed phrase "event timer" does not have a plain and ordinary meaning in the art. The claim language does not limit the "event timer" from consisting of multiple memories or event timers. In addition, the specification teaches that the event timer that directly controls the recording device must consist of nonvolatile memory. As we discussed above, the specification emphasizes that storage of the event timer information in nonvolatile memory is necessary if the system is to control recording even if the memory containing the program schedule listings is erased by a power interruption. See '357 patent, col. 3, ll. 47-65. Furthermore, Figure 2, which is an embodiment of claim 4, consists of two event timers. However, the specification teaches that one of the event timers consists of nonvolatile memory and it is this memory that controls the recording device. Id. at col. 6, ll. 20-39.

The prosecution history further supports this construction. During prosecution, the '357 patentee emphasized that in the claimed invention the schedule listings are automatically converted into event timer information and stored in the event timer such that if the schedule information is lost, the VCR programming information will not be lost. This purpose can be fulfilled only if the event timer memory that controls the recording device consists of nonvolatile memory.

Accordingly, we accept Gemstar's construction and define "event timer" as meaning "at least nonvolatile memory and logic for storing 'event timer information sequences' that are used to control the recording of a television program." The event timer also may include additional information and memories, including volatile memory. However, the nonvolatile event timer memory containing the event timer information sequences must directly control the recording device.

Event Manager

Claims 1, 40, 41, and 42 contain the term "event manager." SFA suggests that the term means "hardware and/or software that takes or directs an action relative to an event." It argues that the term must encapsulate a variety of functions including determining when an event has occurred, determining an event's context, and initiating automatic operations. Furthermore, SFA urges that its definition is in agreement with the standard dictionary definition of "manage" meaning "to direct or control." 2 Conversely, Infor defines the term as "a hardware and/or software module functionally separate and apart from the subsystems that intelligently controls the flow of information between the subsystems." Infor contends that since every description of the "event manager" in the specification has it separated from the variety of subsystems, the definition should include this separation. Further, Infor argues that "intelligent control" was heavily relied upon by the patentee during prosecution to distinguish the invention from the Negrino Reference.

Both sides' definitions redundantly provide for general descriptions of the function of the "event manager" when a more specific description of its function is provided for in the claim language itself. First, Infor's inclusion of the relationship between the "event manager" and the subsystems is unnecessary. Independent claims 1 and 40 describe "an event manager, coupled to the subsystems." The term "coupled to" necessarily implies that the event manager is separate from the various subsystems. Adding an additional "separation" limitation would only be redundant and confusing to the jury. Likewise, both sides attempt to incorporate the general function of the "event manager" in their definitions. Ultimately, these descriptions are vague and redundant of the claim language. Claim 1 provides that the "event manager detect[s] . . . infer[s] . . . and automatically initiat[es] an operation in one or more particular subsystems." Claim 40 has almost identical language. Both Infor's and SFA's definitions are too broad in light of the very specific functions provided for in the claim language. Further, Infor's term, "intelligently controls," is vague and would require even further definition. The claim language already
provides for the "event manager's" relationship with the subsystems as well as its various functions. No additional limitations are necessary beyond the agreed limitation that the event manager must be "hardware and/or software." Accordingly, the Court construes the term as "hardware and/or software."

9. "[E]vent trigger:" "Notification or indication that an event has happened." The parties agree with this construction. The court's construction is consistent with Figure 1 of the specification, which depicts the event processor notifying the task engine that an event has occurred.

7. "non-time based events"

After the Markman hearing, the parties conferred regarding the construction of the term "non-time based events" which appears in both Claims 1 and 2. While they were unable to reach agreement, they now propose identical constructions of this claim term, with the exception that AMS's construction includes language specifying that the term "non-time based events" excludes the use of delays, buffers, and time windows to control bid acceptances in order to control the amount of processing.

"The doctrine of prosecution disclaimer precludes patentees from recapturing through claim interpretation specific meanings disclaimed during prosecution." SanDisk Corp. v. Memorex Products, Inc., 415 F.3d 1278, 1286 (Fed. Cir. 2005) (quotations and alterations omitted). Thus, "where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of the surrender." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). But, an ambiguous disclaimer does not serve a public notice function. Therefore, a disclaimer which is not "clear and unmistakable," but rather which is "amenable to multiple reasonable interpretations" will not serve to limit the scope of the claims. See SanDisk, 415 F.3d at 1287.

The Court finds that AMS's disclaimer was not sufficiently clear and unambiguous to be read to disclaim delays, buffers, and time windows entirely. When read in context, the prosecution history reveals that in every instance where the inventors distinguished their invention from that disclosed in Dinwoodie, they did so on the basis that Dinwoodie taught the use of a "predetermined delay" to establish a "bidding acceptance window of time" in order to "control['] subsequent bid acceptances to prevent system overruns." (J. Ex. C. at 571, 572.) This is no less true for the statement relied upon by Defendants. (See id. at 572 (quoting Dinwoodie as stating: "In this manner, processor 26 controls subsequent bid acceptances to prevent an overrunning of system 10," and pointing out that the use of such "delays, buffers and time windows" was common in the field to control system throughput). The fact that the inventors mentioned buffers on a single occasion in reference to common techniques in the industry does not change this conclusion. Buffers were not disclosed by Dinwoodie and thus, disclaiming buffers was unnecessary to distinguish that art. Therefore, a disclaimer of buffers was not required in order to obtain claim allowance, and any mention of buffers was sufficiently ambiguous to avoid a finding of prosecution disclaimer.

Accordingly, for the above stated reasons, the Court construes "non-time based events" to mean "changing states when prompted by events that are not based on time and excluding the use of delays, buffers and time windows to control bid acceptances in order to control the amount of processing."
A. Does the court's construction of the claim term "default format" mean that every node on the network must be able to communicate with every other node on the network?

The relevant portion of claim 1 of the 830 patent recites:

A computer communications system for transferring data between a plurality of nodes comprising:

(a) a communications medium; (b) a plurality of nodes coupled to said communication medium …

wherein each of said nodes has a format set comprised of one or more formats …[and]

wherein each of said format sets includes at least one default format.

..[and] wherein at least one default format is included in the format sets of each of said nodes. 830 patent, col. 11: 23-55.

It is clear from the language of claim 1 that each of the above "wherein" clauses refers to limitations directed at the "said" --meaning above-mentioned--"plurality of nodes." The term "plurality of nodes" was construed by the court to require "at least three nodes," two of which are supplemented nodes and one of which is a default node. '830 Markman, 172 F. Supp. 2d 478, 2001 WL 1388437 at *10. Because the element of the claimed "communications system" at issue here is satisfied when there are three nodes coupled to a communication medium which can all communicate to each other using the "default format," the fact that other nodes are connected to the medium which cannot "talk to each other" is not relevant to whether that network infringes claim 1. The appropriate inquiry is therefore directed only at the "plurality of nodes" covered by the patent.

It appears that Broadcom has drawn from the following statements the proposition that under the court's '830 Markman ruling, claim 1 requires that all nodes on a network must share a common format:

"The 830 invention, as a whole, is directed at enabling all nodes to communicate with each other using a compatible and optimal transfer format." Id. at *27.

(emphasis added).

"The court finds that the meaning of the term "default format" is a common format that every node coupled to the communication medium can use to transfer data to every other node coupled to that medium." Id. (emphasis added). While the court did not explicitly state so in these lines, the use of the term "nodes" in both statements refers not to all nodes on a given network, but to those nodes included in the claimed "plurality of nodes," which was construed to require at least three nodes. Because all of the wherein phrases in claim 1 are directed at the "plurality of nodes," latter constructions of the terms within those phrases apply requirements only to those nodes. In sum, because the claimed invention is directed only to a computer communications system comprised of a plurality of nodes, these are the only relevant nodes for the purposes of claim 1. The first statement above is a general statement about the purpose of the 830 invention. There is, however, no requirement imposed by the claim language that all nodes on a network be included in the "plurality of nodes" claimed. Rather, the claims only require the inquiry to focus on "at least three" nodes having the claimed characteristics. In the second statement above, the phrase "every node coupled to the communication medium" is meant to refer only to nodes that are included in the "plurality of nodes" that is called for by the claim language. Characteristics of other nodes on the network that are not included in the "plurality of nodes" are irrelevant to the claimed "computer communication system."
Claim 1 of the '611 patent contains the term "exact geographic location": "determining the exact geographic location of the mobile unit place the call requesting emergency service." This term is discussed in the specification: "The exact location of each mobile unit is determined using a Global Positioning System (GPS), LORAN, or other position determining system." ('611 patent, 3:36-39) (emphasis added). "[T]he mobile unit uses the GPS receiver 24 and GPS satellite 22 and to determine its exact geographic coordinates, such as longitude and latitude." ('611 patent, 6:22-24) (emphasis added). EMSAT and LBS assert that this term means "a position in longitude and latitude having a degree of accuracy and precision typical of that obtained from a Global Positioning System (GPS), LORAN, or other position determining system." Centennial argues that "exact geographic location" is indefinite. Alternatively, Centennial proposes "a precise and accurate position in latitude and longitude that is not determined using cell site location, cell site ID, coverage area, signal strength, two-way ranging, or hyperbolic ranging."

Centennial first contends that this term is insolubly ambiguous because the patent provides no objective standard from which to determine how "exact" the geographic location must be. In support of its argument, the defendant cites Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342 (Fed. Cir. 2005), in which the Federal Circuit held that "aesthetically pleasing" failed to provide one of ordinary skill in the art any criteria to determine whether this limitation is met. Id. at 1349. But unlike Datamize, in which the specification provided no objective criteria, the '611 patent explains that the exact geographic location is calculated using GPS, LORAN, or other position determining systems. Although "other position determining systems" does not delineate how exact the determination must be, one of skill in the art would know how accurate and precise GPS and LORAN were. Thus, "exact" refers to the degree of accuracy and precision provided by the specified position determining systems, GPS and LORAN, at the time of the invention.

Second, Centennial argues that "exact geographic location" does not include the following position determining methods: cell site location, cell site ID, coverage area, signal strength, two-way ranging, or hyperbolic ranging. According to the defendant, the patentees disclaimed these position determining methods because they do not provide exact geographic location. In response to a PTO rejection for obviousness in view of the Schaible, Comroe, Freeny, Ito, and Frost references, the applicants amended the claims to add the limitation "exact" before "geographic location" and argued that the cited references are distinguishable. (Dkt. No. 138, Ex. 9). The applicants distinguished Schaible because it uses signal strength, which is merely an "indication of location," and Comroe because it uses cell site location. In response to Centennial's prosecution history disclaimer argument, the plaintiffs contend that the applicants distinguished Schaible and Comroe because they merely estimate distance rather than providing longitude and latitude. But the addition of the modifier "exact" indicates that the applicants were distinguishing based on the prior art's lack of precision and accuracy. The plaintiffs' relative position versus longitude and latitude argument is not apparent anywhere in the applicants' response to the PTO. And, even if the applicants did distinguish Schaible and Comroe based on their failure to provide longitude and latitude, their arguments criticized Schaible's and Comroe's position determination technologies due to this alleged shortcoming. Thus, the applicants disclaimed signal strength and cell site location techniques. On the other hand, the court concludes that the applicants did not clearly and unmistakably disclaim the other position determining methods disclosed by the prior art references, i.e., cell site ID, coverage area, two-way ranging, or hyperbolic ranging. In all, the court construes this term to mean "a position in longitude and latitude, not determined using signal strength or cell site location techniques, having a degree of accuracy and precision typical of GPS and LORAN systems available at the time of invention."

1633

2. Examination Component-Disputed Terms Rooted in "Examination Data"

The parties also disagree on constructions for the root term "examination data" and the branch terms "storing an examination data in a memory," "comparing the examination data to a set of examination criteria to define an examination code," "examination criteria," and "computing a component examination code based on said input and a set of stored examination criteria."

"Examination data"

Like in the case of "historical data," both sides derive their competing constructions of "examination data" from a single sentence in the specification: "The examination component is the actual physical examination by the physician and any tests
or procedures ordered or provided.” '443 Patent, col 4:8-10.

Based on this language, Prompt construes "examination data" to mean "information including the actual physical examination by the physician and/or any tests or procedures ordered or provided that become the basis for the patient's medical record and required documentation." Defendants proposed the construction "information that consists of the actual physical examination by the physician and any tests or procedures ordered or provided that becomes the basis for the patient's medical record and required documentation." Defendants noted that they chose the language "that consists of" solely "for the sake of readability and consistency in [their] proposed constructions." As such, Defendants stated they would not oppose replacing "that consists of" with the word "is" to conform more precisely to the specification's original language.

Like for its argument regarding the nature of the history component, Prompt argues that the nature of the examination component requires its proposed construction. Prompt again cites to the AMA publication to show how the examination component, like the history component, is broken down into different types of patient history analysis, characterized by their level of detail -- specifically, "problem focused exams," "expanded problem focused exams," "detailed exams," and "comprehensive exams." See CPT '95 at 7. Prompt also cites to language from the specification describing Figure 2:

Vision 204 is the first section of the Examination component and if the criteria 204 is not met, Examination-component Code F 242 results. If the criteria associated with Vision is met, the Visual Field section 206 is gathered.

See '443 Patent, col. 8:25-28. Prompt argues that this language exemplifies the fact that physicians require flexibility in the examination process, because certain initial criteria must be met before proceeding with the examination. For reasons similar to those Prompt articulated with respect to Defendants' original construction of "historical data," Prompt contends that Defendants' construction of "examination data" excludes preferred embodiments because it prohibits physicians from being able to choose whether to conduct an examination without additional tests and procedures.

Prompt is mistaken. In using the verb "is," the sentence in column 4, lines 8 to 10—which both sides agree is the source skilled artisans will use to construe "examination data" unambiguously identifies what constitutes the examination component. The language requires the physician to conduct the actual physical examination and provides him or her the option of ordering or providing more tests or procedures. Nothing in Prompt's intrinsic citation would lead a skilled artisan to believe that the sentence in column 4, lines 8 to 10 describes an examination component that does not require an actual physical examination. Although this restricts a physician's flexibility, it is the result of the patentees having acted as their own lexicographers and clearly disavowing any intent to make the actual physical examination an optional aspect of the examination component. See Schoenhaus, 440 F.3d at 1358; Phillips, 415 F.3d at 1316.

Moreover, as Defendants indicate, it strains credibility for Prompt to contend that "examination data" need not always require information obtained from an actual examination. Prompt protests this assertion, citing to a passage from the AMA's publication that indicates CPT codes embrace physician consultations where the original physician seeks a second opinion. But Prompt's extrinsic citation is irrelevant because Prompt does not even contend that consultation constitutes an examination. Insofar as the parties seek to define "examination data," and by extension to memorialize the examination component of the patient encounter, they are bound by the language the patentees chose. Further, even if Prompt's extrinsic citation were relevant, the Court has no cause to consider it for purposes of construing the claims, given the clarity with which the specification identifies what the examination component involves. See Phillips, 415 F.3d at 1324 (noting that the court may consider extrinsic sources, but only if the sources are not used to contradict claim meanings that are unambiguous in light of the intrinsic evidence); Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1332 (Fed. Cir. 2001) ("Relying on extrinsic evidence to construe a claim is proper only when the claim language remains genuinely ambiguous after consideration of the intrinsic evidence.") (internal quotes omitted).

Accordingly, the Court construes "examination data" to mean "information that is the actual physical examination by the physician and any tests or procedures ordered or provided that becomes the basis for the patient's medical record and required documentation." Similar to the case of "historical data," using the verb conjugation "becomes" here helps ensure that the patient's medical record and required documentation are based on all the information that makes up examination data, not merely the tests or procedures. Unlike in the case of "historical data," however, there appears to be no feasible way to ameliorate the redundant occurrence of the word "that" without sacrificing the crucial word "is."
D. First Examination Results/Second Examination Results

With respect to these terms, used in the '192 and the '131 patents, Visto argues that the court should simply construe the term "examination results" and not the words "first" and "second." Visto contends that the term "examination results" means "information regarding one or more workspace elements obtained by examining those workspace elements or related data." Seven argues that the term "first examination results" means "a determination, based on a comparison of a last synchronization signature to first version information stored within a firewall-protected corporate LAN, whether the content of an associated first workspace element stored within the firewall-protected corporate LAN has been modified." Seven further argues that the term "second examination results" means a determination, based on a comparison of a last synchronization signature, whether the content of an independently modifiable copy of a workspace element has been modified.

Seven asserts that the patentee used these terms in the specification in accordance with only these definitions. Again, these definitions incorporate Seven's "content" limitation such that the examination results indicate whether the "content" of a first workspace element or its copy has been modified. Seven's definition also incorporates several of the limitations of the disclosed embodiments (i.e. firewall-protected corporate LAN). The court rejects this approach and therefore adopts Visto's proposed definition of the term "examination results" with a slight modification and defines it to mean "information regarding one or more workspace elements obtained by examining those workspace elements." The terms "first" and "second" require no construction.

E. "examining the payload portion of the packet data" and its variants

The parties dispute whether the invention examines the payload portion of the packet to the exclusion of the non-payload portion when it decides to encrypt a packet. Widevine argues that the claims allow the invention to encrypt based upon an examination of non-payload information as well. Verimatrix argues that the patentee, overcoming a prior art rejection, disavowed that claim scope during prosecution. See Verimatrix Brief at 12-13.

The Court does not see any disavowal of claim scope. The statements the patentee made to the patent examiner are not inconsistent with examining both the payload and non-payload portions of a packet because the references that the patentee overcame did not examine the payload at all. The distinction over the prior art is that the invention does examine the payload, not that it examines the payload exclusively. The Court construes the phrase "examining the payload portion of the packet data," and its variants, to be "examining at least the payload portion of the packet data."
At the center of this dispute is the meaning of the phrase "excess cash payment." EPC's patents describe a method for "apportioning . . . a part of [an] excess cash payment among a number of predetermined accounts" (emphasis added). Again, we "focus[] at the outset on how the patentee used the claim term in the claims, specification, and prosecution history, rather than starting with a broad definition and whittling it down." Phillips, 415 F.3d at 1321. Of particular relevance is the patent specification, which we have described as "the primary basis for construing the claims." Standard Oil Co. v. Am. Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985); see also Metabolite Labs., Inc. v. Lab. Corp. of Am. Holdings, 370 F.3d 1354, 1360 (Fed. Cir. 2004) ("In most cases, the best source for discerning the proper context of claim terms is the patent specification . . . .").

The patents-in-suit are related. For simplicity we refer to the disclosure of U.S. Patent No. 5,621,640. The other patents-in-suit are U.S. Patent Nos. 6,088,682; 6,876,976; and 7,171,370.

In the present case, the patent specification strongly supports the construction of "excess cash" that the district court ultimately adopted. The specification describes the patent as a method "for conveniently and frequently donating to qualified charities and savings or other accounts." This method, in turn, is further described as follows:

In current shopping situations a clerk inputs the price of all items in a cash register and the latter totals the price. The consumer offers either the exact amount of cash or a sum exceeding the price, and the clerk enters that amount. The cash register then subtracts the price from the cash.

The excess cash offers the customers an opportunity to save small amounts of money painlessly. It also affords the consumer to donate [sic] small amounts of money to charity.

The portion of the specification quoted above tells us what "excess cash" means in the context of the patent claim: "excess cash" is what is left over after the merchant subtracts the price of the items the consumer wishes to buy from the cash the consumer tenders to complete the sale. Where the consumer does not offer a sum in excess of the total displayed on the cash register, then there is no excess cash. All this is captured quite well by the construction of "excess cash" that the district court ultimately adopted, according to which "excess cash" refers to "an amount selected by the payor beyond the total amount owed at the point of sale."

EPC has surprisingly little to say about what it alleges is substantively wrong with the district court's construction, or why its proposed construction would be better on the merits. Instead, it attempts to assign error to the district court's construction on a number of procedural grounds. Principally, it argues that the court erred by (1) spending a portion of the claim construction hearing considering the meaning of the phrase "sales price," which was not a disputed claim term; and (2) using the accused products to tailor a construction of the patent claims that would make it impossible for EPC to prove infringement. Neither of these arguments has merit.

EPC's first argument is that the district court erred by spending a portion of the claim construction hearing considering the meaning of the phrase "sales price," which was not a disputed claim term. This argument is somewhat puzzling, since it was EPC's own proposed construction that raised questions concerning the meaning of "sales price." EPC proposed to construe "excess cash" as "an amount . . . offered in excess of the sale price of merchandise" (emphasis added). It admitted, however, that the parties disagree about what constitutes a "sale." According to the defendants, a sale occurs when cash changes hands at the cash register. According to EPC, by contrast, to call a transaction a sale is to imply that the merchant would treat the cash the consumer tenders as income on its accounting statements. EPC also insists--without offering any evidence--that when a consumer purchases a gift card, a merchant would not consider this to be a sale.

In the light of this acknowledged disagreement over the meaning of "sales price," the fact that EPC would both propose to define its patent claims in terms of this phrase and then fault the court for attempting to clarify the phrase's meaning is at best ironic and at worst disingenuous. Again, the court's obligation is to ensure that questions of the scope of the patent claims are not left to the jury. O2 Micro, 521 F.3d at 1361-62. In order to fulfill this obligation, the court must see to it that disputes concerning the scope of the patent claims are fully resolved. Id. In the present case, to evaluate EPC's proposal
concerning the scope of its claims, the court first had to understand this proposal. If the court had adopted EPC's proposed construction without first assigning a fixed meaning to this construction, then it would quite clearly have failed to assign "a fixed, unambiguous, legally operative meaning to the claim." Liquid Dynamics Corp. v. Vaughan Co., 355 F.3d 1361, 1367 (Fed. Cir. 2004). Thus, there was nothing improper about the fact that the court interpreted EPC's (quite slippery) proposed construction. As Michel de Montaigne has said, there are times when "[w]e need to interpret interpretations more than to interpret things." Jacques Derrida, Structure, Sign and Play in the Discourse of the Human Sciences, in Writing and Difference 278 (Alan Bass, trans. 1980) (quoting Montaigne).

Equally without merit is EPC's argument that the district court erred by "tailoring its claim construction to fit the dimensions of the accused product." A court may not use the accused products for the sole purpose of arriving at a construction of the claim terms that would make it impossible for the plaintiff to prove infringement. See Wilson Sporting Goods Co. v. Hillerich & Bradsby Co., 442 F.3d 1322, 1331 (Fed. Cir. 2006). But that is not what the court did here. To the contrary, the court quite properly invited the parties' views of what they thought "excess cash" meant in the context of a series of hypothetical transactions, some of which involved the accused products. For example, the court described a situation in which a consumer tenders $50 for a grocery store gift card with a face value of $50, and then asked the parties to identify whether there was any "excess cash" in that transaction, and if so, what portion of the amount tendered constitutes the "excess." In other words, the court considered the accused products only to elicit the parties' views about what the claim term means in the context of a concrete transaction involving these products. EPC's suggestion that this was improper is way wide of the mark. See id. at 1326-27 ("While a trial court should certainly not prejudge the ultimate infringement analysis by construing claims with an aim to include or exclude an accused product or process, knowledge of that product or process provides meaningful context for the first step of the infringement analysis, claim construction."); Aero Prods. Int'l, Inc. v. Intex Recreation Corp., 466 F.3d 1000, 1012 n.6 (Fed. Cir. 2006) ("Although the court revealed an awareness of the accused device, the court's awareness of the accused device is permissible.").

In short, the district court correctly construed the claim terms in EPC's patents. EPC's attempts to assign error to the process by which the court arrived at its construction cannot succeed.

---

D. "Exchanging"

Lucent contends that this term should be construed in accordance with its ordinary meaning as "a packet transmitted at a rate greater than the subscribed rate." (D.I. 396 at 6.) Extreme contends that this phrase should be construed to mean "a packet from a customer transmitted at a rate greater than the subscribed rate for the virtual circuit connection to which the packet belongs." (D.I. 395 at 18.) Foundry contends that the phrase means "a packet from a customer transmitted at a rate greater than the subscribed rate where the subscribed rate is a rate described in terms of an average rate and burstiness factor over a virtual circuit to which the packet belongs." (D.I. 385 at 10.)

In view of the Court's conclusion that the claims of the '810 and '811 patents are not limited to packet-switching network comprised of virtual circuits, the Court rejects Extreme's proposed construction and that part of Foundry's construction that relies on the presence of a virtual circuit.

With regard to the part of Foundry's proposed construction where the rate is described in terms of an average rate and burstiness factor, the Court finds that the subscribed bandwidth is described in these terms in a preferred embodiment of the invention. ('810 patent at 5:60-64.) Thus, the Court concludes that Foundry impermissibly tries to restrict the claim to the particular subscribed rate used in the preferred embodiment. Accordingly, in the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

---

1638

D. "Exchanging"
Defendant contends that this claim term should be limited to an "exchange-type format," which Defendant explains "is essentially a market system that, like the New York Stock Exchange or the Nasdaq, compares offers to buy and sell and completes transactions automatically as soon as a match is found." (D.I. 50 at 14.) However, "[e]ven when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction." See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (quotations omitted). Thus, where, as here, the specification describes multiple embodiments, the Court is particularly cautious in limiting the claims to a single embodiment, unless such a construction is otherwise dictated by the claim language. Here, the specification describes, in addition to an "exchange type format," an "auction-type format," a "reverse auction-type format," the sale of tickets for a fixed price, and combinations of these methods. See '809 patent at 4:1-24, 4:51-62. In the Court's view, there is nothing about the ordinary word "exchanging" to suggest that it should be limited to only the "exchange-type format." Accordingly, the Court will construe the term "exchanging" to mean, as Plaintiff contends, "giving up something for something else."

Defendant contends that the term "exchanging" should be limited to an "exchange-type format" because the overall claim is structured in such a way that it can encompass only this format. Specifically, Defendant notes that (1) the claims refer to a "bid," but there is no "bid" in a fixed-price sale, (2) the claims call for "comparing the bid to the asks," but a fixed price sale involves, at most, a comparison with only one ask, and (3) the claims call for completing a sale "when the bid price equals the ask," but auctions are completed at the highest bid price, not when a bid price equals an ask price. (D.I. 57 at 10.) However, the parties have proposed competing constructions for all these claim terms. If, as Defendant contends, these are the actual claim terms that limit the scope of the claims to an "exchange-type format," this contention should be addressed within the context of construing these specific terms. Defendant further contends that the claims are limited to an "exchange-type format" because, in the specification, the claim term "asks" is used only in connection with an "exchange-type format." (See D.I. 50 at 15-16 (citing '809 patent at 4:25-50).) However, this is incorrect: the Summary Of The Invention uses the term "asks" to describe the invention, yet does not explicitly refer to an "exchange-type format." Furthermore, on reviewing the specification, the Court concludes that the mere use of the term "asks" to describe the "exchange-type format" does not amount to either an explicit or implicit definition, nor does it establish "a clear intention to limit the claim scope using words or expressions of manifest exclusion or restriction." Liebel-Flarsheim, 358 F.3d at 906.

1639

E. Excitation

The term "excitation" appears throughout the claims of the '580 patent, including in claims 29-31, 34, 37, and 40-43. AT&T proposes two separate definitions: "(noun) an input signal of a system or apparatus; (adjective) relating to an input of a system or an apparatus." (Joint Letter, Ex. B.) Microsoft asserts the definition should be "values that by themselves without other values (such as "pitch period signals" or "voiced and unvoiced amplitudes") replace the difference between actual and predicted speech values." (Joint Letter, Ex. B.) The main difference between the parties is whether an excitation is limited to a single, particular signal.

The plain meaning of "excitation" is defined in a treatise that both parties offer:

A digital processing system acts on a digital input signal and produces a digital output signal. In other words, it establishes a cause-and-effect relationship. The input signal is called the excitation signal or simply excitation. The output signal is called the response of the system to the considered excitation.

(Murat Kunt, Digital Signal Processing at 22 (Artech House, Inc. 1980) (emphasis in original).) Accordingly, an "excitation signal," as contemplated by the treatise is "an input signal." There is nothing in the language of the '580 patent claims to indicate that the plain meaning of "excitation" should not apply.

The claim must also be read in light of the specification and prosecution history to determine whether the patentees chose to
assign to the term "excitation" a definition or scope other than its plain meaning. See Union Carbide Chems. & Plastics Tech. Corp., 308 F.3d at 1177. The specification does not define "excitation." Although the parties agree that the Figure 1 embodiment does not disclose more than one excitation signal being used in a single frame (Tr. at 162), there is nothing in the language of the claims themselves to support a reading that more than one value cannot be associated with the excitation. It is inappropriate to import any limitation from that embodiment into the claims. Teleflex, 299 F.3d at 1325; Brookhill-Wilk 1, 326 F.3d at 1223. Thus, the specification's use of the term "excitation" does not rebut the presumption of plain meaning.

Microsoft asserts that the patentees disavowed the use of "other values" such as "pitch period signals" or "voiced and unvoiced amplitudes" during prosecution:

[In the Atal '302 patent] voiced/unvoiced signals are required to define the type of excitation to be applied to the decoding filter and a noise generator is needed to substitute for unvoiced excitation. All these signals are coded and utilized to construct a replica of the speech pattern. The excitation signal of the instant application is completely distinguished from the multitude of signals required in Atal '302 to perform the same function and advantageously provides improved operation in which voiced, unvoiced and partially voiced intervals may be accurately constructed using a single excitation signal.

(Pros. Hist. at 110-11.)

The cited prosecution history shows that AT&T disavowed any definition of "excitation" requiring the use of multiple signals. The prosecution history states that "the excitation signal of the instant application is completely distinguished from the multitude of signals required in Atal '302." (Pros. Hist. at 111 (emphasis added).) When read in context, that phrase strongly supports limiting the definition of "excitation" to a single input signal, without additional values. That passage also uses equivocal language: "voiced, unvoiced and partially voiced intervals may be accurately constructed using a single excitation signal [in the claimed invention]." (Pros. Hist. at 111 (emphasis added).) Reading the prosecution history as a whole, however, this Court finds that the patentees represented to the examining attorney that the '580 patent's use of "a single excitation signal," rather than voiced/unvoiced signals and a noise generator, distinguished it from the prior art. Other sections of the prosecution history support this conclusion. The patentees represented to the examining attorney that "the voiced/unvoiced coded signal and noise generator are eliminated and more exact replicas can be synthesized at bit rates lower than required for residual signal encoding," (Pros. Hist. at 112), and that the creation of the excitation signal in the invention under review is, again, "completely distinguished from Atal '302." (Pros. Hist. at 113.)

AT&T asserts that the prosecution history does not limit the claim to merely a single excitation signal (Tr. at 147-48), but instead contemplates an invention which may optionally use multiple or a single excitation signal. (Tr. at 150.) However, as noted, AT&T's proposed construction does not comport with the prosecution history's use of unequivocal language to distinguish and disavow the multiple signals feature of the prior art. (Pros. Hist. at 110-11.)

Accordingly, based on the plain meaning of the term "excitation," the specification's written descriptions, and the prosecution history, this Court defines "excitation" as a noun to mean "an input signal of a system or apparatus without additional values," and as an adjective to mean "relating to an input signal of a system or an apparatus without additional values."

1640

On June 24, 2003, this Court issued a Memorandum and Order on claim construction that, inter alia, construed the term "excitation" in the 580 patent to mean "an input signal of a system or apparatus without additional values," as a noun, and "relating to an input signal of a system or an apparatus without additional values" when used as an adjective. AT&T Corp. v. Microsoft Corp., 2003 U.S. Dist. LEXIS 10716, 01 Civ. 4872 (WHP), 2003 WL 2145973, at *14-16 (S.D.N.Y. June 24, 2003). AT&T asks this Court to reconsider its construction of the claim term "excitation," on the ground that "the Court added a negative limitation ('without additional values') not supported by the prosecution history." (AT&T Opposition to Microsoft's Motion for Summary Judgment of Noninfringement ("AT&T Opp.") at 20.) For the reasons set forth below, AT&T's application for reconsideration is granted. 4
During an August 29, 2003 pre-motion conference, AT&T requested that this Court reconsider its construction of the term "excitation." At the parties' request, this Court allowed the parties to address AT&T's application for reconsideration in their summary judgment briefing. Accordingly, the parties addressed construction of the term "excitation" in their memoranda on Microsoft's Motion for Summary Judgment of Noninfringement.

This Memorandum and Order memorializes a ruling made during a conference call with the parties on February 17, 2004.

"To be entitled to reconsideration, the movant must demonstrate that the Court overlooked controlling decisions or factual matters that were put before it on the underlying motion, which, had they been considered 'might reasonably have altered the result reached by the court.'" Chere Amie, Inc. v. Windstar Apparel, Corp., 2002 U.S. Dist. LEXIS 17825, 01 Civ. 0040 (WHP), 2002 WL 31108187, at *1 (S.D.N.Y. Sept. 23, 2002) (quoting Consol. Gold Fields v. Anglo Am. Corp., 713 F. Supp. 1457, 1476 (S.D.N.Y. 1989)); accord Local Civil Rule 6.3. Reconsideration is within the sound discretion of the district court. Dietrich v. Bauer, 76 F. Supp. 2d 312, 327 (S.D.N.Y. 1999). Because it appears that this Court "overlooked certain technical distinctions made in the prosecution history statements" during claim construction, reconsideration is appropriate here. (AT&T Opp. at 20.)

The facts underlying this Court's construction of the term "excitation" were set forth in detail in this Court's Memoranda and Order, dated June 24, 2003. AT&T, 2003 U.S. Dist. LEXIS 10716, 2003 WL 21459573, at *14-15. AT&T contends that this Court's addition of the phrase "without additional values" in its construction is not supported by the prosecution history of the 580 patent. AT&T proposes that this Court construe "excitation" to mean "an input signal of a system or apparatus that does not require use of voiced/unvoiced coded signals and a noise generator," because nothing in the prosecution history prohibits the use of all "additional values." (AT&T Opp. at 23 (emphasis added); Transcript of Oral Argument, dated Dec. 22, 2003 ("Tr.") at 4.) Microsoft urges this Court to maintain its current construction of "excitation", and include the phrase "without additional values." This Court agrees with AT&T that the inclusion of the phrase "without additional values" renders its construction of the term "excitation" overbroad.

During prosecution, the patentees attempted to distinguish their invention from U.S. Patent No. 3,324,302 (the "Atal '302") :

Atal '302 . . . discloses a linear prediction speech analysis and synthesis arrangement in which predictive parameters [1] for a speech pattern interval are generated. Pitch period signals [2] representative of the location of glottal pulses in the applied speech pattern are independently generated. Signals corresponding to voiced and unvoiced amplitudes [3] are produced responsive to the pitch period and prediction parameter signals. Voiced/unvoiced signals are required to define the type of excitation to be applied to the decoding filter and a noise generator is needed to substitute for unvoiced excitation. All these signals are coded and utilized to construct a replica of the speech pattern [5]. The excitation signal of the instant application is completely distinguished from the multitude of signals required in Atal 302 to perform the same function and advantageously provides improved operation in which voiced, unvoiced and partially voiced intervals may be accurately constructed using a single excitation signal.

(MS Ex. 2: Pros. Hist. 110-11 (emphasis added).) As this Court noted in its June 24, 2003 Memorandum and Order, the patentees used both equivocal and unequivocal language in differentiating their invention from the prior art. AT&T, 2003 U.S. Dist. LEXIS 10716, 2003 WL 21459573, at *14-15. This Court found that viewing the prosecution history as a whole, however, the patentees disavowed the use of all multiple signals. AT&T, 2003 U.S. Dist. LEXIS 10716, 2003 WL 21459573, at *14-15. In making that finding, this Court also looked to other sections of the prosecution history:

The voiced/unvoiced coded signal and noise generator are eliminated and more exact replicas can be synthesized at bit rates lower than required for residual signal encoding.

(MS Ex. 2: Pros. Hist. at 112.)

The decoding receiver of Atal '302 requires a noise generator, and a switching arrangement responsive to a voiced/unvoiced decision signal to provide the pitch pulse excitation signal for voiced periods and a noise excitation signal for unvoiced periods. The instant invention advantageously eliminates voiced/unvoiced coding, noise generation for
unvoiced intervals and switching between such intervals and provides better quality speech reconstruction at selectable bit rates and is completely distinguished from Atal '302.

(MS Ex. 2: Pros. Hist. at 112-13.) See AT&T, 2003 U.S. Dist. LEXIS 10716, 2003 WL 21459573, at *15. Upon reconsideration, however, the cited portions of the prosecution history support a more limited disclaimer of scope.

A court must consider the prosecution history of the patent "to determine whether the applicant clearly and unambiguously 'disclaimed or disavowed [any interpretation] during prosecution in order to obtain a claim allowance." Middleton, Inc. v. Minnesota Mining & Mfg. Co., 311 F.3d 1384, 1388 (Fed. Cir. 2002) (quoting Standard Oil Co. v. Am. Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985)) (alteration in original). Disclaimer during prosecution of the patent may include instances where "the patentee distinguished [a] term from prior art on the basis of a particular embodiment, expressly disclaimed subject matter, or described a particular embodiment as important to the invention." CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359 at 1366-67. Prosecution disclaimer must be narrowly tailored, however, to exclude only claim scope that has been "clearly and unmistakably" disclaimed. Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324-26 (Fed. Cir. 2003) ("For prosecution disclaimer to attach, our precedent requires that the alleged disavowing actions or statements made during prosecution be both clear and unmistakable."); accord Sunrace Roots Enter. Co. v. SRAM Corp., 336 F.3d 1298, 1306-07 (Fed. Cir. 2003). "Where the patentee has unequivocally disavowed a certain meaning to obtain his patent, the doctrine of prosecution disclaimer attaches and narrows the ordinary meaning of the claim congruent with the scope of surrender." Omega Eng'g, 334 F.3d at 1324-26 (Fed. Cir. 2003) (finding that the prosecution history indicated a "clear and unmistakable," narrow disclaimer of claim scope); accord Anchor Wall Sys., Inc. v. Rockwood Retaining Walls, Inc., 340 F.3d 1298, 1310-11 (Fed. Cir. 2003).

This Court's earlier construction of the term "excitation" is overbroad, and must be limited to encompass only the extent to which the patentees clearly and unmistakably disavowed a particular claim scope. Omega Eng'g, 334 F.3d at 1324-26. The prosecution history teaches that AT&T only unequivocally disavowed a definition of "excitation" requiring the use of the particular combination of signals essential to practice the Atal 302 patent, which includes use of voiced/unvoiced signals and a noise generator. Indeed, the patentees averred that their invention was "completely distinguished" from the Atal 302 patent's combination of signals. (MS Ex. 2: Pros. Hist. at 110-11.) However, in reference to the 580 patent's use of single or multiple signals, the patentee's averred language in the prosecution history to explain the 580 patent's use of single and/or multiple signals is not the type of clear and unmistakable disavowal essential to limit the use of all types of additional values from the claim scope. Omega Eng'g, 334 F.3d at 1324-26 (noting that "the doctrine of prosecution disclaimer" does not apply "where the alleged disavowal of claim scope is ambiguous"); Anchor Wall, 340 F.3d at 1310-11 (same). The prosecution history undeniably supports the contention that the patentees never unequivocally disclaimed use of all "additional values" in the prosecution history. (MS Ex. 2: Pros. Hist. 110-13.) Indeed, during prosecution of the 580 patent, the patentees only clearly disavowed use of voiced/unvoiced coded signals and a noise generator, which are essential to practice the Atal '302 patent. (MS Ex. 2: Pros. Hist. at 110-13.) Because the prosecution history supports a limited disclaimer of claim scope, construction of the term "excitation" may only be limited to provide that the 580 patent does not require voiced/unvoiced coded signals and a noise generator. (MS Ex. 2: Pros Hist. 110-13.) Omega Eng'g, 334 F.3d at 1324-26.

CONCLUSION

AT&T's application for reconsideration of this Court's construction of the term "excitation" in the 580 patent is granted.

Upon reconsideration, this Court reconstrues the term "excitation" when used as a noun to mean "an input signal of a system or apparatus that does not require use of voiced/unvoiced coded signals and a noise generator," and when used as an adjective to mean "relating to an input signal of a system or apparatus that does not require use of voiced/unvoiced coded signals and a noise generator."
The parties have grouped these terms together. The dispute is whether the "relationship" language requires a construction which imposes a "left-hand side" and "right-hand side" limitation to the terms. Trilogy contends that the term "includes relationship" means "a classification in which a second set of one or more elements is included when all members of a first set of one or more elements exist in a configuration." Selectica contends that the term "includes relationship" means "a relationship that causes the elements on the right-hand side of the relationship to be included in the configuration when all elements of the left-hand side of the relationship are already included."

In discussing the relationship terms, the patents state "[a] relationship relates a first set of parts with a second set of parts." 651 patent, col. 2, 11. 13-14. The patents also state:

Preferably, the part relationships are: included, excluded, removed, and requires choice. An included part is included automatically. A part is excluded from the configuration when it inclusion would result in an invalid configuration. A part may be removed when another part is added. Thus, when a first part exists in the configuration and a second part is added, the first part is removed from the configuration. The requires choice relationship is used to allow a set of choices to be made from a group of parts.

'651 patent, col. 2, 11. 23-31. For essentially the reasons discussed previously, the court adopts the following constructions of these terms:

"includes relationship" means "a relationship that causes the elements on the right-hand side of the relationship to be included in the configuration when all elements of the left-hand side of the relationship are already included;"

"excludes relationship" means "a relationship that causes the elements of the right-hand side of the relationship to be excluded when all elements of the left-hand side are already included;"

"requires choice relationship" means "a relationship in which a number of elements must be chosen from a second set of elements on the right-hand side of the relationship when all elements of the left-hand side are already included;"

"removed relationship" means "a relationship that causes the elements of the right-hand side of the relationship to be removed when all elements of the left-hand side are already included;" and

"optional relationship" means "a relationship in which a number of elements may be chosen from a second set of elements on the right-hand side of the relationship when all elements of the left-hand side are already included."

C. "Exclusion" and "exclusion criteria"

Claims 18 and 50 of the 550 patent claim:

Claim 18:
A method according to claim 16, further including the steps of:

selecting a second portion of said first image or another image; and

creating an exclusion based on said portion.

Claim 50:
A method for blending images, comprising the steps of:

receiving video of an environment;
selecting a first region in said video, said first region includes a first set of different color values;

creating inclusion criteria describing said first set of different color values;

selecting a second region in said video, said second region includes a second set of one or more color values;

creating exclusion criteria describing said second set of one or more color values, said first set of color values overlap with said second set of color values;

identifying a target area in said video after said steps of creating inclusion criteria and creating exclusion criteria;

comparing said color data for said target area to said inclusion criteria and said exclusion criteria; and

blending a graphic with said target area at least partially based on said inclusion criteria and said exclusion criteria.

Sportvision's definition is "An exclusion is a set of characteristics that describe a class of pixels that cannot be modified in video." (Sportvision's Memo at 15.)

SportsMEDIA's definition is "A set of characteristics that describe a set of pixels that are not to be modified in the video." (SportsMEDIA's Memo at 19.)

The written description provides the following definition for the term:

An exclusion is a color range for a pixel that should not be enhanced using the present invention. During operation, the operator can set up one or more inclusions and/or one or more exclusions. For example, the operator may decide that a yard line can be drawn over white (the original yard lines), green (grass) and brown (dirt). Additionally, the operator may want to set up an exclusion so that a line is not drawn over a specific color (e.g. team's uniforms). In an alternate embodiment of the present invention, exclusions also include video frame pixel locations that are not to be enhanced.

'550 patent, 9:6-16.

This description defines "exclusion" as (a) a color range which specifies whether a pixel cannot be modified, or (b) a color range which specifies whether a pixel cannot be modified and a video frame location which cannot be modified. Definition (a) has one criterium for determining whether a pixel color value can be modified and definition (b) has two criteria (color range and location). Sportvision's definition only covers case (a). SportsMEDIA's definition only covers the case in which pixel locations for exclusion are stored.

Consistently with the specification, the Court defines the term "exclusion" to mean: "A color range or a color range in combination with pixel locations that determines which pixels are not to be enhanced."

1643

CLAIM CONSTRUCTION

When interpreting disputed claim terms, this court accords claim terms their customary meaning in the art at the time of invention. Home Diagnostics, Inc. v. LifeScan, Inc., 381 F.3d 1352, 1355 (Fed. Cir. 2004). Further, a construing court should consult the specification to determine whether the patentee gave a claim term a meaning inconsistent with that customary meaning in the proper technological and temporal context. Metabolite Labs., Inc. v. Lab. Corp. of Am. Holdings, 370 F.3d 1354, 1360 (Fed. Cir. 2004).

The district court construed "executable application" to mean "any computer program code, that is not the operating system or a utility, that is launched to enable an end user to directly interact with data." Microsoft asserts that this term should be construed as "standalone programs." Because, absent a disclaimer, the claims of the '906 patent are not limited to the embodiments listed in the specification, this court affirms the district court's construction.
As construed by the district court, "executable application" includes applications or components that are not standalone, i.e., DLLs such as spell check. Such applications or components can only run when invoked by some other application. Microsoft asserts that its construction is consistent with the ordinary meaning of the term and that the specification does not otherwise define the term. Microsoft correctly points out that all of the disclosed embodiments in the specification describe standalone programs (i.e., word processors and spreadsheets). Nonetheless, absent a clear disclaimer in the specification, the embodiments in the specification do not limit broader claim language. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 907-08 (Fed. Cir. 2004).

The record shows that the term "executable application" does not have a customary meaning in the computer science field. Therefore, the district court appropriately declined to impose a sharp limitation on its scope. Accordingly, the trial court correctly perceived that "application" means "a computer program, that is not the operating system or a utility, that is designed to allow an end-user to perform some specific task." The district court also found support for this meaning in technical dictionaries. For instance, the 1994 Microsoft Press Computer Dictionary defined "application" as "a computer program designed to help people perform a certain type of work. An application thus differs from an operating system (which runs a computer), a utility (which performs maintenance or general-purpose chores), and a language (with which computer programs are created). ..." Microsoft Press Computer Dictionary 23-24 (2d ed. 1994). A few years later, the same dictionary defined "application" as "a program designed to assist in the performance of a specific task, such as word processing, accounting, or inventory management. Compare utility." Microsoft Press Computer Dictionary 27 (3d ed. 1997).

Still another source on the meaning of technical language defines "application" as a "program or group of programs designed for end users." ZD Webopædia, at http://www.zdwebopedia.com/TERM/a/application.html.

Neither the specification nor the prosecution history disclaims the district court's construction of "executable application." The '906 patent makes no reference to the phrase "executable application" except in the claims. See generally the '906 patent. In addition, the specification repeatedly indicates that the preferred embodiment is only one possibility for practice of the invention. Id. Because this court "consistently declines to construe claims according to the preferred embodiment," this court agrees with the district court that Microsoft's proposed construction, limiting "executable application" to standalone programs, does not comport with the entire technological and temporal context for this term. N. Telecom Ltd. v. Samsung Elecs. Co., 215 F.3d 1281, 1293 (Fed. Cir. 2000).

The prosecution history does not disclaim the district court's construction of "executable application," and thus supports the trial court's reading of the term. According to Microsoft, the applicants argued that the Khoi patent used library routines (i.e., components), while their invention did not. In addition, Microsoft claims the applicants argued the Koppolu patent taught away from using standalone applications. A review of the prosecution history does not show any disclaimer as Microsoft contends.

The applicants distinguished Khoi on the grounds that the display of the data object provided by the Khoi functionality was not interactive, and in the '906 invention such interactivity could be achieved "without requiring Khoi-like capabilities in the operating system." Thus, the applicants distinguished Khoi on the feature of interactivity, not on its use of standalone programs. While the applicants included language about library routines and DLLs in their response, they did not distinguish the '906 invention based on these features, rather such features were merely included in language that outlined Khoi's operation. Similarly, the applicants distinguished Koppolu by pointing out that the particular kind of object handlers of Koppolu did not allow interactive processing of the object, because Koppolu did not enable such editing of the object.

In light of the applicant's arguments distinguishing Khoi and Koppolu, the examiner's statement that "the claimed external executable application is not a code library extension nor object handler (e.g. windows dll and OLE) as pointed out in applicant's argument. (Paper # 19 pages 12-14)," appears in the context of the applicant's narrow argument. Thus, the examiner's statement also does not evince a clear disclaimer. The arguments the examiner cited in the Reasons for Allowance simply describe OLE object handlers. The applicants cite problems with OLE object handlers, but do not disclaim anything. They simply argue that the cited references do "not disclose or suggest the missing features." In addition, the applicant has "no obligation to respond to an examiner's statement of Reasons for Allowance, and the statement of an examiner will not necessarily limit a claim." ACCO Brands, Inc. v. Micro Sec. Devices, 346 F.3d 1075, 1079 (Fed. Cir. 2003); see also N. Telecom Ltd., 215 F.3d at 1294 (requiring that prosecution history statements have "reasonable clarity and deliberateness" to narrow claim scope). Overall, without a narrow customary ordinary meaning for "executable application," the district court correctly gleaned the proper definition of the term from the intrinsic evidence including the
1644  
4. **executable code**

Plaintiffs' construction: no construction proposed  
Defendant's construction: a type of software that a processor or hardware device can directly execute  

Only defendant has proposed a construction of this term. In support of its construction, defendant cites expert testimony and a technical dictionary. Plaintiffs argue that it is unnecessary to construe the term separately, but they do not argue that defendant's construction is wrong. Therefore, I will adopt defendant's construction of the term "executable code."

**Court's construction:** a type of software that a processor or hardware device can directly execute

1645  
Claim 1i  
associating an executable file with the part number of the selected choice, the executable file for use during manufacture of the computer system  

The parties disagree on the meaning of the above-stated language.  
For the term "executable file", Dell proposed: "a computer program that is ready to run, such as a spreadsheet or word processor."

For the entire phrase, Lucent proposed: "associating a program containing manufacturing instructions that is ready to run on a computer with the part number of the selected choice using the data file generated during the specifying session, which program is employed during manufacturing of the computer system and cannot be a macro (i.e., a symbol, name, or key that represents a list of commands, actions, or keystrokes) or query (i.e., a request for information from a database)."

The court agrees with Lucent's construction of the claim term, as modified, and construes the above-stated claim term as follows:

"associating a program that is ready to run on a computer with the part number of the selected choice which program is used during manufacturing of the computer system and cannot be a macro (i.e., a symbol, name, or key that represents a list of commands, actions, or keystrokes) or query (i.e., a request for information from a database)."

1646  
4. executable play list  

This term appears in claim 1 of the '345 patent. The plaintiff's proposed construction is the same as its proposed construction for the term "play list," namely "a list of works, selected from an inventory of works, that can be stored, retrieved and sequentially played." The defendant's proposed construction of "a list of works that can be played automatically" adds the term "automatically" to its proposed "play list" definition. For essentially the reasons stated with respect to the previous terms, the court defines the term "executable play list" to mean "a play list that can be played automatically."
8. "[E]xecutable portions" 10 are root modules or overlay modules. This construction is consistent with the specification: col. 9:44-57; col. 12:56-58; col. 14:28-31.

10 '499 patent, claim 15 (and dependent claims).
- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -

H. "executable program instructions," as used in claims 9, 10, and 14.

Plaintiff asserts that no construction of "executable program instructions" is necessary and accordingly offers none. Defendants propose that "executable program instructions" must be construed as "object code (i.e., source code that has been compiled)." Here, application of the dispositive claim construction principle—that claim terms must presumptively be given their ordinary meaning as understood by a person of ordinary skill in the art, see Phillips, 415 F.3d at 1313—points persuasively to the construction, "a computer program that directs a client or server to perform certain operations."

In this case, both the claims (Nos. 9, 10, and 14) and the specification make clear that "executable program instructions" are located on both a client's and server's computer readable medium. These claims further teach that the role of the "executable program instructions" is to facilitate a client or server computer's transfer, receipt, or storage of state information or files. See '670 Patent Specification col. 2 11. 41-53 ("[T]he computer readable medium of the server contains computer program instructions for transmitting the file from the server system to the client system and for transmitting the state object to the client system."). In addition, it is plain that "executable program instructions" can take various forms and contain various directives, structured in a certain sequence. For instance, the "executable program instructions" in claim 9 direct the computer to request, receive and store; the "executable program instructions" in claim 10 direct the computer to receive and then transmit.

Neither the claim language nor any other intrinsic evidence supports defendants' proposed construction, which uses the words "compiled" and "object code." These words are arguably technical in their own right and would require further construction. Thus, accepting defendants' construction would undermine the central purpose of claim construction, namely, "elaborating the normally terse claim language[] in order to understand and explain . . . the scope of the claims." Embrex, Inc. v. Serv. Eng'g Corp., 216 F.3d 1343, 1347 (Fed. Cir. 2000) (first alteration in original) (quoting Scripps Clinic v. Genentech, Inc., 927 F.2d 1565, 1580 (Fed. Cir. 1991)).

Accordingly, the most sensible reading of the claim term "executable program instruction" is "a computer program that directs a client or server to perform certain operations."

A. "[E]xecute"

TRG, relying upon a technical definition of the word "execution," asks the Court to construe the term "execute" as meaning to "carry out a trade." (R. 85, Def.'s Mem. at 18.) Plaintiffs, on the other hand, fail to provide a specific definition of the term. Instead, they ask the Court to construe the phrases "execute trades and orders," "execute trades," and "executing trades and orders" to "meancompleting a transaction of buying or selling a stock, a bond, or a commodity future contract through the process of offer and acceptance; executed trades are then cleared." (R. 82, Pls.' Mem., Ex. 1 at 4.) The Court rejects both of these proposed constructions.
To start, the Court notes that Plaintiffs' proposal fails to provide a specific definition of the term "execute." (See R. 82, Pls.' Mem. at 19.) The Court will not attempt to extricate a construction of this specific claim term from its proposed construction of the phrases "execute trades and orders," "execute trades," and "executing trades and orders." Further, the Court rejects TRG's proposed construction as it improperly narrows the definition of the term "execute" to trades. (See R. 85, Def.'s Mem. at 18 ("Execute means to 'carry out a trade.'").) As evident in the claims, the verb "execute" applies to both trades and orders. See, e.g., '923 patent, col. 11, ll. 14-17 ("a principal market maker futures computer operative to receive and automatically execute . . . trades and orders").

17 Plaintiffs also ask the Court to add the following limitation to these phrases: "The PMM computers, not the electronic trading systemssuch as the GLOBEX or Project A systems, execute trades and orders." (R. 82, Pls.' Mem., Ex. 1 at 4.) In support of their request, Plaintiffs point to the specification and portions of the '923 patent's prosecution history. (See R. 82, Pls.' Mem. at 19.) The Court finds it unnecessary to import these limitations to properly construe the term "execute."

The parties both rely on dictionary definitions in their proposed constructions. In the absence of any intrinsic evidence suggesting a different meaning, the Court will also look to dictionary definitions to construe the term "execute." Relying upon its definition in general purpose dictionaries, along with the definition of the term "execution" in a technical dictionary, the Court will construe the term "execute" as follows: "to carry out fully and completely."

18 The Court specifically relies upon the most relevant definitions found in the following dictionaries: (1) Webster's Third New International Dictionary 794 (1981) (defining "execute" as "to put into effect: carry out fully and completely"); (2) Merriam-Webster's Collegiate Dictionary 436 (11th ed. 2003) (defining "execute" as "to carry out fully: put completely into effect"); and (3) Barron's Dictionary of Finance and Investment Terms 172 (4th ed. 1995) (defining "execution" as "carrying out a trade. A broker who buys or sells shares is said to have executed an order.").
It is another object of the invention to enable user-defined transactions to be completed with a reduced number of inputs from the user at the time the transaction is executed.

Typically, the execution of a transaction requires providing user identification information to the system, providing verification information to verify the user is an authorized user, selecting a type of transaction or function, and selecting one or more transaction parameter (e.g., accounts, dollar amounts, etc.) and causing the transaction to be executed.

Upon the user's selection of a desired menu choice, the associated transaction is then executed without the need for further inputs or selections by the user or with limited additional inputs or selections, thereby minimizing the number of selections, inputs or entries required by a user to execute a desired transaction.

The Court construes the terms "execute a financial transaction" and "executing a financial transaction" as meaning:

To fully carry Out a financial transaction.

C. Executing Concurrently

Plaintiff FortuNet's
Defendants Melange and Planet Bingo's

Proposed Construction
Proposed Construction

Executing a computer
Playing simultaneously.

The Court construes the terms "execute a financial transaction" and "executing a financial transaction" as meaning:

To fully carry Out a financial transaction.

Defendants argue the patent specification and prosecution history use the terms "execute" and "concurrently" interchangeably with "play" and "simultaneously." Defendants also assert this Court previously ruled "execute concurrently" means "play simultaneously" in the Stuart litigation. Defendants contend that during prosecution, the patentee distinguished prior art on the basis that the '787 patent discloses the limitation of playing more than one game at a time. Defendants thus argue this term cannot mean play consecutively or play in turn. Additionally, Defendants note that during the Stuart litigation, FortuNet argued that the patent defined concurrent play as the device concurrently executing two games. Defendants therefore argue FortuNet is judicially estopped from arguing otherwise. In response to FortuNet's proposed construction, Defendants assert FortuNet improperly relies on dictionary definitions, i.e. extrinsic evidence, rather than intrinsic evidence. Defendants note that FortuNet's terms of "computer program" and "interval of time" do not appear in the patent claim language, the specification, or the prosecution history.

FortuNet argues its definition is consistent with computer dictionary definitions of "execute" and "concurrent."
asserts the computer need not actually perform the commands simultaneously, but rather within the same interval of time, because a computer executes only one software command at a time, even if it appears to the player that it is happening simultaneously. FortuNet also argues this Court previously interpreted this term to mean both games need not be displayed at the same time. One game can be played in automatic mode in the background without human interaction or display.

The claim language does not define "execute concurrently." However, the specification and prosecution history frequently use the terms "execute" and "concurrently" interchangeably with "play" and "simultaneously." (See, e.g., JA0001; JA0009, Col.1 at 25-35 & 50-53, Col. 2 at 12-16; JA0011, Col. 5 at 37-43; JA0044-45; JA0074-75; JA0161.) The patent claim language, the specification, and the prosecution history do not refer to executing a computer program over the "same interval of time."

The specification's reference to the invention's computer aspects states that the master game device runs under a multitasking operating system where each task is executing a separate game, such as bingo or keno. (JA0010, Col. 3 at 13-25.) Additionally, each game could be displayed in a separate display window on the display screen. (JA0010, Col. 3 at 25-34.) The specification further states that because of "the wide availability of plentiful information in multitasking operating systems and display windowing techniques, we omit the details of implementation of the operating system 14, the concurrent tasks 15, and the windows 20, 24, 26, and 28." n2 (JA0010, Col. 3 at 40-45.)

In finding the defendant in the Stuart litigation infringed the '787 patent, this Court stated that the '787 patent's use of the term executing concurrently "requires that the device play two games at once." (Defs.' App., Ex. 3 at 12.) In re-examining this claim term, the Court reaches the same conclusion. The phrase "execute concurrently" means playing two games simultaneously, or at once. The specification and prosecution history are replete with examples of the patentee interchangeably using these terms. However, the Court also finds "play simultaneously" must be viewed in context of the specification, which states a multitasking operating system where each task is a game achieves simultaneous play. The Court therefore holds "execute concurrently" means "play simultaneously, i.e. at once, through a multitasking operating system where each task is a game. One of those games could operate in the background while the other is played with human interaction." (See Pls.' App. to Markman Claim Construction Br. (Doc. #20), Ex. H at 33-34.)

VIII. "[E]xecutes within"

The phrase "executes within" expressly appears in claims 1 and 2 of the '493 Patent, claim 7 of the '563 Patent, and claims 7 and 16 of the '882 Patent.

A. The Special Master's Proposed Construction

The Special Master interpreted the phrase "[a] window object executes within . . . said web browser client" to mean "that the window object runs inside the [web browser] client." (R&R at 161-62 (emphasis added).) According to the Special Master, there was no issue over whether "within" meant "inside." (Id. at 161.) The Special Master then noted that the "phrase 'executes within,' . . . does not refer to where a window object appears on the web browser screen." (Id.) Rather, as the Special Master pointed out, the "phrase is recited in the context of a 'web browser client,' e.g., 'wherein said each window object executes within' and is directly controlled by said web browser client which operates within said data processing system' called for in claim 1 of the '493 [P]atent." (Id. at 161-62 (also citing '563 Patent Cl. 7 for the proposition that "'The network client according to claim 6, wherein said at least one corresponding window object executes within the network client.'".) This led the Special Master to construe the phrase "in the context of computers"; in other words, as it was commonly understood by one skilled in the art. (Id. at 162.) Citing from various technical dictionaries, the Special Master
then concluded that "'[e]xecute,' in the context of computers, simply means 'run,' 'perform' or 'operate.'" (Id. (citing Computer & Internet Dictionary 200, 488 (3d ed. 1999); Microsoft Computer Dictionary 173 (4th ed. 1999))). In further clarifying his interpretation, the Special Master stated that "'essentially, the web browser client causes, i.e., processes some set of instructions or performs some action, the window object to be manifested within the CME.'" (Id. at 162.) This clarifying language was not however part of the Special Master's final construction of the phrase "executes within," rather it was included to add context. Having summarized the Special Master's proposed construction, the Court will discuss CA's objection and Simple's corresponding counter arguments.

B. CA's Objection and Simple's Counter Argument

CA objects to the Special Master's definition because it may confuse a jury and instead recommends that his clarifying language also be adopted, "verbatim." (CA's Claim Construction Objections at 19 (stating that the Special Mater's "recommended construction -- 'the window object runs inside the client' -- may inadvertently obscure its meaning because a jury may be confused by how a 'window object' can be said to 'run inside the client.'"); CA International, Inc.'s Reply In Support of Objections To Special Master's Report and Recommendation Regarding Claim Construction (Dkt. No. 599) ("CA's Claim Construction Objections Reply"), at 9-10.) In affect, CA argues that rather than merely construing "executes within" as "runs inside the [web browser] client," the Special Master should have defined the phrase in greater detail and incorporated his clarifying language as follows: "'the web browser client causes, i.e., processes some set of instructions or performs some action, the window object to be manifested within the CME.'" (CA's Claim Construction Objections Reply at 10 (citing R&R at 162).) For its part, Simple argues that the Special Master's proposed construction is clear and need not be altered as suggested by CA. (Simple's Reply to CA's Objection at 14-16.)

C. Analysis

The Court's analysis of "executes within" will focus on the plain meaning of the term at the date of invention.

1. One Skilled in the Art at the Time the '493 Patent Was Filed Would Interpret "executes within" to Mean "Runs Inside"

Since the relevant claim language does not indicate that the phrase "executes within" should be given a special meaning, the Court will define the phrase as it would be understood by one of ordinary skill in the art. In fact, the record lacks any evidence that the term "executes within" should be construed other than as it was by one skilled in the art, when the patents in suit were filed. Symantec, 522 F.3d at 1291 (stating that if a patent "specification does not reveal any special definition for… [a term, it must be construed] according to [its]… ordinary meaning").

As implied by the term "executes," the phrase "executes within" does not refer to where a window object appears on a web browser screen. Rather, the Court will turn to technical dictionaries to understand the plain meaning of the term since no special meaning has been indicated by the intrinsic evidence on record. As the Special Master observed, "'[e]xecute,' in the context of computers, simply means 'run,' 'perform' or 'operate.'" (R&R at 162, citing Computer & Internet Dictionary at 200 and 488 (defining 'execute' as ' . . . RUN. Execute means to perform an action, as in executing a program or a command;' defining 'run as '1. To execute a program. 2. To operate.'); Microsoft Computer Dictionary at 173 (defining 'execute' as 'to perform an instruction.).) Neither the parties nor the Special Master had any issue with construing the term "within" as inside. (Id. at 161.) Accordingly, a window object will not act as a separate application on the operating system, rather it will run inside a web browser. For example, a web browser hosting a single content manifestation environment with three window objects will count as one application level program if each window object executes within the web browser. However, if the window objects did not execute within the web browser, there would be at least four application level programs running, one of which would be the web browser while the other three would be the window objects running separately on the operating system, as opposed to executing within the web browser client.

2. "[E]xecutes within" Defined

In light of the foregoing analysis, the Court adopts the Special Master's interpretation of "executes within." Accordingly, the phrase "a window object executes within . . . said web browser client" means "that the window object runs inside the client." (R&R at 161-62 (emphasis added).)

3. Since the Special Master Correctly Focused on the Functional Properties of Window Objects as They Would Be
Understood by One Skilled in the Art, There is No Need to Incorporate His "Clarifying" Language

Since the relevant claim language does not indicate that the term "executes within" should be given a special meaning, the Special Master was correct in defining the term as it would be understood by one of ordinary skill in the art. In addition, the Special Master correctly pointed out that the term "executes within" does not refer to where a window object appears on the web browser screen. (Id. at 161.) Accordingly, the Court will adopt the Special Master's recommended construction of the phrase "executes within," without needlessly incorporating his "clarifying" language.

D. The Court's Ruling on the Phrase "executes within"

CA's objection is denied since the Special Master's proposed construction of "executes within" as "runs inside" is sufficiently clear when viewed in context of the relevant claim language.

B. Claim Construction and Anticipatory Bar

Having concluded that TEXCEN was indeed "on sale" for purposes of assessing the validity of the '643 patent claims, we turn to whether TEXCEN bars those claims. The answer to the question turns on how the claims are construed. We agree with NASDAQ that the district court correctly construed the "executing" step of claim 1. In pertinent part, claim 1 states:

1. A method for trading securities between individuals, comprising:

***

executing a trade of the security based on information contained in the offer for consideration specified in the reply to the offer, whereby the security is traded efficiently between the first [offering] individual and the second [replying] individual;

***.

'643 patent, col. 15, ll. 55-59 (emphasis added). The court construed this step to mean "changing a memory location to indicate that an agreement had been reached between the two [trading] individuals," as Minton had initially proposed and as NASDAQ did not dispute. Minton, 226 F. Supp. 2d at 865 (citing an earlier Markman order). However, in Minton's opposition to NASDAQ's motion for summary judgment of invalidity, Minton argued for a different construction, urging that the court interpret the phrases "between individuals" and "traded efficiently" so as to create distinctions between the claimed invention and TEXCEN.

NASDAQ first contends that Minton's shifting claim construction arguments in the district court should not be accepted, and it argues that we should therefore not entertain the construction he proffered after the Markman hearing. We disagree. However suspect Minton's tactics may appear, the district court in this case did consider Minton's arguments in favor of a new construction before rendering summary judgment. As such, we will review the district court's decision regarding those arguments.

The court did not err in rejecting Minton's arguments in favor of a new construction, Minton contends that the phrase "between individuals" excludes systems like TEXCEN, which required that a broker affirmatively intervene to execute the trade after ensuring that the trade complied with certain conditions, such as the "best execution rule." * We begin our construction of the phrase "between individuals" with the language of the claim itself. Tex. Digital Sys., Inc. v. Tellegenx, Inc., 308 F.3d 1193, 1201 (Fed. Cir. 2002). That phrase appears in two places: in the preamble ("trading securities between individuals") and in a whereby clause of the executing step ("the security is traded . . . between the first individual and the second individual"). Even assuming that we should give weight to both occurrences of the phrase, the phrase does not speak to the questions of how the trade is executed or who or what performs the execution; it simply indicates that a security is traded between individuals -- in other words, that ownership of a security passes from one individual to another. The plain language of the claim itself therefore does not exclude the scenario in which the broker has the "last say" in executing the trade.

- 2051 -
* The best execution rule required brokers to fill a client's order at the best available price. Because an individual user of TEXCEN may select an offer that is not at the best available price, a broker whose client was using TEXCEN may in some instances have overridden the client's selection of an offer to trade and executed the trade at a different, more favorable price.

Moreover, the written description of the invention confirms what the plain language of the claim says. See id. at 1203-04 ("Because words often have multiple dictionary definitions, . . . the intrinsic evidence must always be considered."). The '643 patent describes an embodiment in which a broker's involvement during trade execution is substantial. In particular, the specification describes that a broker will validate that the seller has the security and the buyer has adequate funds before a trade is executed. '643 patent, col. 12, ll. 39-49; col. 12, l. 61 - col. 13, l. 6; col. 13, ll. 26- 31. The district court's construction encompasses that embodiment of the invention, whereas the construction urged by Minton attempts to draw a distinction (i.e., allowing broker pre-approval of the consideration on each side of the trade but not allowing possible broker preemption based on the best execution rule) that the claim language does not support. Even if there were instances in which the best execution rule altered the trading price and parties such that the claimed method was not followed in those instances, the claim would nonetheless have been practiced in instances in which the best execution rule was not invoked to alter the trading price or parties. In those instances, TEXCEN performed the executing step exactly as stated.

The district court was also correct in not giving weight to the "traded efficiently" phrase in the whereby clause of the executing step. A whereby clause in a method claim is not given weight when it simply expresses the intended result of a process step positively recited. Tex. Instruments Inc. v. United States ITC, 988 F.2d 1165, 1172 (Fed. Cir. 1993). That is the case here. The term "efficiently" on its face does not inform the mechanics of how the trade is executed, and nothing in the specification or the prosecution history suggests otherwise. Rather, the term "efficiently" is a laudatory one characterizing the result of the executing step. We therefore hold that the district court correctly declined to give the term the meaning Minton has proposed.

In sum, Minton's arguments in favor of a different construction of the "executing" step are not persuasive, and we perceive no other error in the court's construction of that step. Minton conceded in the district court that TEXCEN performed the trade execution step as construed by the district court and by this court. See Minton, 226 F. Supp. 2d at 867. Minton's validity arguments on appeal are only premised on his proposed construction of the claims, which we have rejected. Given that the court's construction of the "executing" step is correct, it follows that TEXCEN is an anticipatory statutory bar. We therefore affirm the district court's grant of summary judgment that the claims of the '643 patent are invalid under § 102(b).

Executing an installation process that generates at the client a permission that is locked uniquely to the client and that may be found by a later execution of the access checking process

Defendants offer a construction for the entire term, but Digital Reg contends that only "a permission" and "a permission that is locked uniquely to the client" require construction. 3 Thus, the first dispute is whether the executing step should be construed as a whole or whether only portions of it should be construed. Digital Reg argues that Defendants' approach and lengthy construction do not simplify the meaning of the limitation to the jury and adds a number of limitations to the term that are not recited in the claim. Defendants contend that a piecemeal approach will not resolve the parties' disputes. The Court agrees that a piecemeal approach will not address all of the parties' disputes and will construe the term as a whole as well as construe the individual terms that Digital Reg contends require construction.

3 Initially Digital Reg also proposed a construction for "executing an installation process," but the parties have now agreed that this term should be given its plain and ordinary meaning.
Defendants contend "executing an installation process that generates at the client a permission that is locked uniquely to the client and that may be found by a later execution of the access checking process" should be construed as "Running an installation program that generates a permission, which permission is both (1) locked uniquely to the client and (2) may be located in memory by a later execution of the access checking process. This permission must be generated locally, at that particular client, as opposed to occurring across a network or at a central computer. The term 'generates at the client a permission that is locked uniquely to the client' does not cover the storage of a permission or the recalculation of a permission, or any combination thereof, occurring at the client." Digital Reg contends that portions of Defendants' construction mirrors the claim language, but objects to Defendants' limitations that (1) the permission "may be located in memory," (2) that the permission "must be generated locally, at that particular client, as opposed to occurring across a network or at a central computer," and (3) "generates at the client a permission that is locked uniquely to the client' does not cover the storage of a permission or the recalculation of permission, or any combination thereof, occurring at the client."

located in memory and generated locally

At the hearing, the parties resolved their disputes over the first two issues by agreeing to construe the term as "running an installation program that creates a permission locally, which permission is (1) locked uniquely to the client and (2) capable of being found locally by a later execution of the access checking process."

storage of a permission or recalculation of a permission

Defendants contend that "generates at the client a permission that is locked uniquely to the client' does not cover the storage of a permission or the recalculation of a permission, or any combination therefore, occurring at the client." Defendants contend that during prosecution, the applicant distinguished the client-based operations of Wolfe, i.e. storage and recalculation, from the claimed generation of permission at the client.

The examiner's rejection and the arguments made to distinguish Wolfe did not implicate "client-side" activities, but only "server-side" activities. Therefore, specifying that the generation is done "locally" is sufficient, and Defendants' remaining language is not appropriate.

Accordingly, the Court construes "executing an installation process that generates at the client a permission that is locked uniquely to the client and that may be found by a later execution of the access checking process" as "running an installation program that creates a permission locally, which permission is (1) locked uniquely to the client and (2) capable of being found locally by a later execution of the access checking process."

1655

B. "executing said student tasks"

Claim 1 describes "a plurality of student terminals . . . for receiving said student tasks from said central computer, for executing said student tasks by students to provide said responses, for transmitting said responses to said central computer, and for providing feedback to the students." (emphasis added). Better Education contends that this term means "performing student tasks." On the other hand, eInstruction and Qwisdom assert that the proper construction is "enabling the students to access and perform downloaded student tasks and to enter responses."

According to the plaintiff, the specification supports its proposed construction: "It also is an object of the invention to provide classroom facilities for students to perform computer based instructional exercises . . . ." (491 patent, 3:17-19). The defendants argue that the execution of student tasks must occur at the student terminals; this is correct, but this term's construction does not need to reflect the location of execution, as the claim language already states, "a plurality of student terminals . . . for executing said student tasks." The defendants also contend that the student, and not the student terminal, is the entity that actually executes the student tasks. Again, the defendants' position is supported by the claim language, "executing said student tasks by students." As the claim limitation clearly demonstrates that the students perform the task,
there is no need to import this requirement into the claim construction. Finally, "said student tasks" refers back to "student tasks," which has already been construed. As such, the court construes "executing said student tasks" to mean "performing student tasks."

GO BACK

1656

3. executing the play list; presenting the works on a . . . play list

These terms, or variations of them, are found in claims 3, 74, and 112 of the '725 patent and claims 19, 31, 57, and 93 of the '345 patent. The plaintiff's proposed construction is "sequentially playing the works in the play list." The defendant's counter-construction is "automatically playing the works on a play list." The parties agree that the term "executing the play list" means "playing the play list." The parties' dispute is whether the play list must continue playing in its entirety, e.g. upon pushing the play button, or whether the play list must only partially play, in some sequence.

The claim language at issue is "executing the play list" (emphasis added). This suggests that once playback is initiated, either at the beginning of the list or with a selected song, playback continues automatically until the user intervenes or the list is concluded. Moreover, the specification does not disclose a different meaning. The embodiment disclosed in Figure 31 incorporates a flow of operation whereby the execution of the list causes the list to continue to play through the conclusion of the list or until the user stops playback. As a result, the court concludes that Apple's proposed construction is correct and adopts it. The court defines this term to mean "automatically playing the works in the play list."

1657

3. "Execution"

The final element that the court must construe in this case is the term "execution" in Claim 1 of the '981 Patent. Papyrus argues that the term has its ordinary meaning of "carrying out a trade." Pl. PCCO 3. Papyrus contends that the specification uses the term "execute" in various ways, including "an execution report," "a completed trade," and "carrying out a trade," which demonstrates a more expansive meaning rather than a particular definition. 29 Pl. Br. 35; see N. Telecom Ltd. v. Samsung Elecs. Co., Ltd., 215 F.3d 1281, 1291 (Fed. Cir. 2000) ("[T]he 'varied use of a disputed term in the written description  demonstrates the breadth of the term rather than providing a limited definition.'" (quoting Johnson Worldwide Assocs. v. Zebo Corp., 175 F.3d 985, 991 (Fed. Cir. 1999))). Additionally, Papyrus cites the Dictionary of Financial and Investment Terms (6th ed. 2003), to argue that "execution" in the securities context means "carrying out a trade" and that a "broker who buys or sells shares is said to have executed an order." Pl. App. Ex. 47 at 451.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

29 That Papyrus cites the patent in its entirety rather than providing specific examples of the alleged uses weakens this argument.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Although NYSE does not put forth any specific arguments regarding the definition of "execution," it contends that the term means "the consummation of a trade." Def. PCCO 4.

In this case, the court is persuaded by Papyrus's own statements during prosecution that "the cross-trade occurs at the point of sale" and that the "selective transmission is the step by which the cross-trade is done." Pl. App. Ex. 23 at 274 (emphasis added); see Webster's NID 1561 (defining "occur" as "2: to present itself : come to pass : take place : happen"); id. at 664-65 (defining "do" as "2: to bring to pass, carry out . . . 4: to perform (as an action) by oneself or before another: execute . . . 6: to bring to an end: complete, finish"). Moreover, Papyrus's amendment clearly states that the trade is completed at the time the floor broker selectively transmits the cross-trade to the booth clerk. Pl. App. Ex. 23 at 274. Accordingly, the court construes "execution" as "the consummation of a trade."
4. Claim 12 requires that the executable software itself actually generate and transmit the return receipt

With regard to the generation and transmission of the return receipt, claim 12 states: "said opening further causing the execution of the executable software to initiate automatic generation and transmission of said return receipt to said first computer." '688 Patent at col. 10:67, 11:1-3. PostX argues that the plain language of the claim "merely requires the transmitted JavaScript [in the case of SendAnywhere] to initiate the automatic generation of the return receipt, and because the JavaScript clearly initiates the process of requesting a key from the Key Server for the decryption process, thus automatically causing a return receipt to be transmitted to the sender, facts show that this claim limitation is met." Pl.'s Opp'n at 16:4-8 (emphasis in original).

Sigaba argues, correctly in the Court's view, that PostX has failed to show that there is an "automatic" generation of a "return receipt" when an e-mail of the HTML attachment has been opened. Def.'s Reply Br. at 6:17-20. "On the contrary, human interaction is required before any alleged 'return receipt' can be or is generated." Id. at 6:23-24 citing Chakraborty Decl. at PP 6-7. Sigaba cites "manual entry," "human steps," and "human action" or "interaction" to demonstrate their necessity in producing the key request advisement, i.e., the alleged "return receipt."

As a matter of law, "human judgement . . . is . . . neither identical to nor the equivalent of the computer." Clintec Nutrition C. v. Baxa Corp., 988 F. Supp. 1109, 1115 (N.D.Ill. 1997), citing Davies v. United States, 31 Fed.Cl. 769, 778-79 (1994) (granting summary judgment to the defendant on literal infringement, the court held that where "a human being substitutes for a part of the claimed structure," the infringement standard under 35 U.S.C. § 112, P 6, that the structure be same as or equivalent to that disclosed in the specification, is not met).

Sigaba's software operates as follows: "Human steps are required after the HTML attachment is opened and after the JavaScript runs. If and only if this further human action takes place does the Sigaba software then attempt to authenticate the recipient, and only if this is successfully completed does the software attempt to retrieve the decryption key. Only after and if this retrieval is successful is the key request advisement (which is what PostX alleges is the 'return receipt') sent back to the e-mail sender's computer." Def.'s Reply Br. at 6:26 - 7:3, citing Reply Chakraborty Decl. at P 7. PostX and its expert do not refute that human interaction is required. The Court finds that such action is not equal nor equivalent to the automatic transmission of the return receipt.

IV. "Existing Routing Mechanisms"

Claim 1 describes the default path as the path that is "derived by means of one or more existing routing mechanisms of the communications network." Plaintiff argues that the existing routing mechanisms are "the routing mechanisms used by the underlying network." As such, the default path is the one that the message would travel along if there were no overlay network.

Defendant proposes that "existing routing mechanisms" refers to "a prior art system or process employed to select a path to transmit the message from the source to the destination." Defendant thus seeks to limit "existing routing mechanisms" to "a prior art system or process," such that the only routing mechanisms that qualify as "existing routing mechanisms" are those that were in existence on the day the patent issued. Defendant points to nothing in the patent or prosecution history, however, that supports this construction of the claim.

Accordingly, the Court will adopt plaintiff's proposed construction of this phrase.
D. "Existing Schedule"

The penultimate step in Claim 11 involves "locating financial card offers, said offers including said financial card term data selected by comparing said [applicant] rating with an existing schedule assigned to said financial card term data." As explained in the Preferred Embodiments, "[t]he selection criteria as embodied in each financial institution's selection matrix is reviewed to locate the financial card offers appropriate for the applicant." Col. 6, lines 9-11. This "existing schedule," then, is a form of organizing the financial card terms in a manner that allows the assignment of mandatory or minimum applicant ratings for each particular combination or set of financial card terms. Defendant ascribes more to the phrase because of the Preferred Embodiments' used of the word "matrix." In addition to the sentence quoted earlier in this paragraph, the Preferred Embodiments utilize this word when discussing the Table in Column 4. Defendant points to the use of this word to justify its definition of "existing schedule" as "participating financial institutions' selection criteria organized in a matrix as exemplified and disclosed in col. 4, ll. 20-43 of the specification." Defendant's Markman Brief at 21.

The use of the term "matrix" does not suggest any particular form for the chart or other organizing mechanism; in common usage, a matrix only requires an arrangement of numbers bearing a relationship with each other. E.g., The American Heritage Dictionary of the English Language 1110 (3d ed. 1992); Webster's II New Riverside University Dictionary 733 (3d ed. 1994). In this context, the terms "matrix" and "schedule" are synonymous.

The true import of Defendant's suggestion comes from its requirement that the matrix or schedule take the particular form appearing in the Preferred Embodiments set forth on the Table in Column 4. The Preferred Embodiments' declare that the Table is only an example. Col. 4, lines 27-30. Defendant is attempting to the limit the Claims by relying on examples presented in the Preferred Embodiments, but this is not permitted. E.g., In re Omeprazole Patent Litig., 483 F.3d 1364, 1372 (Fed. Cir. 2007); Kraft Foods, Inc. v. International Trading Co., 203 F.3d 1362, 1366 (Fed. Cir. 2000). Nothing in the '645 Patent's Claims requires the matrix or schedule to take any particular form; all that is required is an established relationship between financial card terms and the corresponding and necessary applicant rating.

Defendant also contends the prosecution history supports its definition. On September 23, 2005, the PTO issued its Notice of Intent to Issue Ex Parte Reexamination Certificate indicating, inter alia, that certain claims would be allowed. In allowing Claims 11-22 and 26-31, the examiner wrote that he "interprets . . . the term 'existing schedule assigned to the financial card term data' to read participating institution's selection criteria organized in a ma[tr]ix as exemplified and disclosed in col. 4 L 20-43 of the specification." Shortly thereafter, Plaintiff responded by indicating it "agree[d] with the Examiner's statement to the extent the term 'matrix' relates to the general concept of data associations." In March 2006, the PTO issued a Supplemental Notice that contained the exact same language about Claims 11-22 and 26-31. From this sequence of events Defendant concludes the PTO rejected Plaintiff's interpretation as expressed in its October 2005 submission. There are several problems with Defendant's position. First, the Court finds it difficult to conclude the March 2006 Supplemental Notice was intended to reject Plaintiff's interpretation because it does not even reference it. The cover sheet for the Supplemental Notice provides a summary of the action taken, and it also does not mention Plaintiff's October 2005 submission. In fact, the only difference between the Supplemental Notice and the original September 2005 Notice is an indication that the former "[c]orrects a typo in item 1(h)(1) and 1(h)(2) from the [Notice] mailed 9/23/05." The referenced error relates to the identification of Claims approved as written and Claims approved as amended. This sequence of events does not persuade the Court that the Supplemental Notice was intended to address Plaintiff's October 2005 submission. Cf. Phillips v. AWH Corp., 415 F.3d 1303, 1317 (Fed. Cir. 2005), cert. denied, 546 U.S. 1170, 126 S. Ct. 1332, 164 L. Ed. 2d 49 (2006) (ambiguity in the prosecution history may render it unhelpful as a resource in aid of claim construction). Regardless, the PTO indicated the Table in Column 4 "exemplified" the matrix it intended to describe -- that is, it is an example and not the prescribed form.

Plaintiff's suggested definition -- "an association of selection criteria with financial term data" -- is closer to the appropriate definition. The Court's only disagreement is with the use of the phrase "selection criteria." The schedule is not merely an association of selection criteria to the financial card's terms, but an association of various applicant ratings to the financial card's terms. This interpretation is gleaned from Claim 11(f), which describes the process for locating an offer (itself consisting of financial card terms) by comparing the applicant's rating to the existing schedule. The existing schedule must associate the financial card terms with the applicant ratings established by the financial institution as necessary to qualify.
for those terms; otherwise, Claim 11(f) would permit comparing applicant ratings to something else entirely. The Court therefore concludes the proper definition of "existing schedule" is "an association of financial card term data with the applicant ratings established by the financial institution as necessary to become eligible for those particular financial card terms."

1661

1. Exit Station (Claims 1 and 21)

1 As to all of the terms construed, where the Court has adopted a party's proposed construction, that construction is set forth below without further discussion. Where the Court has adopted one party's construction, but with some modification, or has not adopted either party's proposed construction, an explanation is provided.

The Court finds "exit station" is properly construed as "a portion of the processing machine where wafers are moved after processing and from which said wafers exit the processing machine."

2 Unless otherwise indicated, the parties' respective proposed constructions as set forth herein are taken from the Joint Claim Construction Statement filed May 1, 2006.

The Court finds "exit station" is properly construed as "a portion of the processing machine where wafers are moved after processing and from which said wafers exit the processing machine."

3 The Court has not adopted either party's proposed construction. Plaintiff's proposed construction is overly broad because it does not require that wafers "exit" from the "exit station." Defendant's proposed construction is too narrow; assuming, arguendo, the "exit station" described in the specification is "dedicated" to the removal function, defendant fails to show why the claims are limited to the preferred embodiments.

1662

I. Claim Construction

While the parties dispute the court's construction of many of the claim terms at issue before the district court, we address the construction of only those terms essential for disposition of this appeal.

The independent claims of the '927 patent recite a method or computer for "emulating" target instructions of the instruction set of a target computer using, inter alia, "emulation registers" capable of corresponding to registers in the target computer. The written description defines the term "emulation" generally as "a process in which one computer X behaves identically to another computer Y, as X executes the instructions of Y, where the internal architectures of computers X and Y are different." '927 patent, col. 2, ll. 30-33. We adopt this construction and conclude that the district court correctly interpreted
this term.

Claims 4 and 14 define the particular manner in which the claimed processor emulates. Specifically, both claims require a "M+N bit expanded RISC instruction" with N bits defining the "native instruction . . . configured for emulating target instructions from the instruction set of a target computer." Consistently, the claims require an expanded instruction decoder that uses "M bits from each said expanded RISC instruction to redefine the RISC architecture computer in terms of the target computer." The written description of the '927 patent defines N bits of an expanded RISC instruction, also referred to as the LHS (left-hand side) of the instruction, as the number of bits of the instruction that the microprocessor uses "in its native mode." '927 patent, col. 5, ll. 1-2. With regard to the M bits of the expanded RISC instruction, also referred to as the RHS (right-hand side) of the instruction, the '927 patent states that "contained within the additional M bits [of the expanded RISC instruction] and used in conjunction with the N bits are directions on the use of resources within the RISC computer, peculiar to each emulated instruction." '927 patent, col. 5, ll. 6-9. The written description of the '927 patent explains that the M bits, or RHS, of the expanded RISC instruction are used "to redefine, during emulation of a target processor operation, the register data paths . . . of the LHS [or N bits of the expanded RISC instruction] to correspond to the target processor instruction being emulated, permitting the host processor to mirror, without physical changes, the target processor architecture being emulated." '927 patent, col. 8, ll. 31-37. Consistently, TechSearch's expert, Dr. Hoevel, recognizes that to emulate, "the host computer has to interpret and execute the target instruction set used in the target computer . . . and claims 1 through 3 of the '927 patent reveal the advantages of the special kind of emulation and backwards compatibility found in the '927 patent."

We conclude, as the district court did, that the M+N bit expanded RISC instruction recited in claims 4 and 14 includes N bits corresponding to an instruction of the host microprocessor's instruction set, and M bits which work with the N bits to "redefine" or "translate" the expanded RISC instruction to "emulate" the instructions of the microprocessor of the target computer. We further conclude that the claimed "expanded instruction decoder" is a decoder that "redefines" or "translates" the native instruction identified as N bits of the expanded RISC instruction, using M bits of the expanded RISC instruction, thereby enabling the instruction set of the microprocessor of the computer to emulate the instructions of a target computer.

9. Expanding the Received Set of Reference Cell Values

The term "expanding the received set of reference cell values" means a process for generating a complete set of values for the digital words based on the reference cell values that have been received up to that point in time.

Expert System

Claims 41 and 42 of the '525 Patent contain the term "expert system." SFA cites to a host of dictionary definitions and proposes that the term should be defined as "a system that learns successful actions and automatically implements them in the future" in conformity with those definitions. Infor counters that SFA's definition describes the "expert system's" purpose rather than its structural function. Infor claims that the prosecution history along with the specification require that the term be defined as "a system that includes an inference engine to provide rules-based decision making using a knowledge base and a set of rules." As discussed below, the proper construction of "expert system" in accordance with the specification is "a software program operating on a set of rules which can be automatically updated based upon successful sales approaches."

Infor is correct in noting that SFA's definition fails to disclose anything about an "expert system's" structure. Rather, SFA's definition describes very generally the result that an "expert system" seeks to obtain. Patent system claims protect the system's structure and not its effect. See Hewlett-Packard Co. v. Bausch & Lomb Inc., 909 F.2d 1464, 1468 (Fed. Cir. 1990) (explaining that apparatus claims "cover what a device is, not what a device does"). As a result, SFA's definition is too broad and must be rejected.
Conversely, Infor seeks to narrow the scope of "expert system" by requiring that the system necessarily contain an inference engine. The specification clearly suggests an inference engine "in accordance with one embodiment," but there is no support in the specification for the proposition that an expert system must contain an inference engine. See '525 Patent at 34:23-44. Regardless, Infor claims that the prosecution history suggests that the patentee disclaimed all embodiments of an expert system that do not contain an inference engine.

An inference engine is a particular type of software program. As it is described in the '525 Patent, an inference engine relies upon a number rules that take the general form of the statement IF X THEN Y. Based upon a series of these rules, the inference engine is able to determine whether a particular action should be taken in light of the existence of a set of conditions. See id. The term "expert system" only appears in dependent claims 41 and 42. Those claims refer to independent claim 40 which was amended during prosecution to include the step of "infer[ring] occurrence of the event and a context" after the examiner's rejection of all the initial claims in light of the Negrino Reference. See Plaintiff's Opening Ex. 2, Amendment of December 10, 1997. Infor contends that because the only mention of the word "infer" in the specification occurs during explanation of the inference engine, the inference engine is the only disclosed structure capable of "inferring." Infor concedes that this argument has the result of collapsing claims 40-42 and violates the presumption of claim differentiation. See Phillips, 415 F.3d at 1314-15.

While the presumption of claim differentiation may be rebutted if a patent's specification makes clear that independent and dependent claims share the same scope, the specification in this case is careful to do just the opposite. See Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1370 (Fed. Cir. 2007). For example, the specification provides not only that an inference engine is applicable in "one embodiment," but refers to the inference engine several times as an "example." '525 Patent at 33:63. The specification clearly indicates that the inference engine is a component of a particular embodiment of an expert system and not required. Id. at 34:23-26. Further, claim 42 teaches "[a] system as recited in claim 40, wherein the event manager comprises an expert system configured to automatically monitor events occurring in the sales process, identify which events lead to a desired outcome in a use of the sales system, and produce a knowledge database for use in subsequent operations as the prior sales experience using the sales system." None of these functions necessarily requires an inference engine as described in the specification. To include that additional limitation would be improper.

Finally, Infor's argument concerning the addition of the word "infer" in claim 40 would not only require an inference engine to necessarily be included in claims 41-42, but would mandate that an inference engine be included wherever the word "infer" appeared in the patent. This would require that all claims in the '525 Patent include an inference engine. As further explained below, there is no evidence in the specification or the prosecution history that such a limitation is warranted. Thus, Infor's definition is rejected.

The specification describes an expert system's structure. An expert system may be "programmed to monitor the sales process for desired (successful) sales events." '525 Patent at 33:34-36. Thus, the expert system is a computer program. Further, the expert system is identified as operating on a set of rules. Id. at 33:44-47, 34:44-46. Finally, the specification indicates that the rules are automatically updated in a way that targets the most successful sales approaches. Id. at 33:41-46. Thus, the specification identifies an expert system as "a software program operating on a set of rules which can be automatically updated based upon successful sales approaches."

1665

E. expert system knowledge base

Ricoh contends that the term means "a database used to store expert knowledge of highly skilled VLSI designers." Aeroflex defines "expert system" and "knowledge base" separately. Aeroflex states that "expert system" should be defined as "software that solves problems through selective application of the rules in the knowledge base by an inference engine, as distinguished from conventional software, which uses a predefined step-by-step procedure (algorithm) to solve problems." Aeroflex asserts that a knowledge base is a "portion of the expert system software having a set of rules, each rule having an antecedent portion (e.g. IF) and a consequent portion (e.g., THEN), and embodying the knowledge of expert designers for application specific integrated circuits."

Ricoh's proposed construction relies heavily on the '432 patent's specification. Specifically, the specification states that
"[t]he knowledge base 35 contains ASIC design expert knowledge required for data path synthesis and cell selection." '432 patent, col. 5:6-8. "Using a rule based expert system with a knowledge base 35 extracted from expert ASIC designers, the KBSC system selects from the cell library 34 the optimum cell for carrying out the desired function." '432 patent, col. 5:25-29. Based on these passages, Ricoh argues that an "expert system knowledge base" is a collection of data that represents knowledge obtained from experts in ASIC design.

Aeroflex dismisses Ricoh's proposed construction as overly simplistic. Aeroflex argues that a person of ordinary skill in the art in 1988 would have known that two distinct approaches existed for selecting hardware cells: 1) rule-based expert system software; and 2) conventional algorithmic software. Aeroflex further contends that a person of ordinary skill in the art would have understood that rule-based expert system software must contain an inference engine, a knowledge base, and a working memory, which enable the inference engine to selectively apply the rules stored in the knowledge base to what is stored in the working memory (as distinguished from conventional algorithmic software, which uses a predefined step-by-step procedure). To support its argument, Aeroflex cites to a technical dictionary entitled "Artificial Intelligence Terminology" that states: "An expert system will generally consist of a rule base, an inference engine and a user interface (which will generally provide an explanation facility)." Aeroflex also cites the Court to the Dunn Patent 4,656,603 ("the '603 patent"). The '603 patent speaks in general terms regarding the distinction between the two types of software and states that since rule-based expert systems "often make conclusions based on incomplete or uncertain information, they differ substantially from conventional computer programs which solve problems in accordance with pre-defined algorithms and complete data sets." '603 patent, col. 1:44-49.

Aeroflex also argues that the distinction between the rule-based expert system approach and the conventional algorithmic approach is evident from the prior art that the patentee distinguished in the patent's file history. In the November 1989 Amendment, the patentee added the following language to application claim 5 (patent claim 1): "said cell selection means comprising an expert system including a knowledge base containing rules for selecting hardware cells from said cell library and inference engine means for selecting appropriate hardware cells from said cell library in accordance with the rules of said knowledge base." November 1989 Amendment at 2. The patentee stated that application claim 5 (patent claim 1) was amended to "clearly distinguish it over the cited prior art by more clearly defining the expert system aspects of applicant's invention including the provision of a knowledge base containing rules for selecting hardware cells, inference engine means for selecting appropriate hardware cells, and netlist generator means for generating a netlist defining the hardware . . ." November 1989 Amendment at 8. Although this amendment applied only to application claim 5 (patent claim 1), the patentee also amended application claim 20 (patent claim 13) to include "applying . . . a set of cell selection rules stored in said expert system knowledge base . . . ." The patentee explained that this language was added to "emphasize the expert system aspects of applicants' method." November 1989 Amendment at 9. Thus, Aeroflex is essentially arguing that the description of an expert system in patent claim 1 (including an inference engine) should also be read to encompass the expert system described in patent claim 13.

Ricoh responds that the patentee's statement in the November 1989 Amendment only further proves its point. Ricoh argues that this statement does not establish that an "expert system" had become an element of claim 13, but merely confirmed the patentee intent to claim certain aspects (i.e., the claimed "expert system knowledge base") of an expert system - not an expert system itself. 8 Moreover, Ricoh argues that even if the Court finds that the patentee intended to encompass both an "expert system" and a "knowledge base," there is nothing in the claim language, specification, or prosecution history that requires that an expert system contain an inference engine and a working memory.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

8 In other words, Ricoh is arguing that the term "expert system" is grammatically read as an adjective or other modifier for the noun "knowledge base."

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

Initially, the Court finds no support for Ricoh's argument that "expert system" is simply an adjective modifying the noun "knowledge base." The patentee explicitly stated that claim 13 was "amended to emphasize the expert system aspects of applicant's method." November 1989 Amendment at 9. Therefore, the Court finds that "expert system" was an element of claim 13.
Next, the Court finds that Aeroflex's assertion that a person of ordinary skill in the art would have understood that rule-based expert system software must contain an inference engine, a knowledge base, and a working memory is simply not supported by the intrinsic evidence. As noted by Ricoh, claims one through nine of the '432 patent specifically claim an inference engine, while claim 13 does not make such a claim. Aeroflex's attempt to have the Court read the description of an expert system from patent claim 1 onto the expert system described in patent claim 13 is unpersuasive. Additionally, the technical dictionary definition provided by Aeroflex states that an inference engine is "generally" an element of an expert system. Given the qualified language of the definition, in combination with the fact that claim 13 makes no mention of an "inference engine," the Court finds the technical dictionary definition unhelpful in this context. Finally, Aeroflex's reference to the '603 patent is ultimately unhelpful, as the "603 patent describes an intentional expert system, as opposed to a knowledge-based expert system, and makes no mention of an inference engine. "603 patent, col. 5:53-56. Given these considerations, the Court defines "expert system" and "knowledge base" separately. "Expert system" should be defined as software that solves problems through selective application of rules in the knowledge base. "Knowledge base" should be defined as a portion of an expert system software having a set of rules and embodying expert knowledge of highly skilled VLSI designers.

4. Claim 17. "A method as set forth in claim 1 further including the step of: after said fuse portion forming step, removing said fuse portion from said interconnect by directing a laser light on said exposed optically absorptive layer to melt said fuse portion."

Cypress asks the court to construe the meaning of the term "exposed." Claim 17 derives from, and is identical to, the language of claim 20 of the original patent application. As written, claim 20 of the application depends from claim 1 of the application. Claim 20's term "said exposed optically absorptive layer," however, lacks an antecedent basis, as claim 1 of the application makes no reference to such an exposed layer. The examiner apparently overlooked this defect.

The meaning of the term "said exposed optically absorptive layer" is ambiguous. The word "exposed" is used twice in the application's claims. In one context, "exposed" means "exposed to laser light." This use of the word "exposed" is found in claims 12, 17, and 18. In a second context, "exposed" is used to refer to the state of the absorptive layer once the overlying passivation layer has been etched away. This use of the word "exposed" is found in claims 15 and 19.

The language of claim 20 indicates that "exposed," as used therein, means exposed from the etching of the passivation layer, as recited in claim 19 of the application. Claim 20 reads "directing a laser light on said exposed . . . layer." Since there is only one laser light at use in the claimed process, the "exposed layer" must first become exposed through etching if it is then to have a laser light directed upon it.

EMI argues that claim 17 of the patent derives its antecedent basis from claim 1 of the patent, and as such means "exposed to the directed energy source." Claim 1 of the patent, however, did not acquire the word "exposed" until after the claim was twice amended. The court declines to find that amending claim 1 to overcome rejections on other grounds somehow redefined the antecedent basis of application claim 20, which was not a focus of the prosecution history. Moreover, to posit that the term "exposed" of claim 17 derives its antecedent basis from claim 1 leaves a nonsensical claim, as claim 17 recites directing a laser light upon an "exposed" absorptive layer. Since the claims recite the use of only one laser, the absorptive layer cannot be "exposed" prior to having a laser light directed upon it, unless it is exposed through etching.

The court rules that "exposed," as used in claim 17 of the patent, means "exposed by removal of the overlying passivation layer."

1667

1. "exposure apparatus"

The patent specifications note that the '336 patent "invention relates to a projection exposure apparatus for use to form a
pattern of a semiconductor integrated circuit, or a liquid crystal device, or the like." See Patent '336 at 1:17-21. Throughout the '336 patent specifications, the "exposure apparatus" is described as an entity that forms a pattern of a semiconductor integrated circuit, liquid crystal device, or the like on a substrate. See, e.g., '041 Patent at 1:17-21; 12:10-14:14; 26:52-28:13; 40:59-42:6. Nothing persuades the court to ignore this teaching, and much in the caselaw of the Federal Circuit counsels reliance on it. See, e.g., Vitronics, 90 F.3d at 1582; Bell Atlantic Network Services, Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1268 (Fed. Cir. 2001) (noting that specification language can "act as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication") (internal quotation marks and citation omitted). Neither ASML's entirely pleonastic construction nor Nikon's elliptical alternative persuade the court otherwise; thus, the court construes "exposure apparatus" to mean "a structure used in the photolithographic projection processes to form or to transfer a pattern of a semiconductor integrated circuit, or a liquid crystal device, or the like on a substrate." GO BACK

1668

2. Expressions

The first element of claim 1 provides: "establishing expressions quantifying the unwanted dynamics of the physical system" ('635 patent Col. 10 lines 44-45) (emphasis added).

Plaintiffs argue that the term "expression" indicates any means of symbolizing, and so in this context, an "expression" would be anything that quantifies the unwanted dynamics of the system. (Pls.' Claim Construction Br. For U.S. Patent No.'s '635, '267, and '473 at 40). Plaintiffs base this meaning on the dictionary definition of an expression. The dictionary definition most relevant to the context of the patent is: "A sign or a character or a finite sequence of signs or characters (as logical or mathematical symbols) representing a quantity or operation." Merriam-Webster's Third New International Dictionary Unabridged, Merriam-Webster, Inc., 1993. Defendants insist that the meaning be limited to mathematical equations which are in the time domain. (Defs.' Proposed Claim Construction Order for U.S. Patent Nos. '635, '267, and '473 at 1). A mathematical equation in the time domain is one which expresses some value, here the unwanted dynamic, as a function of time.

The correct interpretation must be consistent with the use of the term in the specification. See Texas Digital, 308 F.3d at 1202. The terms "expression" and "expressing" or "expressed" appear several times in the specification: "establishing expressions quantifying the unwanted dynamics" ('635 patent Col. 3 lines 62-63); "a system's unwanted dynamic response will be expressed as a function of its transient input" ('635 patent Col. 4 lines 54-57); "the same result can be obtained mathematically by adding two impulse responses and expressing the result for all times greater than the duration of the input" ('635 patent Col. 5 lines 17-21); "elimination of vibration after the input has ended requires that the expression for Aamp equal zero at the time at which the input ends..." ('635 patent Col. 5 lines 44-46); "in order to quantify the residual vibration level for a system, a vibration-error expression must be defined..." ('635 patent Col. 6 lines 1-3); "it can be shown that the same expressions that guarantee zero derivatives with respect to frequency also guarantee zero derivatives with respect to damping ratio" ('635 patent Col. 6 lines 41-44); "these sequences can be obtained by expressing the same (or some other equivalent) constraint equations..." ('635 patent Col. 7 lines 10-12).

Imposing defendants' "time domain" limitation would be inappropriate. While many of the "expressions" discussed in the specification are solved for time, see, i.e., '635, Col. 5, lines 44-46; '635, Col. 5, lines 44-45, all of these examples occur in the preferred embodiment of the specification. Since limitations cannot be imposed based solely on the preferred embodiment, defendants' argument requires that the patentee evinced a clear intent to act as his own lexicographer. Consistent and explicit use of a claim term in the specification to mean something other than the ordinary meaning indicates this intent. See Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1388 (Fed. Cir. 1992) (noting "so long as the meaning of an expression is made reasonably clear and its use is consistent within a patent disclosure, an inventor is permitted to define the terms of his claims.") The patentee did not consistently and uniformly use "expression" to unambiguously refer to time-domain equations, See, i.e., '635, Col. 6, lines 46-48 (referring to a graph in the frequency domain as "the vibration-error expression for the same three sequences of impulses ...") The use in the specification is not sufficiently definite to demonstrate the necessary "unequivocal intent," therefore the plain and ordinary meaning is presumed.

Within the context of the specification, and to be consistent with the plain meaning, "expression" cannot include all possible methods that quantifies a dynamic. There must be a solution that minimizes that which is quantified expression. ('635, Col.

- 2062 -
10, lines 50-52). The only type of "expression" offered by plaintiffs which quantifies and can be solved is a mathematical characterization. (Pls.' Reply to Defs.' Responsive Claim Construction Br. for U.S. Patent Nos. '635 and '267 at 3). Plaintiff has argued that "expression" should not be limited to "equations where there must be an equal sign" (Transcript of Proceedings Held on 3/31/2004 at 262). Given the character of the invention, which is designed to meet or exceed a threshold level of unwanted dynamics, there is no reason to impose a requirement for "an equal sign." Accordingly, the term "expression," as used in independent claim 1 is interpreted to mean: "a mathematical characterization that quantifies." 7

7 This interpretation was not offered by either party. The Court of Appeals for the Federal Circuit permits adoption of claim constructions not offered by either party when they are consistent with the standards of claim construction. See, e.g., Bilstad v. Wakalopoulos, 386 F.3d 1116, 1121-1123 (Fed. Cir. 2004).

1669

18. Extended mathematical element

The plaintiff proposes that "extended mathematical element" be construed to mean "a unit that performs additional mathematical operations that are specialized operations for efficient media processing." The defendants object to the plaintiff's use of the language "specialized operations for efficient media processing." They also contend that the specification of the 840 patent provides that "operations performed by the extended mathematical unit are higher level' than those performed by the ALU . . ." Defendants' Sur-reply Brief at 13. Thus, the defendants urge that "extended mathematical element" be construed to mean "a unit that performs higher level mathematical operations than the arithmetic unit." After considering the submissions of counsel, the court construes "extended mathematical element" to mean "a unit that performs additional mathematical operations other than addition, subtraction, multiplication, division, and other floating point operations."

GO BACK

1670

19. An extended mathematical element coupled to the data path and programmable to implement additional mathematical operations at substantially peak data throughput

The court construes "an extended mathematical element coupled to the data path and programmable to implement additional mathematical operations at substantially peak data throughput" to mean "a programmable unit coupled to the data path that performs additional mathematical operations other than addition, subtraction, multiplication, division, and other floating point operations at substantially peak data throughput."

GO BACK

1671

D. How does the charge sink means extend laterally?

Finally, the parties interpret differently the phrase "extending laterally from said contact toward said light sensing element." The term "extending laterally" conveys a directional meaning. The specification and prosecution history provide little guidance for detecting the precise compass reading for this direction. However, that direction must run from the contact toward the light sensing element. Thus, the charge sink means, as interpreted by the court, must extend parallel to the top surface and perpendicular to a contact toward the light sensing element.
The plaintiffs propose "a clock not derived from the first clock, and which is not originated on the same semiconductor substrate upon which the entire variable speed clock is located." The defendants contend that no construction is necessary, but if a construction is necessary, then they propose "a clock not on the integrated circuit substrate."

As discussed previously, the defendants appear to agree that, like the second clock, the external clock is independent of the first clock. The plaintiffs' proposed construction includes limitations already in the claims. The Court construes "external clock" to mean "a clock not on the integrated circuit substrate."

1673

External clock signal

The Court construes "external clock signal" as "a single timing signal from outside of a device." MEI argues that the term should be construed as "a clock signal from outside of a device." Samsung argues that the construction should be "a single external timing signal provided to a single input pin." MEI acknowledged in its brief that a clock signal provides timing information. MEI Claim Const. Br. at 7 (Docket No. 112). Samsung's argument that the external clock signal is limited to a single input pin is presumably based only on an amendment to claim 1. See Response to Examiner at 113-14 (Exh. 5, Docket No. 120). This statement is not sufficient to establish a waiver of claim scope.

Samsung also argues that the term is limited to a single clock signal. The Court agrees. The specification of the patents-at-issue consistently emphasize and disclose the use of a single clock signal on the random port. See '921 Patent col. 2:17-19 (distinguishing the invention on the basis that it uses a single clock signal); col. 2:25-29 ("Under the teachings of the present invention, a single clock pulse drives an internal state machine to provide the control pulses thereby minimizing the number of signal paths to and from the chip . . . .") (emphasis added); col. 3:31-34 (stating that a single clock pulse is used); col. 7:36-40; col. 8:13-15; col. 9:57-58; col. 14:14-18; col. 15:38-40. Furthermore, the patentees responded to the examiner's rejection by distinguishing their claimed invention from the Target Specification because the Target Specification did not operate on a single random port clock input: "the Target Specification does not operate in response to a single clock as claimed in claim 1 . . . . The Target Spec [sic] . . . . requires more than one clock to perform this function." Response to Examiner at 115 (Exh. 5, Docket No. 120). A construction limiting clock signal to a single timing signal is consistent with the express purpose of the invention, the specification, and the prosecution history.

1674

C. "External Memory Device"

Claim 1 of the '353 uses the phrase "external memory device." For example, it discloses an apparatus comprising: "an external memory device having computer software," col. 6, l. 6, and "means for reading said external memory device, said reading means located in the computer." Id., l. 12.

1. Disputed Definitions

Plaintiff defines "external memory device" as "computer memory other than the main, relatively fast, memory of the computer which is generally erased when the power is removed, and includes magnetic disks, tapes and CD-ROMS."

Defendant defines "external memory device" as "[a] disc (or other transportable recording medium) on which an executable software program and first and second authorization codes are stored."
2. Analysis

Plaintiff's proposed definition ignores the word "external." He contends that "external" simply means memory which is generally erased when the power is removed and claims further that his definition is consistent with the Rosenberg Dictionary definition of external storage: "storage that is accessible by a computer only through input-output channels." The Rosenberg definition makes clear, however, that the storage, that is, the external memory device, is something separate from the computer (as the Court has defined it above) since it cannot be "accessible by the computer" if it is part of the computer. At the claim construction hearing the defendant stated that it agreed with the Rosenberg definition, provided "computer" is interpreted as defendant has urged. Since the Court has concluded that the intrinsic evidence compels defendant's construction of "computer," the Court will adopt the Rosenberg Dictionary definition of external memory, a definition proffered by plaintiff.

Plaintiff's extrinsic evidence is not inconsistent with external memory being defined as memory that is connected to, but not part of, the computer. For example, the Computing Course Materials identified by plaintiff describe "main memory" as "the working memory of the CPU, with fast access and limited numbers of bytes being transferred," and "external memory" as the "long term storage of information." The definition thus distinguishes between the memory of the computer (as the Court has defined it) and memory outside the computer.

The Court is not construing "external memory" to require that the memory be housed in a different casing from the microprocessor system. Rather, external memory is memory that is connected to the computer (as "computer" is used in claim 1), that is, it is external to the computer, not external to the casing in which the computer is housed. Thus a disk drive or CD ROM which is "housed" in the same casing as the computer would still be external memory under the Court's interpretation since it is not part of the computer, but rather is accessible to the computer.

"External modulator" means "a modulator that acts on the optical carrier signal output from a signal emitter, as opposed to acting on the signal emitter itself."

b. "Externally coupled to said bus."

Plaintiff argues that this phrase means, in the context of the 948 patent, "externally coupled to said bus via any of a number of known means, including, but not limited to, a diagnostic port or the engine wiring harness." Defendants contend that the appropriate construction is "externally coupled to said bus through a diagnostic port." Mr. Lundell's recommended construction is "externally coupled to said bus via either the diagnostic port or the wiring harness."

The Court finds Mr. Lundell's construction to be the appropriate reading of the term. As Mr. Lundell points out, the 948 patent specification discloses two embodiments, one using the diagnostic port and the other using the wiring harness. Because the claim language can plausibly be read as encompassing both embodiments, the Court adopts the following construction of "externally coupled to said bus": "externally coupled to said bus via either the diagnostic port or the wiring harness."

B. "A module externally coupled to said bus"

The plain language of this term means that the module is physically connected to the bus of the fixed system by a direct connection from outside of the fixed system. Hypertech's proposed construction would add the phrase "and stays connected during the normal operation of the vehicle." (Dft.'s Claim Construction Statement at 10). Such an addition is unnecessary.
and unsupported by the plain language of the term.

**1678**

4. "Extract": Plaintiff has proposed the meaning "to select and obtain specific information from a file." However, the intrinsic evidence offered by plaintiff is a selection from the '697 Patent specification, stating "Portions of the stored document information are selected in accordance with content instruction." '697 Patent, col. 2, lines 52-53 (emphasis added). Because the claims and specifications of the '697 patent and others refer to extracting information from documents, the Court adopts the construction proposed by defendant, with modifications: "to select and obtain nontextual electronic information from a hard copy document (e.g., scanning a hard copy document) and/or to convert nontextual electronic information into a textual form."

**1679**

B. Extracting

3M asserts the term "extracting" should be construed as "obtaining" -- as the term is used to refer to the act of obtaining the preemption request and the identification code from the signal that is sent to the phase selector. 3M further asserts this construction is supported by the specification's discussion of Figure 9, "a step 106 extracts a data packet from the data field 82 and sends the data packet . . . to the main phase selector microprocessor." Id. 14:4-6. This construction is also consistent with the dictionary definition of "extract" -- "to derive or obtain (information, for example) from a source." Ex. 18 at 485.

Tomar does not provide a specific construction for "extracting" in its Markman briefs. In its discussion of the specific limitation that includes "extracting", Tomar does not appear to dispute the argument that "extracting" should be construed as "obtaining". See Tomar Proposed Claim Interpretations Brief, p. 30-31; Reply Brief, p. 18. Accordingly, the term "extracting" will be construed to mean "obtaining."

**1680**

C. "Extracting a correction condition" (claims 1, 6, 9)

As noted in the foregoing section, one of the steps of the method disclosed in claim 1 is: "extracting a correction condition by extracting information corresponding to an alignment state of said process[]." The parties dispute the scope of another limitation in this step: "extracting a correction condition."

The parties agree that "extracting a correction condition" is a step in the photolithography process that involves obtaining information that is used to correct the "optimal working condition" in order to arrive at the "current working condition." 6:11-18. Samsung's proposed construction is: "Creating a value or data set to be used to affect the determination of a current working condition." AMD proposes the following construction: "Subtracting an objective value from a resultant value so that, when this difference value is added to the optimal working condition, a process can be performed without error."

The Court finds that Samsung's construction accurately conveys the function of the "correction condition" as it is taught in the claim language. The Court rejects AMD's construction for two reasons. First, it adds terminology -- "resultant value" and "difference value" -- that is unlikely to be clear to a jury. Second, AMD's proposed language is taken from the section of the preferred embodiment that teaches calculating an "optimal condition." 3:31. The preferred embodiment supplies the following equation for this calculation: The specification teaches that in this equation, the italicized E "indicates a correction element obtained by subtracting an objective value from a resultant value." 3:43-44. AMD argues that this explanation of the equation should be used to construe "correction condition." The Court disagrees. Claim 1 makes clear that the steps of "extracting an optimal working condition" and "extracting a correction condition" are distinct. 6:7-11. AMD provides no reason for defining "correction condition" by using the preferred embodiment's description of how to calculate the "optimal condition."
Accordingly, the Court adopts Samsung's construction of this term.

A VID argues that the term should mean "extracting information from the measure of the variation in the magnetic field as a function of time utilizing the association being employed, wherein the association functions to relate a variation in the magnetic field with an item of information." According to A VID, the specification explains that the multi-mode reader can extract information from a magnetic field in accordance with multiple protocols in order to read tags of different designs and tags from different manufacturers.

Once again, the Defendants argue that the claim should be construed under 35 U.S.C. § 112 P 6 as a step-plus-function limitation. They also argue that the claim is drafted in purely functional terms, without any hint as to the acts required to extract information. According to the Defendants, the corresponding structure includes a reconfigurably programmable microprocessor 170 programmed to perform six routines (i.e., the algorithm) for extracting information. The acts performed by these routines constitute the corresponding acts of the extracting information limitation of claim 73.

After carefully considering the parties' proposed constructions and the '326 patent, the Court adopts A VID’s proposed construction. The absence of the signal "step-for" creates a presumption that a method claim is not in step-plus function form. Cardiac Pacemakers, Inc., 381 F.3d at 1382. The Defendants have not overcome this presumption and the Court adopts A VID’s construction.

Extraction circuit outputting a plurality of data segments, each of which being selected from a respective one of said plurality of data frames; extraction circuit selecting each of a plurality of data segments from a respective one of said plurality of frames

The Court adopts Ciena’s proposed construction and construes the terms as a “circuit extracting a data segment from each of a plurality of data frames.” Ciena again argues that the terms do not need to be construed and offers its proposed construction in the alternative. Nortel argues that the terms should be construed as “circuit extracting a data segment from each of a plurality of successful data frames.” Nortel presents the same arguments in support of its proposed construction here as it did in support of its construction of the “extracting each of a . . . plurality of data segments from a respective one of a . . . plurality of frames; extracting each of a plurality of data segments from a respective one of a plurality of data frames” terms discussed above. For the same reasons discussed above in reference to the terms “extracting each of a . . . plurality of data segments from a respective one of a . . . plurality of frames; extracting each of a plurality of data segments from a respective one of a plurality of data frames,” the Court construes these terms as a “circuit extracting data segment from each of a plurality of data frames” without modifying the data frames with the word “successful.”

"Extracts data" appears in independent claim 1 of the '077 patent. Yodlee seeks to construe the term as meaning to "locate and retrieve data from a web site in a way that allows summarization and/or aggregation," asserting that is necessary to clarify that "extract" means to "copy" data, rather than "to pull out" as would be consonant with the normal definition of the
term "extract." CashEdge asserts that this term needs no construction. The Court agrees with CashEdge that no reasonable person, and certainly not someone with ordinary skill in the art, would think that the term "extract" as used in the patent involves erasure. **This term need not be construed.**

The disputed terms are located in each of the asserted independent claims: "wherein the application software facilitates the generation of the second menu by allowing selection of categories and items from the first menu." The plaintiff argues that its proposals "reflect that the application software is configured or enabled to perform certain recited functions, but that those functions are not required to be performed." Plaintiff's Brief at 26. Plaintiff's assessment of facilitates, at least as it is used in Claim 1 of the '850 patent, is not entirely accurate. The language of claim 1 reads,

>[A]pplication software for generating a second menu from said first menu and transmitting said second menu to a wireless handheld computing device or Web page, wherein the application software facilitates the generation of the second menu by allowing selection of categories and items from the first menu, addition of menu categories to the second menu, addition of menu items to the second menu and assignment of parameters to items in the second menu . . . .

The parties have agreed that the preamble is a limitation. Therefore, the apparatus of the claims has the purpose of "generating and transmitting menus," and the application software must perform the recited functions of generating and transmitting a second menu.

The plaintiff is correct that the "allow[ed]" functions, namely selection, addition, and assignment, as recited by the claims, are not required to be performed. However, those functions are not what the application software facilitates. The application software facilitates the generation of the second menu--which the claim requires--by permitting one or more of the optional functions of selection, addition, or assignment. The plaintiff's proposal "configured to perform" would make the generation of the second menu optional. The court therefore adopts the defendant's construction for "facilitates." The court adopts the plaintiff's construction for "allowing."

**3. "Store and Forward Facility" Limitation 7**

---

**Footnotes**
7 The SAFF is also referred to as the "call handling facility." The parties have agreed that "SAFF" and "call handling facility" should have identical constructions.

The term "store and forward facility" is not written in standard "means" format and is thus presumptively not subject to § 112, P 6. However, even where the words "means" or "step(s) for" are absent, § 112, P 6, will still apply if the claim phrase fails to provide sufficient structure or acts for performing its function. See, e.g., Mas-Hamilton Group v. LaGard, Inc., 156 F.3d 1206, 1213-14 (Fed. Cir. 1998). Accordingly, Defendants argue that because the "SAFF" is comprised of two means-plus-function phrases (computer means and mass storage means) and the claims do not recite sufficiently definite structure, the "SAFF" should also be construed as a means-plus-function limitation.

The Court finds that the means-plus-framework applies to the "SAFF" because the claim term is written as a functional term and has no inherent structure. n8 The "SAFF" has numerous functions in the claims, all related to receiving facsimile messages, storing them, and determining when and where to transmit, them. (926 patent, claim 55.) The corresponding structure is the structure to be used for performing these functions, including both the physical hardware and the software required performance.

Catch Curve again relies on the dictionary definitions of the terms "facility" and "store and forward" as proof that the "SAFF" has a definite structure associated with it. However, even these definitions describe the function of storing in more detail than the structure that does the storing. Given that the "SAFF" is characterized by two means-plus-function terms and the claims do not recite a definite structure, the Court finds that it is also a means-plus-function term. It is therefore limited to the structure disclosed in the specification.

A. Facsimile/Facsimile Protocol

Catch Curve argues that "facsimile protocol" should be construed as a "format and procedure that governs the transmission of facsimile messages from an originating facsimile machine to a call handling facility." Catch Curve contends that because the term "facsimile protocol" is recited only in one claim, it should not be imported as a limitation on all use of the word "facsimile."

Defendants argue that although the term "facsimile protocol" only appears explicitly in claim 69 of the '021 patent, the concept of "facsimile protocol" is necessarily present in all of the claim limitations that discuss fax machines or fax messages. To hold otherwise, Defendant argue, would give Catch Curve the rights to technology outside the scope of its invention. Accordingly, Defendants request that the Court adopt a definition of the word "facsimile" that limits it to the protocol that defined the word at the effective filing date.

To resolve this dispute, the Court first turns to language of the claims themselves. According to the claim language, the fax messages are transmitted by a facsimile machine to the SAFF. The SAFF then forwards the fax messages to recipient facsimile machines. Because the patentees claimed their invention in terms of this particular kind of transmitting machine and this particular kind of message, it is important to give meaning to these limitations in the claims. For a machine to be a "fax" machine that sends "fax" messages, it must use a certain protocol - what the parties often refer to as a "digital dialogue" - to communicate. Otherwise, nothing distinguishes these, machines from any other machine used for communication.

Another component of all of the asserted claims that confirms that the fax-related terms require the use of facsimile protocol is the "SAFF." In the claims, the SAFF is the facility that receives the fax message from the transmitting fax machine, stores it, then forwards it to a recipient fax machine. Catch Curve admits that, in so doing, the SAFF acts "as a proxy" for the fax machines. Given that these fax machines - to be called as such - must necessarily engage in the protocol unique to facsimile communications - the SAFF, which simply forwards the message from one fax machine to the next, must similarly engage in facsimile protocol to send and receive the fax.
The preambles to the claims are additional intrinsic evidence that the fax-related terms contemplate the use of facsimile protocol. Courts determine whether a preamble limits a claim on a case-by-case basis in light of "the overall form of the claim, and the invention as described in the specification and illuminated in the prosecution history." Allen Eng'g v. Bartell Indus., 299 F.3d 1336 (Fed. Cir. 2002). Although no litmus test defines when a preamble limits claim scope, Catalina Mktg. Int'l v. Coolsavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002), the general rule is that preamble language acts as a limitation on the claim when it is necessary to give life, meaning, and vitality to it. Kropa v. Robie, 187 F.2d 150, 152, 38 C.C.P.A. 858, 1951 Dec. Comm'r Pat. 177 (CCPA 1951). Moreover, if it helps to determine the scope of the patent claim, then it is construed as part of the claimed invention. NTP, Inc. v. Research in Motion, Ltd., 418 F.3d 1282, 1305 (Fed. Cir. 2005).

Here, Venali has requested that the Court consider the preambles to the claims as additional evidence that the asserted claims require the use of facsimile protocol. The preambles to claim 55 of the '926 patent and claim 24 of the '302 patent are identical, describing the inventions as "a method for facilitating facsimile communications between a transmitting facsimile machine and at least one intended facsimile machine." The preamble to claims 30 and 48 of the '584 patent and the preamble to claim 1 of the '034 patents describe the inventions as "a method for operating a facsimile store and forward facility to facilitate facsimile communications." This preamble language constitutes a limitation on the asserted claims because it sets forth a fundamental characteristic of the invention - a system for fax machine to fax machine communication. Because the preambles help determine the scope of the claims, the Court construes them as part of the claimed invention. NTP, 418 F.3d at 1305.

Given the foregoing, the Court finds that it is clear from the language of the claims that "facsimile protocol" means the standardized procedure that governs the transmitting and receiving of facsimile messages, excluding other protocols whereby the substance of a facsimile message is converted into a different format and then retransmitted using some other protocol. However, mindful of the instruction in Phillips that "the specification is always highly relevant to the claim construction analysis" and is "the single best guide to the meaning of a disputed term," the Court has also reviewed the specifications in this case to reach this conclusion. Phillips, 415 F.3d at 1315.

According to the specifications, "all fax transmissions initiated by a subscriber to the fax management system are first intercepted by an originator SAFF." The SAFF then "engages the originating machine in the same digital dialogue that would have occurred if a direct connection to the destination machine had actually been made . . ." thereby ". . . agreeing to accept the fax format requested by the originating machine." Finally, the SAFF "engages the destination machine in the necessary preliminary digital dialogue." 4 This language makes clear that, at the transmitting and receiving ends of the communication and at the SAFF, the fax messages are transmitted and received using the "digital dialogue" that is the core feature of facsimile protocol. As the Federal Circuit emphasized in Phillips. "[t]he construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." Phillips, 415 F.3d at 1316.

Moreover, the specifications contain no indication that the inventors ever considered that their patents covered anything more than fax-to-fax services. The specifications make clear that the scope of the invention was limited to transmission of messages over a telephone line from an originating fax machine to a destination fax machine, with the benefit of a store and forward facility as part of the switched telephone network. (926 patent, col. 2.) The specifications emphasize that in order to receive a fax message from the SAFF, the receiving device must operate using "fax mode or format." (302 patent, col. 16.) Although the specifications and each of the figures address facsimile machines and computers connected to telephone lines, 5 the specifications are devoid of any reference communicating faxes using other means than facsimile protocol. This is the case because the invention was based on communications between fax machines conducted over the switched telephone network, not a packet switched network.
Finally, the Court has reviewed the file history, which also confirms that the technology requires the use of fax protocol. Significantly, the PTO initially rejected draft claims from the '926 patent because of the existence of technology that received messages in digital teletype protocols and converted those messages into fax protocols so that the receiving fax machine could receive the message. However, the '926 patent was eventually approved specifically because Catch Curve argued that the existing technology could not "accept, process, or communicate a message originating from a fax machine."

In short, Catch Curve used the distinction between fax and other protocols to obtain its patents. The Court construes the claims now in such a way as to render the patents invalid.

In an attempt to persuade the Court that the claims are not restricted by the use of facsimile protocol, Catch Curve makes several arguments. First, Catch Curve argues that Defendants' position is inconsistent with their descriptions of their own products and services. Catch Curve points to several of Defendants' advertisements describing Defendants' fax-to-e-mail services as enabling customers to receive "faxes" in their e-mail inboxes. (Pls. Reply at 7.) Thus, Catch Curve contends, even Defendants recognize that a "fax" can be received through the use of non-facsimile protocol.

The Court disagrees with Catch Curve's characterization of the Defendants' advertisements - which, it notes, are the type of extrinsic evidence that carries little weight in claim construction. A brief review of these advertisements reveals that they do not use the term "fax" in the same way that it would have been used by a person of ordinary skill in the art in question at the effective filing date of these patents. Instead, they use contemporary a lay definition of "fax" that does not comport with its meaning for the purpose of claim construction.

In further support of the idea that the patents-in-suit describe fax "conversion," Catch Curve invokes the doctrine of claim differentiation. Catch Curve contends, that because the term "facsimile protocol" only appears in one claim - claim 69 of the '021 patent - then that term must be limited to that claim. Catch Curve argues that its patents require the use of facsimile protocol only with respect to the transmission of the fax message from the transmitting fax machine to the call handling facility, i.e., the SAFF, and not with respect to the forwarding of the fax message from the SAFF to the recipient fax machine. Thus, Catch Curve argues, its claims are not limited to the use of facsimile protocol unless that term is explicitly stated.

As an initial matter, the Court notes that the doctrine of claim differentiation only applies when the failure to differentiate would render a claim - not a limitation - superfluous. Toro Co. v. White Consol. Indus., 199 F.3d 1295, 1302 (Fed. Cir. 1999) (doctrine applies "[t]o the extent that the absence of such difference in meaning and scope would make a claim superfluous). Because Catch Curve is not arguing that claim 69 of the '021 patent would be superfluous if "facsimile" requires the use of a facsimile protocol, the doctrine of claim differentiation appears inapplicable.

Moreover, there is nothing in the claims to suggest that the transmitting fax machine of claim 69 of the '021 patent is different from the transmitting fax machine of the other asserted claims. Catch Curve's position that they are different - one uses fax protocol, the other does not - violates the principle that when all patents "derive from the same parent application and share many common terms," the courts must "interpret the claims consistently across all asserted patents." NTP, 418 F.3d at 1293.

In addition, when the claims contemplate conversion from one protocol to another, the claims say so. For example, the '302 patent, claim 9, claims "converting facsimile message signals received from said store and forward facility into suitable video display signals for display on the normal television set." The '302 patent, claim 13 claims "a video display generator and RF modulator means for converting facsimile messages received from a store and forward facility." Claim 34 of the '302 patent claims "a conversion means for converting facsimile signals received from said store and forward facility into suitable video display signals for display on the normal television set." Given that the patentee was capable of specifying when a claim required conversion, it follows that where no conversion is specified, none is contemplated.

Finally, in support of its position that SAFF "outbound" communication need not use facsimile protocol or be transmitted on a switched telephone network, Catch Curve argues that some of the claims fail to recite the words "switched telephone
network" to limit the outbound transmission. However, the failure to recite these words in describing the outbound
transmission does not indicate that the inventor contemplated that this transmission might take any or all forms. The use of
the word "facsimile" in the same claims clearly indicates that the scope of possible formats for the outbound was limited to
facsimile protocol.

For the foregoing reasons, the Court proposes the following construction of "facsimile":

CONSTRUCTION: image data transmitted using facsimile protocol on the switched telephone network

The Court proposes the following construction of facsimile protocol:

CONSTRUCTION: the standardized procedure that governs the transmitting and receiving of facsimile messages over the
switched telephone network

Catch Curve argues that the district court erred by limiting the claims to a specific protocol. It asserts that a "facsimile
message" or "facsimile communication" should be construed to refer to the image data that is initially transmitted by a
facsimile machine, and that the communication remains a "facsimile message" or "facsimile communication" regardless of
any subsequent changes in the format used to convey that data after it is sent. Venali, on the other hand, contends that the
district court properly limited the claims because the patents use the terms "fax message" and "fax communication" to mean
messages that are communicated in fax protocol over a switched telephone network, and because those terms do not include
messages that are converted into different formats for transmission over the Internet.

The district court correctly noted that "[f]or a machine to be a 'fax' machine that sends 'fax' messages, it must use a certain
protocol . . . to communicate. Otherwise, nothing distinguishes these machines from any other machine used for
communication." In the common specification of the five patents, the inventors made clear that they used the term
"facsimile communications" to refer to communications between conventional fax machines or their proxies over a switched
telephone network. The specification describes the subject matter of the patents as "'[t]he electronic transmission of
documents by way of facsimile (fax) systems, employing public and private switched telephone networks," '021 patent, col.
1, ll. 29-31, and it describes the inventions generally as consisting of "a system and method for providing a comprehensive
interactive facsimile message management system embedded in a switched telephone network," id., col. 21, ll. 27-29. The
disclosed method, according to the specification, is designed "to achieve this in a way which is fundamentally compatible
with existing fax terminal machines." Id., col. 3, ll. 2-3. The "basic approach," the specification adds, "is to provide special
computer-based fax Store And Forward Facilities (SAFFs) as an integral part of a switched telephone network system." Id.,
col. 3, ll. 3-6. Because the specification was first filed in 1988, the reference to "existing fax terminal machines," like the
references to other features of fax technology, pertains to the technology as it existed at that time.

Nothing in the specification suggests that the fax messages of the invention are converted to a different format and
transmitted to the recipient over a medium other than a switched telephone network. If the destination fax machine is within
the service region of the SAFF that first receives the fax message from the sending fax machine, the system temporarily
stores the fax message and attempts to call the destination fax machine. If contact is established, the SAFF delivers the fax
message immediately. '021 patent, col. 3, ll. 13-16. If the destination fax machine is within the service area of a different
SAFF, "the system forwards the fax document data to that facility by long-distance lines, in which case the second facility
attempts to call the destination machine" so as to deliver the fax message. Id., col. 3, ll. 16-24. If the attempt to deliver the
fax message to the destination machine fails on the first try, the message is stored at the second SAFF and subsequent
attempts are made to deliver the message from that SAFF. Id., col. 3, ll. 25-56.

Although Catch Curve contends that the term "fax message" refers to any image data that replicates the original fax
communication, regardless of what format is used to communicate or store that data and regardless of what medium is used
to transmit the data, that is not the way the patents use the terms "fax messages" or "fax transmissions." Rather, the common
specification makes clear that the fax messages that are the subject of the patent are sent and received by conventional fax
machines or their proxies over a switched telephone network using fax protocol. When the specification refers to devices other than traditional fax machines that can be adapted to receive fax communications, such as computers or ordinary television sets, it explains that those devices can be made to function as "paperless fax terminals." In describing the computer that can serve as a "paperless fax terminal" to receive fax messages from the SAFF mailbox, the specification makes clear that the computer uses a computer communications code to initiate telephonic contact with the Mail Box Service Control and that the Mail Box Service Control switches the computer from computer terminal mode to fax terminal mode for delivery of the requested fax messages over a telephone network, after which the fax message is delivered just as it would be to a traditional fax machine. '021 patent, col. 15, ll. 57-65. There is nothing in the specification to suggest that the fax message is converted to a different protocol for purposes of transmission, nor is there anything to suggest that the fax message is transmitted to its destination over a system quite different from a switched telephone network, such as the Internet.

Catch Curve argues that fax protocol must be used for the communication of image data between a fax machine and a SAFF, but need not be used for the communication of image data between two SAFFs. Because the SAFFs are computers, not fax machines, Catch Curve contends that the communication between the two SAFFs must be in a digital language. While that may be, the common specification makes it clear that the SAFFs are required to communicate with one another over a switched telephone network. For example, the patent teaches that the two SAFF machines communicate "through a long-distance interface over long-distance circuits." '021 patent, col. 8, ll. 24-25; see also id., col. 12, ll. 33-36 (noting that the invention "can significantly enhance the efficiency of the . . . long-distance and local telephone circuits"). Therefore, even if the district court's claim construction was unduly restrictive with respect to the use of fax protocol in every phase of the communication process, it was not in error with respect to the requirements that the communications take place over a switched telephone network and that the fax messages be delivered to a traditional fax machine or a proxy for such a machine by fax protocol over a switched telephone network.

Venali's accused system operates in a fundamentally different manner. Venali's system converts messages into formats other than fax protocol before storing or forwarding the messages and then transmits the messages to their intended destinations via SMTP, HTTP, or HTTPS protocol over the Internet. The messages are not sent to, and are not retrievable by, a conventional fax machine or a "paperless fax terminal" operating in fax protocol. Thus, all the data storage and transfer functions in Venali's system, after the initial receipt and conversion of the fax message, are inconsistent with fax protocol. In particular, Venali's Internet transmissions are quite different from the claimed transmissions of fax message signals over a switched telephone network. The district court therefore correctly concluded that Venali does not practice the methods or systems that are disclosed in the asserted patents and claimed in the numerous claims originally asserted by Catch Curve.

2. Facsimile Machine

Catch Curve argues that the "facsimile machine"/"fax device" term should be construed as "equipment for receiving or transmitting facsimile messages." Venali argues that it should be construed as "a device that uses facsimile protocol to transmit and receive fax messages over a telephone call," and Protus argues that it should be construed as "a machine that, transmits and receives messages over a switched telephone network using facsimile protocol."

For the reasons described above," Catch Curve's definition is too broad. Accordingly, the Court construes this term as follows:

CONSTRUCTION: A machine for transmitting or receiving messages while using facsimile protocol

Catch Curve argues that this term means "image data for facsimiles." Defendants argue that this term means either "a
message transmitted and received using facsimile protocol," or "a message transmitted and received over a switched telephone network using facsimile protocol."

Under Catch Curve's litigation position, any further transmission of a document that was once transmitted by a facsimile machine remains a fax transmission. This position cannot be reconciled with the patents that the PTO issued. For a fax message to be a "fax" message within the meaning of the patents, it must be:

CONSTRUCTION: A message transmitted and received by facsimile protocol

---

2. "Facsimile Transceiver"

The first portion of dispute in claim 1 is the term "facsimile transceiver" which is found in the language, "An information station comprising … a facsimile transceiver for converting printed information into digital electronic signals and for converting digital electronic signals into printed information." The parties offer differing constructions of the term "facsimile transceiver." Plaintiffs propose the following construction:

A facsimile transceiver is used which includes a scanner that scans a printed image on a piece of paper and turns the image into digitized information. The facsimile transceiver also has a printer which allows the facsimile transceiver to take digitized information, such as a digitized picture or words, and print the picture or words on a piece of paper.

Joint Claim Construction Statement at 4.

In comparison, Defendants claim that "facsimile transceiver" should be constructed as follows:

The facsimile transceiver must be capable of scanning printed information (e.g., printed text, pictures, photographs, and graphics) on a piece of paper, and digitizing the printed information into digital electronic signals representing the printed information, and transmitted the digital electronic signals to a destination outside the facsimile transceiver.

The facsimile transceiver also must have the capability of receiving digital electronic signals representing printed information (e.g., printed text, pictures, photographs, and graphics) from a source outside the facsimile transceiver, and printing the printed information in human readable form on a piece of paper.

The facsimile transceiver converts printed documents into digital signals and converts digital signals into printed documents. Within the context of the '911 patent claims and specification, these digital signals are necessarily encoded by a modem into analog signals for transmission over the telephone lines, and the analog signals are decoded by a modem into digital signals.

The facsimile transceiver must have the capability of communicating with a public telephone network through a modem.

Id. at 5.

While acknowledging that the two constructions are similar, Plaintiffs argue that Defendants' proposed construction is nonetheless unsupported by the claim language, the patent specification, and the prosecution history of the patent. See Pls.' Br. in Resp. to Defs.' Joint Brief in Supp. of Claim Construction at 5 (hereinafter referred to as "Pls.' Resp. Br."). Specifically, Plaintiff contends that Defendants improperly import several limitations into the claim: "First, Defendants appear to argue that (sic) 'facsimile transceiver' limitation must he read to encompass only so-called 'conventional' facsimile transceivers. Second, Defendants' construction appears to improperly require that any communications to or from the facsimile transceiver pass through a modem in the facsimile transceiver." Id. at 5-6.

Citing Defendants' Joint Brief in Supp. of Claim Construction, Plaintiffs state that Defendants, while not expressly using the term "conventional" to describe the facsimile transceiver in their proposed construction, "pointedly try to convey the impression that the scope of the 'facsimile transceiver' limitation should somehow be limited to 'conventional' facsimile
transceivers." Id. at 6. Plaintiffs argue that the word "conventional" is too ambiguous to be used to describe the type of facsimile transceiver contemplated by the claim. In Plaintiffs' estimation, the U.S. Patent and Trademark Office would likely have rejected the claim under 35 U.S.C. 112 as too indefinite had it used to word "conventional." Id.

Defendants argue that the specifications and prosecution history, as dictated by the claim language, describe a conventional facsimile transceiver that requires a modem-to-modem connection. See Defs.' Joint Reply Br. in Supp. of Claim Construction at 3 (hereinafter referred to as "Defs.' Joint Reply Br."). Because the specifications refer to a Fujitsu Model 2010 facsimile transceiver, which is only capable of modem-to-modem serial communication of analog signals through a telephone-compatible port and over a telephone line, Defendants argue that Plaintiffs' claim should be limited to facsimile transceivers with the same type of structure and functionality. Defendants further argue that "[t]he specification, and Kirsch during prosecution of the patent, explained that the invention was to use a conventional fax, and add a switch to enable the fax to connect directly to the computer's modem without any modification to the fax."

The Court is not persuaded by Defendants' argument. The specifications note that the claimed invention could be used with a "commercially available" facsimile transceiver. The Fujitsu Model 2010 is one "commercially available" unit. The Fujitsu Model 2010 referred to in the specifications, and others of similar make, require a modem-to-modem connection. The specifications merely acknowledge this fact and describe the claimed invention as being within the unit, and the unit being attached to a telephone line. However, there is no indication that other types of "commercially available units" did not exist at the time of patent prosecution. Indeed, "Defendants have identified numerous examples of alleged prior art facsimile transceivers—and, therefore, 'conventional' facsimile transceivers—having structure and/or functionality different than the exemplary model cited in the Kirsch patent." Pls.' Resp. Br. at 7; see Defs.' Joint Reply Br. at 17-19. The Court is not convinced that Kirsch intended to limit his claim to devices such as the Fujitsu Model 2010.

Defendants claims that the prosecution history supports its construction because Kirsch explained that his "invention can be implemented using conventional facsimile transceivers and without requiring such transceivers to be modified." Defs,' Joint Br. in Supp. of Claim Construction at 23 (hereinafter referred to as "Defs.' Br.") (emphasis in original) (citing Rosso Decl., Ex. 2c, p. 3). Again, the Court is not convinced that Kirsch's use of the term "conventional facsimile transceivers" was intended to limit his claim. There were other "conventional facsimile transceivers" in existence at the time patent prosecution; Kirsch chose to describe the use of his invention in one.

The specifications state that "[t]he facsimile transceiver … may be a commercially available unit." (Emphasis added). The prosecution history reveals that his "invention can be implemented using conventional facsimile transceivers and without requiring such transceivers to be modified." The Court concludes that the specifications do not identify the Fujitsu Model 2010, which was but one type of "commercially available unit," to the exclusion of others. The specifications describe but one embodiment, albeit the "Preferred Embodiment" in this instance, of Plaintiffs' invention. A patentee is not required to disclose every embodiment of his invention, SRI Int'l v. Matsushita Elec. Corp. of Amer., 775 F.2d 1107, 1121-22 (Fed. Cir. 1985)(en banc). The Court accepts Plaintiffs' construction of the term "facsimile transceiver."

1691

"Fair Allocation of Bandwidth"

Alcatel argues that the term should be construed as "an algorithm or policy to share the available bandwidth." Cisco argues that this term is indefinite, under 35 U.S.C. § 112 P. 2.

Alcatel claims that the patent specifications describe a fair allocation of bandwidth as a forced sharing of link capacity between active conversations, even during periods of severe congestion. See Watt Supp., col. 2, 11. 1-9 (hereinafter Watt, at 2:1-9). However, the patent indicates that it is up to the user to determine exactly how that link capacity is to be shared, by way of selecting particular policies, and setting values to reflect those policies. See id., at 4:16-27. The patent discusses the method of "express queuing," as well as "an ever-so-slightly modified form of express queuing" called "fair queuing." See id., at 5:59-6:16, Fig. 4.

Cisco contends that the patent does not describe what is meant by "fair," and thus is indefinite. "The specification shall conclude with one or more claims particularly pointing out and distinctly claiming the subject matter which the applicant..."
regards as his invention." 35 U.S.C. § 112 P 2. As stated in Union Pacific Resources Co. v. Chesapeake Energy Corp., 236 F.3d 684 (Fed. Cir. 2001), "The definiteness inquiry focuses on whether those skilled in the art would understand the scope of the claim when the claim is read in light of the rest of the specification." Id. at 692. See also Personalized Media v. ITC, 161 F.3d 696, 705 (Fed. Cir. 1998) ("If the claims read in light of the specification reasonably apprise those skilled in the art of the scope of the invention, § 112 demands no more."); Exxon Research v. United States, 265 F.3d 1371, 1376-80 (Fed. Cir. 2001).

A canon of claim construction instructs that, if possible, claims should be construed so as to preserve their validity. See Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1556 (Fed. Cir. 1997) (finding that the court "seeks to interpret claims to preserve, rather than defeat, their validity"); Carman Indus., Inc. v. Wahl, 724 F.2d 932, 937 n.5 (Fed. Cir. 1983). However, "if the only claim construction that is consistent with the claim's language and the written description renders the claim invalid, then the axiom does not apply and the claim is simply invalid." Rhine v. Casio, Inc., 183 F.3d 1342, 1345 (Fed. Cir. 1999).

Cisco argues that Alcatel's proposed construction reads the term "fair" out of the claimed "fair allocation of bandwidth." In doing so, Alcatel has arguably failed to properly acknowledge the significance of the term in limiting the scope of the claim. See Lantech, Inc. v. Keip Machine Co., 32 F.3d 542, 546 (Fed. Cir. 1994) ("All limitations in a claim must be considered meaningful."); Wright Med. Tech., Inc. v. Osteonics Corp., 122 F.3d 1440, 1444 (Fed. Cir. 1997). The crux of Cisco's argument therefore relies on its notion that the term "fair" must be properly defined so that one with ordinary skill in the art would know the limitations of the claim.

Cisco attempts to demonstrate that one with ordinary skill in the art would not know what is meant by "fair allocation of bandwidth" by relying on the testimony of its expert (see Lumish Decl., Ex. C ("Acampora '532 Report"), at 6-7), as well as the testimony of the inventor himself. Essentially, through the use of this extrinsic evidence, Cisco has demonstrated that what exactly "fair" means is not uniform, but rather changes over time in response to particular user needs as well as market expectations. See Watt Depo., at 87:13-88:3, 90:17-91:2.

Nevertheless, the exact definition as to what is "fair" is not necessary in order to properly construe the limitations of this term. As Alcatel points out, "fair allocation of bandwidth" is a term of art used both now and in 1993 when the foreign patent first issued. See Lucantoni '532 Decl., at PP 26-35. Several technical papers had been published at that time that included discussions on what constitutes fair in the context of allocating bandwidth, as well as proposing queuing algorithms for achieving that fair allocation. See id., at P 27. In fact, one of those articles is referenced directly in the patent specification. See id., at P 33; Watt, at 4:4-7. It is not necessary to determine what precisely constitutes "fair," as that definition will vary depending on the user's desired result. The notion of "fair allocation of bandwidth," however, is understood by someone with ordinary skill in the art as a concept by which multiple conversations share the available bandwidth along a common link in a manner specified by the user, but generally in a way that does not allow a heavy usage application to dominate the available bandwidth simply by virtue of its greater load.

Therefore, in light of the presumption of validity in construing a claim, and the determination that one with ordinary skill in the art could understand what is implied by the term "fair allocation of bandwidth," the Court finds that the term is not indefinite. Thus, the Court construes the term "fair allocation of bandwidth" as "an algorithm or policy to share the available bandwidth."

11. "fault monitoring data"

Power-One proposes this term be construed as "data concerning the status of one or more POL regulators in a distributed power system or surrounding conditions," while Artesyn suggests "information about a possible fault of the POL regulator or its output obtained through systematic measurements using an external device or sensor circuit." Again, the Court finds Artesyn's proposal too limiting and not justified in view of the specification. The '798 specification is clear that "fault monitoring data" is not limited to data "about a possible fault" as Artesyn proposes. See '798 patent, col. 5:40-46. Further, there is nothing in the '798 specification requiring that data be obtained through "systematic measurements." Concerning Power-One's proposal, the Court finds that the phrase "surrounding conditions" is not supported by the specification. The
Court construes "fault-monitoring data" as "data concerning the status or operating condition of one or more POL regulators used to determine if there is a fault."

10. "fault protection data"

Power-One suggests this term should be construed to mean "data concerning identification of or response to faults," while Artesyn proposes a construction of "a form of monitoring data provided by a POL regulator in which each datum is a value reflecting a characteristic of the POL regulator sending the message, such as the temperature, output voltage, or output current of the sending POL regulator." To support its proposal, Artesyn relies on column 2, lines 20-28 and column 5, lines 20-23 of the '916 patent. However, to construe these terms as Artesyn advocates would suggest that the term is limited to examples provided in the specification. Indeed, these passages use "e.g." showing that types of fault protection data discussed are exemplary only. See Varco, 436 F.3d at 1375. Artesyn's proposal also includes limitations, i.e., "form of monitoring data" and "each datum is a value reflecting a characteristic of the POL regulator," that are unnecessarily vague and find no support in the cited passages. Thus, the Court construes "fault protection data" as "data concerning identification of or response to faults."

6. "feature activation mode"

Plaintiffs' construction: a mode in which aspects of the system can be made active

Defendant's construction: the system has exited its previous state and has entered a suspended state in which the system is incapable of imaging and is waiting for feature key data to be inputted

Plaintiffs argue that this term has an ordinary and customary meaning, which can be gleaned from dictionary definitions. Defendant contends that "feature activation mode" means the same thing as "feature key activation mode," a term used in other claims of the '225 patent. Both approaches leave something to be desired. Although defendant is correct that the two terms are used in somewhat similar ways, this is not sufficient to demonstrate that they mean the same thing. Next, even if plaintiffs are correct and "feature activation mode" has an ordinary and customary meaning, they have not shown that their construction is proper. Rather than presenting the court with a widely accepted technical definition for the term as a whole, plaintiffs attempt to cobble together a construction from dictionary definitions of the individual words. Because both constructions are flawed, I conclude that the term "feature activation mode" would not benefit from either construction.

8. Feedback and feedback signal.

The defendants ask the court to limit the terms "feedback" and "feedback signal" to signals that can be used to determine current through the load. The court rejects this position. Although Samsung correctly contends that certain claim limitations add language that further describes the feedback signal, the terms, standing alone, are not limited to feedback signals that can be used to determine current through the load. Instead, as O2 correctly observes, the term "feedback signal" simply connotes a signal that is indicative of feedback.
The key issue raised by the parties' competing constructions of this term is whether the feedback signal must be an actual electronic signal, i.e., a series of bits, as Broadcom suggests, or whether the term may also include the absence of a signal, as Agere contends.

Review of the claim language clearly demonstrates that the term "feedback signal" must contain actual information. Claim 1 states that the feedback signal is "receive[ed]" from a receiver, and that the determination of whether to scale an operating characteristic from a first to a second level must be "based on said feedback signal received from a receiver." (‘550 patent, col. 10, ll. 64, 67 (emphasis added).) Claim 15 states that the feedback signal is "generat[ed] . . . based on said OFDM signal" and "provid[ed]" to "dynamic control circuitry." (Id., col. 12, ll. 8-10 (emphasis added).) It would be anomalous to speak of a device "receiving," "generating," or "providing" the absence of a signal. (See Cox Dep. at 128.) In fact, in response to direct questioning from the Court at the Markman hearing, Agere's counsel was unable, despite tenacious efforts, to explain how a receiver could "generate" the absence of a signal. (R. at 30-35 (May 7, 2004).)

Agere argues that one portion of the specifications supports its construction. This specification describes how the signal quality of a transmission line can be measured "by one of the following: received signal strength, received signal to noise plus interference ratio, detected errors (CRC), the presence of acknowledgments (lack of acknowledgments the link for communication signals is bad)." (‘550 patent, col. 7, ll. 56-61.) Agere correctly notes that the non-parenthetical portion of the quoted language lists types of feedback that can be used by the dynamic control circuitry to assess transmission signal quality. (See Goodman Rep. P 22.) The text within the parenthetical, however, does not also constitute a "feedback signal" as that term is used in the claim language. Rather, it is an independent, albeit inarticulate, clause indicating that the lack of an acknowledgment may also convey information to the transmitter, i.e., that the link for communication signals is bad. Accordingly, this portion of the specifications does not alter the clear meaning of the term "feedback signal" as evidenced by the claim language.

Agere advances the additional argument that its construction is supported by dictionary definitions, specifically the definitions of "feedback" and "signal." 3 The Academic Press Dictionary of Science and Technology defines "feedback" as "the return of information about a system or process that may effect a change in the process." 4 ACADEMIC PRESS DICTIONARY OF SCIENCE AND TECHNOLOGY 812 (Christopher Morris ed., 1992). The Sixth Edition of the IEEE Standard Dictionary of Electrical and Electronics Terms defines "signal" as "a visual, audible or other indication used to convey information." (Goodman Rep. P 20.) Agere combines these two definitions to arrive at its proposed construction: "An indication depending in part on an original signal." Agere's combined definition, however, does not resolve the key dispute noted above regarding whether an "indication" includes the absence of a signal. Agere merely asserts that the indication "could come in the form of an acknowledgment (indicating that the message was received by the receiver accurately) or the absence of an acknowledgment (indicating that the message was not received by the receiver accurately)." (Id. P 21; Agere Opening at 24.) Neither the dictionary definitions nor Agere's combined definition, however, compels this conclusion. In fact, the IEEE Dictionary definition of "signal" cited above could be plausibly read to require an actual physical signal and the IEEE definition of "feedback" definitely so requires. Seesupra n.4. Furthermore, even if the dictionary definition of "feedback signal" includes the absence of a signal, that definition would be contrary to the clear import of the claim text.

--- Footnotes ---

3 Agere argues that it was necessary to examine the definitions of "feedback" and "signal" separately because, although the IEEE Standard Dictionary of Electrical and Electronics Terms defines the composite term "feedback signal" as it relates to "control system" applications, that definition does not comport with how the term is used by communications engineers in relation to OFDM transmissions. (Goodman Rep. P 19.)

4 Notably, Agere's expert's report utilizes the IEEE definition of "feedback," which is "the returning of a fraction of the output of the input." (Goodman Rep. P 20.) Presumably, Agere abandoned this definition of "feedback" because, as Dr. Goodman admitted at the Markman hearing, it contradicts Agere's proposed construction. (R. at 6 (May 7, 2004) (noting that IEEE definition "required [an] electronic signal, an actual signal, not the absence of a signal . . . because [it] required returning a fraction of the original signal").)
In light of the foregoing analysis, the Court finds that the "feedback signal" must contain an actual electronic signal. Broadcom's proposed construction, however, includes the further limitation that a "feedback signal" is a "series of bits." Broadcom's only support for this language is its expert's assertion, which is unsupported by a dictionary definition or reference to the intrinsic record. (Broadcom's Resp. at 18.) Instead, the Court adopts the broader construction proposed at the Markman hearing: "An actual electronic signal constituting information about the communication environment which allows an originating source to adapt in response to that information." 5

5 Broadcom indicated at the Markman hearing that it would be willing to accept this revised construction. (See R. at 41 (May 7, 2004) ("A signal means actually sending some electronic form of signal.").)

The parties dispute whether the term "article feeder means" in claims 1, 20, and 24 is governed by Section 112, paragraph 6. Goss argues the statute does not apply despite the presumption that attaches because the word "means" is used in the claim. Pl. Memo. at 11. Goss contends the term "article feeder" recites sufficient structure on its own to rebut the presumption. Id. In addition, Goss argues the claim sets forth sufficient structure because it contains detailed descriptions of the location and components of the article feeder means. Id. at 12. Goss draws support for its construction from the specification, the patent examiner's repeated use of the term "feeder" without discussion of its function, and a dictionary definition of the term. Id. at 13. According to Goss, a person of ordinary skill in the art would understand the term to describe a known structure. Id.

K&M responds that Goss has not rebutted the presumption in favor of means-plus-function analysis. K&M contends that the only structure identified to perform the function of "feeding sheet material articles to said receiving locations" is a variable speed motor. Def. Memo. at 10; Pat. at col. 14, ll. 51-53. But an article feeder requires structures in addition to a variable speed motor to move the sheet material to the pockets, such as a hopper, feed drum, sucker mechanism, gripper, variable speed feed motor, and feed motor drive circuit. Id. at 12; Pat. at Fig. 4 (included within the dashed line denoting the "sheet material article feeder 54" is a host of structures other than variable speed motor). K&M concludes the element is functional and falls under Section 112, paragraph 6. Id. at 13. Employing means-plus-function analysis, K&M argues for a construction that includes all the structures necessary to determine the position of the pockets and transport the sheet material to them. Id. at 13.

The "article feeder means" element is not governed by Section 112, paragraph 6. Although use of the term "means" presumes application of the statute, that presumption may be overcome if the claim recites structure sufficient to perform the claimed function. See Altiris, 318 F.3d at 1375. That structure is apparent. First, the term "article feeder" provides enough structural detail on its own to render Section 112, paragraph 6 inapplicable. In MIT v. Abacus Software, the court
found means-plus-function analysis did not apply to the term "aesthetic correction circuitry." 462 F.3d 1344, 1355 (Fed. Cir. 2006). The court determined the word "'circuitry,' by itself, connotes structure." Id. The court based its decision on general-usage and technical dictionaries defining the term. Id. "Article feeder," like "circuitry," describes a known structure. The specification is rife with references to different types of feeders. See e.g., col 1, ll. 34-38; col. 2, ll. 46-47. None of the references are described functionally. In addition, the prosecution history makes clear that the patentees and the patent examiner understood the term "article feeder" to identify a specific item. See Pl. Memo. at Ex. B, PAT00185 (term is used without explanation or qualification in discussion of the Maoploski patent, which is referenced as prior art in the '724 patent). Moreover, as in MIT, dictionaries identify a "feeder" as a known device consistent with the '724 patent's use of the term. Id. at Ex. C, Ex. 7 ("feeder" defined as a "device that feeds materials into a machine for further processing"). See also Cole, 102 F.3d at 531 ("perforation means . . . for tearing" was not means-plus-function element because the element's precise structural character was defined by its own description).

Second, aside from the element's description, the claims set forth structure sufficient to overcome application of Section 112, paragraph 6. The claims describe the location of the article feeder means ("disposed along said conveyer") and some of its components ("each one of said article feeder means includes a variable speed motor"). Pat. at col. 14, ll. 52-54. By doing so, the claims do not merely depict the article feeder means as a function, they describe the element's structure by explaining its operation. When a structural term is coupled with operational terms, "sufficient structural meaning will generally be conveyed to persons of ordinary skill in the art." Linear Tech. Corp. v. Impala Linear Corp., 379 F.3d 1311, 1320 (Fed. Cir. 2004); see also MIT, 462 F.3d at 1356 (structural term "circuit" described by reference to additional operational structure); Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1304-05 (Fed. Cir. 1999) ("positioning means" was not means-plus-function element because claim recited additional structures for performing function).

K&M argues the element's description does not embody all the structures necessary to perform the element's function; therefore, the presumption in favor of means-plus-function analysis is not rebutted. This argument is unavailing. "It is well established that it is not necessary to claim in a patent every device required to enable the invention to be used." Asyst Techs., Inc. v. Empak, Inc., 268 F.3d 1364, 1371 (Fed. Cir. 2001). Thus, it is not fatal to Goss' position that the claim recites a variable speed motor as additional structure, but fails to recite more. Id. The recitation of operational components and the article feeder means' location indicates the element is structural.

In any event, K&M's proposed construction fails because it commits a cardinal sin of claim construction: it seeks to import structures unnecessary to perform the element's function. See Wegner, 239 F.3d at 1233. The majority of structures K&M includes in its construction relate to controlling the specific location sheet material is delivered to the pockets, e.g., feed motor position sensor, operator advance/retard control, home position and receiving location proximity sensors, etc. Def. Memo. at 14; Pat. at Fig. 3. But these structures are not necessary for the article feeders means to perform the limited function of "feeding sheet material articles to said receiving locations." Pat. at col. 14, ll. 51-53. The structures K&M adds enable or enhance, rather than perform, the specified function. See Asyst Tech., 268 F.3d at 1371. The court cannot construe claims in a way that adds unnecessary structures. Wegner, 239 F.3d at 1233. To be sure, the patent's drawings create some ambiguity regarding what structures are contained in the article feeder means. Pat. at Fig. 3 (item 54, identified as a "sheet material article feeder," drawn to include all structures within dotted-line); Fig 4 (item 54 points to unspecified group of structures). However, the specification clearly sets forth the element's function. Claim language, not the drawings, define the scope of the patent. See Cummins Engine Co. v. Gen. Motors Corp., 299 F. Supp. 59, 88 (D.C. Md. 1969).

Further, K&M's construction would violate the doctrine of claim differentiation, which requires the court to construe independent claims in a way to avoid nullifying dependent claims. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 908 (Fed. Cir. 2004). Many of the structures K&M includes as part of claim 1's "article feeder means" element are recited as separate elements in dependent claims. See e.g., Pat at col. 15, ll. 62-65 (construction of claim 1 includes sensors, but "sensor means" are described in claim 9). Adopting K&M's construction would render many dependant claims redundant. Therefore, the court construes the "article feeder means" element in claims 1, 20, and 24 consistent with Goss's proposed constructions.
Fargo  ferromagnetic: of or relating to a class of substances characterized by abnormally high magnetic permeability, definite saturation point, and appreciable residual magnetism and hysteresis
magnetic material pins: pins made of a magnetic material
unmagnetized magnetic material: magnetizable material that is not permanently magnetized

Iris  ferromagnetic: a material that exhibits ferromagnetism, but is not magnetized
magnetic material pins: pins made of a material that is capable of being magnetized, but is not magnetized
unmagnetized magnetic material: material that is capable of being magnetized but, in the absence of an applied external magnetic field, is not magnetized

n5 Iris offered this proposed construction at oral argument.

The focus of Iris's arguments regarding these terms is that, within the context of the patent, they all refer to material that is capable of being magnetized, but is not magnetized. Iris highlights evidence in the prosecution history where the applicant sought to distinguish prior art on the basis that the supply rolls have "no magnets." (Fink Aff., Ex. C, pt. 4, at C61-C62.) The document states:

Claim 11 [issued Claim 8] is specific to the positioning of the identifier indicia, using an unmagnetized magnetic material. This feature is very important, again, from a pollution control standpoint, because there are no magnetic materials that are utilized on the roll, but yet the reliability of a magnetic sensor can be utilized using one stationary detector of the present invention.

* * *

With the present invention the magnetic material pins are cheap, they are non-polluting, and since there are no magnets, there are no plurality [sic] requirement. They can be placed on the supports or inserted into the apertures without regard to polarity.

The doctrine of prosecution disclaimer prevents a patentee from recapturing a specific meaning that it disclaimed during prosecution. Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1323 (Fed. Cir. 2003). The disclaimer must have been clear and unambiguous for the doctrine to apply. Id. at 1324. Fargo argues that there is no clear and unmistakable disavowal of the ordinary and customary meaning of "magnetic material pins." The problem with Fargo's argument, however, is that its proposed construction for "magnetic material pins" is "pins made of a magnetic material." Yet the prosecution history clearly indicates that the "invention" has "no magnets." Neither Fargo's arguments nor its proposed definition help explain how "material" that is "magnetic" is nevertheless not a "magnet."

At oral argument, Iris offered a new definition for "unmagnetized magnetic material" to counter any objection that its previous definition might have excluded the pins in the patent because they are briefly magnetized as they pass through the magnetic field that is part of the sensor. The resulting definition, "material that is capable of being magnetized but in the absence of an applied external magnetic field is not magnetized," is a better definition than Fargo's because it avoids the ambiguity of the word "permanent." In light of the prosecution history indicating that the supply rolls have "no magnets," the Court will adopt this definition for "unmagnetized magnetic material" and a similar definition for "magnetic material pins:" "pins made of material that is capable of being magnetized but in the absence of an applied external magnetic field is not magnetized." In so doing, the Court is aware that it is defining different terms to have essentially the same meaning. Although a patentee's use of different terms normally indicates that it intended those terms to carry different meanings, a reading of the patent and prosecution history does not reveal what that difference might be in this case, and Fargo's
objections to Iris's proposed definitions ignore the clear statement in the prosecution history regarding the lack of magnets.

Finally, in light of that same prosecution history, the Court will adopt Iris's definition of "ferromagnetic," modified as follows: "a material that exhibits ferromagnetism, but, in the absence of an applied external magnetic field, is not magnetized." Because Iris concedes that Fargo's definition of "ferromagnetic" is correct "in the abstract," the Court will adopt Fargo's definition of "ferromagnetic" insofar as it is necessary to define the word "ferromagnetism" in Iris's definition of "ferromagnetic."

a. Meaning of the phrase "objects fetched from said clients"

Defendants interpret the phrase "objects fetched from said clients" to mean that "the clients are the source of the objects." Defs.' Mot. for Invalidity of Claim 29 at 12:25; Danzig Decl I P 33. Plaintiff does not dispute that, as drafted, the phrase "objects fetched from said clients" means that objects come from clients. Instead, plaintiff interprets the "ordinary meaning of the phrase to be "fetched from said servers" or "fetched for said clients." Pl.'s Opp'n at 12:10 (emphasis in original). Plaintiff states that the phrase is the result of "an unambiguous typographical error," and that a person of ordinary skill in the art would identify and understand it as such. Id. at 13:9-10 (emphasis in original). For this proposition, plaintiff relies on the testimony of its expert, Dr. Frederick Hayes-Roth. Id. at 13:22-14:25. Plaintiff urges the Court to make one of two corrections to the claim language: either change the word "from" to the word "for," or change the word "clients" to the word "servers."

The Court finds that, even if this phrase contains a typographical error, it cannot re-draft the claim language to render claim 29 valid. It is true that patents are presumed valid, and this presumption of validity may only be overcome by clear and convincing evidence. 35 U.S.C. § 282; Eli Lilly & Co. v. Barr Labs., 251 F.3d 955, 962 (Fed. Cir. 2001). Moreover, as plaintiff correctly points out, "where claims are amenable to more than one construction, they should where reasonably possible be interpreted so as to preserve their validity." Process Control Corp. v. Hydrelclaim Corp., 190 F.3d 1350, 1357 (Fed. Cir. 1999), citing Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). However, in this case, the Court finds that the language of claim 29 is susceptible to only one meaning, and that the strict prohibition against courts re-drafting claims prevents it from "correcting" the error to conform the language to plaintiff's proposed interpretation.

The language of element (b) of claim 29 clearly states that objects are being "fetched from said clients." The dictionary definition of "from" is "a function word to indicate starting point" or "source, cause, agent, or basis." Webster's New Collegiate Dictionary (1981). The word "fetch" means "to cause to come." Id. The Court agrees with defendants that, interpreted literally, the phrase "from said clients" indicates that the clients are the starting point or source of the objects. The words, in this context, "mean exactly what they say." Chef America, Inc. v. Lamb-Weston, Inc., 358 F.3d 1371, 1373 (Fed. Cir. 2004). Defendants' expert testifies that this is also the plain meaning of the phrase to persons of skill in the art. Danzig Decl. I P 33.

In the absence of the patentee's clear intent to give claim terms some other, special meaning, the ordinary meaning controls. Chef America, Inc., 358 F.3d at 1374, citing Process Control. 190 F.3d at 1357. Courts look to the claims, specification, and prosecution history to discern whether some other meaning was intended. The testimony of the inventor about his or her subjective intent "is of little or no probative weight in determining the scope of the claim." Markman v. Westview Instruments, Inc., 52 F.3d 967, 985 (Fed. Cir. 1995) (en banc), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1976). In addition, if a party states that the claims have special meaning to those of ordinary skill in the art, that party must explain how the words would convey that special meaning. See Chef America Inc., 358 F.3d at 1375.

Here, there is no intrinsic evidence that the patentees themselves defined "from" as "for" or "clients" as "servers." The prosecution history indicates that the patentees understood "client" and "server" to mean different things, because the applicants amended another claim, claim 36, which depends upon claim 29, by changing the word "server" to "client" in two places. Cooper Decl. on Non-infringement, Ex. C, Tab 9 at INKT0074741. Plaintiff's evidence that the claims carry this special meaning to those of ordinary skill is the testimony of Dr. Frederick Hayes-Roth, one of the patent's inventors, who testified that "fetched from said clients" is equivalent to "fetched for the clients or fetched by the clients." Pl.'s Opp'n at 14:4-5. But this testimony, in addition to lacking probative weight, does not create a genuine issue of material fact because it
does not explain how the word "from" could be read to mean "for" or "client" could be read to mean "server." The testimony is no more than a "restatement of [plaintiff's] basic contention "that unless [the Court] rewrites the claim, the patented process cannot perform its intended function." Chef America Inc., 358 F.3d at 1375

The Court "must construe the claims based on the patentee's version of the claim as he himself drafted it." Process Control Corp., 190 F.3d at 1356-57. Consequently, the Court finds that the phrase "objects fetched from said clients" has only one plain meaning to those of skill in the art: that clients are the source of the objects.

b. Typographical error

Plaintiff's contention that the claim contains a typographical error does not alter this conclusion. Plaintiff actually proposes two possible typographical errors, only one of which needs to be corrected: either the preposition "from" should be changed to "for," or the noun "clients" should be changed to "servers." Plaintiff then attempts to distinguish the Federal Circuit authority relied on by defendants on grounds that the cited cases deal with purposeful drafting errors rather than inadvertent, typographical errors. Plaintiff does not demonstrate that this is a distinction with a difference in this case, and the Court cannot conclude that it is one. 1

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

1 Defendants argue that this is not a typographical error as a matter of law. For purposes of summary judgment, viewing the evidence in the light most favorable to the non-moving party, the Court will assume that the error is typographical, and instead assess whether it can correct the error under these circumstances.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The Federal Circuit has acknowledged that "not all clerical or typographical mistakes are immediately apparent, and even where the mistake is apparent, it may not be clear how the mistake should be corrected." Superior Fireplace Co. v. Majestic Products Co., 270 F.3d 1358, 1370. 2 In Novo Industries, L.P. v. Micro Molds Corp., 350 F.3d 1348, 1354 (Fed. Cir. 2003), the Federal Circuit addressed "whether a district court can act to correct an error in a patent by interpretation of the patent where no certificate of correction has been issued," and held that "a district court can do so only if (1) the correction is not subject to reasonable debate based on consideration of the claim language and the specification and (2) the prosecution history does not suggest a different interpretation of the claims." Id. at 1354.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 Plaintiff distinguishes Superior Fireplace, where the court concluded that the error was not typographical because the claim language had been changed from "rear wall" to "rear walls" by an examiner's amendment, and thus the patentee could not have it changed back by a certificate of correction. The Court does not rely on Superior Fireplace, and recognizes that here, the language has never been altered at all. However, the issue is whether this language (if a typo) can be corrected by the Court.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Here, the correction is clearly subject to reasonable debate. Plaintiff itself proposes two possibilities for the correction. In addition, as defendants point out, three co-inventors of the patent have offered different interpretations of the claim. Dr. Hayes-Roth considers "from the clients" to be equivalent to "for the clients" or "by the clients." Pl.'s Opp'n at 14:3-4. Chris McMahon testified that the language does not include a typographical error and that the word "from" need not be read as "for." Supplemental Declaration of Monte M.F. Cooper in Support of Defs.' Mot. for Summ. J. of Invalidity and Non-infringement of Claim 29 ("Supp. Cooper Decl."), Ex. G (Rough Tr. of Depo. Chris McMahon) at 78:5-6, 9; 76:17-18. James Manley stated that "clients" was intended to mean "servers." Id., Ex. H (Rough Tr. of Depo. James Manley) at 80:17-19.

In addition, the prosecution history does not support an inference that the claim should be interpreted as urged by plaintiff. When the 175 Patent was filed on October 26, 1995, it had ten claims, none of which contained the language of claim 29. Cooper Decl. on Non-infringement, Ex. B. The applicants filed a non-provisional application in June 1996, which included
65 claims, one of which was claim 29, then identified as claim 33. Id., Ex. C, Tab 1 at INKT0074641. The applicants made a "preliminary amendment" to correct typographical errors in the new application. Id., Tab 4 at INKT0074715-17. Claim 29 was one of 17 claims allowed by the PTO. After the patent issued, the applicants filed a formal "certificate of correction" under 35 U.S.C. § 254 to correct typographical errors in six of the claims. Id., Tab 16 at INKT0074960-61. Claim 29 was not changed. The applicants never made changes to this language, while they did change the word "server" to the word "client" twice in another claim. Plaintiff contends that because it never altered this claim language, the language contained a mistake from the beginning, and the failure to correct the mistake shows that it was inadvertent. Pl.'s Opp'n at 13:10-17. But the Court is not persuaded, and there is no evidence, that plaintiff's inaction means what plaintiff says it does. The Court finds nothing in the patent's prosecution history that suggests a different interpretation than the ordinary meaning of the language as drafted.

c. The Court cannot re-draft this claim language

The clear line of Federal Circuit authority dictates that this Court may not re-draft claims to change their ordinary meaning, even if the ordinary meaning produces a nonsensical result. See Chef America Inc., 358 F.3d at 1374; Process Control Corp., 190 F.3d at 1357. The language "objects fetched from said clients," according to its ordinary meaning, conveys that objects will be fetched from clients. Viewing the evidence in the light most favorable to plaintiff, and even assuming that this was a typographical error, the Court cannot redraft the claim to render it operable.

The purpose of claim language is to "put[] competitors on notice of the scope of the claimed invention, and to "prevent[] unduly burdening competitors who must determine the scope of the claimed invention based on an erroneously drafted claim." Hoganas AB v. Dresser Industries, Inc., 9 F.3d 948, 951 (Fed. Cir. 1993); Process Control Corp., 190 F.3d at 1357. In the recent Federal Circuit decision of Chef America, the district court granted summary judgment and interpreted literally claim language requiring "heating the resulting batter-coated dough to a temperature in the range of about 400 [degrees] F. to 850 [degrees] F.," instead of adopting the plaintiff's interpretation of the claim as requiring "heating the . . . dough at a temperature of (meaning that the oven should reach that temperature rather than the dough itself). Chef America, Inc., 358 F.3d at 1373. The Federal Circuit affirmed, despite the fact that the claim language, as written, produced the result of burning the dough to a crisp. Id.

Here, the Court agrees with defendants that the claim language, as written, produces the nonsensical result of making the clients the source of the objects, which does not make sense in the context of the claim and the invention. 3 Defs.' Mot. on Invalidity of Claim 29 at 14:10. The Federal Circuit "repeatedly and consistently has recognized that courts may not redraft claims, whether to make them operable or to sustain their validity." Chef America, Inc., 358 F.3d at 1374. "It is the job of the patentee, and not the court, to write patents carefully and consistently, "and this Court must construe the claim "as written, not as the patentees wish they had written it." Id. at 1373. The Court cannot substitute the word "for" for the word "from" or the word "server" for the word "client" to change the nonsensical result.

--- Footnotes ---

3 Defendants argue that plaintiff's contention that the claim contains a typographical error is "an admission that the language as drafted is, in fact, nonsensical." Defs.' Reply in Support of Mot. for Summ. J. of Invalidity and Non-infringement of Claim 29 ("Defs.' Reply on Invalidity of Claim 29") at 6:17-18.

b. "field of view"

In the field of optics, "field of view" has a commonly understood meaning to persons of skill in the art. The Court examines the patent documents to determine if the inventors used the phrase in any specialized way. In the written description, the inventor uses the phrase "field of view" to describe the environment which is detectable by the full photosensor array.

The sensor array and the processing circuitry 18 are mounted on the front of the controller device 10 with the array facing outwardly. A lens 26 is shown in FIG. 1 as being partially cutaway in order to expose the array and circuitry. The lens may be an inexpensive plastic lens that is molded to the integrated circuit package 12. The focus of the lens is set nominally at infinity. The lens provides an image of a region of the surrounding environment to the sensor array 16.

('804 Patent, Col. 5:23-30.)

The width of the field of view for imaging the environment is a matter of balancing the desire of capturing as much visible detail as possible with the requirement of avoiding excessive distortion. A 64 [degrees] field of view provides a reasonable compromise between the two concerns. The dashed lines 28 in FIG. 1 represent the field of view for the sensor array 16. The arrangement of the optics and the sensor array may be selected to reduce any adverse effects of curvilinear distortion of the attitude-tracking approach of the invention.

('804 Patent, Col. 5:38-47.)

The inventor also uses the phrase "field of view" when discussing the environment which is detectable by each individual photosensor:

As previously noted, the field of view 28 is contemplated to be approximately 64 [degrees]. In a sensor array of 32X32 photosensors, a single pixel will have an approximately 2 [degrees] field of view (64 [degrees] /32 pixels).

('804 Patent, Col. 6:34-37)

In both instances the inventor is using the phrase with its customary and ordinary meaning. A person of ordinary skill in the art would understand that the inventor used the phrase "field of view" to mean the region of the environment optoelectrically detectable by the array of photosensors.

D. "Field of view information from a camera"

Claim 70 of the 406 Patent claims:

An apparatus comprising:

a set of one or more field view sensors adapted to sense field of view information from a camera;
one or more storage devices; and

one or more processors in communication with said one or more storage devices and said set of one or more field view sensors, said one or more processors perform a method of adding a graphic to a video representation of an environment originating from said camera, said method comprising the steps of . . .

Sportvision contends the phrase should be defined as: "Information about which is viewed by the camera." (Sportvision's Memo at 21.)

SportsMEDIA proposes: "Information describing the pan, tilt and/or zoom of the camera, and the location of the camera." (SportsMEDIA's Memo at 25.)

"Field of view information" is "information" (or "data" as described in the 553 patent) which is used to determine the field of view of the camera. (See Section C above). The 553 patent refers to "field of view information" in the same context as "field of view data":

The signal sent by multiplexer 206 to processor 200 includes the information from the field of view sensors.

1704
9. "field oxide"

All three parties offer different definitions of "field oxide." UniRAM's proposed definition is "oxide that physically and electrically isolates active areas." Jt Cl Const, Ex B at 8. TSMC adds in the requirement that the field oxide must be "grown;" MoSys contends that the field oxide must be "grown" and "thick." Id.

Although the patent often uses field oxide to define a trench capacitor's edges, field oxide formation is only described once: "The first step is to define active area 1502, and grow isolation field oxide 1504 to separate those [sic] active area." 229 patent at 19:50-52. This intrinsic evidence indicates that the field oxide is isolated and is "grown." But this passage is one of many that describes alternative manufacturing procedures for the invention. Id at 19:52-21:4. Limiting field oxide to that which is "grown" would improperly import limitations from the specification to the claim. Phillips, 415 F3d at 1323.

Moreover, there is no intrinsic evidence suggesting that the field oxide must be "thick." Accordingly, the court adopts UniRAM's proposed construction.

GO BACK
1705
B. "sides of said channel" and "field stop regions"

The '776 patent requires "field stop regions in said substrate having edges defining the sides of said channel for said memory device and for separating each of said memory cells from others of said memory cells in said array."
One dispute about the field stop regions involves whether they must enclose all four edges of the memory cell, as defendant claims, or whether they must only define the sides of the cell and not necessarily the ends, as plaintiff claims. The word "sides" in the claim language might conceivably mean any edge (as in the phrase "a square has four sides") or might mean "side" as opposed to "end" (as in the phrase "the sides of a truck"). The specification uses the word "side" in the latter sense, suggesting that that is what is meant by the claim as well. See '776 patent, 5:14-15 ("memory cells may be separated . . . from one another at the channel ends . . . and at the channel sides . . ."); Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1561-62 (Fed. Cir. 1991) (court may use specification to ascertain the meaning of the claim). The specification also describes groups of memory cells with no "channel end field oxide regions . . . separating individual cells at the channel ends." '776 patent, 5:20-23. Defendant's proposed reading would make impossible such mirror cells. Despite defendant's contention to the contrary, plaintiff's construction of "sides" is consistent with the claim language requiring the field stop region separate "each cell" from "others" in the array. This language can be read to mean that the region must separate the cell from "some others," not from "all others." The specification of the '776 patent therefore strongly supports plaintiff's construction.

Defendant argues that the term "field stop regions" in the '776 patent should be construed consistently with the term "field oxide regions" in the '750 patent. See Abtox v. Exitron Corp., 122 F.3d 1019, amended 131 F.3d 1009 (Fed. Cir. 1997) (requiring consistent construction of "indisputably interchangeable" terms in patents with a common ancestor). With this argument, defendant seeks to import the requirement of the '750 patent that there be "four opposed field oxide regions." '750 patent, 12:53. The Court is not convinced that "field stop regions" and "field oxide regions" are indisputably interchangeable terms. Even if they were, Abtox would not require that device claimed in the '776 patent have four such regions as opposed to two. In Abtox, the Federal Circuit held that it was inconsistent to construe the singular term "gas-confining chamber" to mean "a single chamber" in one patent but "multiple chambers" in a related patent. See Abtox, 122 F.3d at 1022. Abtox would control the outcome here if both patents claimed a singular "region," and the parties were disputing whether a "region" encompassed four sub-regions or two subregions. The patents in this case, however, both describe multiple "regions." The fact that the patents happen to require different numbers of such regions does not mean that the term "regions" is being construed inconsistently. The Court therefore holds that the field stop regions in the '776 patent need only define the sides, and not necessarily the ends, of the memory cell.

A second dispute involves what substances may compose the field stop region, and where the region may be located. Plaintiff argues the field stop region may be "any oxide which functions to partially or completely separate one structure from another." This proposed definition is too broad. The claim language does not suggest that the field stop regions can separate any structures; rather, it specifies that field stop regions must separate memory cells from other memory cells. Nor does plaintiff provide any convincing argument for why "separate" can mean "partially separate." It would be improper to limit the device to the preferred embodiment described in the specification. Nor has defendant provided anything other than expert testimony as an explanation for why the claim language means that the field stop regions cannot encroach upon the "active region." Under Vitrionic, in the absence of an ambiguity, this is not a permissible way to interpret the claim language.

The Court holds that the claim means neither more nor less than what it actually says. The patent requires that there must be field stop regions located in the substrate that define the channel sides and that completely separate cells from at least some other cells.

GO BACK

1706

C. "Field view sensors"

Claim 70 reads:
An apparatus comprising:

- a set of one or more field view sensors adapted to sense field of view information from a camera...

Sportvision defines the phrase as: "Sensors that provide information about that which is viewed by the camera [adapted to sense]." (Sportvision's Memo at 20.)

SportsMEDIA contends that this phrase is vague, indefinite and incapable of construction, as the phrase is not used in the patent and does not have a known standard meaning. (SportsMEDIA's Memo at 24.)

The 406 patent does not directly identify what "field view sensors" are. However, given the limitations in Claim 70, the Court finds that one skilled in the art would have known what field view sensors are.

The specification provides:

A set of camera view sensors can include one or more of the following: a zoom sensor, a pan sensor and/or a tilt sensor.

'406 patent, 5:40-42.

From the claim language and specification, the Court finds that these sensors are used to obtain view of field information from the camera(s).

Though the Court is satisfied that the intrinsic record is sufficient to define "field view sensors," the Court refers to extrinsic evidence to resolve any doubt with respect to the exact meaning of the phrase. Vitronics, 90 F.3d at 1583, 1585; Digital Biometrics Inc. v. Identix Inc., 149 F.3d 1335 (Fed. Cir. 1998) (extrinsic evidence may be considered to enable the court to construe disputed claim terms.) In the CROSS-REFERENCES TO RELATED APPLICATIONS section of the 406 patent specification, the 5,917,553 patent (A Method And Apparatus For Enhancing The Broadcast Of A Live Event) is included by reference. The 553 patent describes "field of view sensors" as:

- One embodiment of the present invention includes one or more field of view sensors coupled to a camera such that the sensors can detect data from which the field of view of the camera can be determined. The field of view sensors could include pan, tilt and/or zoom sensors.

'553 patent, 2:33-37.

Accordingly, the Court construes the term "field view sensors" to mean: "Sensors that provide information about the area being viewed by the camera."

</thead>
<tbody>
<tr>
<td>plurality of data input fields</td>
<td>more than one simultaneously appearing data input field</td>
</tr>
</tbody>
</table>

- 2088 -
The first term for which the parties offer different constructions—"plurality of data input fields"—is found within the following step of Claim One: "Invoking an input area, including a plurality of data input fields." The parties agree that "plurality" refers to more than one data input field, but they disagree as to how the multiple fields can be displayed. Plaintiff's proposed construction would allow a broad range of display options, allowing for fields "occurring at various locations." Defendants' proposed construction is narrower, requiring that the data input fields appear "simultaneously."

Defendants support their proposed construction, first, by reading "an input area" as "one input area." (Defs' Br., at 21.) If the plurality of data input fields must be included in a single input area, then they must appear simultaneously. Plaintiff responds that in this context, an open-ended claim containing the transitional word "comprising," "a" or "an" must be read as "one or more." (Pl's Resp., at 1-2, citing Baldwin Graphic Systems, Inc. v. Siebert, Inc., 512 F.3d 1338, 1342-43 (Fed. Cir. 2008).) Based on that reading, the plurality of data input fields may appear in one or more input areas, that is, not simultaneously. Plaintiff also urges that the input area should not be confused with the device's display. (Pl's Resp., at 2-3.) As the Patent's abstract explains, "The input area is created by a computer program on a display capable of receiving touch-screen input." (873 Patent, at 1.)

Defendants next argue that even though the word "simultaneously" does not appear in the specification, their proposed construction is supported by the intrinsic record. (Def's Br., at 22.) They point, first, to the preferred embodiment of the claim, which displays seven data input fields simultaneously. That the preferred embodiment seems to display all data input fields simultaneously is not dispositive, however. It is well recognized that "the fact that the specification describes only a single embodiment, standing alone, is insufficient to limit otherwise broad claim language." Howmedica Osteonics Corp. v. Wright Medical Technology, Inc., 540 F.3d 1337, 1345 (Fed. Cir. 2008). Defendants attempt to overcome this rule by pointing out that the specification calls the embodiment "a pictorial representation . . . of the present invention." (873 Patent, col. 2, ll. 55-58.) But describing a figure as "a" representation does not demonstrate a "clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction.' " Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (quoting Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002)). As Defendants conceded at the Markman hearing, the preferred embodiment does not limit the invention to uses that have seven data input fields. Similarly, it does not limit the invention to uses where all data input fields appear simultaneously.

Defendants also argue that their construction is consistent with arguments the inventors made regarding the Buxton Patent. (Def's Br., at 22-23.) According to Defendants, the inventors successfully distinguished the '873 Patent from Buxton by arguing that Buxton had only one data input field while the '873 Patent had a plurality of data input fields. (Id.) In support of their contention, Defendants cite a statement by the inventors in an amendment filed in response to a rejection by the PTO:

The graphical keyboard is always present with the "plurality of data input fields" of claim 1. Thus, where input is required for the data input fields, the graphical keyboard is always present as the user cannot accidentally terminate the graphical keyboard.

(P's Ex. 2, at 177. 3) As the court reads that statement, it does not support Defendants' argument; the statement says nothing about displaying multiple input fields simultaneously. Instead, it emphasizes that, in contrast to Buxton, the keyboard described in the '873 Patent cannot be accidentally terminated. And that is especially clear when the selection is read in context with the remainder of the amendment (id.) and the patent official's rejection that preceded it. (Id. at 164-74.) For these reasons, the court declines to adopt Defendants' proposed construction of "plurality of data inputs."

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

3 In their briefs, Defendants refer to documents within the more than 250 pages of prosecution history by the documents' titles only. The court cites instead to the record material provided by Plaintiff—specifically, a Bates-stamped copy of the prosecution history, permitting references to the individual pages by Bates numbers.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

The court thus turns to Plaintiff's proposed construction—"data input fields, occurring at various locations, as requested by the computer application or program." This construction relies principally on language from the specification: "The application may ask for user input at various locations through the use of text boxes or other fields." (873 Patent, col. 3, ll.
Defendants argue that this language—presumably, the word "may"—does not support the proposed construction because it is optional as opposed to mandatory. (Def's Br., at 24.) Defendants' argument is that Plaintiff's construction requires something that the specification states is optional. In fact, however, Plaintiff's proposed construction does not require that the input fields occur at various locations. It only allows for that possibility.

Defendants also contend that Plaintiff's proposed construction is inconsistent with the reading of the word "plurality" in another part of Claim One. (Def's Br., at 24.) The court presumes that when the same term appears in different portions of the claim it has the same meaning. Paragon Solutions, LLC v. Timex Corp., 566 F.3d 1075, 1087 (Fed. Cir. 2009). According to Defendants, when Claim One refers to a "graphical keyboard having a plurality of keys," it refers to a keyboard on which all keys appear simultaneously. Aside from the preferred embodiment, Defendants provide no support for this argument, however. The court has already explained why it is not relying on the preferred embodiment in this context. Moreover, anyone who has used a touch-screen keyboard knows that some keys—for example keys representing numbers, symbols, or even emoticons—may be displayed on separate screens. For these reasons, Defendants' argument against Plaintiff's construction fail.

Accordingly, the court adopts Plaintiff's proposed construction of "plurality of data input fields" as "data input fields, occurring at various locations, as requested by the computer application or program."

---

8. "File"

Plaintiff asserts that the term "file" is entitled to its ordinary meaning, but if the Court deems construction necessary, "file" should be construed to mean "a complete, named collection of information." Plaintiff's construction is based on the definition of "file" in the Microsoft Computer Dictionary (Joint app., Ex. I.), and is consistent with the use of the term in the claims and specification. The Court, as well as Defendants, agree with Plaintiff's construction. (Defs.' Opening, at 12:4-5.) Therefore, the Court construes "file" to mean "a complete, named collection of information."

---

F. "file," as used in claims 1, 9, 10, and 14.

Plaintiff first asserts that no construction of "file" is necessary; alternatively, it proposes the construction, "information, such as data or a program, associated with an identifier or name." Defendants' proposed construction defines "file" as an "HTML document" in claims 1, 9, and 10, and simply a "document" in claim 14 because that claim does not refer specifically to the http context. Here, the dispositive claim construction principles are (i) the prohibition against using embodiments or limitations found in the specification to narrow the scope of the claim terms, and (ii) the rule of internal consistency. Application of these principles here compels the conclusion that "file" means "electronically stored or transmitted information or data" wherever that term appears in the '670 patent claims.

Both the plain language of the claims and the specification support this construction. In common computer parlance, "file" is widely understood to include electronically stored information or data in the form of text, images, documents, videos, other media, or even whole programs. As figure 2 indicates, a requested "file" under the '670 patent may be text or an image.

Defendants' proposed construction limits "file" to "html document," which defendants derive from references in the specification to an "HTML document." See, e.g., '670 Patent Specification col. 12 11. 14-17 ("The merchant Web server responds to the request with an HTML document . . . ."). Yet, defining "file" in this manner commits the "cardinal sin" of "reading a limitation from the written description into the claims." SciMed Life Sys., 242 F.3d at 1340-41; see also Phillips, 415 F.3d at 1323 ("[W]e have repeatedly warned against confining the claims to . . . embodiments."). Thus, while some embodiments in the '670 patent do refer to an html document, the claims may nonetheless "embrac[e] different subject matter than is illustrated in the specific embodiments in the specification." Nazomi Commc'ns, Inc. v. Arm Holdings, PLC, 403 F.3d 1364, 1369-70 (Fed. Cir. 2005).
In addition, defendants attempt to bifurcate their construction of "file," giving the claim term one meaning in claim 14 and a separate meaning in the remaining disputed claims. Yet, this proposal contravenes the well settled claim construction principle requiring consistent interpretation of claim terms. See Rexnord Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001); Chamberlain Group, Inc., 516 F.3d at 1337; PODS, Inc. v. Porta Stor, Inc., 484 F.3d 1359, 1366 (Fed. Cir. 2007); Phillips, 415 F.3d at 1314. Defendants present no intrinsic evidence, nor do they forecast any extrinsic evidence, justifying a departure from this rule of internal consistency and supporting a bifurcated approach to claim construction. Accordingly, the claim term "file" must have a singular meaning, applicable in all instances.

Finally, plaintiff's proposed construction, "data," is unpersuasive because it does not fulfill the mandate of the Supreme Court's Markman decision, which essentially tasks a court undertaking claim construction with "elaborating the normally terse claim language[] in order to understand and explain . . . the scope of the claims." Embrex, Inc. v. Serv. Eng'g Corp., 216 F.3d 1343, 1347 (Fed. Cir. 2000) (first alteration in original) (quoting Scripps Clinic v. Genentech, Inc., 927 F.2d 1565, 1580 (Fed. Cir. 1991)). It follows that claim construction must aid the jury in resolving the parties' dispute. In this case, substituting the single word "data" for the claim term "file" does not provide clarification, and would amount to little more than an "exercise in redundancy." O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351, 1360-63 (Fed. Cir. 2008).

In sum, the claim term "file" is not limited to an "html document" because such a narrow construction would impermissibly use an embodiment to limit the claim term's scope. Accordingly, the claim term "file" is construed to mean "electronically stored or transmitted information or data."

IX. "information file" or "message file" 23

23 The term "information file" is contained in claim 1 of the '612 patent.
The parties dispute the meaning of the term "information file" in claim 1 of the ’612 patent. The parties generally dispute the meaning of "file" as it is used in the ’612 patent specification: "a method and system for protecting an information file from unauthorized access, and more specifically to the encryption of a message or file..." ’612 patent at 1:8-10 (emphasis added). The same passage additionally states that ",[a] method and system is disclosed for protecting sensitive information files and messages from access by unauthorized parties..." ’612 patent at 3:12-14 (emphasis added).

PACid contends that this specification language supports a generalized definition of "information file." PACid argues that the limitations imposed in Defendants' proposed construction find no support in the specification and narrows the claim term to a meaning that is inconsistent with what would be understood in the context of the patents-in-suit and the relevant art. OPENING at 16.

Defendants respond that the ’612 patent specification "consistently distinguishes" between an "information file" and a "message" by referring to the two terms in conjunctive form. RESPONSE at 20. Defendants further contend that "message" should not be a part of the construction because during the prosecution history, the inventor amended claim 1 to differentiate between "information file" and "message." Id. (citing RESPONSE, EXH. 10, ’612 PROS. HIST. (12/28/98 AMENDMENT)). Arguing that this claim term was not provided with a "special definition" in the patent, Defendants suggest that a contemporaneous dictionary definition should be used to understand the meaning of "file." Id. at 21.

As the claim term is used in the specification, the patentee did not ascribe any special meaning to "information file," nor is there any explicit disclaimer in the file history that limits the meaning to the specific requirements suggested by Defendants. Cordis Corp. v. Boston Scientific Corp., 561 F.3d 1319, 1329 (Fed. Cir. 2009) (holding that unclear prosecution history cannot be used to limit the plain language of the claims). Defendants must overcome the "heavy presumption" in favor of giving the claim terms their ordinary meaning, as expressed in the ’612 specification, fails to confine an "information file" to a collection of information with "a unique name." Phillips, 415 F.3d at 1312-13, 1323; Liebel-Flarsheim, 358 F.3d at 913 (finding that claim terms must be given their ordinary meaning unless the claim language is overcome by statements of "clear disclaimer" expressly indicating "manifest exclusion or restriction"). To the contrary, the requirement of a "unique name" is wholly absent from the intrinsic record, and therefore, the patentee is entitled to the full scope of the claim language. Home Diagnostics, 381 F.3d at 1358.

To that end, when determining the scope of the claims, there is indication that the ’612 patent uses "file" in a broad sense, but PACid's proposed construction does not define the claim term with sufficient particularity to be readily applied by a jury. For the sake of clarity, the dual terms "information file" and "message" are defined separately to reflect differences in the type of data being accessed, as well as the conjunctive form in which they appear in the specification. Accordingly, in the absence of an intrinsic definition for these terms, the Court adapts the dictionary definition provided by Defendants to include the ordinary meaning that a file may be accessed and manipulated as a single unit. This definition determines the ordinary meaning of the terms according to how one of ordinary skill in the art would read the claim language, but without the unsupported limitation that the data be "identified by a unique name."

The proper construction for "information file" is "an organized collection of information that can be accessed and manipulated as a single named unit." Similarly, the proper construction for "message file" is "a message that can be accessed and manipulated as a single named unit."

3. "file retrieval requests prepared"/"preparing file retrieval requests"/"preparing reply messages"

The term "file retrieval requests prepared" appears in claims 10 and 14 of the 366 Patent and claims 7 and 12 of the 918 Patent. For example, claim 10 of the 366 Patent recites:

[a] network file server for use with a data network and message storage device, said network file server comprising...
a communication path coupled directly between [a] network control module and [a] file system control module, said communication path carrying file retrieval requests prepared by said network control module in response to received NFS requests to retrieve specified retrieval data from the mass storage device . . .

Once again, plaintiff asserts that no construction is required because the disputed terms have an unambiguous meaning to persons ordinarily skilled in the relevant art. Defendant largely rehashes its arguments advanced in favor of its construction of "decoding NFS requests" and "encoding NFS reply messages," arguing that "file retrieval requests prepared" should be construed to mean "requests created by the network control module by processing all layers of a request from the network and converting them into different format." Similarly, for the term "preparing reply messages," defendant proposes the construction "processing all protocol layers and converting data into reply messages ready for network transmission."

As an initial matter, the court notes that defendant's proposed construction of the terms at issue here is substantially identical to its favored construction of the terms "decoding NFS requests" and "encoding NFS reply messages." However, the scope of procedures encompassed by the verb "to prepare" is much broader than the encoding and decoding process discussed above. While decoding and encoding necessarily involve a process of translation or conversion, no such requirement is inherent in the process of preparation. Moreover, under the doctrine of claim differentiation, different claim terms "are presumed to reflect difference in the scope of the claims." Forest Labs., Inc. v. Abbott Labs., Inc., 239 F.3d 1305, 1310 (Fed. Cir. 2001). Thus, absent a strong showing that the same meaning is intended by the different claim terms, importing the limitations from claims containing the "decoding" and "encoding" terms into claims that contain the "file retrieval requests prepared" and "preparing reply messages" limitations is improper.

To rebut the presumption that "preparing" has a meaning distinct from that of "decoding" and "encoding," defendant relies heavily on the preferred embodiments disclosed in the specifications of the 366 and 918 Patents, which reveal a method for preparing file retrieval requests and reply messages that involves decoding NFS requests sent from clients on a networked Unix system and encoding NFS reply message to be sent to those clients. If the preferred embodiment defined the scope of the claimed invention, it is indeed possible that the term "preparing file retrieval requests" could have the same meaning as "decoding NFS requests." However, the Federal Circuit has repeatedly cautioned against limiting the scope of the claimed invention to the embodiments disclosed in the specification. See, e.g., Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (collecting cases); see also CCS Fitness, 288 F.3d at 1366 (noting that "simply . . . pointing to the preferred embodiment or other structures or steps disclosed in the specification" is not sufficient to narrow the meaning of an unambiguous claim term). Because defendant has done nothing more than suggest that "file retrieval requests prepared" and "preparing reply messages" should be construed according to the preferred embodiment, the court declines its invitation to read these limitations into the disputed claim terms.

Having rejected defendant's attempt to limit the claim to the preferred embodiment of the invention, the court returns to -- and here, agrees with -- plaintiff's argument that the terms "file retrieval requests prepared" and "preparing reply messages" are unambiguous and need not be construed by the court. Unlike the terms "encoding" and "decoding," the word of the claim terms at issue here do not involve technical terms of art. Indeed, the technical definitions of "retrieval" and "request" differ little from the ordinary meaning of the terms as used in everyday English. See IEEE Dictionary at 553 (defining "information retrieval" as "[t]he techniques used to recover information from an organized body of knowledge"); id. at 966 (defining "request" as, inter alia, "a command generated by a requester, to initiate an action on a responder"). Where there is no better way to define a disputed claim term than the claim language itself, there is no need for the court to construe the term. Johnson Worldwide Assocs., 175 F.3d at 989-90 ("[C]laim terms cannot be narrowed by reference to the written description or prosecution history unless the language of the claims invites reference to those sources.") Accordingly, the court holds that construction of the terms "file retrieval requests prepared" and "preparing reply messages" is unnecessary.
7. "file server means for receiving data from said media means, receiving data inquiries and transmitting data in response to said data inquiries"

The parties dispute the construction of the term, "file server means." The term appears in claim elements 1, 1(b), 3, 3(b), 3(c), and 3(d). (Herbst Decl. P 5, Ex. 3.) Within Claim 1, the term appears as follows:

1. A method of acquiring and displaying real estate information utilizing an information processing system containing file server means for serving files, said file server means having i/o means for receiving and transmitting data, and database storage means for storing information in database files, the method comprising the steps of:

   . . .

   b) storing digitized real estate data and related information as information records in said database storage means of said file server means in a manner in which data can be selectively accessed . . . .

(Id.) The complete phrase at issue appears in Claim 3 as follows:

3. A method of acquiring and displaying property related information utilizing an information processing system containing media means for receiving analog and digitized data and transmitting digitized data; file server means for receiving data from said media means, receiving data inquiries and transmitting data in response to said data inquiries; databases and database storage means for sorting, storing and retrieving information received, the method comprising the steps of: . . . .

   . . .

   b) transmitting said property related information in appropriate format to said file server means;

   c) said file server means analyzing said property related information and storing said property related information in related database storage means,

   . . .

   d) said file server means receiving an information request from multiple end users relating to the end users' information needs, the extent of information available to said end users being determined by said end users' access code . . . .

(Id.)

a. Is the term at issue a means-plus-function element?

The threshold issue is whether "file server means" constitutes a mean-plus-function element subject to Section 112(6). The parties dispute whether the phrase is a means-plus-function element.

As previously discussed, Section 112(6) applies to a limitation expressed as a "means or step for performing a specified function without the recital of structure, material, or acts in support therefor." 35 U.S.C. § 112, P 6. A means-plus-function claim "shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof." Id. However, a means-plus-function claim is limited to the structure, and equivalents, disclosed in the specification for performing that function. Default Proof Credit Card Sys., Inc., 412 F.3d at 1298. Thus, a court first must determine whether Paragraph 6 applies. Apple Computer v. Burst.com, Inc., 2007 U.S. Dist. LEXIS 33863, 2007 WL 1342504 at * 18 (N.D. Cal. 2007). Where it applies, the court must then identify the claimed function and the corresponding structure. Id. (citing Medical Instr. & Diag. Corp. v. Elekta AB, 344 F.3d 1205, 1210 (Fed. Cir. 2003). As noted above, the use of the word "means" in a term creates a presumption that Paragraph 6 applies. Id. However, that presumption is rebuttable by evidence that the limitation "recites sufficient structure or material for performing [the] function." Id. (citing
In determining whether section 112(6) applies here, the Court notes that the disputed phrase uses the word "means" combined with another term: "file server." Thus, as a threshold matter, the Court must determine whether Plaintiffs have overcome the presumption that section 112(6) applies. Plaintiffs contend that the presumption "fails" because the term, "file server," connotes a structure to a person of ordinary skill in the art, citing Cole and Envirco Corp. Defendants, in turn, argue that the presumption does apply, citing WMS Gaming, Inc. v. Int'l Game Tech., 184 F.3d 1339 (Fed. Cir. 1999).

In Cole, the issue was whether section 112(6) applied. There, the Federal Circuit affirmed the district court's conclusion that the term "perforation means … for tearing" was not a means-plus-function clause, because the claim sufficiently described a structure (i.e., the perforation itself) to perform the function of tearing. Cole, 102 F.3d at 531. Relying on the dictionary definition for the word "perforation," the court construed the term, "perforation means … for tearing" to mean "perforations." Id.

Similarly, in Envirco Corp., the issue was whether section 112(6) applied. There, the Federal Circuit held that the word "baffle" alone constituted sufficient structure, and trumped the use of the word "means." Envirco Corp., 209 F.3d at 1364-65. Relying on the dictionary definition of "baffle," the court stated "[b]ecause the term 'baffle' itself imparts structure, meaning a surface which deflects air, its use in the claims rebuts the presumption that § 112, P 6 applies." Id. at 1365. Accordingly, the court determined that the district court erred in construing the "second baffle means" as a means-plus-function claim element under § 112, P 6. Id.

However, in WMS Gaming, the Federal Circuit addressed a different issue. There, Federal Circuit had already determined that section 112(6) applied, and subsequently held that the district court erred by identifying the corresponding structure for a means-plus-function limitation as "an algorithm executed by a computer." WMS Gaming, 184 F.3d at 1349. The court held that this identification of structure was overly broad because it was not limited to the algorithm disclosed in the specification. Id. at 1348. Specifically, the court stated, "[i]n a means-plus-function claim in which the disclosed structure is a computer, or microprocessor, programmed to carry out an algorithm, the disclosed structure is not the general purpose computer, but rather the special purpose computer programmed to perform the disclosed algorithm." WMS Gaming, 184 F.3d at 1349.

Here, the Court finds Defendants have misapplied WMS Gaming. Unlike the current case, in WMS Gaming, the issue was not whether section 112(6) applied. There, the court had already determined that section 116(6) applied. Id. Rather, the issue there was whether the patent sufficiently disclosed the corresponding structure. Id. Because the issue in the current case is whether section 112(6) applies, the Court finds that WMS Gaming is factually inapposite.

The current case is more analogous to Cole and Envirco Corp. because there the courts considered the same issue now before this Court—whether section 112(6) applies. Similar to Cole and Envirco Corp., this Court finds the dictionary definition of the term at issue to be instructive here. As noted above, the relevant dictionary definitions of "server" are: (1) "a computer that manages centralized data storage or network communications resources. A server provides and organizes access to these resources for other computers linked to it." American Heritage Science Dictionary (2007); and (2) "On a local area network, a computer running administrative software that controls access to all or part of the network and its resources (such as disk drives or printers). A computer acting as a server makes resources available to computers acting as workstations on the network." Microsoft Computer Dictionary (4th Ed. 1994); see also American Heritage Dictionary (2007) (defining "file server" as "[a] computer that controls a central repository of data that can be downloaded or manipulated in some manner by a client."). Thus, the relevant dictionary definitions connote an inherent structure in the term, "file server."

Additionally, reviewing the operative claims on an element-by-element basis, the Court concludes that "server means" is not a means-plus-function term. Each of the functions recited as part of the claimed method have a corresponding structure that is evident from the language of Claim 1 itself or from Claim 3. First, it is clear from the patent and Claim 1 that the "file server" has "[input/output] means for receiving and transmitting data, and database storage means for storing information in database files." (Herbst Decl., P 5, Ex. 3.) Second, Claim 3 provides that the "file server" "receive[s] data . . . , and
transmit[s] data in response to said data inquiries." (Id.) Thus, consistent with the relevant dictionary definitions the term "file server" inherently connotes a sufficient structure such that the section 112(6) presumption does not apply here. Because the "file server means" element does not qualify for section 112(6) treatment, it is not limited to the structure corresponding to the claimed function as "described in the specification and equivalents thereof." 35 U.S.C. § 112, P 6. Instead, this Court construes the term in accordance with standard claim construction rules.

b. "file server"

The parties' proposed constructions are as follows. Plaintiffs' proposed construction for the term, "file server," is "a server that receives property related information, analyzes and stores that information in files, and provides data derived from one or more files responsive to requests." Plaintiffs' proposed construction for "file server" is inconsistent with their previous proposed construction for "server." As noted above, in construing "server" Plaintiffs opposed Defendants' importation of a "digital property information" limitation. However, in their proposed construction of "file server," Plaintiffs now seek a construction that imports a "property related information" limitation. Because Defendants argue that "file server" is a means-plus-function element, they do not offer an alternative construction. In construing "file server," the Court now turns to the claim language, the specification, and the prosecution history.

As to the claim language, the Court initially emphasizes that it has previously construed part of the term at issue when it construed the term, "server," as "computer system that receives, stores, and provides data." Because claim terms are normally used consistently throughout the patent, the usage of a term in one claim can often illuminate the meaning of the same term in other claims. See Rexnord Corp., 274 F.3d at 1342; CVI/Beta Ventures, Inc., 112 F.3d at 1159. As such, from the outset, the Court is partially guided by its previous construction of "server." To that end, a claim term is to be given its ordinary meaning unless the patentee has explicitly redefined the term, or the term itself is so ambiguous it is incapable of being understood without reference to the specification. See Johnson Worldwide Assocs., Inc., 175 F.3d at 991. Therefore, this Court will look to the ordinary meaning of "file server" unless there is evidence the patentee has otherwise redefined "file server" as having a wholly independent and unrelated meaning. In considering the term's ordinary meaning, the Court finds that "file server" does have an ordinary meaning as set forth in the relevant dictionary definitions, as noted above.

However, before turning to the '025 Patent specification, the Court does recognize that the claims at issue do limit themselves to "real estate information," (Herbst Decl. P 5, Ex. 3 at col. 14, ll. 34-36, Claim 1), and "property related information," (id. at col. 15, ll. 3-4, Claim 3).

Turning to the '025 Patent specification, the Court again finds that the specification's description of the term, "server," is compelling. (Herbst Decl. P 5, Ex. 3 at col. 5, ll. 23-25); see Vitronics, 90 F.3d at 1582 ("Usually, [the specification] is dispositive; it is the single best guide to the meaning of a disputed term."). The specification also references "file" and "server" together. The specification reads "]each file sent [from the Media's multimedia device 100] to the Server's computer 412 is designated a location, ensuring that it will be stored with other similar files on the database in the Server's computer 412. (Herbst Decl. P 5, Ex. 3 at col. 7, ll. 67-col. 8, ll. 3.) Consequently, if the Court is to construe "file server" differently than "server," the specification supports only a slight modification.

Turning to the '025 Patent prosecution history, the Court has not located, and the parties have not provided, guidance as to how to construe "file server."

Thus, having considered the claim terms and the specification, the Court construes "file server" as "computer system that receives, stores, and provides data. Said file server that stores data in the form of files and provides data responsive to user requests."
3. "filesystem facility"/"filesystem utility"

The term "filesystem facility" (or "filesystem utility") appears in claims 2, 3, 5, 8, 9, 10, and 13 of the 037 Patent. Following the pattern set out in its proposed construction of the term "network communications facility," plaintiff urges the court to define "filesystem facility" as "a facility that provides for the performance of a pre-determined filesystem function." For its part, defendant seeks to limit the disputed term to "the peer-level facility that consists of the file system and its associated multi-tasking interface function."

Because the court has determined that a multi-tasking interface function is a separate element of the claimed invention and not a component of any of the peer-level facilities, the sole remaining issue in construing the filesystem facility term is whether the filesystem facility's function must be "pre-determined," as plaintiff's proposed construction requires. The source of this limitation appears to be claim 5 of the 037 Patent, a dependent claim that recites a "filesystem facility [that] provides for the performance of [a] predetermined filesystem function." 037 Pat, 56:15-17. However, no such limitation appears in connection with use of the term in claim 2, a claim on which claim 5 depends. Generally, it is improper to read a limitation from a dependent claim into the independent claim on which it depends. See, e.g., Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1304 (Fed. Cir. 1999), cert. denied, 528 U.S. 1115, 145 L. Ed. 2d 812, 120 S. Ct. 933 (2000) (noting that if the patentee "intended or desired" to include a claim limitation present in a dependent claim in a broader, independent claim, "it could have done so explicitly"). The court sees no reason why it should do so in the instant case, and thus declines to read the "predetermined" limitation that appears in claim 5 of the 037 Patent into the filesystem facility term.

Reading the claim in light of the specification, the court concludes that the function performed by the filesystem facility is best described as "file system control." See 037 Patent, 3:53-3:56. The court therefore construes "filesystem facility" as "a peer-level facility for performing file system control functions."

5. "Filing Electronically"

Simplification's Construction
Submitting or transmitting to a taxing authority by way of devices, circuits, or systems utilizing electron devices.

Block's Construction
The act of entering a legal record by means of a computer automatically without manual intervention from the user.

With regard to the meaning of "filing," Block relies on a definition from Merriam-Webster's Online Dictionary. (D.I. 79 at 29.) Simplification, on the other hand, notes that in describing the process of filing the tax return ("Step 15" in the specification), the specification explains that the "electronic intermediary" "transmits the electronic forms to the taxing authorities." (052 patent at 6:66-67.) The Court concludes that Block's dictionary definition is not suitable. First, as Simplification notes, tax return information is confidential. 26 U.S.C. § 6103 ("Returns and return information shall be confidential . . . ."). Thus, construing "filing" to include entering into the "public record" would be inappropriate in the context of the patents-in-suit. Second, the Court's review of the claims reveals that the term "filing electronically" is used exclusively in conjunction with the term "tax return." Thus, as with the term "collecting electronically," see supra Part II.C.2, the Court sees no need to include the vague term "legal document" in its construction of "filing." Accordingly, the Court shall construe "filing" to mean, as Simplification contends, "submitting or transmitting to a taxing authority," a definition that is well supported by the specification's description of the electronic filing process. The Court shall further construe the term "filing electronically" to mean "submitting or transmitting to a taxing authority by means of a computer without manual intervention from the user."
d. filling the empty payload fields in said frames with data in packetized format

According to Bellcore, an "empty payload field" means "bits or time periods representing an absence of source data to be transmitted." (D.I. 144 at 11). Consistent with its definition of "empty payload field," Bellcore contends that "filling the empty payload fields" refers to outputting source data when it is available during a payload field interval. In support of its position, Bellcore directs the Court to Figure 12 of the '306 Patent and that portion of the specification which provides: "if the particular DTDM frame is empty and data is available at the parallel input, a signal is applied by the control to the tristate device to enable the data to be inserted into the particular DTDM frame via bus before it leaves the framer unit." ('306 Patent, col. 16, lines 49-55 (emphasis added)).

In response to Bellcore's proposed construction, FORE contends that an "empty payload field" means that a frame's payload has zero data in it. (D.I. 144 at 12). Consistent with its proposed construction of the term "empty payload field," FORE contends that "filling the empty payload fields in said frames" requires two steps: (1) that a complete empty frame is first created; and (2) after creation of the empty frame, the frame's payload is 100% filled with a packet. FORE contends that its construction is supported by the plain and ordinary meaning of the words used in the claim, as well as by the specification and prosecution history of the '306 Patent. For example, FORE points out that the language of Claim 1 contemplates generating multiple empty frames with frame timing information that can subsequently be filled with packets. 2 FORE also points out that Figure 2 of the '306 Patent shows a generated train of empty frames entering the DTDM assembler. In addition, the language accompanying Figure 2 provides: "[A] train 10 of DTDM frames with empty payload fields is generated" and "each of the frames in the train 10 has an occupied transmission overhead field (T)." ('306 Patent, col. 7, lines 27-28). FORE further points out that Figure 4 and its accompanying text illustrates how the train of empty frames is generated in the first instance. The text provides: "The topmost framer 52 in Figure 4 does not have any input service connected to it. It generates the train of empty DTDM frames which are sent to the following framers 53." ('306 Patent, col. 9, line 59-61).

2 Fore relies on that portion of Claim 1 providing:

- generating a bit stream comprising a sequence of frames, each of said frames including . . . frame timing information and an empty payload field, and

  filling the empty payload fields in said frames with data in packetized format. . . .

( '306 Patent, col. 17, lines 47-52 (emphasis added)).

In addition to the claim language and specification, FORE also directs the Court to the prosecution history of the '306 Patent. FORE contends that Bellcore distinguished prior art known as the Baran patent by stressing that the '306 Patent requires the generation of a sequence of empty frames first, and then filling the frames. Distinguishing Baran during the prosecution of the '306 Patent, Bellcore explained:

The transmission bit streams are formed entirely differently in the claimed invention in Baran et al. Thus, as indicated above, the transmission stream of the claimed invention is formed by first generating a bit stream comprised of frames with empty payload fields. Data from a plurality of sources which have access to the transmission stream are packetized. The packets are then inserted into the empty payload fields of the frames. The Baran reference in no way discloses the formation of a transmission bit stream by generating a sequence of frames with empty payload fields and picking up packets from a plurality of sources to fill the payload fields.

(D.I. 147, Ex. 7 at FSI001338 (emphasis added)). Similarly, Bellcore explained the '306 Patent during the prosecution with
the following analogy:

The stream of empty frames may be analogized to a train of empty freight cars. The empty freight cars are filled with data in packetized format from various sources which have access to the train of freight cars. The train, with its now filled freight cars, transmits the data to remote locations.

(D.I. 147, Ex. 7 at FSI001333 (emphasis added)).

After reviewing the parties' arguments in the context of the claim language, specification and prosecution history of the '306 Patent, the Court agrees with FORE's construction of the phrase "filling the empty payload fields in said frames with data in packetized format." The grammatical structure of the claim language confirms that multiple empty payload fields are generated, and then the empty payload fields are detected and then filled with packets. Stated another way, the frames cannot be filled until after they are generated and empty frames are detected. Indeed, the Court believes that this interpretation is consistent with Figures 2 and 4 of the patent specification and consistent with the position stressed by Bellcore during the prosecution of the '306 Patent. Accordingly, the Court construes the term "empty payload field" to mean that a frame's payload has zero data in it. The Court further construes "filling the empty payload fields" to mean that first the empty frames must be generated, and second the frames' empty payloads are filled with data.

The first and most salient dispute over construction of the '306 claims is whether a complete frame must be generated before a framer may begin filling it with data (FORE's position), or whether the framer can begin filling the "front" part of the frame with data while the "rear" end is still being generated (Bellcore's position). Although the district court's claim construction does not explicitly require that a "complete" frame must be generated before the payload fields are filled with data, we accept the parties' interpretation that the district court so held. Thus, the question before us is whether the first claim step ("generating") must be completed, for at least one frame, before the second step ("filling") can begin.

We conclude that it does not. FORE, citing several cases in which we have construed method claims to require sequential performance of their steps, seems to suggest a general principle that method claims should be construed to require sequential performance of their recited steps. The precise question here is not whether the first step must be performed before the second step is performed, but whether it must be completed before the second step is begun. Regardless, as we recently reiterated in Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1369-71, 65 USPQ2d 1865, 1869-70 (Fed. Cir. 2003), the steps of a method claim need not be performed in the order written unless logic, grammar, or the content of the specification dictates otherwise. See also Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1342, 59 USPQ2d 1401, 1416 (Fed. Cir. 2000) ("Unless the steps of a method actually recite an order, the steps are not ordinarily construed to require one.").

In the case of the '306 patent, neither logic, grammar, nor the specification compels the conclusion that "generating" must be complete before "filling" may begin. It is undisputed that some "generating" must precede "filling," because at least part of a frame must be generated before it can begin receiving data. But unlike railroad boxcars, in which filling of a partially generated car might pose some problems, frames are capable of receiving data even if they are only partially generated. Consequently, logic does not demand that the filling process must wait until the rear boundaries of the frame have been generated.

Nor does grammar demand such a result. Because both "generating" and "filling" are continuous and concurrent processes in the method of the claims, it makes little sense to speak of the generating process being "complete" before filling begins. Indeed, as Bellcore notes, a strict grammatical requirement that the first step be complete before the second begins would lead to an unreasonable interpretation of the claim. The first step of the claim recites generation not of a single frame, but a "bit stream comprising a sequence of frames." If the first step must be completed before the second step begins, then all the frames, not just one, must be generated before any data may be inserted into the bit stream. While such a mode is theoretically possible, it would be manifestly unsuitable for continuous transmission of data in a telecommunications network.

Nor does the specification teach that generating must be completed before filling can begin. It is fair to say that the
specification is silent on the subject of whether frames are generated "byte-by-byte," as Bellcore suggests, or whether complete frames are generated before data insertion begins, as FORE contends. FORE argues that Figures 2 and 4 of the specification indicate that empty frames must be generated before they can be filled. However, we agree with Bellcore that Figure 2 depicts the claimed process only schematically, not literally. While Figure 2 does show a train of pre-generated frames entering a "DTDM assembler," Figure 2 obviously does not attempt to explain how frames arise, because Figure 2 shows frames arriving from an undepicted source. Moreover, despite FORE's argument to the contrary, Figure 4 of the patent clearly depicts a "DTDM assembler" comprising a framer (52) that generates empty frames. Thus, to interpret Figure 2 literally would set it at odds with Figure 4: Figure 4 indicates that a "DTDM assembler" generates empty frames internally, instead of receiving them from an external source as depicted in Figure 2. Figures 2 and 4 therefore do not compel FORE's interpretation.

Nor does the specification describe any circuitry or algorithm that would delay the filling process until a complete empty frame was generated or received, or any indication that frames are passed from framer to framer as frame-long chunks of data rather than byte-by-byte. Such features might be expected if FORE's interpretation were correct. However, the specification does disclose a feature that would allow a framer to begin filling frames before generation was complete. According to the specification, each frame comprises a "transmission overhead field" containing information about the contents of the frame. Included in the overhead field may be a flag indicating whether the frame is empty or full. '306 patent, col. 6, ll. 61-65. Because the transmission overhead field is shown preceding the payload field in the bit stream, see id. Fig. 1, a framer can determine whether an incoming frame is "empty" or "full" when it receives the overhead field, even if the remainder of the frame has yet to be generated. Accordingly, the embodiment described in the specification permits a framer to begin inserting data once it has received the overhead field and the first bytes of the payload field, without complete generation of an empty frame. This description supports Bellcore's interpretation.

Finally, FORE contends that Bellcore limited itself to a "sequential" interpretation of the claims during prosecution. When distinguishing the pending claims from the prior art (the Baran reference), Bellcore described the claimed method as "first generating a bit stream comprised of frames," and "then" inserting packets "into the empty payload fields of the frames." Statements in the prosecution history will limit claim terms to exclude interpretations disclaimed during prosecution. Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 USPQ2d 1673, 1676-77 (Fed. Cir. 1995). However, no such disclaimer took place here. The Baran reference which Bellcore was traversing used a completely different system of multiplexing. Bellcore did not disclaim coverage to concurrent generating and filling to overcome Baran, nor did Bellcore distinguish Baran by arguing that its invention required complete generation of the frames before filling could begin. The prosecution history therefore does not address whether generation of an entire frame must be completed before filling begins.

In summary, neither precedent, grammar, logic, specification, nor prosecution history dictates that a complete frame be generated before the filling process may begin. Given that the specification discloses features of the overhead field that would permit filling to begin before generation is complete, it would be error to impose upon the claims a requirement that filling cannot begin until one or more empty frames are generated completely. We therefore agree with Bellcore that the claims encompass the insertion of data into a frame's empty payload field while the frame is still being generated.

MAYER, Chief Judge, dissenting.

While I do not take issue with the court's construction of the simultaneous transmission language or the empty payload field requirement, Bell Communications ("Belcore") conceded that under the district court's claim construction, it could not prove infringement of these limitations as well as the frame limitation of claims 1, 3, and 4 of United States Patent No. 4,893,306 ("'306 patent"). Because the district court correctly concluded that the '306 patent requires generation of a complete frame prior to filling, however, I would affirm the judgment of non-infringement.

Claim 1 of the '306 patent requires, inter alia, "generating a bit stream comprising a sequence of frames, each of said frames including a transmission overhead field containing frame timing information and an empty payload field, and filling the empty payload fields in said frames with data in packetized format from a plurality of sources ... " '306 patent, col. 17, ll. 47-53, (emphasis added). While the steps of method claims may not necessarily have to be performed sequentially or each
step fully completed before the next begins, there are method claims that require full completion of each step prior to the start of the next and a strict adherence to the sequential order. The plain meaning of the claims themselves, the place that all claim construction must begin, mandates that the generating step must be completed prior to the beginning of the filling step. CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366, 62 USPQ2d 1658, 1662 (Fed. Cir. 2002) (There is a heavy presumption that the plain meaning of the claim language controls and can only be overcome in limited circumstances.).

"Fill" is defined as "to supply with as much as can be held or contained; to put or pour something into (a receptacle) till no more can be received." 5 Oxford English Dictionary 908 (2nd ed. 1989). The Webster's Dictionary provides almost the identical definition. Webster's Third New International Dictionary 849 (1993). Logic dictates that an incomplete container or frame cannot be filled because filling requires a finite volume. The patentee could have chosen alternative language to convey partial frame filling, whether by expressly stating the possibility or using a verb such as "placing" which would not require a finite volume, but did not do so. The prosecution history confirms this construction. In overcoming the Baran reference, the patentee stated that the claims require "first generating a bit stream comprised of frames with empty payload fields. . . . The packets are then inserted into the empty payload fields . . . " The patentee stated that first frames, plural, are generated and then data is inserted. The patentee makes no mention of generating the transmission overhead field of a frame and the first boundary of the payload field and then inserting data on a byte-by-byte basis. And the fact that Baran uses a different type of multiplexing is of no matter. Clear assertions made during prosecution in support of patentability, whether or not actually required to secure allowance of the claim, can create an estoppel. Texas Instruments, Inc. v. United States Int'l Trade Comm'n, 988 F.2d 1165, 1174 (Fed.Cir.1993).

The court frames the issue as whether the specification or the prosecution history obviates the construction that filling could begin into a partially generated frame and answers in the negative. While the specification may not expressly exclude such a construction, nothing supports it either. The specification only speaks of generated frames and is silent as to anything less.

The court cites to a paragraph in the specification and argues that it presents a possible mechanism for byte-by-byte insertion prior to completion of the frame. Ante, at 8-9. The cited portion of the specification states: "Typically, the bit rate of the DTDM bit stream illustrated in FIG. 1 is about 150 Megabits/sec. The following information may be available in the overhead field of every DTDM frame; frame alignment word for frame timing, empty/full status of the frame, and span identification." '306 patent, col. 6, ll. 61-65. This statement offers nothing more than the components that make up a frame and certainly does not provide support for partial frame filling. While the court is correct that it is fair to say that the specification is silent about whether frames are generated byte-by-byte or whether complete frames are generated before data insertion begins, the patentee should bear the burden for the lack of information and the plain meaning of the language chosen by the patentee should control.

2. Film

A film is a thin layer of material. A film may have voids, cracks, or other discontinuities.

J. Filter Conditions: Defendants propose the following definition of "filter conditions":

Limitations or conditions that determine which of the network vendors will receive a buyer's request for quotation and/or which buyers will receive a response from a network vendor.

The limitations or conditions included in the RFQ and/or the response are filter conditions, but they certainly are not the only filter conditions described in the '328 patent. For example, the specification also refers to additional filter conditions that the network adds that prevent all sellers and all buyers from being matched equally when the buyer and seller filter conditions match each other (e.g., Col. 7, ll. 19-47). These filter conditions are not typically in the request or response, and thus are not part of the discussion at column 8 of the '328 patent relied upon by Defendants.
This definition is consistent with the language of the specification and applies regardless of whether the filter conditions are set by a buyer, vendor, or network software. For example:

filter conditions determine which of the network sellers will receive a buyer's request for quotation

Col. 1, ll. 14-16.

Alternatively, or in addition, the vendor responses may likewise be filtered to satisfy conditions of the vendors responding or in accordance with predefined conditions for facilitating a linkage between the prospective buyer and an acceptable seller.

Col. 8, ll. 16-20

The buyer and vendor filters may represent in their simplest form defined classes of suppliers and/or buyers and may extend to delineate conditions of sale and/or purchase. Limitations or conditions included in the RFQ and/or in the response are defined for purposes of the present application as filter information or simply "filters". Filtering performed by a quotation system computer may simply involve limiting the network members to whom the RFQ is given and/or to whom responses are given or may be a more complex selection process.

Col. 5, ll. 15-25 (emphasis added).

It is SST's contention that the term "filter conditions" must exclude product information. In its opening brief SST expressed the belief that "defendants will try to claim that the buyer filter conditions may consist merely of a code or label that specifies the product or class of products that the buyer wants to buy. In other words, if the buyer merely states he is interested in purchasing light bulbs, defendants are expected to argue that the code designating light bulbs in the RFQ is a buyer filter condition, and thus meets the language of the claim." (at p. 16).

Defendants disavow such a narrow meaning of filter conditions imposed by the buyer: "Defendants' argument is not that a filter condition set by a buyer must be a product code. Defendants acknowledge that the specification describes filter conditions other than product codes (e.g., geographical limitations, quantity limitations, etc.), but there is simply no support for SST's contention that the intrinsic record requires that the buyer-set filter conditions exclude product information." (Defs' Opening Br. at p. 6). (emphasis in original). Thus the issue is whether filter conditions can include product designation, as Defendants contend or whether filter conditions must exclude product designation, or SST contends.

The term "filter condition" is used extensively in the claims. At no point are specific goods and services excluded from being selected as filter conditions. SST argues that the language of claims 12 and 13 demonstrates that the product cannot be a filter condition. Claim 12 of the '328 patent specifies that the filter means filters a buyer's RFQ to determine which sellers can supply the goods and services specified in the RFQ. Claim 13 which is dependent on claim 12 adds the additional "step of accepting filtering conditions from said potential buyer, and utilizing said filter conditions in said step of filtering to determine a subset of potentially capable sellers." SST contends that Defendants position that goods and services specified in the RFQ are buyer filter conditions cannot be correct because then claim 13 would be rendered superfluous. If the product of claim 12 were a filter condition, claim 13, which adds the step of accepting filtering conditions from the buyers, would add nothing to claim 12. Defendants respond that there is nothing inconsistent with having a product serve as a filter condition in both contexts with other filter conditions added in the claim 13 context.

Relying upon preferred embodiments in the specification, SST proffers examples that are consistent with its contention that a product cannot be a filter condition. Fig. 7 shows a separate line for "Product Identification" and below it has a line reading "Vendor Qualifications (Filter Conditions)." A note at the bottom reads: "Buyer Filter Conditions Might Include Language Spoken, Currency of Quotation, Type of Vendor (e.g. Manufacturer, Distributor, Retailer, Etc.). Or Location of Vendor."

Fig. 2A of the patent includes a flow chart. In the box representing the second step it is stated that "The Buyer Next Selects A Product Type, e.g.: Computer Products, Appliances, Electronic Parts and Components, Et Cetera." In the box representing the fourth step it is stated: "The Quotation System Processes The Request by Selecting a Class of Vendors Who Sell The
Requested Product(s) and Meet The Filter Requirements Of The Buyer, Vendor and The Quotation System." SST argues that his demonstrates that simply designating a product does not constitute specifying a filter condition.

SST relies upon the steps designated in Fig. 5 and Fig. 6 for the same purpose. These examples cannot serve to define filter conditions. Fig. 7 does not state that filter conditions cannot include product identification. It may be a preferred embodiment, but a preferred embodiment may not be used to narrow a claim construction.

SST quotes from the Summary of the invention to support its contention that filter conditions are optional: "selecting one or more appropriate vendors to receive the buyer's request for quotation based on filter conditions, if any, set by the buyer, vendor and the network software." (Col. 2, ll. 2-4). Read in its entirety the Summary of the Invention portrays the selection of vendors strictly through the use of filter conditions. The "if any" probably reflects that the network and the vendor might not set filter conditions, but the process must be through the use of filter conditions.

The claims themselves do not exclude the product from the term "filter condition." The specification includes goods and services as a category of filter condition. Use of filter conditions by a vendor is described as follows:

When a vendor wants to receive requests for quotation over the network, the vendor notifies the network of the class of goods or services in which the vendor deals (a "request for quotation class definition"). This can be communicated by voice, telephone, fax, et cetera, or by use of programming provided for that purpose, but the preferred method is to use programming provided for that purpose by the network. The request for quotation class definition is transmitted to the network and the network uses that definition to filter all requests for quotation routed to the vendor, i.e., to the class defined by a buyer of which the vendor is a member. In this way the vendor receives only those requests for quotation which conform to the vendor's request for quotation definition. The number of vendors within a class to receive a request for quotation may be very large. To keep the process manageable network software may be arranged to limit the number of vendors to receive a request for quotation.

Col. 7, ll. 31-47 (emphasis added).

Here the vendor first defines a class of goods or services in which the vendor deals. The network then uses that class definition to filter requests for quotation routed to the vendor. The class of goods and services set by the vendor is a filter condition as that term is used in the specification.

Defendants' definition of "filter condition" is the proper one.

G. Filter Means: The term "filter means" appears in claims 1, 4 and 12.

Claim 1 recites:

filter means for filtering the network members in said storage to determine which network members are to receive said request for quotation based upon filter conditions set up by the network buyer in said request for quotation or by the central processing unit in accordance with preestablished conditions.

Claim 4 recites:

filter and broadcast means for receiving, over said data network, requests from said requestor to engage in transactions with unspecified vendor terminals, and for filtering said requests to determine with which vendor terminals said requests should be matched.

Claim 12 recites; in pertinent part:

- 2103 -
communicating, over said data network, to a filter means, at least one request for a quotation from a potential buyer of said goods or services

filtering, at said filter means, the at least one request in order to ascertain a set of sellers potentially capable of supplying said goods or services.

The parties agree that these limitations are written in means - plus - function format, making applicable 35 U.S.C. § 112, P 6 (1994). "Under that provision, '[a]n element of a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.' We have stated that 'for a means-plus-function limitation to read [literally] on an accused device, the accused device must employ means identical to or the equivalent of the structures, material, or acts described in the patent specification. . .'."

WMS Gaming, Inc. v. International Game Technology, 184 F.3d 1339, 1347 (Fed. Cir. 1999).

The "filter means" terms are means-plus-function limitations, and because the claims limitations in each of these claims do not by themselves provide any structure, the term is subject to construction under 35 U.S.C. § 112, P 6.

Defendants contend that these claims fail the § 112 test as applied in WMS Gaming, Inc., 184 F.3d at 1349: "[i]n a means-plus-function claim in which the disclosed structure is a computer, or microprocessor, programmed to carry out an algorithm, the disclosed structure is not the general purpose computer, but rather the special purpose computer programed to perform the disclosed algorithm."

The next step in construing a means-plus-function claim limitation is to look to the specification and identify the corresponding structure, if any, for the function. Med. Instrumentation & Diagnostics Corp. v. Elektra AB, 344 F.3d 1205, 1210 (Fed. Cir. 2003).

There is an initial question whether one evaluates the recital of the structure that implements the means through the eyes of a lay person or through the eyes of one skilled in the art. At the Markman hearing counsel for defendants argued that skill in the art is irrelevant in this inquiry and that it is an English test, not a technical test:

This patent doesn't use a means plus function test once, it uses it repeatedly. And, the price of using means plus function is that you must in fact describe what is the mechanism that actually performs the function. You can't just say any old means. You can't say, well, anybody of ordinary skill would know that a computer could store or could write a computer program to sort or could write a computer program to select. That may be true. But, . . . that isn't the issue.

The issue is whether the patentee, in the specification, has described it in sufficient detail that it could be built, not that it's anyway that you could do it but the way, and he limits it to the way he discloses it.

Finally, the skill [in] the art. Your Honor has made it clear, from your earliest questions, that you're influenced by what, how skilled somebody of ordinary skill would be in trying to decide could you use a computer to store this. I think that may be true but it's irrelevant to the issue. Because, the question is not whether a rocket scientist or a computer expert or simply a purchasing agent would understand that you could use a computer memory or hard drive to store things, we'll stipulate that. The issue is whether there's any linkage to the function of storing the membership described in the specification. That's an English test. That's not a technical test. And, in fact, there is no such linkage that is found here.

Transcript, March 31, 2006 hearing, pp. 94, 96.

Defendants' linkage analysis is based upon a faulty premise. The determination of whether the specification has described the structure in sufficient detail is not simply an English test; it is a technical test in that the sufficiency of the disclosure of
the structure is based on the understanding of one skilled in the art.

We have previously observed that an analysis under § 112, P 2 is inextricably intertwined with claim construction, and that in the § 112, P 6 context, a court's determination of the structure that corresponds to a particular means-plus-function limitation is indeed a matter of claim construction. As it is well established that claims are to be construed in view of the understanding of one skilled in the art, the closely related issue concerning whether sufficient structure has in fact been disclosed to support a means-plus-function limitation should be analyzed under the same standard.

For the reasons outlined above, we thus conclude that the District Court erred by failing to assess whether sufficient structure was disclosed in the specification to support the high-voltage means limitation based on the understanding of one skilled in the art.

Turning to the claim 1 function, "filtering the network members . . . to determine which network members are to receive said request for quotation," Defendants argue that the only structure disclosed in the '328 patent that corresponds to this function is the software running on the computer system, i.e., specific flow chart/algorithm illustrated in Figures 5 and 6, rather than the quotation system computer itself.

Defendants submit as the structure related to filtering function of claim: "the algorithm set forth in Figures 5 and 6 but not including or using a central data base that contains more information than is required to determine which network vendors should receive an RFQ." The court has already construed the disclaimer upon which Defendants rely to support the "but not including" portion of this proposed structure. SST argues that the algorithm disclosed in Figures 5 and 6 is not the only filter means disclosed in the specification and that the term "filter means" should be more broadly construed as "a computer programmed to apply or compare specified conditions to an item(s) of information to determine if the condition is met or not by the item(s) of information." (Pl.'s Responsive Br. at 6).

In WMS Gaming Inc. v. International Game Technology, 184 F.3d 1339 (Fed. Cir. 1999) the court noted that 35 U.S.C. § 112 permits the use of means-plus-function language in claims with the proviso that the claims are limited to the structure, material, or acts disclosed in the specification and their equivalents. The Federal Circuit determined that the District Court had erred in construing the claim in question to cover any table, formula, or algorithm that performed the recited function rather than limiting the claim to the specific algorithm disclosed in the specification.

As the Federal Circuit stated, "[t]he written description of the . . . patent [was] almost completely devoid of any structure to support [the] limitation of the claim. The district court apparently took [that] lack of disclosure to indicate that the limitation read[] on any means for performing the recited function. However, [such a] construction is at odds with the requirements of 35 U.S.C. § 112." Thus, the structure in the present case must be limited to the tables, formulas, and algorithms recited in the specification.

Defendants argue that the algorithm in Figures 5 and 6 is the only relevant structure disclosed in the specification. SST disagrees with that proposition and cites several examples of other structures.

For example, SST cites to Col. 7, ll. 3-2, of the '328 Patent as an example of additional filter means recited in the specification. That section describes filters for time sequencing the transmission of RFQ's based upon distance, and for transmitting RFQ's based upon type of service selected by a vendor.

Additionally, Figure 2A is a flowchart that describes the system's user interface and how a user (buyer or vendor), and the network, might set filter conditions. The chart further demonstrates that filtering consists of comparing information to various conditions in order to see if those conditions are satisfied.

Figure 3 also pertains to filter means. It describes a process by which vendors can send specific offers to buyers that meet certain filter conditions that can be set by the vendor, buyer, and quotation system.

Thus, filter means cannot be limited to the algorithm in Figures 5 and 6. Rather, the definition of that term must encompass each of the various descriptions of the structure found throughout the specification. Moreover, the various figures described
above demonstrate that the algorithm operates to compare filter conditions set by the buyer, vendor and system, to various pieces of information provided by those same parties, to determine whether the conditions have been satisfied. As such, the court accepts SST's definition of filter means: "A computer programmed to apply or compare specified conditions to an item(s) of information to determine if the condition is met or not by the item(s) of information."

Finally, Defendants argue that "[b]ecause the function associated with the 'filter means' recitation in each of [the three] claims is slightly different, a separate claim construction analysis is appropriate for each of the claims reciting 'filter means.'" (Defs.'Opening Br. at 9). However, as stated above, when interpreting a claim term, one should read it not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification. Moreover, claim terms are normally used consistently throughout the patent. Thus, the above definition applies to filter means as it is used in each claim.

1723

10. "Final results file"

The parties dispute the meaning of the term "final results file." Defendants assert "final results file" should be construed to mean "a persistently saved file that includes all the records present in the first and second intermediate results files." Plaintiff contends the term is entitled to its ordinary meaning, but if the Court deems construction necessary, "final results file" should be construed to mean "a file that includes one or more records or fields from the first intermediate results file and one or more records from the second intermediate results file."

Because "final results file" has no ordinary meaning, this term must be construed. As discussed above, the claims and specification do not support a construction limiting a "final results file" to a file that is "persistently saved." The Court further finds neither the claims nor specification limits a "final results file" to a file that includes "all the records" from the intermediate results files. The specification explains that the "final results file" may go through post-processing so that "only unique instances of the records satisfying the query" are returned. Col. 18, lines 9-13. Therefore, the Court adopts Plaintiff's construction and construes "final results file" to mean "a file that includes one or more records or fields from the first intermediate results file and one or more records from the second intermediate results file."

1724

A. "Financial Card"

This term is used throughout the '645 patent. Plaintiff suggests the proper definition of the phrase is "any medium issued to a holder that provides access to financial benefits and resources." The Court agrees that Defendant's definition - "a tangible piece of plastic or similar material issued by a financial institution that authorizes the cardholder to purchase goods and services on credit or by debiting a bank account, for example, a credit card or debit card" - is more consistent with the intrinsic evidence.

Plaintiff's definition utilizes the broader - and more ambiguous - term "medium." This is an attempt to define an ordinary term that is readily understood in a manner that improperly expands the meaning beyond its customary understanding. A "financial card" is not a technical term; it is one understood by ordinary people, and the Court has little difficulty concluding that the ordinary meaning of this phrase refers to a tangible piece of plastic or other material, possession and ownership of which entitles the owner to credit or other sources of money.

This ordinary understanding of the phrase is confirmed by its usage in the patent and other components of the prosecution history. The '645 Patent's Abstract describes the invention as a "system . . . for presenting financial card (e.g., credit card, debit card) offers to potential customers." The Background of the Invention compares the invention to the use of direct mail campaigns to solicit customers, and observes the shortcomings of such efforts include the need for prospective customers to "complete the applications manually, mail them back to the financial institutions, wait for them to be processed, and then wait for the financial card to arrive in the mail." Col. 1, lines 47-51 (emphasis supplied). The Detailed Description of
Preferred Embodiments ("Preferred Embodiments") summarizes the process as concluding when "[t]he financial institution . . . processes the application and makes arrangements to send the financial card to the applicant." Col. 5, lines 3-5. The Summary of Invention describes the final step of the process as occurring when "a financial card in accordance with accepted offer terms is sent to the user." Col. 2, lines 28-29. This is reiterated in Claim 25, which consists of "[t]he method of claim 24 further comprising the step of sending to said applicant a financial card in accordance with said offer accepted by said applicant." Col. 8, lines 18-20. All of these references contemplate the "financial card" as a tangible item, and further contemplate the receipt of the financial card as both a necessary part of, and the culmination of, the process. In context, the card does not merely represent a token confirming a financial relationship, but is the means by which financial transactions are to be conducted. Therefore, not all acquisitions of credit (or other accesses to money) are described; only those that can be accessed via the use of a "financial card" are described.

Some of Plaintiff's statements during the initial examination process confirm the meaning gleaned from the patent itself. The PTO initially indicated it was rejecting certain claims because it regarded a financial card as "an abstract concept" and "merely a representation of the abstraction and therefore merely a model." In insisting "that the distribution, review, and acceptance or rejection of financial card offers is a real world activity," Plaintiff discussed current practices in the credit card industry and noted "[i]t is very difficult for credit card companies to determine if their marketing efforts are effective and whether they are soliciting appropriate candidates." Amendment to Patent Application filed February 2, 1999. This is merely one example; Plaintiff's response to the PTO is replete with references to the "credit card industry." At no time did Plaintiff suggest its invention could be used for other financial products, nor did Plaintiff utilize a term with greater breadth than "financial card." Indeed, to now argue for a more abstract understanding of the phrase appears inconsistent with the position Plaintiff took to persuade the PTO to reverse its initial rejection of the patent.

The Court also notes the '645 Patent, as approved on reexamination, included new claims 34 and 35. New Claim 34 consists of "[t]he method of claim 11 wherein said financial card is selected from the group consisting of credit cards and debit cards." Reexamination Certificate, Col. 2, lines 13-15. Claim 11 refers to "[a]n electronic method for applying for a financial card comprising" certain specified steps. Col. 7, lines 18-19. In supporting Claim 34 before the PTO, Plaintiff explained that "New Claim 34 depends from claim 11 and is directed to the type of financial cards for which an applicant may apply." Plaintiff's Response to Official Action dated December 3, 2003 at 5 (hereafter "Plaintiff's 2003 Response"). Thus, in declaring the invention selects financial cards from credit cards and debit cards - and not from anything else - the definition of financial cards is limited in the manner indicated by the Court.

Finally, by means of confirmation, the Court observes the prior art's use of the phrase is consistent with the Court's interpretation. See Arthur A. Collins, Inc. v. Northern Telecom Ltd., 216 F.3d 1042, 1044-45 (Fed. Cir. 2000) ("Even when prior art is not cited in the written description or the prosecution history, it may assist in ascertaining the meaning of a term to a person skilled in the art."). For instance, Patent No. 5,619,559 - Financial Card Authorization System - "relates generally . . . to a system for authorization of financial card transactions." The Background and Summary of the Invention explains that "[f]inancial cards, usually credit cards, are commonly used by purchasers in retail establishments," and proceeds to explain the use of an electronic device to obtain information from the card and transmit it to a financial institution to insure verification of the card and approval for the transaction. Col. 1, lines 14-28. Patent No. 5,038,022 - Apparatus and Method for Providing Credit for Operating a Gaming Machine - describes a device that "enables the player to obtain credit without having to leave his place at the [gaming] machine with the use of a financial card of the type such as any well known credit card or a debit card such as an ATM card." Col. 3, lines 15-19. The patent elsewhere discusses use of an electronic reader that transfers data to and from the magnetic strip on the card. These and other examples 2 confirm not only that a financial card is a tangible object, but also that the tangible object is more than a mere talisman confirming a contractual relationship between the customer and the financial institution.

--- Footnotes ---

2 A non-exhaustive list of additional prior art using the term "financial card" in the same or similar manner includes Patent Numbers 5,530,232, 5,884,289, 5,608,203 and 5,650,604.

--- End Footnotes ---
the phrase in the manner Defendant suggests, which is true - but this does not mean the definition of "financial card" is not already limited in light of the meaning it already has.

Plaintiff also contends the PTO understood the term to be as broad as Plaintiff now suggests, but the Court is not persuaded. First, Plaintiff points to the Examiner's initial rejection on reexamination of all the '645 Patent's claims based on Patent No. 5,878,403 - Computer Implemented Automated Credit Application Analysis and Decision Routing System (referred to by the parties as either "the '403 Patent" or "DeFranscisco"). DeFranscisco's Summary of the Invention describes "a centralized credit application entry and routing system which accepts applications from, for example, automotive dealerships, electronically and selectively forwards them to funding sources, including funding sources having computerized credit application systems." Col. 8, lines 60-67. In seeking reexamination of the '645 Patent, Defendant argued before the PTO that DeFranscisco already broadly described or anticipated all computerized applications for credit, including the '645 Patent. Plaintiff discerns some meaning from the initial rejection of the '645 Patent based on DeFranscisco, contending that because DeFranscisco did not involve a "tangible plastic card" the Examiner must have understood the '645 patent also did not require a "tangible plastic card." The Court believes Plaintiff reads too much into the sequence of events. Plaintiff's invention can be understood as a means for applying for a particular type or form of credit. In citing DeFranscisco, the PTO indicated Plaintiff's invention was anticipated and embraced by a prior invention designed to allow for the computerized application for a broader universe of credit, regardless of whether a financial card is involved. This is supported by language from DeFranscisco, most notably where it states "[t]he present invention allows a bank to have one standardized network and application interface . . . however as would be readily appreciated by one skilled in the art, this can be expanded to include non-automotive customers." Col. 31, lines 36-40. The involvement of a "financial card" was simply not relevant to the PTO's citation to DeFranscisco. Moreover, the PTO - at Plaintiff's urging - reversed itself and determined DeFranscisco did not anticipate the '645 Patent. Assuming any meaning can be gleaned from the PTO's initial position, that meaning ceased to be relevant when the PTO's position changed.

3 Plaintiff insists Defendant must explain its "position shift." The Court discerns no position shift. Defendant initially contended DeFranscisco is so broad that it encompassed Plaintiff's invention. That position was rejected because, essentially, Plaintiff's invention is different from DeFranscisco. Defendant now contends the scope of Plaintiff's invention is narrower than Plaintiff asserts. These positions are not inconsistent.

Finally, Plaintiff relies on another communication from the PTO dated July 16, 2004, that rejected certain claims in the '645 Patent due to obviousness. On page four the PTO referenced that portion of DeFranscisco indicating "[e]ach funding source is able to send back additional information, such as score, grade, etc., . . . . There is also a comment field to enter more complex things, for example, a list of rate/term options.' Col. 13, lines 65- Col. 14 line 2." The PTO then referred to Figure 3Q from DeFranscisco "which shows financial card (i.e. loan) term data from a plurality of financial institutions." This reference does not clearly indicate the PTO interpreted "financial card" as coextensive with or more broadly than the word "loan." In fact, considering the context, it appears the PTO considered the term "loan" to be broader than and encompassing of "financial card," such that a "financial card" is only one type of a loan arrangement. At best, the PTO's usage on July 16, 2004, is ambiguous, and is insufficient to overcome the other clear sources cited above.

B. "Financial Card Terms"

The parties' competing definitions of this phrase are remarkably similar. Plaintiff suggests the phrase refers to "terms that relate to a financial card offer, e.g., type of offer, interest rate, fees, amounts, etc." Defendant advances a definition limited to "material terms of a financial card offer (such as APR, annual fees, etc.) that are pre-set by each financial institution and can be presented to consumers." The crux of Defendant's argument seems to be its belief that the phrase is limited to terms of the card offered to customers, and not to requirements or restrictions imposed by the financial institution. Defendant's Markman Brief at 16. Plaintiff does not attempt to include such concepts within the rubric of "financial card terms," but insists the phrase may "include detailed information concerning how the applicant can proceed with the transaction" or
"details about the incentive program involved with the offer." Plaintiff's Reply Brief at 15. The Court agrees with both parties.

Language in the '645 Patent suggests the "terms" consist of information perused and considered by the consumer, not the financial institution. For instance, "[t]he applicant may peruse, via the computer display, the 'federal box' and other details of each of the offers to find the one that is most attractive..." Col. 4, lines 65-67. Claim 28 comprises an apparatus "for presenting to said applicant...financial card term data..." Col 8, lines 61-63. This understanding is further confirmed by Plaintiff's explanation to the PTO. Plaintiff's 2003 Response at 19. In the absence of any argument to the contrary, the Court agrees the phrase "financial card terms" does not include eligibility policies or requirements imposed by the financial institution. Finally, without disagreement from Plaintiff, Defendant contends financial card terms are pre-set by the financial institution for presentation to consumers. In fact, Plaintiff does not even address this aspect of Defendant's argument, and it serves to reinforce the limitation acknowledged above.

On the other hand, aspects of Defendant's definition are unduly narrow. There is no support for further limiting "financial card terms" to the interest rate, APR, annual fees, and other information specifically detailed as examples in various places within the Patent. E.g., Col. 4, lines 31-43.

With these conclusions, "financial card terms" are "terms that relate to a financial card offer, e.g., type of offer, interest rate, fees, APR, credit limit, incentive programs, etc., that are pre-set by the financial institution and presented to consumers for consideration in deciding whether to accept the offer." This definition contains the breadth necessary (and to which Plaintiff is entitled) to include information about the offer that may be important or enticing to a potential customer. It also excludes requirements imposed by the financial institutions before a particular offer may be presented to a particular consumer.

A. "Financial Instrument"

EBS argues that when taken together, the prosecution history and the ordinary meaning of the term, "financial instrument" requires the broadest of definitions:

Any instrument (e.g., note, contract, agreement) having monetary value.

(Gingerer, Att'y for Pl., Decl., Ex. 2 at 1.) EBS comes to this conclusion by synthesizing definitions from two financial dictionaries, the Dictionary of Banking and Financial Services, 294 (2d ed. 1985), and the Dictionary of Financial and Investment Terms, 202 (3d ed. 1991).

Conversely, ICE argues that EBS's construction is overbroad, outside the scope of the '627 Patent, and should be more narrowly construed. ICE emphasizes a definition of "financial instrument" constrained by the understanding of one skilled in the art of finance and trading at the time the '627 Patent was issued. (Harrison, Att'y for Def., Hr'g Tr. 15: 6-9.) According to ICE, one skilled in the art would understand a "financial instrument" to mean "a contract involving currency, equities, securities, fixed securities, or indexes thereof." (Harrison, Att'y for Def., Hr'g Tr. 13: 6-8.) In other words, a financial instrument "must have some underlying financial asset." (Harrison, Att'y for Def., Hr'g Tr. 13: 10-11.) In particular, ICE maintains that "financial instrument" does not include "commodities" and points to the fact that the Commodities and Futures Trading Commission (CFTC) website distinguishes between "commodities" and "financial instruments." (Harrison, Att'y for Def., Hr'g Tr. 53: 11-17.)

The industry to which the '627 Patent relates is that of "traders dealing in financial instruments." n3 U.S. Patent No. 6,014,627 (issued Jan. 11, 2000). In general, the term, "financial instruments," does not appear to include only those instruments directly tied to an underlying financial asset. For example, the Dictionary of Banking and Finance, 159 (Standard Chartered Bank, 1st Ed., 1998), defines financial instrument as:

A contractual claim held by one party on another, such as a security, currency, or derivatives contract. A financial instrument entitles the other to be paid in cash or with another financial instrument.
The Handbook of International Financial Terms, 220 (Oxford Univ. Press, 1st Ed., 1997), maintains an even broader definition:

Generic term for those securities or contracts which provide the holder with a claim on an obligor. Such instruments include common stock, preferred stock, bonds, loans, money market instruments, and other contractually binding obligations. The common feature which differentiates a financial instrument from a commercial or trade credit is the right to receive cash or another financial instrument from the obligor and/or the ability to exchange for cash the instrument with another entity. The definition can also include instruments where the claim is contingent, as with derivatives.

An enforceable contract obligating one party to pay money or transfer property to another. Credit documents, (e.g. drafts, bonds, etc.) are instruments, as are documents of title, such as deeds or stock certificates.

--- Footnotes ---

n3 This Court, like other courts in this district, notes that the Federal Circuit is currently examining the role of dictionaries in claim interpretation. See Phillips v. AWH Corp., 376 F.3d 1382 (Fed. Cir. 2004); see also Astrazeneca Pharma., LP v. Mayne Pharma., Inc., 352 F. Supp. 2d 403 (S.D.N.Y. 2004).

--- End Footnotes ---

The aforementioned dictionaries do not limit or restrict the definition of "financial instrument" to the characteristics of an intangible asset. While financial instruments are as a rule created to raise capital, the definition of a financial instrument is not contingent upon the underlying asset being a physical asset such as currency. For instance, the Department of the Treasury, 12 C.F.R. §§ 563, 567, simply provides that:

A fundamental characteristic of all financial instruments is that they give rise to cash flows. The value of any financial instrument can be estimated by projecting the amount and timing of future net cash flows associated with the instrument, and discounting those cash flows with appropriate discount rates.

See 12 C.F.R. §§ 563; 567. As such, reading the '627 Patent in light of the relevant industry standards and the ordinary meaning of the terms, at least insofar as current dictionary definitions are concerned, the contested language must be construed as:

Any enforceable instrument having a monetary value.

OutlookSoft is correct that, in many respects, Hyperion chose to act as its own lexicographer for the term "financial schedule." The statements made during prosecution of the Hyperion patents clearly act to define "financial schedule" as a type of document. However, Hyperion did not surrender electronic documents in this definition. Accordingly, "financial schedule" is "a kind of document (whether a paper document or electronic file) that data comes from."

Claim Construction: "Financial Transaction"

A clear definition of "financial transaction" as used in the preamble is necessary to a determination of the meaning of many of claim 1's elements. The first reference to "financial transaction" in claim 1 appears in the claim's preamble, and many of claim 1's elements contain additional references to "transactions," including "transaction type," "transaction parameters" and "transaction information."

In their claim construction briefs, both parties agree that in this case, the preamble of claim 1 provides a limitation pursuant to Federal Circuit case law. See e.g., Corning Glass Works v. Sumitomo Elec. U.S.A., Inc., 868 F.2d 1251, 1257 (Fed. Cir.1989); Phillips Petroleum Co. v. Huntsman Polymers Corp., 157 F.3d 866, 872 (Fed. Cir. 1998). The parties vigorously dispute, however, the meaning of the critical phrase "financial transaction;" contained in the preamble to claim 1. Amazon generally contends that the phrase limits the claim to cover only transactions performed using electronic fund transfer systems, whereas IPXL generally contends that the phrase allows the claim to cover a much broader array of transactions. For the reasons set forth below, the Court finds Amazon's more narrow construction to be correct.

The language of the claim's preamble itself assigns two characteristics to "transactions

the transactions being characterized by a transaction type and a plurality of transaction parameters.

As such, each reference in claim 1 to "transaction" invokes both a "transaction type" and a "plurality of transaction parameters." An understanding that a claim 1's "transaction" is composed of a "transaction type" and a "Plurality of transaction parameters," while helpful when interpreting the limitations of claim 1, only affords a circular and incomplete understanding of "financial transaction"

Reference to the additional intrinsic evidence, namely the specification and the prosecution history, is required to further define claim 1's "financial transaction" limitation.

The '055 specification dictates that:

Except as otherwise used in connection with a specific activity, the term "transaction" is intended to broadly describe a wide variety of activities that are or may be performed using an EFT system. By way of example, but without limitation, this includes withdrawing cash, travelers' checks, bonds, and other negotiable instruments or other articles, depositing cash, checks, other negotiable instruments or other articles, transferring funds from one account to another, paying bills, credit card balances; or loan payments, casing checks or other negotiable instruments, obtaining account balance information, paying for the purchase of goods or services, operating gaming devices (e.g., casino games, lottery games) and performing a wide variety of other activities.

Col. 5, 11. 36-49.

Although this passage sets forth broad and sweeping language when defining "transaction," it is clear from the patentee's express definition that a "transaction" must be limited to "activities that are or may be performed using an EFT system." In this case, "the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in . . . the specification. . ." CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002). Because the patentee, in the
specification, has expressly incorporated "activities that are or may be performed using an EFT system" into the definition of "transaction," it is that definition that controls. Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998).

Consistent with the patentee's express incorporation of "EFT systems" into the definition of "financial transaction," the patent specification generally speaks of the invention as relating to EFT systems:

."ELECTRONIC FUND TRANSFER OR TRANSACTION SYSTEM." Invention Title.

."An electronic fund transfer (EFT) system" . . . Abstract (first words).

. electronic fund transfer systems such as automated teller machines." Col. I, ll. 12-13.

Moreover, the patentee has also given express guidance as to the meaning of "EFT system." In addition to the examples set forth at Col. 5, ll. 36-49, all of which the patentee claims "are or may be performed using an EFT system," the specification provides further guidance concerning the nature of an EFT system:

Electronic fund transfer (EFT) systems in general are well known. One example of an EFT system is an automated teller machine (ATM).

Col. 1. ll. 22-24.

EFT systems also include point-of-sale terminals and a number of other systems. Point-of-sale (POS) or point of interaction terminals (collectively referred to herein as "POS terminals") are used for example at grocery checkouts, gas station pumps and other retail locations to enable a user to pay for a purchase by using an ATM card, a credit card, a debit card or other similar methods. POS terminals also typically require a number of user inputs and transaction parameters to effect a transaction.

Col. 2, ll. 29-37.

Unsurprisingly, at least one unifying characteristic is found in every example of an EFT system set forth in the patent: each system directly and promptly allows the user to transfer or inquire about funds. This characteristic of allowing for direct and prompt transfer of or inquiry about funds is consistent with the plain meaning of "EFT system" and with the dictionary definitions offered to support that plain meaning.

Footnotes

1 The Court's understanding of the plain meaning of "EFT system" is supported and confirmed by the following dictionary definitions in accordance with Texas Digital Systems, Inc. v. TelegemixInc., 308 F.3d 1193, 1202 (Fed. Cir. 2002):

Electronic Funds Transfer: electronic funds transfer (EFT) utilizes computer and electronic components in order to transfer money or other financial assets. The New Palgrave Dictionary of Money & Finance (1992) at 745.

Electronic Fund Transfer System (EFTs): A variety of systems and technologies for transferring funds electronically rather than by check. The Language of Banking (1994) at 55.

These definitions are taken from specialized finance and banking dictionaries. As such, the risk of arriving at an "absurd result" from "indiscriminate reliance on definitions found in dictionaries" remains minimal. Liebscher v. Boothroyd 258 F.2d 948, 951, 46 C.C.P. A. 701, 1958 Dec. Comm'ty Pat. 437 (CCPA 1958). The '055 invention is generally directed to financial transaction systems and discloses a common banking and transaction system, an ATM system, as its preferred embodiment. Indeed, definitions taken from finance and banking dictionaries are particularly well-suited to analysis of the '055.
The Court finds further support for its interpretation of "transaction" from the prosecution history, which includes several statements by the patentee limiting his invention to only those transactions involving ATM machines. For example, in response to a January 6, 1999, office action rejecting the application's claims under 35 U.S.C. § 103 in view of prior art references Nadan and Martino, the applicant argued that Madan is not directed to an ATM machine as recited in claim 1. . . Neither Madan nor Martino discloses an ATM that enables a user to select from a single Screen transaction type and transaction parameters. Madan is not an ATM machine and does not address the same problems as those addressed by the present invention.

Such comments might suggest that the applicant intended the "transactions" related to his invention to include only ATM machine transactions in particular, rather than EFT systems in general. Despite these comments, the Court is not inclined to prescribe such a narrow construction of "financial transaction" so as to limit the claim to covering only transactions involving ATM machines. The Court does, however, note the apparent inconsistency between the positions taken by the applicant during his prosecution of the patent and the carefully hedged language of the '055 specification, which indicates that ATM systems stand as only the preferred embodiment and that other EFT systems may also be covered.

In light of the express definitions chosen by the patentee the prosecution history of the patent in suit, and the plain meaning of the term EFT, the Court construes the term "financial transaction" as follows:

The electronic transfer of funds, or the electronic inquiry as to funds, using an electronic funds transfer ("EFT") system such as an ATM system or a point of sale ("POS") system. Such electronic transfer of funds, or electronic inquiry as to funds, being characterized by both a transaction type and a plurality of transaction parameters.

The claim language of the '192 patent was construed in recent litigation in the Eastern District of Texas. See Mot. at 6; Khaliq Decl., P 2 and Ex. A (April 20, 2005 Claim Construction Order in Visto Corp. v. Seven Networks, Inc., Civil Action No. 2:03-CV-333 (Ward, J.)). Judge Ward's order is persuasive and highly relevant here, though not issue-preclusive against Sproqit or otherwise binding. See Verizon California Inc. v. Katz Technology Licensing, 326 F. Supp.2d 1060, 1069 (C.D. Cal. 2003). For the purposes of the motion for preliminary injunction (and only for purposes of the instant motion), the parties stipulate to adopting Judge Ward's Claim Construction Order, with the exception of the construction of the claim term "firewall." 4 Accordingly, for purposes of this motion, the Court adopts Judge Ward's Claim Construction Order per the stipulation.

4 Visto challenges Judge Ward's construction of the term "firewall" as incomplete for failing to exclude validation and authentication features, which are separate security features from firewalls. Mot. at 8-9. This issue was not raised before Judge Ward in the Eastern District of Texas litigation, but is raised here for the first time. Id. at 9 n.14. Visto suggests an alternate construction of the term "firewall" based on the Microsoft Computer Dictionary definition to exclude validation and authentication features. Motion at 10; Khaliq Decl., Ex. E. Sproqit does not oppose Visto's proposed construction or suggest an alternative.

Given there was no opposition in connection with the instant motion to Visto's proposed construction of the claim term "firewall," the Court adopts the following construction of the term:

software and/or hardware for protecting an organization's network against external threats, such as hackers, coming from another network, such as the Internet. A firewall prevents computers in the organization's network from communicating directly with computers external to the network and vice versa by routing all communications through a proxy server outside of the organization's network for a determination whether a particular message or file will be permitted to pass through to the organization's network.

Kahliq Decl., Ex. A ("Claim Construction Order") at 14-15; Mot. at 8, 10; Khaliq Decl., Ex. E (The Microsoft Computer
E. Firewall

Visto contends that the term "firewall," as used in the claims of the '708 patent and the '192 patent, means "software and/or hardware for protecting a network against external threats coming from another network, which allows or blocks packets of information traveling between the networks." Seven argues that the term has a broader meaning and maintains that the court should define the term as "software and/or hardware for protecting an organization's network against external threats, such as hackers, coming from another network, such as the Internet." With respect to this term, it is Visto, rather than Seven, who is attempting to narrow the scope of the claim. Seven's definition is appropriate, as there is no suggestion that the inventors intended to disavow the scope of this claim term. The court therefore adopts Seven's proposed definition and defines "firewall" to mean "software and/or hardware for protecting an organization's network against external threats, such as hackers, coming from another network, such as the Internet."

26. Firing time information

This term is used in the '037 patent, asserted against only ADI. Biax contends this term means information pertaining to the time when an instruction is to be executed. ADI argues that it means a line of computer code providing the specific time when an instruction is to be executed. The court construes the term "firing time information" to mean "intelligence used to indicate when a given instruction may be executed." This construction is consistent with the court's prior construction of "instruction firing time."

7. "first" and "second" ('702 patent)

Beneficial's Proposed Construction

Defendants' Proposed Construction

The terms "first" and "second" are used in the claim to distinguish two instances of the same thing. For example, "first user" means a user other than a "second user." The terms "first" and "second" do not refer to time sequence. The Court essentially agrees with the proposed construction and arguments by Beneficial. The Court notes that the Defendants do not provide any argument on these terms. The Court finds that in this case "first" and "second" should be instances of the same thing. See Free Motion Fitness, Inc. v. Cybex Intern., Inc., 423 F.3d 1343, 1348 (Fed. Cir. 2005) ("[t]he use of the terms 'first' and 'second' is a common patent-law convention to distinguish between repeated instances of an element or limitation."). Thus, consistent with Beneficial's proposal, the Court construes the terms "first" and "second" as follows: "the terms 'first' and 'second' are used to distinguish repeated instances of the same element or limitation."

IV. "first" and "second" 10
10 The terms "first" and "second" are in claims 1, 11, 12, and 18.

11 While Plaintiff has provided a modified proposal regarding claim 18, PL. SUPP. at 2, the Court finds no reason to depart from the parties' original agreement as to claim 18 for the purposes of this litigation. Plaintiff has indicated that it agreed because the dispute did not matter for the purposes of infringement. PL. SUPP. at 1. Thus, the Court will address claim 18 only as necessary to properly resolve the parties' dispute as to claims 1 and 30.

Looking first to claim 1, this claim discloses:

1. A method of doing business over a global communications network comprising the steps:
   communicating to a buyer via the global communications network, a description of a product;
   accepting a first request from the buyer to buy the product for a price to be determined within a price range;
   accepting a second request from the buyer to allow the price to be determined based upon a performance of the buyer while participating in a Price-Determining-Activity (PDA);
   receiving data from the buyer over the global communications network, said data representing the performance of the buyer during the PDA; and
determining the price of the product based at least partially upon the data received, said price being within the price range and scaled to the performance of the buyer.

'253 patent at 9:31-49 (claim 1). Nothing in this claim precludes step [a] from occurring at any points during the claimed method, nor steps [b], [c], or [d] from occurring at any time before step [e]. There are no explicit, nor inherent disclosures in the claim that require a particular order.

Moreover, logic does not require Defendants' proposed sequential limitation. Without support or citation, Defendants assert that "[i]n order for the system to 'accept' a first request from the buyer to buy the product for a price to be determined within a price range,' the product must first be communicated to the buyer in step [a]." RESPONSE at 27; see also D. SUPP. at 2. In the Background section of the '253 patent, the patentee discloses that "Priceline.com uses a model which allows the buyer to present a bid or offer price they wish to pay for a product or service, and a seller then accepts the buyer's offer to enter into a binding contract, typically as the result of a reverse auction process." '253 patent at 1:31-35. In this example--a reverse auction--the seller first accepts a request from the buyer to buy a type of product or service, and then after the seller accepts the buyer's offer, a description of the particular product or service is communicated to the buyer. Such reverse auctions are noted within the specification as optional business models that can be incorporated into the claimed invention.

The present invention thus may be used independently of other business models, or in combination therewith, to form binding contracts. For example, using the auction or reverse auction models, the buyer may be entitled to a further discount of the auction or reverse auction price, which discount may be greater if the buyer performs well at the PDA, and not so great if the buyer performs poorly.

'253 patent at 4:36-43. In such a situation, step [a] would not necessarily occur first, as Defendants propose.

While Defendants are correct that the preferred embodiments disclose methods that are performed in an order that corresponds to that expressed in the claims, D. SUPP. at 2-3, the specification fails to indicate that this order is required. In fact, referring to one disclosed embodiment, the specification expressly indicates that the step where the buyer provides payment information "may occur at any stage in the process." '253 patent at 5:13-15. The specification adds that "[w]hile certain embodiments are illustrated in the drawings and are described herein, including preferred embodiments, it will be apparent to those skilled in the art that the specific embodiments described herein may be modified without departing from the inventive concepts described. . . . Accordingly, the invention is not to be restricted except by the claims which follow." Id. at 9:11-28.

Defendants--citing to E-Pass Techs. v. 3Com Corp.--argue that if a few of the steps must be performed in a certain order, as Plaintiff concedes, then all of the steps must be performed in order. D. SUPP. at 3-4 (citing E-Pass, 473 F.3d 1213, 1222 (Fed. Cir. 2007)). However in E-Pass, the parties' dispute was whether summary judgment of non-infringement was properly granted--whether the steps of the claim must be performed in order. The passing statement made by the Federal Circuit--and cited by Defendants--cites to Mantech Environmental Corp. v. Hudson Environmental Services, Inc. 152 F.3d 1368, 1375-76 (Fed. Cir. 1998). There, the Federal Circuit held that due to the sequential nature of the limitations of the claim, the method logically required that the steps be performed in order. Id. at 1376-1377. Here, as discussed above, the claim language fails to set forth such a required logical or sequential order.

Moreover, the use of the terms "first" and "second" do not impose a temporal limitation, but instead are used as a common patent-law convention to distinguish between repeated instances of an element or limitation. 3M Innovative Properties Co. v. Avery Dennison Corp., 350 F.3d 1365, 1371 (Fed. Cir. 2003). Defendants cite to LifeNet, Inc. v. Musculoskeletal Transplant Foundation, No. 3:06cv6876, 2007 U.S. Dist. LEXIS 45172, 2007 WL 1815629, *8 (E.D. Va. June 21, 2007) in support of the argument that the recitation of "first" and "second" requests necessarily requires a sequential order. RESPONSE at 26. In LifeNet, the claim language indicated that such a sequential limitation was intended by the patentee. For example, dependent claim 20 of the asserted patent disclosed the step of "sonicating said second cleaned bone graft with sterile water prior to sonicating with said third solvent." LifeNet, 2007 U.S. Dist. LEXIS 45172, 2007 WL 1815629 at *8. This limitation explicitly indicates that the second bone graft must be sonicated prior to the third. Id. Similarly, dependent claim 19 disclosed that a second bone graft is sonicated to produce a third bone graft. Because the second bone graft must be sonicated prior to the third and the third bone graft is produced from sonicating the second bone graft, the order of steps...
is necessarily implied. Here, claim 1 includes no such language, nor implication.

Turning to claim 30, this claim discloses a "system for conducting e-commerce over a global communications network" which is comprised of a computer server with particular functionality. '253 patent at 11:13-23, 12:1-7 (claim 30). Defendants argue that because Plaintiff agrees that the steps of claim 18 must be performed in order, it follows that the steps of claim 30 must be performed in order as well because claim 30 discloses a computer system that performs the steps disclosed in claim 18. RESPONSE at 27. Plaintiff has indicated--and Defendants do not dispute--that the accused products perform the steps of claim 18 in the order recited, and this is why Plaintiff does not dispute that the steps of claim 18 must be performed in order. PL. SUPP. at 1. This agreement, alone, is not a justifiable basis for holding that claim 30 has a sequential limitation.

Moreover, claim 30 discloses a system that performs certain functions. Unlike the cases cited by Defendants, the functions disclosed in claim 30 need not be performed in order. In Oak Tech., Inc. v. Int'l Trade Com'n--like LifeNet, discussed above--the claim language indicated that such a sequential limitation was intended by the patentee. 248 F.3d 1316, 1325 (Fed. Cir. 2001). In Versata Software, Inc. v. SAP Am., Inc., the system claims disclosed steps that were "essentially similar" to those disclosed by a method claim that had a required order. No. 2:07-cv-153, 2009 U.S. Dist. LEXIS 45751, 2009 WL 1408520, *13 (E.D. Tex. May 19, 2009). In Visto Corp. v. Good Tech., Inc., the claims at issue were method claims--not system claims. No. 2:06-cv-039, 2008 U.S. Dist. LEXIS 3244, 2008 WL 163576, *6 (E.D. Tex. Jan. 16, 2008). Here, claim 30 discloses a system for conducting e-commerce, and the recited steps have no explicit, implicit, or logical required order for all the reasons set forth regarding claim 1. Therefore, the Court finds that the steps of claim 1 may be performed before, at the same time as, or after any other step, except that steps [b], [c], and [d] must occur before step [e]. Pursuant to the parties' agreement, the Court also finds that he steps of claim 18 must be performed in order, however, claim 30 does not have a sequential limitation. Further, the terms "first" and "second" also do not impose a sequential limitation.

1734

a. "first . . . and [] second light beam"

In the photolithographic pattern-transfer process, two light beams (viz., the "first light beam" and the "second light beam") illuminate a pattern from no fewer than twelve different directions. Upon contact with the pattern, the two beams are diffracted into distinct orders of diffracted beams; these diffracted beams, in turn, travel through the projection optical system along a shared optical path. To differentiate between these two beams, the claim refers to "first" and "second" "light beams." According to Nikon, the "first . . . and [] second light beam" claim language should be construed to denote "beams of light that are, at least during some portion of their paths, separate and discrete." ASML does not contest inclusion of the concluding phrase of Nikon's construction, but ASML offers a substantially more specific alternative; according to ASML, the court should construe "first" and "second light beams" to mean "separate and discrete beams, as are produced by the disclosed spatial filter, emanating from discrete areas on the Fourier transform plane (like holes in the spatial filter)."

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

14 Aware that courts are, in general, not permitted to import exogenous limitations into a claim, ASML posits its construction as an illustrative one, using the word "like" to suggest that the limit is simply an example of the type of beams the claim language contemplates. According to ASML, in fact, its construction best comports with the '041 patent specification because the specification denotes the "spatial filter" as part of the underlying "invention."

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

The court does not disagree with ASML's presentation of the relevant technology; the beams do indeed emanate from discrete areas, interacting at a point with spatial filters. But the court cannot adopt ASML's expansive reading of "first . . . and [] second light beam" to mean "separate and discrete beams, as are produced by the disclosed spatial filter, emanating from discrete areas on the Fourier transform plane (like holes in the spatial filter)." As the court understands the intrinsic record and the claim language, all that is at issue is two separate light beams that are, for at least part of their lengths, separate. See, e.g., '041 Patent at 13:55-14:17. Nothing in the patent specifications undercut the thrust of this understanding, and the court thus construes "first . . . and [] second light beam" to mean "two beams of light that are, for
some portion of their paths, separate and discrete."

In construing the claims, the district court explained: "The integrated circuit must have at least one common reference clock (either digital or analog . . .)." The district court further stated: "[The phrase] 'first clock signal' . . . indicates the analog circuit clock signal comes prior to the 'second' digital circuit clock signal. Again, this language does not limit the claims construction to one clock."

As the district court correctly noted, "a first clock signal" does not require a single clock signal to control sampling. As previously discussed, the word "comprising" in the transitional phrase of a patent claim creates a presumption that the body of the claim is open. Because claim 4 uses "comprising," it encompasses more than one clock unless the written description or the prosecution history clearly limits claim 4 to its recited elements. Similarly, the article "a" in "a first clock signal" generally suggests one or more clocks. The written description and figures of the '899 patent actually disclose two analog clocks, ACLK1 and ACLK2, in the preferred embodiment. See, e.g., col. 2, ll. 52-56; col. 4, ll. 16-26; Fig. 3. According to the preferred embodiment, analog clock ACLK1 accepts the analog input voltage (the charge), analog clock ACLK2 transfers the charge to or from the feedback capacitor.

Although ACLK1 provides the first clock signal for controlling the sampling of an analog input voltage, neither the written description nor the prosecution history precludes more than one clock or clock signal.

### 1735

**D. "First and Second External Clock Signals"**

The parties agree that the bus of the invention carries two external clock signals which pace the exchange of information over the bus and provide timing synchronization for the memory system. The dispute arises over whether the second external clock signal must contain information that is different from the timing information sent by the first clock signal.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

36 As has been the convention of both the patent documents and the parties, the terms "clock signal" and "clock" are used interchangeably.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

Although referred to as a "clock" by one skilled in the art, the clock of a memory chip is actually a set of timing information derived from an oscillating reference voltage ("V[REF]") which cycles between two voltage levels. Rambus' proposed definitions do not require that the two signals contain different timing information, while Infineon's proposed definitions require that the second signal contain different information from the first.

1. The Claim Language

Every asserted claim in the '214 patent (the double data rate invention) and the '804 patent (the delayed lock loop invention) contains the terms "first external clock signal" and "second external clock signal." 37 Most of the claims simply indicate that data is to be output on the bus in response to the first and second external clock signals. Three claims, however, reveal that the two clock signals can be used by the memory device to create an internal clock:

25. The method of claim 15 further including generating at least one internal clock signal using the first and second external clock signals wherein the first amount of data corresponding to the first block size information is output onto the bus synchronously with respect to at least one internal clock signal.
'214 patent, claim 25.

26. The method of claim 25 further including generating a first internal clock signal using a delay locked loop and the first and second external clock signals.

'214 patent, claim 26.

26. An integrated circuit device having at least one memory section which includes a plurality of memory cells, wherein the integrated circuit device outputs data on an external bus synchronously with respect to first and second external clock signals, the integrated circuit device comprises:

. . . .

Delay locked loop circuitry to generate an internal clock signal using the first and second external clock signals . . .

'804 patent, claim 26.

--- Footnotes ---

37 See claims 1, 2, 4, 9, 10, 11, 15, 16, 18, 24, 25, and 26 of the '214 patent and claim 26 of the '804 patent.

--- End Footnotes ---

The claim language thus indicates that somehow the memory device is to use the information derived from the first and second clock signal to create in internal signal. One must consult the specification to understand how this is accomplished.

2. The Specification

In the "Background of the Invention" section, the specification relates that one "object of this invention is to provide a clocking scheme to permit high speed clock signals to be sent along the bus with minimal clock skew between devices." '918 patent, col. 3, ll. 27-29. "The two clocks together provide a synchronized high speed clock for all the devices on the bus." '918 patent, col. 8, ll. 29-30. Most significantly, in the "Clocking" subsection of the "Detailed Description," the inventors explain:

Clocking a high speed bus accurately without introducing error due to propagation delays can be implemented by having each device monitor two bus clock signals and then derive internally a device clock, the true system clock. The bus clock information can be sent on one or two lines to provide a mechanism for each bused device to generate an internal device clock with zero skew relative to all the other device clocks.

'918 patent, col. 18, l. 63 through col. 19, l. 4. This idea of clock skew can be best understood by reference to Figures 8a and 8b of the specification.

[SEE FIG. 8A IN ORIGINAL]

[SEE FIG. 8B IN ORIGINAL]

The specification clearly demonstrates how these figures represent the two clock signals:

Referring to FIG. 8a, in the preferred implementation, a bus clock generator 50 at one end of the bus propagates an early bus clock signal in one direction along the bus, for example on line 53 from right to left, to the far end of the bus. The same clock signal then is passed through the direct connection shown to a second line 54, and returns as a late bus clock signal along the bus from the far end to the origin, propagating from left to right. A single bus clock line can be used if it is left unterminated at the far end of the bus, allowing the early bus clock signal to reflect back along the same line as a late bus clock signal.
FIG. 8b illustrates how each device 51, 52 receives each of the two bus clock signals at a different time (because of propagation delay along the wires), with constant midpoint in time between the two bus clocks along the bus. At each device 51, 52, the rising edge 55 of Clock1 53 is followed by the rising edge of 56 of Clock2 54. Similarly, the falling edge 57 of Clock1 53 is followed by the falling edge 58 of Clock2 54. This waveform relationship is observed at all other devices along the bus. Devices which are closer to the clock generator have a greater separation between Clock1 and Clock2 relative to devices farther from the generator because of the longer time required for each clock pulse to traverse the bus and return along line 54, but the midpoint in time 59, 60 between corresponding rising of falling edges is fixed because, for any given device, the length of each clock line between the far end of the bus and that device is equal. Each device must sample the two bus clocks and generate its own internal device clock at the midpoint of the two.

'918 patent, col. 19, ll. 4-32. See also Fig. 13 of the '918 patent (showing how the rising and falling edges of the two bus clocks can be synchronized).

In essence, this portion of the specification explains how chips N and O, which are located in different positions along the bus lines, receive the clock signals at different points in time due to their locations relative to the origin of the clock signal. By reflecting the signal along a second line, the memory system can compensate for this delay and create a second clock signal. From these two signals, chips N and O create an internal clock signal which corrects the clock skew caused by propagation delay. In order to correct the skew, the two signals must necessarily contain different information, as Rambus' expert admitted. See Markman Hearing, Tr. pp. 296-298 (testimony of Dr. Huber). Although the specification lists this clocking scheme as a preferred embodiment, it is actually the only embodiment of the clock in the entire specification. As with the analysis of the term "bus," it is significant that the specification limits the clock to a single embodiment. See generally Wang, 197 F.3d at 1380; Toro, 199 F.3d at 1301; O.I. Corp., 115 F.3d 1576 at 1581.

3. The Extrinsic Evidence

The constructions taught by the specification are confirmed by the testimony of Mr. McAlexander who explained that to one ordinarily skilled in the art that the Rambus clock scheme allows the memory devices to sample each clock signal as it is received over the line and then averages the two signals such that every device is operating off the same clock, regardless of that device's location relative to the origin of the clock signal. Markman Hearing, Tr. pg. 457, line 2 to pg. 458, line 1 (testimony of Mr. McAlexander). Thus "the timing information and the difference between them is essential to this inventive concept of the clock design." Id. 38

--- Footnotes ---
38 Mr. McAlexander's testimony also explains how the clocking scheme comes full circle to the primary objective of the invention and the use of a multiplexed bus:

In the prior art where the address information goes down one bus and data is responded to the bus on a totally different bus - so you have a data bus that's separate and distinct from the address bus - you could send down the control [or] the address information to a chip, activate it, . . . it goes in, finds the data from the storage cells and immediately sends it out to the data bus which is a separate bus.

In the multiplexed design, the data must share the same bus as the address information. And so the . . . controlling system must assure that at no time does address or control information reside on the bus at the same time that data . . . is coming back on the bus; otherwise, you would end up with a collision. . . .

So in order to arbitrate that and to make sure that nothing is on the bus when it's not supposed to be, the whole system has to be in sync. Every system, every . . . chip, every component on the bus has to be operating under the exact same timing constraints.

That's why it's important and valuable . . . to use a clock design that will synchronize everything together.

Markman Hearing, Tr. pg. 465 l. 6 to pg. 466, l. 10.
--- End Footnotes ---
In the interpretation of these terms, Rambus once again eschews the language of the specification, choosing to rely instead on the testimony of its expert who says that one skilled in the art would recognize that the first and second external clock signal can have, but does not need to have, different timing information in each signal. Therefore, according to Rambus, it is unnecessary to tie the claim definition to the language of the specification. 39 This approach runs afoul of the principle that the patent specification must always be reviewed to see if the patentee used the terms in a manner other than their ordinary meaning. Vitronics, 90 F.3d at 1582. Thus, even if one accepted Rambus' contention that the ordinary and accustomed meaning of first and external clock signals would be known to one of skill in the trade, the patent specification only describes a clocking scheme which corrects clock skew by creating an internal clock based on differing external clock signals.

--- Footnotes ---

39 See Testimony of Dr. Huber, pg. 302, l. 25 - pg. 303 l. 2 ("I don't need to go to the patent to interpret the term. Clock signal is a well known term").

--- End Footnotes ---

4. Construction

Based on the claim language and the specification the term "first external clock signal" is construed to mean "a periodic signal received by the memory device from an external source to provide first timing information." The term "second external clock signal" is construed to mean "a periodic signal received by the memory device from an external source to provide second timing information that is different from the first timing information."

1737

11. "First External Clock" and "Second External Clock"

a. Proposed constructions

Hynix contends that "first external clock" should be construed as "a periodic signal received by the memory device from an external source to provide first timing information." See Infineon I, 2001 U.S. Dist. LEXIS 10990, 2001 WL 34138091 at *26. Rambus proposes that the term should be construed the same as "external clock signal" -- "a periodic signal from a source external to the device to provide timing information."

Similarly, Hynix contends that "second external clock" should mean "a periodic signal received by the memory device from an external source to provide second timing information that is different from the first timing information." See Infineon I, 2001 U.S. Dist. LEXIS 10990, 2001 WL 34138091 at *26. Rambus, in contrast, proposes second external clock signal to be interpreted as "another external clock signal."

The parties agree that "external clock signal" should be construed as "a periodic signal from a source external to the device to provide timing information." JCCS at 3. They disagree over whether the terms "first" and "second" refer to timing, or whether they refer to two separate signals without reference to time. "Although referred to as a clock' by one skilled in the art, the clock of a memory chip is actually a set of timing information derived from an oscillating reference voltage ("VREF") which cycles between two voltage levels." Infineon I, 2001 U.S. Dist. LEXIS 10990, 2001 WL 34138091 at *24. As Rambus claimed in Infineon I, Rambus's proposed definitions here "do not require that the two signals contain different timing information," while Hynix's construction requires "that the second signal contain different information from the first." Id.

In a July 28, 2003 order, this court vacated in its entirety its previous November 21, 2001 order granting partial summary judgment to Hynix finding, inter alia, that "the elements of collateral estoppel are no longer met in this case." Order of 7/25/03 at 3. Besides briefing the collateral estoppel issue extensively, Rambus offers in support of its construction the IEEE Dictionary definitions for "clock" and "signal." See JCCS at 17.
To operate the Rambus bus architecture at high speed, "every system, every . . . chip, every component on the bus has to be operating under the exact same timing constraints. That's why it's important and valuable . . . to use a clock design that will synchronize everything together." Infineon I, 2001 U.S. Dist. LEXIS 10990, 2001 WL at 34138091 at *26 n.38. Reviewing figures 8A and 8B of the '918 patent, the court first explained that chips N and O were located in different positions along the bus lines, and therefore received the "clock signals at different points in time due to their locations relative to the origin of the clock signal." 2001 U.S. Dist. LEXIS 10990, [WL] at *25. In order to correct this delay, the memory system reflects a signal along a second line to create a second clock signal, and from these two signals "chips N and O create an internal clock signal which corrects the clock skew caused by propagation delay." Id. Notably, Rambus's expert in Infineon admitted that in order to correct the skew, the two signals must contain different information. Id. The district court went on to note that the only embodiment of the clock in the entire specification required two external signals containing different information in order to create an internal clock, thus correcting the clock skew problem. See 2001 U.S. Dist. LEXIS 10990, [WL] at *26.

--- Footnotes ---

20 U.S. Patent No. 6,034,918. These figures are the same for the '152 and '263 patents.

--- End Footnotes ---

Besides introducing evidence from the IEEE Dictionary defining the terms "clock" and "signal," Rambus does not address the Infineon district court's analysis. Rambus also fails to suggest an alternative embodiment in the specification under its proposed construction that would address the clock skew problem. "Where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question." Scimed Life Sys. v. Adv. Cardiovascular Sys., 242 F.3d 1337, 1341 (Fed. Cir. 2001); Watts v. XL Sys., Inc., 232 F.3d 877, 883 (Fed. Cir. 2000) (where specification describes only one method to achieve sealing connection, claim limited to that disclosed method); Toro Co. v. White Consol. Indus., 199 F.3d 1295, 1301 (Fed. Cir. 1999) (limiting claims to preferred embodiment, and noting the "specification shows only a structure whereby the restriction ring is part of the cover, in permanent attachment. This is not simply the preferred embodiment; it is the only embodiment.").

The court construes "first external clock" as "a periodic signal received by the memory device from an external source to provide first timing information," and "second external clock" as "a periodic signal received by the memory device from an external source to provide second timing information that is different from the first timing information."

A First Fraction Of A Clock Pulse Interval

Defendants also argue that "a first fraction of a clock pulse interval" must begin at the rising edge of the clock pulse interval. (Def. Br. at 31.) Again, Defendants' interpretation is unsupported by the claim language and '740 specification. The '740 patent describes the start signal as "a transition on the data wire from '1' to '0', while the signal on the clock wire [remains '1']." (740 patent, Col. 4, lines 19-21.) Thus, the key requirement is that the signals on the clock and data wires must be high (or "1") for some fraction of time--a "first" fraction--before the transition on the data wire. After the transition on the data wire, the signal on the data wire must be low (or "0") for some fraction of time--a "second" fraction--while the clock wire remains high (or "1"). Those fractions of time are illustrated below on Figure 3 of the '740 patent:

[SEE Transmitting A Start Signal IN ORIGINAL]

Thus, the term "first" does not refer to the beginning of a clock pulse interval. Instead, it refers to the first "fraction," that is, before another "fraction" in time. The dictionary definition for "first" is completely consistent with this interpretation: "1: a: before another in time, space, or importance b: for the first time 2: in preference to something else: SOONER." (Webster's at 466, Reply Br., Ex. D.)
Defendants' interpretation would require the clock to switch to low after each stop signal and then back to high before the next start signal. There is nothing in the claims or the '740 specification that would require this unnecessary switching. Indeed, the '740 patent describes the exact opposite—that after a stop signal, the clock and data wires remain high ("1") until the next start signal is issued. (See, e.g., '740 patent, Col. 4, lines 64-66.) Thus, Defendants' interpretation is incorrect, because it would exclude this preferred embodiment of a clock pulse. See, e.g., Burke Inc. v. Bruno Indep. Living Aids Inc., 183 F.3d 1334, 1341 (Fed. Cir. 1999) ("The district court's claim interpretation [] would exclude the preferred embodiment described in the specification and, thus, cannot be sustained."); Johns Hopkins Univ. v. Cellpro Inc., 152 F.3d 1342, 1355 (Fed. Cir. 1998). Accordingly, I find Philips' construction to be correct.

2. First, Second, Third, and Fourth Frame Store Means

Claim 5 discloses a "first frame store means," a "second frame store means," a "third frame store means," and a "fourth frame store" for storing frames. Adobe seeks a declaration from the court that the recitation of four frame store means requires four separate corresponding structures. Quantel argues that there is nothing in the claim language or the specification to suggest that the four frame store means recited must be separate structures, and that the claim's recitation of four frame store means does not exclude a shared, or even combined, physical storage structure, or some other combination of physical units.

Although it is true that a single structure may satisfy more than one means element of a claim, see, e.g., Sun Studs, Inc. v. ATA Equip. Leasing, Inc., 872 F.2d 978, 989 (Fed. Cir. 1989) ("An apparatus claim describing a combination of components does not require that the function of each be performed by a separate structure in the apparatus."). Quantel's argument is contradicted by the clear language of claim 5, which recites four frame store means. If claim 5 did not contemplate four separate structures, it could simply recite "frame store means" for storing each of the frames disclosed, rather than enumerate four separate frame store means. Accordingly, the court concludes that claim 5 requires four separate structures corresponding to the first, second, third, and fourth frame store means disclosed in claim 5.

3. "first manipulation of a first operator input device"

Plaintiffs' construction: a first operation of an operator input device

Defendant's construction: first manipulating a first keyboard, trackball, pushbutton, knob, or other device, such as a "Print/Store" button, which a user manipulates to provide input to the imaging system

Neither parties' proposed construction of the term "first manipulation of a first operator input device" is helpful. Plaintiffs turn immediately to a general dictionary to define the term "manipulation" as "operation." Defendant cites the patent specification, which identifies "a keyboard, a trackball," "pushbuttons" and "knobs" as examples of "operator input devices" '327 pat., col. 6, Ins. 64-68. Although I agree with defendant that these are examples of operator input devices, including this list of examples into the claim language is of little value, especially because the patent specification explains that "other input devices" are used as well. Id. at ln. 67. Therefore, I conclude that both parties' proposals are flawed and that the term "first manipulation of a first operator input device" would not benefit from either construction.

5. "first-order low-pass filter section" ('347 patent, claim 1) and "second-order low-pass filter section" ('992 patent, claim 1)

Pulse offers that these disputed terms do not require specific construction because the required elements are expressly
defined in the claims. In contrast, Mascon argues they cannot be construed because they are indefinite. The court notes any potential open-ended interpretation of these terms to include additional electrical components is mitigated by its construction of the modifiers "formed of" and "connected to."

Mascon's first supporting argument refers to Pulse's Infringement Contentions. (Doc. No. 33 at 21) The court may not properly consider the alleged infringing device during a Markman analysis. See Ferguson Beauregard/Logic Controls, Div. of Dover Res., Inc. v. Mega Sys., LLC, 350 F.3d 1327, 1340 (Fed. Cir. 2003)(finding the district court erred in claim construction "because it was influenced by the structure and function of the alleged infringing device."). In its second argument, Mascon contends "first-order low-pass filter section," as used in claim 1 of the '347 patent, is indefinite because the connection of the "fourth inductor" to the "fourth output pin" and the "third capacitor," also connected to the "fourth output pin," creates a short across the inductor. This issue is addressed in section 6, supra, and the court finds it does not render the claim term indefinite.

These terms are not "insolubly ambiguous," and thus, the court finds they are not indefinite and they do not require specific construction by the court.

A.1.d. "first/second response unit means"

Despite the use of "means" language, the parties appear to agree that the term "response unit means" connotes sufficiently definite structure to avoid the interpretational mandates of 35 U.S.C. § 112, P 6. In addition, both parties agree that "response unit means" is an audio response unit. See Verizon Brief at 18:8-10; Katz Brief at 26:26-27. Verizon asserts, however, that the first and second response unit means must be embodied in physically separate structures. See Verizon Brief at 18.

While the claim language requires two functionally distinct response units, the claim language does not appear to require that the first and second response unit means reside in physically separate structures. See Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001) (refusing to interpret "portion" as requiring separate structures, where disclosed embodiments featured physically separate parts, but plain meaning of "portion" encompassed both separate and integral parts). The specification of the 734 patent appears to be consistent with this interpretation. See 734 patent, Col. 4:3-13 ("three separate audio response units are illustrated . . . Alternatively, a single composite unit might be utilized."). Verizon points to nothing in the specification or prosecution history of the 734 patent that requires deviating from the plain and ordinary meaning of the claim terms to require that the first and second response unit means be embodied in physically separate structures.

A first signal part and a second signal part

Claims 18 and 19 of the '714 Patent contain the term "a first signal part and a second signal part," which is preceded by "to separate the unmodulated optical signal into" and "separating an optical signal into," respectively. Cheetah contends that the term means "to separate the optical signal into at least two parts, for example, into two or more wavelengths," while Mitsubishi contends that it means "first and second copies of the 'unmodulated optical signal.'" The parties disagree whether the term "a first signal part and a second signal part" requires separation into two identical copies.

The relevant embodiment of Claims 18 and 19 is Figure 15, as cited by both parties, which is described as:

Fiber optic tap 1018 receives optical signals 1012 and sends one copy of the signal including at least header information 1014 to demultiplexer 1024, and sends another copy of the signal including at least payload information 1016 to delay line 1022.
'714 Patent, col. 21:6-10. Cheetah asserts that the two portions of the signal may be different from each other, as one may be only the header and the other may be only the payload portion of the signal. According to Cheetah, the specification confirms that "copy" does not mean the separated portions are the same, but merely portions of the whole. Cheetah also asserts that the prosecution history confirms its construction because the prior art cited by the Patent Office examiner did not have identical copies. Mitsubishi counters that the specification makes clear that the signal is split into copies and that nothing suggests the copies are different from each other.

The passage from the specification cited by both Cheetah and Mitsubishi makes clear that what is separated need not be identical "copies" and may contain different information, because the fiber optic tap may send one copy that includes at least header information and one copy that includes at least payload information. Furthermore, Figure 15 below shows the header 1014 alone at the input to DEMUX 1024 and the payload 1016 alone at the input to the DEMUX 1032. '714 Patent, fig. 5.

The specification also describes the electronic processor 1028 processing the header information 1014 and the optical add/drop multiplexer array 1030 processing the payload 1016. '714 Patent, col. 21:11-32.

Mitsubishi's use of the term "copies" causes confusion as to whether the copies need to be identical or not, particularly in light of the specification that discloses the portions do not need to be identical. Additionally, Cheetah has not provided support for the inclusion of "two or more wavelengths," other than asserting that it is known to those of skill in the art that headers and payloads may be distinguished by wavelength. Accordingly,

1744

4. remotely controlled (...) by (...) first, second and third (channel) switch commands

The switching system is controlled by switch commands that are generated at the remote control center, which is at a location that is remote, or separate, from the switch system. 12 A "command" is an instruction to a computer; in the context of these claims, the instruction tells the computer in the switch system which of three video signals to select and apply as the output signal of the switch. 13 Consistent with the specifications in both the '883 and '825 Patents, the "first, second, and third switch commands" would be understood to be three distinct commands. Thus, the first switch command is an instruction that directs the video switch to select the programmed channel video signal as the output from the video switch; the second switch command directs the video switch to select the commercial insert video signal as its output; and the third switch command directs the switch to select the local video signal (locally generated video signal) as its output.

12 Defendants state that "remote" is described throughout the patents as being at a distance requiring a satellite or fiber optic cable transmission, as opposed to switch commands generated locally at the head-ends, which would be referred to as being 'local.'" SeaChange and the Cox Companies' Markman Br. on the Interpretation of Disputed Claim Language, at 18. Although the switch commands are generated externally to the switching system, there is no specified minimum distance between the source of the commands that effectuate the control and the switch system. Nothing in the patent documents indicates that a certain distance is necessary for the patented invention to function. The fact that the inventors may have assumed that a significant distance might exist between the remote control center and the headend in an implementation of the invention is not grounds for importing such a limitation into the claim. Thus, while the court agrees that the commands are not generated at the headend, the court does not agree that the commands are generated at a significant distance from the headend.

13 Defendants offer the following dictionary definition of "command": "An expression that can be input to a computer system to initiate an action or affect the execution of a computer program." IEEE Standard Computer Dictionary 44 (Institute of Electrical and Electronics Engineers ed., 1990).
The switch commands are sent to the switching system via the second telecommunications network from the remote control center. As described in the specifications, the remote control center has a monitoring device that detects cue tones in the programmed channel signal. The remote control center generates the switch commands in response to those cue tones, and then sends the switch commands to the switching system. See '883 Patent, col.6, 11.15-38; '825 Patent, col.4, 11.16-23. Thus, the commands are sent to the switch in real time; i.e., the switch commands, which determine which video signal will be output by the switch, are sent to the switching system as the cue tones signal an upcoming local avail. 14

14 For example, the specification of the ’883 Patent explains that the computer at the switch is fast enough to process the commands in response to the cue tones so that the commercial insert signal or local video signal can be inserted at the appropriate time. See ’883 Patent, col.6, 11.45-54; id. col.7, 11.12-21.

Beam Laser objects to the inclusion of these additional limitations in the asserted claims. While acknowledging that "real time" remote control is disclosed in the preferred embodiments of both patents, Beam Laser argues that this does not imply that "real time" control is a limitation in the asserted claims. Furthermore, Beam Laser argues that whether the control is in real time or not is a matter pertaining to the operation of the control center, which is the subject of a separate claim, and not the switching system, which is the subject of the asserted claims. All that is required of the switching system, according to Beam Laser, is that the system be capable of being remotely controlled.

The claim language itself indicates that the commands are generated at a location other than the switch system: All asserted claims state that the switch commands are sent to the switch system via the second telecommunications system, and the commands are received at a control input of each switch. Thus, it is not necessary to resort to the specifications to understand that the commands are generated outside the switching system, i.e., the commands are not generated at the headend. In any case, nothing in the specifications suggests that the commands are generated at the switching system. The court must look outside the claims covering the switching system to understand how the remote control, which is an express limitation in the asserted claims, is effected, because the asserted claims are incomplete in this regard. In particular, the timing of the control cannot be determined from the asserted claims alone. The court must not lose sight of the purpose of the invention: the automated insertion of commercial spots into a programmed channel signal. A person of ordinary skill in the pertinent art would understand that the insertion of commercials into the program channel signal is controlled by cue tones. Thus, although not an explicit limitation in the asserted claims, it is clear that the switch commands must be tied in some way to the cue tones that signal the time avails. Only by looking to the specifications can the timing of the control be determined. The court is not importing limitations from the specifications into the claims; rather, the court is looking to the specifications to understand a limitation implicit in the asserted claims.

1745

"First units of data"

Alcatel's proposed construction is "the units of data generated from the data received from the receive channels." 18 Cisco believes this term is plain on its face and has no special or uncommon meaning, and thus should not be construed by the Court.

18 The parties have agreed that the term "receive channels" should be construed as "logical channels of data received by the network." Revised Joint Statement, Ex. C, at 43.
Alcatel argues that its proposed construction is supported by the specification, in particular Figure 3 and its description. See Valizadeh, at 4:5-9, Fig. 3. However, Alcatel's construction is not supported by the claim language. 19 First, the word "generated" does not appear as part of the specification referenced by Alcatel, or in the claim language in claim 1. In fact, it is only in dependent claims 2 and 3 where the claim language specifically discusses the notion of generating the first units of data described in claim 1. Thus, there is no support for using the language from a dependent claim to interpret the term in an independent claim, when such language is absent from the independent claim. Second, Alcatel's proposed construction would render the language of claim 14 to effectively read as follows: "A plurality of receive channels to receive [the units of data generated from the data received from the receive channels.]" The Court will not unnecessarily construe a term to create that type of confusion and inconsistency in the reading of a claim. Moreover, the claim language specifically refers to the origin of the "first units of data" in claims 1 and 2 as the receive channels, again making it unnecessary to construe this claim in order to incorporate that concept into the claim.

The only apparent reason why the term "first units of data" was used instead of simply "units of data" was to distinguish it from "second units of data," which is found in claims 2 and 3. Thus, there is no additional meaning ascribed to that term that would require construction. Therefore, the Court agrees with Cisco that the term "first units of data" requires no further construction in order to describe its origin.

F. The '529 Patent (Claim 29)

Claim 29 of the '529 patent differs from claim 27 in two important respects. First, it does not require the second control image specifying the foreground object, as recited in the dependent portion of claim 27. Second, it specifically requires in the dependent portion that the first and only control image be created by painting using "inherently non-aliased strokes."

Claim 29 depends from independent claim 28. The claims read as follows, the disputed terms and phrase appearing in italics:

28. A method comprising:

providing first pixel signals representing pixels forming a first image;

storing a frame of said first pixel signals in a first addressable memory area;

providing second pixel signals representing pixels forming a second image;

storing a frame of said second pixel signals in a second addressable memory area;

providing first control pixel signals representing pixels forming a first control image;

storing a frame of said first control pixel signals in a third addressable memory as signals having a first value for pixels of a composed image based on one of said first pixel signals and said second pixel signals, a second value for pixels of said composed image based on the other of said first pixel signals and said second pixel signals, and intermediate values for pixels of said composed image based on combining proportions of said first pixel values and said second pixel values;

providing addresses for writing and reading said first and second pixel signals and said first control pixel signals into and from selected addresses of the respective memory area to maintain upon reading the respective pixel signals a desired pixel
relationship between said second pixel signals and said first control pixel signals;

forming composed pixel signals representing the pixels of said composed image by: (a) selectively outputting pixel signals read from one or from the other of said first memory area and said second memory area when the first control pixel signals have respectively said first values or said second value; and (b) selectively combining said first and said second pixel signals output from said first memory area and said second memory area in proportions dependent upon the first control pixel values when said first control pixel signals have said intermediate values;

displaying said composed image;

and manually controlling the step of providing addresses to cause the spatial relationship of the second image together with the first control image to be smoothly and selectively modified relative to the first image;

whereby the second image from the second memory area, as defined by said first control image, moves progressively and selectively relative to the first image from the first memory area by said manual control of the addressing while the corresponding selective and progressive spatial changes of the displayed composed image are observable.

29. A method according to claim 28 including the step of painting with an electronic brush said first control image, said electronic brush having a shape in one or both of intensity and color to paint in inherently non-aliased strokes, and storing the image resulting from said painting step in said step of storing a frame of said first control pixel signal as said first control image.

1. "Addressable Memory Area"

Claim 29 recites several steps whereby frames of pixel signals are stored in addressable memory areas. Adobe contends that the term "addressable memory area" has the same meaning as the term "addressable memory portion" in claim 27, i.e., an "addressable memory area" is sufficiently large enough to store data representing an entire frame of video and is a contiguous portions of random-access memory in which the pixels representing a frame are stored in the same order in which the display is scanned by its electron gun. Again, by "contiguous" Adobe means only that the "addressable memory portion" be capable of supplying pixels representing a frame to the display monitor in the same order in which they are scanned by the electron gun.

The court will construe "addressable memory area" as it construed the term "addressable memory portion" in claim 27. First, the language of claim 29 confirms that an "addressable memory area" must be capable of storing an entire frame. For example, the second element recites the step of "storing a frame of said first pixel signals in a first addressable memory area." In addition, Dr. Phillips' testimony that a "frame" is data representing an entire screen of video is uncontroverted, and Quantel has not challenged Adobe's contention that an "addressable memory area" be capable of supplying pixels representing a frame to the display monitor in the same order in which they are scanned by the electron gun.

2. First, Second, And Third Addressable Memory Areas

Claim 29 recites a first, second, and third addressable memory area for storing frames of pixel signals. Adobe once again seeks confirmation that such a recitation requires three separate structures. As discussed above, the plain language of the claim controls. Claim 29 requires three separate addressable memory areas.

1. "first command interpreter" and "sends a signal regardless of the type of data transmit/receive device"

These terms are used in the context of the '399 Patent as follows: "the first command interpreter . . . , when receiving an inquiry from the host device as to a type of a device attached to the multi-purpose interface of the host device, sends a signal, regardless of the type of the data transmit/receive device attached to the second connecting device of the interface device, to the host device which signals to the host device that it is an input/output device customary in a host device, whereupon the host device communicates with the interface device by means of the driver for the input/output device

The Camera Manufacturers would define "first command interpreter" as a "software program for interpreting an inquiry from a host device and sending a signal to the host device in response to the inquiry that 'lies to the host computer as to the real nature of the data transmit/receive device.'" CMs' Slides at 96. They argue:

Because the first command interpreter is expressed as being "include[d]" in the interface device as a result of "configure[ing]" by the processor and memory, and that it is "configured in such a way" to respond to any inquiry, the first command interpreter must be a software program or module. Then, when receiving an inquiry from the host device, the first command interpreter sends a signal in response, which necessarily requires that it must have interpreted the inquiry to determine what signal to send. This part of the construction appears to be undisputed by Papst. See Papst [Markman] Br. at 18.

CMs' Markman Br. at 18-19. Papst says that "[t]he first command interpreter should be construed to be capable of receiving an 'inquiry' from the computer ('host device'). An 'inquiry' should be construed to mean an instruction seeking information concerning the type of the device attached to a computer." Papst's Markman Br. at 18. Papst contends that the phrase "sends a signal . . . to the host device" means that "the signal sent by the first command interpreter in response to the inquiry [is] consistent with a signal that an input/output device customary in a host device would provide in response to that inquiry, and that such [a] response is not based on what data transmit/receive devices may be associated with the interface device."

Papst's App. at 3-4.

In its briefs, Papst initially explained, "The patent attorney for the '399 patent argued that the claims were allowable over the cited prior art because, among other things, 'when asked by the host device to the type of device connected to the interface, [the first command interpreter] lies to the host computer as to the real nature of the data transmit/receive device.'" Id. at 19 (emphasis added). In its Reply brief, Papst shifted its position. It now insists that "the CMs mistakenly argue that the first command interpreter 'lies' to the host computer as to the true nature of the data transmit/receive device. However, that is not what the claim says . . . . The signal sent in response to the inquiry identifies the interface device as an input/output device customary in a host device, regardless of what data transmit/receive device may be attached." Papst's Reply at 18 (emphasis added). Disavowing its initial interpretation, Papst argues that it is not necessary for the invention to lie, id., and then states that, "by identifying itself as an input/output device customary in a host device, the interface device could be said to 'lie' about the data transmit/receive device because customary devices (disk drivers, CD-ROMs, etc.) do not have data transmit/receive devices." Id. Papst urges the Court to "give effect to the claims of the patent as finally worded, not to the remarks of an attorney." Id. at 20.

To bring the critical language back to the discussion, Claim One of the '399 Patent states:

wherein the first command interpreter is configured in such a way that the command interpreter, when receiving an inquiry from the host device as to a type of a device attached to the multi-purpose interface of the host device, sends a signal, regardless of the type of the device data transmit/receive device attached to the second connecting device of the interface device, to the host device which signals to the host device that it is an input/output device customary in a host device, whereupon the host device communicates with the interface device by means of the driver for the input/output device customary in a host device . . . .

'399 Patent, col. 12:64-67 & col.13:1-8 (emphases added). Since the parties do not dispute that the first command interpreter is a software program or module that, when receiving an inquiry from the host device, interprets the inquiry and sends a signal in response, the Court need only construe the antecedent of "it" in the sixth line of the quote above.

Papst's Reply argument is correct -- the interface device sends a signal that it, the interface device, is an input/output device that can communicate with the computer by way of a driver that is customary in the computer. Notably, it is the interface device itself that is "attached to the multi-purpose interface of the host device." '399 Patent, col. 12:67 & col. 13:1. However, this fact does not fully resolve the issue because both the interface device and the data transmit/receive device can be said to be attached to the computer -- by way of the first and second connecting devices. The data transmit/receive device is merely the point of data origin and the computer is merely the point of data destination (or the reverse) along a single continuum effected by the invention. See id., col. 4:60-62 ("The data transmit/receive device itself can also communicative actively with the host device via the first and second connecting device . . . .").
The '399 Patent specification informs how the invention would work. When the interface device is connected between a computer and a data transmit/receive device and the computer is booted up, the normal BIOS routines of the computer issue an INQUIRY instruction. See id., col. 5:2-15. "The digital signal processor 13 in the interface device receives this inquiry instruction via the first connecting device and generates a signal" to the computer. Id., col. 6:10-12. This signal indicates to the computer that, for example, a hard disk drive is attached. Id. Upon receiving this response, the computer asks to read the boot sequence of a customary hard disk drive and the interface device's digital signal processor sends a virtual boot sequence. Id., col. 5:19-32. "Once the host device has received this data, it assumes that the interface device . . . is a hard disk drive." Id., col. 5:32-35 (emphasis added); see also id., col. 5:58-59 ("As described above, the interface device appears to the host device as a hard disk" in the preferred embodiment.). While this description relates most precisely to the preferred embodiment of a hard disk drive, its description of how the interface device operates provides clarity to define the "it" from the quote above. "It" must be the interface device and not the data transmit/receive device. Any question about which device is "it" is further answered by the fact that data does not begin to be sent from the data transmit/receive device to the interface device until the computer and the interface device have established communication; only then does the second command interpreter begin "to transfer data from the data transmit/receive device via the second connecting device" where analog data is sampled and converted to digital data, then on to "the first connecting device and via the line 11 to the host device." Id., col. 5:64-67.

In arguing that "it" refers to the data transmit/receive device and not the invented interface device, the Camera Manufacturers rely on the prosecution history. Mr. Tasler specifically distinguished the '399 Patent over prior art (the McNeill Patent, U.S. Patent No. 5,499,378), by stating, "[McNeill] does not include a first command interpreter that . . . lies to the host computer as to the real nature of the data transmit/receive device." 399 File History at 6 (emphasis added). Mr. Tasler also told the PTO, "[In McNeill,] the initiator asks for a hard disk and the target states that there is a hard disk" and, unlike the invention, the McNeill device "does not lie as to the true type of the data transmit/receive device." Id. (emphasis added). The Claims and specification for the '399 Patent control, however, with prosecution history a third, but less important, leg to the stool. "An applicant's inaccurate statement cannot override the claim language itself, which controls the bounds of the claim." Storage Tech. Corp. v. Cisco Sys., Inc., 329 F.3d 823, 832 (Fed. Cir. 2003).

The Court thus construes "first command interpreter" in the '399 Patent to be "a software program for interpreting an inquiry from a host device and sending a signal to the host device in response to the inquiry, which signal tells the host computer that the interface device is an input/output device customary in a host device regardless of the type of transmit/receive device attached to the interface device."

J. "second command interpreter"

While Papst suggests that "a second command interpreter is capable of receiving a data request command from the host device, and to initiate [sic] the transfer of digital data to the computer," Papst's App. at 4, the Camera Manufacturers propose to construe "second command interpreter" in the '399 Patent as "a software program for translating data request commands from the host into data transfer commands understandable by a plurality of dissimilar data transmit/receive devices." CMs' Markman Br. at 20.

More specifically, Papst objects to defining the second command interpreter as a software program for "translating" data request commands for use by another device. Tr. 2:127 (Papst). But Papst concedes that the command interpreter "decodes" such commands: "[S]o what the command interpreter does is it takes those numbers and it decodes them and it figures out what it's been asked to do and then it does it . . . . It's not something that translates it into use by another device." Id.

The '399 Patent contemplates "translating" by describing in the specification that the second command interpreter interprets and decodes commands from the host computer:

[T]he second command interpreter carries out the read/write assignment to specific functions. If the user now wishes to read data from the data transmit/receive device via the line 16, the host device sends a command, for example "read file xy", to the interface device. As described above, the interface device appears to the host device as a hard disk. The second command interpreter of the digital signal processor now interprets the read command of the host processor as a data transfer command, by decoding whether "xy" denotes, for example, a "real-time input" file, a "configuration" file or an executable file, whereby the same begins to transfer data from the data transmit/receive device via the second connecting device and
via the line 11 to the host device.

'399 Patent, col. 6:53-67 (emphases added).

The construction proposed by the Camera Manufacturers is clearer and derives directly from the Claims and specification. Therefore, the Court construes "second command interpreter" in the '399 Patent to mean "a software program for translating data request commands from the host device into data transfer commands understandable by a plurality of dissimilar data transmit/receive devices."

G. "a first connecting device for interfacing the host device with the interface device via the multi-purpose interface of the host device"

The parties part ways dramatically on the construction of the term "the first connecting device" in the phrase "a first connecting device for interfacing the host device with the interface device via the multi-purpose interface of the host device." See '399 Patent, col. 12:51-53; '449 Patent, col. 11:53-55. The Camera Manufacturers propose that the "first connecting device" is "a physical plug or socket for permitting a user to readily attach and detach the interface device with the host device." CMs' Slides at 77. Papst does not construe the term "connecting device" as an object, but jumps instead to the interfacing function of the first connecting device and proposes that the first connecting device be construed to mean "the circuit device used to couple the interface device to the multi-purpose interface of a computer." Papst's App. at 3 (emphasis added). Papst asserts that "the first connecting device needs to be interpreted along with the entire paragraph . . . and it's the connecting device for interfacing with the multi-purpose interface." Tr. 2:12 (Papst). Papst then goes on to describe its interpretation of "interfacing:"

[Interfacing] means adhering to the protocols for the electrical signals and the formatting of the data as it goes out [and] when it's being transmitted from one device to another. And that's how you achieve interfacing in the context of this claim.

. . .

So while the software is generating the information that gets sent, the connecting device is what actually, . . . that's where the information gets turned into a signal and in the case of a SCSI [small computer system interface] interface gets put on a wire . . . [T]hat's what is meant by interfacing and this is getting the right electrical signals in the right order with the right voltages with the right timing.

Id. at 12-13 (Papst).

The Claims, Figure 2, and the specification do not support Papst's definition as it would apply to "first connecting device." The Claims explain that the first connecting device is used "for interfacing," for establishing communication as defined above. That function does not describe the physical nature of the first connecting device itself. Taken into a different context, Papst's proposed construction would confuse a wall socket that accepts the plug from a lamp with the function that, once a plug is entered into a wall socket, the wall socket allows alternating current to reach the lamp and light its bulb. Despite this function, no one could confuse the wall socket itself with the current that flows after a plug is inserted.

The specification illustrates the physical nature of the first connecting device. The specification describes the first connecting device as containing various devices which require a physical, wired connection:

In the preferred embodiment of the interface device 10 shown in FIG. 2, the first connecting device 12 of FIG. 1 contains the following components: an SCSI interface 1220 and a 50-pin SCSI connector 1240 for attachment to an SCSI interface present on most host devices or laptops. The SCSI (small computer system interface) 1220 translates the data received via the SCSI connector 1240 into data understood by the DSP 1300, as known by those skilled in the art. Further, the first connecting device 12 comprises an EPP (enhanced parallel port) with a data transfer rate of approx. 1 MBps which delivers a more moderate data transfer rate of 1 MBps by comparison to the data transfer rate of 10 MBps of the SCSI interface. The EPP 1260 is connected to a 25-pin D-shell connector 1280 to permit attachment to a printer interface of a host device for
example. Optionally, the first connecting device 12 also comprises a 25-pin connector 1282 which permits the attachment of 8 digital outputs and 8 digital inputs 1284 at the host device.

'399 Patent, col. 9:29-47; '449 Patent, col. 8:30-48. Figure 2 shows a "25-pin connector," a "25-pin D-shell connector," and a "50-pin SCSI connector" for connecting a cable between the interface device and the host device/computer. See '399 Patent, Sheet 2; '449 Patent, Sheet 2; see also Tr.1:164-65 (Papst) (the SCSI device shown in Figure 2 would require a wired connection).

Further, the specification refers to "attachment" of various types of transmit/receive devices, via the interface device, to a host computer. See '399 Patent, col. 1:56-59 ("It is therefore desirable that an interface be sufficiently flexible to permit attachment of very different electrical or electronic systems to a host device by means of the interface.") (emphasis added); '449 Patent, col. 1:57-60 (same). And, the specification refers to a "line" connecting the host computer and the interface device: "whereby the [second command interpreter] begins to transfer data from the data transmit/receive device via the second connecting device and via the line 11 to the host device." '399 Patent, col. 6:53-67 (emphasis added). The terms "attachment"and "line" connote a physical connection.

The "first connecting device" is, therefore, a socket with a varying physical arrangement of pins (connectors) that allows different cables -- whatever cable would allow connection to the relevant host device/computer -- to be plugged into the interface device. The socket's pin arrangement could change as the nature of cables changed. The applicable cables that were known to those trained in the art as of 1998, when Mr. Tasler applied for the '399 Patent, were exhibited to the Court during the tutorial and were physical objects that required physical pin receptors to connect to a device. 15

A similar assortment of connectors, although considerably smaller, can be seen on the back and sides of today's laptop computers.

A socket is the opposite of a plug; that is, a socket is the "female" end of a connection and a plug is the "male" end. While Figure 2 illustrates sockets with pins that allow cables to connect the host device/computer with the invented interface device, such an arrangement is only a preferred embodiment and its opposite might also be anticipated to comply fully with the invention. Thus, a first connecting device may be either a physical socket or a plug. See, e.g., CMs' Markman Br., Ex. D, Am. Heritage Dictionary of Computer and Internet Words 59 (2001) (connector defined as "A coupler used to join two cables or to plug a cable into a port or interface."); id., Ex. E, Am. Heritage Dictionary of Computer Words 54 (1995) (same). 16

Papst contends that a first connecting device does not need to be a physical plug or socket because the patented device could use a wireless multi-purpose interface. Tr. 1:159-61 (Papst). Papst confuses "interfacing" and "connecting device." The former concerns "the protocols for the electrical signals and the formatting of the data," Tr. 2:12 (Papst), while the latter is a physical device in these Patents. Accordingly, the Court construes "first connecting device" to mean "a physical socket or plug for permitting a user to attach and detach the interface device to and from a host device/computer."
The parties construe the "second connecting device" in ways similar to their constructions of the term "first connecting device." The Camera Manufacturers propose a "physical plug or socket for permitting a user to readily attach and detach the interface device with a plurality of dissimilar data transmit/receive devices." CMs' Slides at 87. Papst distinguishes between the '399 and '449 Patents in its definition: Papst would define the "second connecting device" in the '449 Patent just like it would define the term "first connecting device" as "the circuit device used to couple the data transmit/receive device to the interface device" -- and Papst would interpret the term "second connecting device" in the '399 Patent as the structure recited in the Claim, that is, "a sampling circuit for sampling the analog data provided by the data transmit/receive device and an analog-to-digital converter for converting data samples by the sampling circuit into digital data." Papst App. 3 & 9-10; see '399 Patent, col. 12:55-60. Papst contends that the second connecting device in the '399 Patent is a device for sampling and converting analog to digital, not a mere connector.

It is unlikely that the same term, used in different parts of essentially the same patent, should have entirely different meanings. See Fin Control Sys. Pty. Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001) (there is a presumption that the same term used in multiple patent claims has the same meaning). In the '399 Patent, Papst would substitute specific functions that the second connecting device performs in the stead of its physical reality while the Camera Manufacturers would omit altogether any reference to the necessary capabilities. For the '449 Patent, Papst again retreats to the electronic circuitry that is operable when the second connecting device of the interface device is attached to the transmit/receive device by defining the second connecting device by its function and ignoring the physical nature of the connecting device itself.

The prosecution history is helpful. As initially presented to the PTO, Claim One of the '399 Patent referred to a second connecting device for interfacing. Tr. 1:185 (CMs). To avoid prior art, Mr. Tasler later amended his patent by inserting the language specifying that the second connecting device included a sampling circuit and an analog to digital converter. '399 File History at 7 (version with markings to show changes). This history indicates that the processing capabilities of the second connecting device, although present and critical in the interface device, do not detract from its fundamental status as a physical connector.

The "second connecting device" itself is a plug or socket that accepts the "output line" and allows the connection to be made between the invented interface device and the data transmit/receive device. The specification states that the second connecting device "can be attached by means of an output line 16 to a data transmit/receive device which is to receive data from the host device or from which data is to be read, i.e. acquired, and transferred to the host device." '399 Patent, col. 5:56-60 (emphases added); '449 Patent, col. 4:55-59 (same). The specification again refers to physical "attachment" via a "line" when it describes the flexibility of the interface device: "[U]sers of the interface device 10 are able to perform essentially identical operator actions for almost any data transmit/receive devices which can be attached to the second connecting device via the line 16, thus eliminating a source of error arising from users having to know many different command codes for different applications." '399 Patent, col. 7:39-43 (emphasis added); '449 Patent, col. 6:39-42 (same). The preferred embodiment of the second connecting device is a BNC [Bayonet Neill-Conselman] input. See '399 Patent, col. 9:49-53 ("Preferably, the second connecting device comprises 8 BNC inputs . . . ."); '449 Patent, col. 8:49-53 (same). The specification underscores the physical nature of the second connecting device by referring to the "actual hardware required to attach the interface device 10 to the data transmit/receive device," '399 Patent, col. 7:26-27; '449 Patent, col. 7:26-27, and the "specific hardware symbolized by the second connecting device." '399 Patent, col. 8:34; '449 Patent, col. 7:34.

The Court construes the "second connecting device" in the '399 Patent to mean "a physical plug or socket for permitting a user readily to attach and detach the interface device with a plurality of dissimilar data transmit/receive devices, including a sampling circuit for sampling the analog data provided by the data transmit/receive device and an analog-to-digital converter for converting data sampled by the sampling circuit into digital data." In the '449 Patent, the "second connecting device" means "a physical plug or socket for permitting a user readily to attach and detach the interface device with a plurality of dissimilar data transmit/receive devices."

GO BACK

1749

IV. First Data Processing Element
Claim 1 of the ’846 Patent and Claim 1 of the ’835 Patent each recite a "first data processing element, coupled to the system bus [means], for processing data from primary memory." Intergraph claims that this does not require construction, but proposes the construction: "a device that is coupled to the system bus and that processes data communicated from the primary memory through the system bus." Additionally, Toshiba claims that the term to be construed is the broader term "first data processing element coupled to the system bus for processing data from the main memory." In any case, the dispute once again boils down to whether all communication from the primary memory must be conducted over the system bus. Because this issue has been resolved via the construction of "system bus," no construction of "first data processing element" or "first data processing element coupled to the system bus for processing data from the main memory" is necessary.

1750

A. "first header having parameters stored therein for use by said audio player in decoding said digitally encoded music stored in said memory"

This order will start with the phrase "first header having parameters stored therein for use by said audio player in decoding said digitally encoded music stored in said memory," found in independent claim 1 of the patent. The parties indicated at the claim construction hearing that it is the most important phrase targeted by this order. Proposed constructions are shown below:

<table>
<thead>
<tr>
<th>LSI'S PROPOSED CONSTRUCTION</th>
<th>SANDISK'S PROPOSED CONSTRUCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>OF &quot;FIRST HEADER . . .&quot;</td>
<td>OF &quot;FIRST HEADER . . .&quot;</td>
</tr>
<tr>
<td>&quot;A data structure that includes information used by the audio player to decode digitally encoded music stored in memory&quot;</td>
<td>&quot;A single data structure that precedes digitally encoded music and contains information used by the audio player in decoding all digitally encoded music stored in memory&quot;</td>
</tr>
</tbody>
</table>

The term "data structure" -- used by both sides -- simply refers to the fact that the "first header" consists of structured data. FIG. 2 below illustrates what a data structure looks like in a preferred embodiment of the invention. The portion labeled (22) in FIG. 2 is what the specification called a "global header." As explained below, a "global header" is similar in many ways to a "first header." The "global header" in FIG. 2 provides a good example of why the term "data structure" is used: data, such as algorithm, bitrate, distributor, and other information, in stored in a structured, organized manner.

[SEE FIG. 2 IN ORIGINAL]

The constructions proposed by the parties present three key questions: (1) whether the "data format" of claim 1 allows for multiple "first headers" or just a single "first header," (2) whether the "first header" must precede the digitally encoded music, and (3) whether the "first header" must contain information to decode all digitally encoded music stored in memory. All of these questions stem from the fact that the term "first header" never appeared in the specification! Rather, the term "first header" appeared solely in claims 1 through 17. In other words, after five columns of discussion and disclosure by the patentee, the claims introduced -- for the first time -- a term never previously seen in the patent.

At oral argument, two explanations were put forth by the parties for the absence of "first header" from the specification: LSI argued that the term "first header" was simply used by the patentee as common patent parlance (i.e. standard drafting language) for listing multiple elements in a claim, as in "first means" and "second means," for example. The existence of a "second header" alongside the "first header" in claim 1 was cited in support of this argument. SanDisk, however, asserted that the absence of any reference to "first header" in the specification meant that it was the same as the "global header," a term used frequently and exclusively within the specification. To support their position, SanDisk pointed to the prosecution history, wherein LSI -- at times -- used "global header" and "first header" interchangeably.

Having considered both sides, this order finds that LSI's rationale for the patente's use of "first header" and "second
header" carries more weight, and a person having ordinary skill in the relevant art at the time the patent application was filed would have understood "first header" to be broader in scope than the disclosed "global header." As explained below, however, this does not mean LSI's proposed construction will be adopted in full.

i. "Single" Data Structure

While this order has concluded that "first header" is entitled to a broader construction than "global header," this breadth is not unlimited. Indeed, the claims cannot encompass more than what the patentee invented, which was a hierarchical approach to storing digitally encoded audio on a music chip (col 2:25-27). Here, LSI asks the Court to allow multiple "first headers" to be used in claim 1. SanDisk argues that there can only be a single "first header." As explained below, SanDisk's position on this issue seems to be correct.

The language used by the patentee in claim 1 strongly supports limiting the "first header" to a single data structure. Phillips, 415 F.3d at 1314. Indeed, as the undersigned noted at the claim construction hearing, the patentee's choice to use the phrase "first header," but then the phrase "at least one second header," supports a presumption that the "first header" was intended to be a single data structure.

An examination of the purpose of the "first header" in the context of the present invention further supports this limitation. As the specification explained, "[t]he present invention is a protocol . . . includ[ing] a hierarchical arrangement of headers about selections on the chip and the method in which they were coded" (col. 1:47-51) (emphasis added). The specification disclosed a particular two-tiered embodiment of this hierarchy. At the top of the hierarchy was the aforementioned "global header," and at the bottom were "individual headers" (see cols. 1:51-65). The "global header" -- exactly like the "first header" as described in claim 1 -- contained information to decode the digitally encoded music stored in memory (e.g., encoding algorithm, bitrate, etc.). The "individual headers" -- exactly like the "second headers" described in claim 1 -- contained information about individual music tracks (e.g., artist, album, genre, etc.).

Given this intrinsic evidence, a person having ordinary skill in the relevant art at the time the patent application was filed would have understood the "first header" and "second headers" as arranged in a similar hierarchy as the "global header" and "individual headers." Supporting this conclusion is the fact that neither the specification nor the prosecution history discussed the possibility of using multiple "global headers" or "first headers." Indeed, the intrinsic evidence never explains how the headers would still be hierarchical if this were possible.

LSI's best argument, made at the claim construction hearing, involved the "MP3" digital audio encoding format, which existed at the time the patent application was filed. In the MP3 data format, there are actually multiple "decoding" headers (called "frame headers") within every music track. A single music track may contain thousands of these frame headers. Thus, argued LSI, a person having ordinary skill in the relevant art at the time the patent was filed would have understood, having knowledge of the MP3 format, that multiple "first headers" (which claim 1 described as including "decoding" information) could be associated with a single "second header" (which, LSI argued, are "ID3" data tags associated with individual MP3 music tracks).

This argument, however, cannot overcome the great weight of intrinsic evidence showing a clear intent by the patentee to limit the invention to a hierarchy of headers, where multiple "music-track-specific" headers corresponded to a single "decoding" header. True, claim 1 uses the open-ended term "including." See CIAS, Inc. v. Alliance Gaming Corp., 504 F.3d 1356, 1360-61 (Fed. Cir. 2007) ("including" means "comprising"). The Federal Circuit, however, explained in Elkay Mfg. Co. v. Ebeco Mfg. Co., 192 F.3d 973, 977-79 (Fed. Cir. 1999), and Abtox, Inc. v. Exitrion Corp., 122 F.3d 1019, 1023-27 (Fed. Cir. 1997), that a term in a "comprising" claim may nevertheless be limited to "one" rather than "more than one" when the specification or the prosecution history showed that the term was "used in its singular sense." See Norian Corp. v. Stryker Corp., 432 F.3d 1356, 1359 (Fed. Cir. 2005).

As discussed above, the patentee's choice of claim language between "first header" and "at least one second header" reflected such an intent. See id. at 1358-59. Moreover, the specification disclosed no embodiments other than the "global header," which always was described in singular form. Finally, in a response to a USPTO office action dated June 17, 1996, the patent holder described the "first header" as containing "algorithm, bit rate, distributor of music, label, and copyright" information (Liu Decl. Exh. 7 at 10) (emphasis added). If the patentee truly intended the "first header" to be used as a "frame header" in an MP3 bitstream, the patentee would not have described the first header as containing information...
pertaining to the distributor of music, label, or copyright. Such information would have served no purpose in thousands of frame headers within a single music track. Additionally, all references to "first header" and "global header" in the prosecution history provided to the Court were used in a singular sense.

In sum, the intrinsic evidence demonstrates that a "single data structure" was clearly intended. See LiebelFlarsheim Co. v. Medrad, Inc., 358 F.3d 898, 905 (Fed. Cir. 2004); see also ICU Medical, Inc. v. Alaris Medical Systems, Inc., 558 F.3d 1368, 1375 (Fed. Cir. 2009).

ii. "Precedes" the Digitally Encoded Music

This proposed limitation by SanDisk is curious. The claim language says nothing about the "first header" preceding the digitally encoded music. Perhaps more problematic, however, is that it is not entirely clear what "precedes" even means in this context. Does it mean "precedes the digitally encoded music" in a bitstream? Or does it mean "precedes the digitally encoded music" in memory? At the claim construction hearing, the parties were asked this very question, and each gave a different answer.

Claim 1, however, provides a clear answer. It discusses a data format for digitally encoded music stored in memory. Unlike data presented in a bitstream, where the data is read sequentially as the stream is processed bit-by-bit, data stored in memory does not have to be read from the start of memory to the end of memory. Instead, data stored in memory can be accessed based upon its address. For example, the specification described the "global header" as located at "the very start of memory, presumably at 0x0" (cols. 1:51-54, 2:42-44). "0x0" is the lowest possible address for data storage in memory.

There is no reason, however, why the "first header" must be stored at this or any particular address in memory. For example, the "first header" could be stored at memory address "0xFFFF0" or 0xF0FF0." All that matters is that the audio player knows the memory address of the "first header" so that it can read the data stored therein. Given this backdrop, a person having ordinary skill in the relevant art at the time the patent application was filed would have understood that the "first header" need not "precede" the digitally encoded music stored in memory.

iii. "All" Digital Music

The final question pertaining to this phrase is whether the "first header" must contain decoding information for all digitally encoded music in memory. On this issue, nothing in the claim language compels this limitation.

Claim 1 merely set forth a hierarchical data format for storing digital music in memory. It did not require that the claimed format extend across the full scope of memory on a music chip. Indeed, a person having ordinary skill in the relevant art at the time the application was filed would have understood that memory can be partitioned and subdivided in various ways. For example, the memory on a music chip could be divided in half, each half storing a different set of music, each set encoded with different bit rates and algorithms. Under such a scenario, each set of music could have its own "first header" and corresponding "second headers." In sum, nothing in the claim language or intrinsic evidence restricts the possibility that multiple iterations of the claimed data format could be present on the same music chip.

iv. Final Construction

Based upon the preceding analysis, this order construes the phrase "first header having parameters stored therein for use by said audio player in decoding said digitally encoded music stored in said memory" as "a single data structure that includes information used by the audio player to decode digitally encoded music stored in memory." This construction is consistent with an earlier construction given to "first header" by the district court in Agere Systems Inc. v. Sony Corporation, 2008 U.S. Dist. LEXIS 39605, 2008 WL 2078308, at *1 (E.D. Tex. May 15, 2008) -- a decision to which both parties cited for various aspects of their arguments (Br. 6, Resp. 5-6, Reply 3-4). 1

1 The Sony construction, which involved a different accused infringer and for which there is no Federal Circuit opinion, is not binding on this court. See Comcast Cable Commec'ms Corp. v. Finisar Corp., 2007 U.S. Dist. LEXIS 28994, 2007 WL 1042821, at *2 (N.D. Cal. Apr. 6, 2007). This court is free to perform an independent construction of the disputed claim.
A "first layer to be etched" is a layer of a semiconductor device from which some amount of material is removed in order to create a pattern in the layer. The first layer may consist of any type of material and need not be present in the completed device.

M. "First Message"

Claim 18 of the '932 patent recites the claim term "first message." Sprint contends that this claim term should be construed to mean a signaling message that is distinct from the claimed second message. Vonage contends that it should be construed to mean a narrowband signaling message.

Vonage argues that the specification recognizes that the first signal is a narrowband signaling message. A careful review of these excerpts, however, reveals that none of them contain the word "narrowband." Moreover, as Sprint points out, the claim language refers to "a call having a first message," '932 Patent at 23:20-21, which is not necessarily synonymous with the "first signal" referred to in the specification. As to Vonage's prosecution disclaimer argument, Vonage has not presented evidence establishing a clear and unmistakable disavowal of claim scope. Vonage cites comments from an amendment to the '605 application, purportedly relating to "claim 121." The court is unable to determine from the record presented that the emphasized language has any relationship to claim 18 of the '932 patent, let alone whether it is pertinent to the "first message" recited in that claim. Given this lack of clarity in the prosecution history submitted by Vonage, the court does not find any valid basis to import the limitation urged by Vonage. The court therefore rejects Vonage's arguments on that basis.

Turning to Sprint's argument, Sprint contends that the claimed "first message" should be construed to mean that it is distinct from the second message. In support of this argument, Sprint relies on the language of the claim itself. The claim recites a communications system for handling a call having "a first message" in which the system is comprised of (1) a processing system that is configured to process and receive "the first message" and to generate and transmit "a second message," and (2) an asynchronous communication system configured to receive "the second message." This claim language seems to reflect, as argued by Sprint, that the claim uses the terms "first" and "second" messages essentially as terms to distinguish between the respective roles of the two messages within the communications system. Because the claim construction urged by Sprint is an accurate characterization of the claim term "first message" according to the language of the claim itself, then, the court construes this claim term to mean a signaling message that is distinct from the second message.

F. "A first metallization layer comprising aluminum being defined overlying said gate region" ('419 patent, claim 1)

1. APT's suggested "In electrical contact"

Mapping its argument above, APT again suggests that this court read the requirement of electrical contact between the first metallization layer and the polysilicon layer into the claim. For the reasons described above, the court declines to do so.

2. "Overlying said gate region"
Both parties agree that the "gate region" consists, in relevant part, of a polysilicon layer overlying channel regions, and possibly other areas. See '419 patent, 7:59-60; '715 patent, 5:22-26. Their disagreement stems from the question of whether this claim should be understood to require that the first metallization layer overly the gate region as part of the requirement that it overly the gate region. APT would seem to argue that the gate region consists of only that part of the polysilicon that overlies the channel region, which would imply that the first metallization layer must be found directly above the channel region in order to literally overly the gate region. See '419 patent, 7:59-60 (the gate region is "defined overlying said channel region."). However, as discussed above, the word "overlying" here does not imply exclusivity: the gate region may include portions of the gate polysilicon that overly other areas in addition to the channel region. The '715 patent, a sibling of the '419 patent, makes this point when it discusses "portions overlying the channel and field region." '715 patent, 6:10-11. The court thus finds it inappropriate to limit the gate region to that area that overlies only the channel region, and at the same time inappropriate to extend the gate region to anything covered by the polysilicon gate layer. In order to overly the gate region, the first metallization must overly either the channel region or the field region.

3. "Being Defined"

Regrettably for a court that is not as skilled in the art of MOSFET design as the parties to this case, neither side's submission regarding the terminology "being defined" is a model of clarity. In its reply brief, Ixys urges that the construction of this term retain the word "defined" because such a word is well known in the art, but does not elucidate what the word actually means. APT urges that "defining" a layer necessarily means using a mask, and points to several places within the specifications in which a mask is used to define a particular alignment. However, none of these specifications appear to contemplate a mask as the sole means of defining a layer, and Ixys notes that the specifications of the '715 patent reference a non-mask method for defining a layer. '715 patent, 5:46-49.

APT's reference to the '715 patent's prosecution history is similarly inconclusive; the submission to the examiner states that Korman et. al and Jones et. al failed to suggest "defining such first metallization layer to form a portion overlying a portion of said polysilicon layer." Catalano Dec. Exh. 11, at 5. Yet contrary to APT's assertion, the distinction is drawn not between the current invention and prior art that used a "selective process" and thus failed to "define" a layer using a mask, but between the present invention that defines a first metallization layer overlying silicon oxide as well as polysilicon and prior art that defines it overlying only the latter.

Divining the proper interpretation of "defining" from these legal hieroglyphs is far from a straightforward task. As best as this court can determine, to "define" a layer is to determine where that layer will be deposited--a layer may be "defined" by any number of different processes, including mask patterning or via the physical structure of the substrate itself.

4. Step-Plus-Function

In the alternative, APT suggests that Claim 1 be read as a "Step-Plus-Function" claim element under 35 U.S.C. § 112, P6. The steps-plus-function analysis "is implicated only when steps plus function without acts are present." O.I. Corp. v. Tekmar Co., Inc., 115 F.3d 1576, 1583 (Fed. Cir. 1997). This claim does not use the phrase "steps for;" the omission creates a strong presumption that it is not claiming a steps-plus-function element. Id. Moreover, this claim includes descriptions of acts to be taken, rather than the functioning of the invention at issue. APT is unable to point to any "function" being described within the claim language. Hence, it would be inappropriate to treat this claim as step-plus-function.

The court construes the claim language to mean: "A metallization layer that includes aluminum, at least a portion of which is specifically deposited overlying at least a portion of the polysilicon layer directly above either the channel or field region."

1754

E. "A first metallization layer comprising aluminum having portion overlying said polysilicon layer" ('715 patent, claim 1)

"A first metallization layer comprising aluminum having a portion overlying a portion of said polysilicon layer" ('715 patent, claim 23; '419 patent, claim 11)
The construction of these claim terms involves the necessary resolution of several issues, each of which are considered in turn below.

1. "Comprising aluminum"
