Moreover, Ritek concedes that the court's original construction of "array" is correct. Ritek conceded at the claim construction hearing that the additional language it proposes merely makes the court's previous construction "extra right" in light of the guidance provided by the Federal Circuit with respect to the "partitioning" construction. A construction need not be "extra right" to avoid being wrong. Since the court will address the Federal Circuit's guidance in the "partitioning" construction, the court declines to adopt Ritek's proposed additions.

Accordingly, the court's original construction of the term "array" stands.

Because the court declines to adopt Ritek's proposed modifications to the construction, SanDisk's motion to strike Ritek's "new" construction of "array" is moot and DENIED. See Doc ## 393, 405-2.

An array of optical signal processing devices

Claims 18 and 19 of the '714 Patent contain the term "an array of optical signal processing devices." Cheetah contends that the term means "a plurality of mirrors arranged in a regular pattern that process the optical signal," while Mitsubishi contends that it means "an array of variable blazed gratings." The parties disagree whether the term "an array of optical signal processing devices" is limited to variable blazed gratings.

Cheetah asserts that the specification indicates that configurations other than variable blazed grating may be used for the optical signal processing devices. Cheetah also points to the prosecution history as providing evidence as to how the Patent Office interpreted this term to include digital micro-mirrors, which are not variable blazed gratings, when applying the prior art. Mitsubishi counters that all of the signal processing devices disclosed in the specification are variable blazed gratings. Mitsubishi also points out that the title of the patent is "Variable Blazed Grating Based Signal Processing" and that "blazed grating" appears 145 times in the specification, and argues that collectively these statements demonstrate that blazed gratings are part the invention, not merely a preferred embodiment.

Although the specification provides extensive reference to the use of blazed gratings, it states that "any shape can be used consistent with the invention" for the strips and "switches implementing different geometric configurations or different numbers of blazed grating elements, circulators, reflective surfaces, or other optical elements are contemplated as being within the scope of the invention." '714 Patent, col. 3:37-42, col. 14:58-65. In addition, Claims 18 and 19 themselves provide additional explicit detail regarding the array of optical signal processing devices without limiting the devices to variable blazed gratings. '714 Patent, col. 25:48-67, col. 26:16-22. Further, the fact that the title of the patent is "Variable Blazed Grating Based Signal Processing" is of very little significance to claim construction. See Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1313 (Fed. Cir. 1999) (stating the fact that "the patent title has only been mentioned
once by [the Court of Appeals for the Federal Circuit] in the context of claim construction and, even then, merely to make an illustrative point in one sentence, makes a powerful statement as to the unimportance of a patent's title to claim construction”). Thus, limiting the array to variable blazed gratings would be improperly importing a limitation of the preferred embodiment. Phillips, 415 F.3d at 1323 (stating that "the danger of reading limitations from the specification into the claim" should be avoided). Accordingly, the Court construes the term "an array of optical signal processing devices" to mean "a plurality of devices arranged in a regular pattern that process the optical signal."

The text of claim 1 is set forth below with the key disputed term highlighted in bold type.

A method of on-line reorganization of data in a storage system having n+1 disks arranged in a RAID array when one of said disks fails while preserving concurrent access to said array by a user application, each of said disks in said storage system having a plurality of data blocks, a plurality of parity blocks, each parity block associated with n data blocks, a plurality of groups of parity block state bits, each group of parity block state bits indicating that said associated parity block contains parity information or data or the contents are undefined, and a group of array state bits indicating the condition of the array as "normal," "folding," "fully folded" or "unfolding," said method comprising the steps of:

(a) receiving a read request from said user application to read a targeted data block;

(b) interrogating said array state bits to determine the condition of said array;

(c) if said array state bits indicate said array is in said "normal" state, then proceeding with a read operation;

(d) if said array state bits indicate said array is in said "folding" state, then proceeding with a "folding" read operation;

(e) if said array state bits indicate said array is in said "fully folded" state, then proceeding with a "fully folded" read operation; and

(f) if said array state bits indicate said array is in said "folding" state, then also proceeding with a deliberate process to complete said reorganization concurrently with user application access to said array.

The text of claim 7 is set forth below, with the key disputed term highlighted in bold type.

A method of on-line reorganization of data in a storage system having n+1 disks arranged in a RAID array when one of said disks fails while preserving concurrent access to said array by a user application, each of said disks in said storage system having a plurality of data blocks, a plurality of parity blocks, each parity block associated with n data blocks, a plurality of groups of parity block state bits, each group of parity block state bits indicating that said associated parity block contains parity information or data or the contents are undefined, and a group of array state bits indicating the condition of the array as "normal," "folding," "fully folded" or "unfolding," said method comprising the steps of:

(a) receiving a write request from said user application to write to a targeted data block;

(b) interrogating said array state bits to determine the condition of said array;

(c) if said array state bits indicate said array is in said "normal" state, then proceeding with a write operation;

(d) if said array state bits indicate said array is in said "folding" state, then proceeding with a "folding" write operation;

(e) if said array state bits indicate said array is in said "fully folded" state, then proceeding with a "fully folded" write operation; and
if said array state bits indicate said array is in said "folding" state, then also proceeding with a deliberate process to
complete said reorganization concurrently with user application access to said array.

HP asks the Court to construe this term as: "Bits indicating the state of the array as a whole." EMC proposes: "Bits stored on
each disk in a RAID array that indicate the condition of the RAID array as being normal,' folding,' fully-folded,' and
unfolding.'"

The claim language reveals that array state bits may indicate the condition of the array as normal, folding, fully folded, or
unfolding. Nevertheless, a list of things that an object may indicate does not necessarily define the object. Indeed, the
specification acknowledges that array state bits identify other information as well. For example, "[i]n the preferred
embodiment, two array state bits identify the missing or replacement member disk and two additional array state bits
identify the state of the array." 327:11/67-12/2. Similarly, "[t]he state information for the array as a whole includes the
following: (a) Identity of the missing or replacement member disk and (b) Array state. The array state includes (a)
normal,' . . . (b) folding,' . . . (c) fully folded,' . . . and, (d) unfolding."' 327:11/50-57. Accordingly, looking to the
specification to help define the term without importing limitations, the Court concludes that "array state bits" contain
information relating to the identity of a missing or replacement disk and the state of the array.

EMC's proposal further requires the array state bits to be "stored on each disk in a RAID array." However, nothing in the
claim or the specification indicates that a location limitation is necessary for proper claim construction.

Accordingly, the Court construes this term as "bits that identify either the missing or replacement member disk or the state
of the array."

A. "A Method of Screening the Data as It Is Being Transferred"

The parties first dispute the meaning of the phrase "a method of screening the data as it is being transferred" as used in the
preamble of Claim 1 (and which, of necessity, constitutes part of dependent claims 2-17). Defendant proposes that this term
be construed as "a method of screening the data while it is being moved or copied and before the data is written to the
computer storage medium." Joint Claim Construction Statement ("JCCS"), Appx. A, at 3 (term 8). Plaintiff proposes that the
phrase be construed as "a method of screening the data prior to storage." Id. Preliminarily, however, plaintiff contends that
this phrase is part of the claim preamble, and because the preamble ordinarily does not limit the claim it is not necessary to
construe this term.

1. Whether the Phrase Needs to Be Construed

Plaintiff argues that the phrase "a method of screening the data as it is being transferred" is, as part of the preamble to Claim
1, not a limitation on the claimed invention. As plaintiff correctly notes, if the preamble is not limiting, "then the preamble
is of no significance to claim construction because it cannot be said to constitute or explain a claim limitation." Schumer v.
Laboratory Computer Sys., Inc., 308 F.3d 1304, 1310 (Fed. Cir. 2002) (quoting Bristol-Myers Squibb Co. v. Ben Venue
Labs., Inc., 246 F.3d 1368, 1373-74 (Fed. Cir. 2001)). Thus, the Court must first determine whether this language of the
preamble has any limiting effect on the claimed invention.

In general, "a preamble is not limiting where a patentee defines a structurally complete invention in the claim body and uses
the preamble only to state a purpose or intended use for the invention." Catalina Mktg. Int'l, Inc. v. Coolsavings.com, Inc.,
289 F.3d 801, 808 (Fed. Cir. 2002) (quoting Rowe v. Dror, 112 F.3d 473, 478 (Fed. Cir. 1997)); see also, Pitney Bowes, Inc.
v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999). "No litmus test defines when a preamble limits claim scope." Catalina Mktg., 289 F.3d at 808 (Fed. Cir. 2002). Rather, "[w]hether to treat a preamble as a claim limitation is determined
on the facts of each case in light of the claim as a whole and the invention described in the patent." Storage Tech. Corp. v.
Cisco Sys., Inc., 329 F.3d 823, 831 (Fed. Cir. 2003); see also, Poly-America, L.P. v. GSE Lining Tech., Inc., 383 F.3d 1303,
1309 (Fed. Cir. 2004). Nevertheless, "[s]ome guideposts . . . have emerged from various cases discussing the preamble's
effect on claim scope." Catalina Mktg., 289 F.3d at 808. These guideposts establish three general situations in which
language in the preamble may have limiting effect.

- 669 -
First, "[w]hen limitations in the body of the claim rely upon and derive antecedent basis from the preamble, then the preamble may act as a necessary component of the claimed invention." Eaton Corp. v. Rockwell Int'l Corp., 323 F.3d 1332, 1339 (Fed. Cir. 2003); see also, Catalina Mktg., 289 F.3d at 808. Second, and relatedly, "a preamble generally limits the claimed invention if it 'recites essential structure or steps, or if it is necessary to give life, meaning, and vitality to the claim.'" NTP Inc. v. Research in Motion, Ltd., 392 F.3d 1336, 1358 (Fed. Cir. 2004) (quoting Catalina Mktg., 289 F.3d at 808); see also, Poly-America, L.P., 383 F.3d at 1309. Finally, "because such reliance indicates use of the preamble to define, in part, the claimed invention," Catalina Mktg., 289 F.3d at 808, preamble language is limiting if there is "clear reliance on the preamble during prosecution to distinguish the prior art." Intirtool, Ltd. v. Texar Corp., 369 F.3d 1289, 1295 (Fed. Cir. 2004) (quoting Catalina Mktg., 289 F.3d at 808).

Defendant contends that the language at issue was added during patent prosecution in order to distinguish the claimed invention from the prior art. The Court agrees. As originally submitted, the preamble to Claim 1 read: "In a data transfer system for receiving a transmission of digital data for storage in a computer storage medium, a method of identifying and inhibiting the storage of data containing at least one predefined sequence, comprising: . . . ." Def.'s Claim Construction Br. ["Def.'s Br."] at 2. On November 21, 1991, in part to overcome the prior art, the inventors amended the preamble to read: "In a system for transferring digital data for storage in a computer storage medium, a method of inhibiting the storage of data containing at least one predefined sequence, comprising the steps of . . . ." Id.; see also id. at 6-7 (explaining reason for amendment). After the application was again rejected, the inventors amended the application once more, altering the preamble to read: "In a system for transferring digital data for storage in a computer storage medium, a method of screening the data as it is being transferred and automatically inhibiting the storage of screened data containing at least one predefined sequence, comprising the steps of . . . ." Def.'s Br., Ex. 15, Amendment filed 8/26/92, at 1 (emphasis added).

Importantly, counsel for the inventors explained that this amendment was sufficient to overcome the prior art. Counsel explained that "the art relied upon does not teach or suggest a method or apparatus for screening the data as it is being transferred (on the fly) . . . ." Id. at 5 (emphasis added). Thus, counsel indicated that the prior art was distinguishable because it did not "screen the data as it is being transferred," the precise language added to the preamble by the amendment. "This language shows a clear reliance by the patentee on the preamble to persuade the Patent Office that the claimed invention is not anticipated by the prior art. As such, the preamble is a limitation of the claims." In re Cruciferous Sprout Litig., 301 F.3d 1343, 1348 (Fed. Cir. 2002); see also, Invitrogen Corp. v. Biocrest Mfg., L.P., 327 F.3d 1364, 1370 (Fed. Cir. 2003); Middleton, Inc. v. Minnesota Mining & Mfg. Co., No. 99-1201, 1999 U.S. App. LEXIS 29872, 1999 WL 1072246, at *3 (Fed. Cir. Nov. 16, 1999). See generally, Catalina Mktg., 289 F.3d at 808 ("[C]lear reliance on the preamble during prosecution to distinguish the prior art transforms the preamble into a claim limitation because such reliance indicates use of the preamble to define, in part, the claimed invention.").

This conclusion is buttressed by the language of the specification. The specification notes that the problem with the then-existing technology was that it only allowed for scanning of files already on the destination storage medium, when the virus has already corrupted that medium. See '776 patent, col. 1, Ins. 45-54. As stated by the specification, the invention disclosed constitutes an improvement over the prior art because it solves this problem "by performing an in transit detection of computer viruses," '776 patent, col. 1, In. 36 (emphasis added), and notes that the invention "is able to test for viruses 'on the fly.'" '776 patent, col. 1, Ins. 59-60. "The specification therefore indicates that the inventors believed their invention to be a method for screening the data during transfer, as recited in the preamble to Claim 1. Cruciferous Sprout Litig., 301 F.3d at 1347. Thus, "both the specification and the prosecution history indicate that the phrase ["a method of screening the data as it is being transferred"] helps to define the claimed invention and is, therefore, a limitation of Claim 1 [and the claims that are dependent upon Claim 1]." Id.

This conclusion is not altered by Bristol-Myers Squibb Co. v. Immunex Corp., 86 F. Supp. 2d 447 (D.N.J. 2000), aff'd in relevant part sub nom. Bristol-Myers Squibb Co. v. Ben Venue Labs., Inc., 246 F.3d 1368, 1373-74 (Fed. Cir. 2001), upon which plaintiff relies. As plaintiff notes, the Bristol-Myers court noted that the fact "[t]hat the examiner insisted on including certain language . . . does not automatically make the claims' preambles limitations." Id. at 451. However, as the Federal Circuit explained on appeal, in that case the language which was added to the preambles was not added for the purpose of distinguishing the prior art, and was added voluntarily by the patentee after the claim had already been allowed. See Bristol-Myers, 246 F.3d at 1375. In other words, the patentee did not rely on the preamble language during prosecution to distinguish the prior art. Here, as explained above, the patentees did just that, and under the cases discussed above this
renders the language added to the preamble a limitation on the claim. Accordingly, the Court finds it necessary to construe the phrase "a method of screening the data as it is being transferred." 6

6 Because the prosecution history and specification lead to this conclusion, the Court need not consider the effect of Mr. Schallop's deposition testimony and the additional argument based on that testimony in defendant's supplemental brief.

2. Construction of the Phrase

As noted above, defendant proposes that this term be construed as "a method of screening the data while it is being moved or copied and before the data is written to the computer storage medium." JCCS, Appx. A, at 3 (term 8). Plaintiff proposes that the phrase be construed as "a method of screening the data prior to storage." Id. The Court concludes that defendant's construction is correct.

Plaintiff's construction merely equates "prior to storage" with transfer. It may ultimately be, as plaintiff argues, that everything between sending and "storage" constitutes transfer, and thus the terms mean the same thing. This cannot be resolved, however, without independently construing each term. As used in Claim 1, the phrase "a method of screening data as it is being transferred" by its plain terms contemplates screening while the data is being moved or copied. This conclusion is buttressed by the specification and the prosecution history, both of which point up the method's ability to detect viruses "on the fly" as central to the merits of the claimed method. Whether this construction of the phrase adds any limitation which is not already encompassed by other terms in the claims need not be decided here. Accordingly, the Court concludes that the phrase "a method of screening the data as it is being transferred" means "a method of screening the data while it is being moved or copied and before the data is stored to the computer storage medium." 7

7 The Court has substituted the word "stored" here in placed of "written" as set forth in defendant's proposed construction. This use of "written" assumes that the Court adopts defendant's definition of "storage," which is discussed below, see infra part IV.D.1. It is enough in construing this term to used the word "stored," with "stored" taking the further meaning discussed below.

8. Defining and Loading, as Required by the Formation of the Particular Monochromatic Images, at Least Some of the Font Patterns in the Font Memory

The phrase "defining and loading, as required by the formation of the particular monochromatic images, at least some of the font patterns in the font memory" means that as new characters are encountered in the image, new font patterns (or monochromatic characters) can be formed and stored in the font memory.

D. As the Interrupt Signal ('950 patent, claims 1, 13; '780 patent, claims 1, 7)

Agere contends that the term means "as the one and only signal to the host computer from the device that forces the host processor to temporarily suspend other tasks while addressing the device, which signal is not asserted in conjunction with Direct Memory Access transfers." PCTEL contends that the term means "as a signal that attempts to get the attention of a
Agere's proposed construction is based on the ordinary meaning of the term, the intrinsic evidence, and the prosecution history. Agere contends that the ordinary meaning of "interrupt" is "[a] temporary suspension of a process caused by an event outside of that process. . . ." (Mills-Robertson Decl., Ex. 14 at 13, Newton's Telecom Dictionary (1997). Agere also states that "as the interrupt signal" refers to only one signal, as the word "the" is used to modify the term that follows it by making that word singular and specific. Agere contends that this conclusion is supported by the following claim language: "the selection logic selects the first signal as the interrupt signal when the device is operating in the first mode and selects a second signal from the communication lines as the interrupt signal when the device is operating in second mode." '950 patent, col. 6:53-57. Agere also cites to the specification to support its position. '950 patent col. 4:32-61, 4: 62-5:6, 5:22-29; '780 patent col. 4:23-53, 4:54-64, 5:13-22. Finally, Agere asserts that the prosecution history reveals that PCTEL limited the claim coverage to a single, specific interrupt signal.

PCTEL responds that it has become standard practice to use indefinite articles (i.e., "a" and "an") the first time a claim term is introduced, and definite articles (i.e., "the" and "said" when the claim term is mentioned subsequently. n11 PCTEL also asserts that the term "comprising" in a claim term means that the claim covers devices that contain "at least" the elements in the claim. See Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997) ("Comprising" is a term of art used in claim language which means that the named elements are essential, but other claims may be added. . . ). PCTEL contends that the '950 and '780 patents reflect both of these general drafting principles. Hence, PCTEL argues that the definite article "the" in the claim term "as the interrupt signal" simply makes clear that the signal that is selected by the selection logic is the same signal that causes the software to be executed by the host processor. Moreover, PCTEL argues that the use of the indefinite article "an" in conjunction with the open-ended claim term "comprising" evidences the applicant's intent that the claims cover products wherein the software is executed in response to more than one interrupt signal.

In construing this term, the Court agrees with Agere that ordinary meaning of "interrupt" is a signal that forces the host processor to temporarily suspend other tasks. (Mills-Robertson Decl., Ex. 22, Oxford Dictionary of Computing (1996)) ("A signal to a processor indicating that a asynchronous event has occurred. The current sequence of instructions is temporarily suspended (interrupted), and a sequence appropriate to the interruption is started in its place."); (Ex. 23, Webster's New World Dictionary of Computing Terms (1997)) ("A signal to the microprocessor indicating that an event has occurred that requires its attention. Processing is halted momentarily so that input/output to other operations can take place."); (Ex. 26, The IEEE Standard Dictionary of Electrical and Electronics Terms (1996)) ("The suspension of a process to handle an event external to the process.").

Regarding the parties' dispute over whether "as the interrupt signal" refers to only one signal, the Court finds Agere's reliance on the prosecution history is unpersuasive. The PTO originally rejected claim 1 because it was unclear where the interrupt signal was coming from. (Mills-Robertson Decl., Ex. 19 at 14982). Accordingly, the applicant specifically amended claim 1 to include "as the interrupt signal" to overcome the examiner's objection:

The Examiner indicated that claim 1 was unclear as to the source of the interrupt signal. Amended Claim 1 now recites, "the selection logic being coupled to select the interrupt signal provided to the host processor, wherein the selection logic selects the first signal as the interrupt signal when the device is operating in the first mode and selects a second signal from the communication lines as the interrupt signal when the device is operating in the second mode." Accordingly, amended claim 1 clearly indicates the source of the interrupt signal.

(Mills-Robertson Decl., Ex. 7 at AL 14994 (emphasis added).

Based on this amendment, the U.S. Patent examiner for the '780 patent approved claim 1 precisely because it distinguished
between interrupts from two different sources:

The following is an examiner's statement of reasons for allowance: the selection logic that distinguishes between interrupts from two different sources when in two different modes.

(Mills-Robertson Decl., Ex. 20 at AL 15079).

However, by clarifying that the selection logic selects the interrupt that causes the host processor to execute the software, the Court is not convinced that PCTEL limited the claim so that either the first or the second signal must be exclusively selected as the interrupt. See Omega Eng'g, Inc. v. Raytek, Corp., 334 F.3d 1314, 1326 (Fed. Cir. 2003) (stating that for prosecution disclaimer to attach, the alleged disavowing actions or statements made during prosecution be both clear and unmistakable). It is certainly possible that the patentee, by using the term "and" to connect the two "selections" made by the selection logic, intended the claim to cover selection logic that can select signals in addition to the first signal when in the first mode and can select signals in addition to the second signal when in the second mode. Thus, the Court construes "as the interrupt signal" as the signal to the host processor from the device that may cause the host processor to temporarily suspend other tasks while addressing the device. n12

n12 The Court rejects Agere's use of the phrase "which signal is not asserted in conjunction with Direct Memory Access transfers" for the reasons stated in Sec. II(C).

6. **Ascertaining a georeferenced map that contains the geographic coordinates**

This limitation appears in claim 1 of the 698 patent. The plaintiff contends that no construction is necessary. Alternatively, the plaintiff urges that the term means "determining a georeferenced map that includes the geographic coordinates." The defendants contend that the term means "determining the georeferenced raster FEMA map image containing the property latitude and longitude or other coordinate set that defines the position of the property on the earth's surface using a virtual grid of rectangular regions covering all geographic areas contained within the FEMA maps, creating a list of insets that intersect with each grid-rectangle, selecting the grid rectangle containing the property latitude and longitude, and determining which inset associated with the grid rectangle contains the property."

Previously, the court rejected the defendants' attempt to limit claim 1 to the disclosed embodiment. That holding largely determines the outcome of this issue. The court adopts the plaintiff's alternative construction and defines the term to mean "determining a georeferenced map that includes the geographic coordinates."

5. "Ascertaining as a function of an outcome of a comparison whether an access of the at least one subscriber station (5, 10, 15, 20) to the at least one telecommunications channel is enabled"

HTC contends that this clause should be construed mostly according to its plain meaning as "comparing (S) to ® to determine whether access to the common telecommunications channel is allowed, or whether the subscriber station (cell phone) must wait for and check the next transmission of access authorization value." Chart at 5. IPCom asserts that it means, "the microprocessor is programmed . . . to determine, based on an outcome of a comparison of the access threshold value and the random (or pseudo-random) number, whether to authorize the particular subscriber station access rights to the common telecommunications channel." Id.
IPCom contends that HTC's construction improperly imports the concept of waiting for and checking the next transmission. But this concept is fully supported by the specification, which states, "[a]fter the end of the program, the mobile station informs the user that the access to the r30 was not possible, and waits for further inputs from the user. Alternatively, by means of a waiting loop embodied in the mobile station, the program is executed over again, so there is a wait for the next information signal with the next bit pattern, and the information signal is then evaluated . . . ." '751 Patent at 10:3-10; see also HTC's Resp. [Dkt. # 151], Ex. D. (Dep. of Martin Hans) at 175-76 (inventor testified that once the mobile station attempts to gain access and has been denied authorization, it will not immediately seek re-access).

The Court concludes that HTC's construction is the better one, as it more closely follows the claim terms and the specification. The phrase "ascertaining as a function of an outcome of a comparison whether an access of the at least one subscriber station (5, 10, 15, 20) to the at least one telecommunication channel is enabled" is construed to mean "comparing an access threshold value to a random or pseudo-random number to determine whether access to the common telecommunications channel is allowed or whether the subscriber station (cell phone) must wait for and check the next transmission."

---

**F. "Asks"**

<table>
<thead>
<tr>
<th>Plaintiff's Construction</th>
<th>Defendant's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>An ask quantity and an ask price.</td>
<td>A plurality of offers to sell tickets, each of which can be accepted.</td>
</tr>
</tbody>
</table>

The primary dispute between the parties is whether this term is limited to the plural (Defendant's position) or whether it encompasses the singular as well as the plural (Plaintiff's position). Defendant contends that the term is limited to the plural because "[t]he claims and the specification only use the noun 'asks' in the plural form because the term is intended to refer to the asks submitted by a plurality of sellers." (D.I. 50 at 16.) However, this does not appear to be correct. Indeed, Claim 14, which is unasserted, requires a "means for receiving from secondary market event ticket owner electronic asks comprising an ask quantity and an ask price." Likewise, Claim 17, also unasserted, calls for "receiving from the secondary market paperless ticket seller electronic asks comprising an ask quantity and an ask price." Thus, at least two claims associate the term "asks" with only a single "owner" or "seller," undermining Defendant's position that the term "asks" is plural because it is always linked to a plurality of individuals.

"[I]n context, the plural can describe a universe ranging from one to some higher number, rather than requiring more than one item." Versa Corp. v. Ag-Bag Int'l Ltd., 392 F.3d 1325, 1330 (Fed. Cir. 2004). On reviewing the specification and claims, the Court is unable to identify anything stating that the exchange of tickets in a secondary market requires multiple sellers to collectively provide a plurality of "asks." In other words, the Court finds nothing that strictly precludes use of the invention in connection with a single seller that provides a single "ask." Indeed, the specification even describes the invention with reference to the sale of a single ticket, which is presumably associated with a single seller and a single "ask." See '809 patent at 4:63-5:8 ("During the step of offering the ticket 126, a price is associated with the ticket.") (emphasis added). Thus, the Court concludes that this claim term should encompass the singular as well as the plural. See also Every Penny Counts, Inc. v. Bank of Am. Corp., No. 2:07-cv-42, 2008 U.S. Dist. LEXIS 75672, at *16-*17 (M.D. Fla. Sept. 29, 2008) (construing the term "accounts" to include the singular where nothing in the claim language or specification suggested that it was limited to the plural). Furthermore, the claims specifically state that the "asks [comprise] an ask quantity and an ask price," and therefore, the Court will construe the term "asks" to mean "one or more asks each of which comprises an ask quantity and an ask price."

---

Modavox defines this phrase as "manipulating computer code instructions that include a service response." Tacoda's counter-definition is "creating at the server, a customized, executable computer program that controls user access to additional Web page functionality."

Frankly, there is very little difference between these two definitions. Where Modavox uses the words "service response," Tacoda inserts a variant of the definition of that term selected by the court. And while Tacoda includes a great deal of additional and (or so it appears) unnecessary "stuff" in its proposed definition of the term "assembling," Modavox's "manipulating computer code" is unnecessarily broad. The word "assemble" has a commonly understood meaning -- "put together" -- that can be used to create the following definition:

The term "Assembling Said Second Code Module Having Said Service Response" means putting together a second code module (which, as you already know, is a computer program) that includes, as part of the program, a service response (which I have previously defined for you).

II. "Assign" and "Assignment"

Defendant contends that its construction reflects the ordinary meaning of the term as it is used in the specification and claims. Defendant argues that an assignment must be a present transfer of the right to receive a payment that is not conditioned upon further performance.

The Court finds that the scope of the terms is limited to the present transfer of a property right, which is tantamount to Plaintiff's proposal. Permutations of the term "assign" appear throughout the specification. See '829 Patent col. 1:44-49; 1:62-63; 2:1-2, 51-53; 3:1-8, 60-64; 4:53-55; 5:1-4. The terms are used not only to describe a transfer of an interest between a taxpayer and a spending vehicle provider, but also unclaimed transfers between spending vehicle providers, see '829 Patent col. 4:53-55, and transfers between the taxpayer and a tax preparer. See '829 Patent col. 5:1-4. In each instance, the terms are used in their ordinary meaning to indicate the present transfer of a right or interest from one party to another. See Black's Law Dictionary (8th ed. 2004) (defining the term assign as "to transfer rights or property"); see also Mar. 21, 2005 Amendment, p.10 (describing an assignment as something "which transfers a property right to another party"). It is unnecessary to muddle the definition by explicitly stating that a transfer is unconditional; an agreement to assign may be conditional, but an assignment is simply a transfer.

Having determined the scope of the claim terms, the Court must now determine how best to communicate them to a lay jury. The Court finds that the terms "assign" and "assignment" are readily understandable for a jury and thus no construction is necessary. See O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351, 1362 (Fed. Cir. 2008); Fenner Inv. Ltd. v. Microsoft Corp., No. 6:07-cv-8, 2008 U.S. Dist. LEXIS 65686, 2008 WL 3981838 at *3 (E.D. Tex. Aug.22, 2008) (finding that a court need not construe a disputed term as long as it has resolved the claim scope dispute between the parties). Although the Court will not construe the terms, the parties may not interpret the terms in a manner that is inconsistent with
The phrase "assigned in buckets" appears in claims 17 and 31 of the '446 patent and claim 17 of the '438 patent. Claim 17 of the '446 patent states: "The automated method of claim 1 wherein a group of said some cells are assigned in buckets and operated upon." (See '446 Patent at 18:36-37.) Claim 31 states: "The automated method of claim 21 wherein a group of said some cells are assigned in buckets and operated upon in order to determined [sic] the initial intended area of each of the group of said some cells." (See id. at 19:38-41.) Claim 17 of the '438 patent states: "The automated method of claim 1 wherein a group of said some cells are assigned in buckets and operated upon in order to determined [sic] the initial intended area of each of the group of said some cells." (See '438 Patent at 18:46-49.)

The only discussion of "buckets" in the specification appears in a section of the specification that discusses cell placement in one embodiment of the invention. (See '446 Patent at 15:65-16:22.) In such discussion, the specification states:

In step 225 (FIG. 4), the placement of cells is performed. FIGS. 10A and 10B show how a circuit design is transformed from a logical hierarchy 830 to a physical hierarchy 832 during the cell placement step 225 (FIG. 4). In the physical hierarchy 832, the intermediate logic levels in the logical hierarchy 830 are associated in or grouped in buckets 834 wherein each bucket 834 holds, for example, about one-hundred (100) cells 836. The buckets 834 are arranged in an array as shown in FIG. 10C. If the designer chooses to keep a group of cells 836 together, then the group of cells 836 are grouped in the same buckets 834 or in neighboring buckets. Preferably, a bucket 834 is sized small enough such that cell placement within a bucket 834 has an insignificant effect on timing. In other words, the size of a bucket 836 is such that the wire delay in a bucket 834 can be ignored. However, the size of a bucket 836 should be large enough to accommodate remapping and resizing of the cells 836 contained in the bucket. The number of cells which can be placed within a bucket can range, preferably, from about 20 cells to about 200 cells.

Pre-routes and pre-places (for driving the placer and global router) are driven into the bucket 834 structure. It is further noted, however, that the present invention may be practiced or incorporated with conventional placement methods and systems.

(See id.)

Dr. Harris atests, referring to three technical dictionaries, that "bucket" is a term of art in the computer science industry that has been defined as "an area of storage that may contain more than one record," "a storage cell in which data may be accumulated," and "[a]n area of storage where items with a common property are stored." 10 (See Harris Decl. P 76 and Exs. H, N, and O.) Dr. Harris further atests that the use of the term "buckets" in the specification is "entirely consistent with the normal dictionary definition of the term 'buckets.'" (See id. P 79.)

--- Footnotes ---

10 Magma's expert, Dr. Sechen, atests that the definitions cited by Dr. Harris "relate to computer storage or memory and are not useful for understanding the meaning of the term 'buckets' in the context of the '446 patent." (See Sechen Decl. P 56.) Magma's proposed construction, however, although purportedly tethered solely to the language of the specification, (see Magma Mem. at 13), is, as discussed infra, unpersuasive.
In the instant patent, "buckets" are used in the course of placement of cells on an integrated circuit. (See '446 Patent at 15:65-16:22.) Said placement is part of the process of transforming the "logical hierarchy" of the chip to a "physical hierarchy." (See id. at 15:65:1.) According to Dr. Harris, the term "hierarchy" indicates a subdivision of a complex whole into multiple simpler pieces, and the term "physical hierarchy" is "a hierarchy applied to the layout of an integrated circuit." (See Harris Decl. P 79 and n.1.) Dr. Harris further attests that, "[a]s is known to one of ordinary skill in the art, the physical hierarchy is a subdivision of the whole placement area into partitions or sectors." (See id.) Synopsys's proposed construction of "buckets" as "areas in which items are stored or contained, such as partitions or sectors of a placement area" thus applies the standard technical dictionary definition of "bucket" and applies it to the specific field of integrated circuit design.

Magma's proposed claim construction, requiring "buckets" to be "fixed-sized two-dimensional regions of the chip area," is not supported by the claim language, the specification, or the dictionary definitions cited by Dr. Harris. Magma relies on the statement in the specification that the buckets "are arranged in an array as shown in FIG. 10C," and points to the uniform grid set forth in that figure as evidence that the buckets must be both fixed in size and arranged in a two-dimensional array. (See '446 patent at 16:5-6 and Fig. 10C.) Although Figure 10C is the only figure in the '446 patent depicting the arrangement of buckets on a chip, nothing in the specification requires that the buckets be either fixed in size, or arranged in a two-dimensional array. As noted, the Federal Circuit has "expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment." See Phillips v. AWH Corp., 415 F.3d 1303, 2005 WL 1620331 at *15.

Accordingly, the Court will adopt Synopsys's proposed construction and will construe "assigned in buckets" as "assigned to areas in which items are stored or contained, such as partitions or sectors of a placement area."

B. "assigned incoming telephone number"

Stanacard proposes that the term "assigned incoming telephone number" either be given its plain and ordinary meaning or, to the extent it must be defined, be given the definition "telephone number assigned to initiate calls into a system." Rebtel argues that the term is indefinite or, to the extent it may be defined, should be given the definition "telephone number preprogrammed by a caller to correlate to a recipient."

Rebtel has argued that "assigned incoming telephone number" is indefinite because it does not specify whom or what does the assigning nor does it specify to whom or what the number is assigned. However, there is no requirement that the claim be limited in this manner, and "[w]ho or what performs claimed method steps is generally irrelevant to claim scope." Alcatel USA Sourcing, Inc. v. Microsoft Corp., No. 6:06 CV 499, 2008 U.S. Dist. LEXIS 64351, at *24 (E.D. Tex. Aug. 21, 2008) (finding that "while the specification discloses that a user enters the first user identification information, the disclosed embodiments do not require a user to perform that method step").

Rebtel's proposed construction seeks to introduce the phrase "preprogrammed by a caller." However, the term "preprogrammed" is not found anywhere in the specification or the prosecution history, and the only use of a variant of
"preprogrammed" is in a single passage in the specification that states "for example, the caller programs the system 300 to connect with a particular recipient when the caller dials one of the assigned incoming telephone numbers." '156 Patent, col. 4:21-23. This reference provides only a single example of the claimed invention, and it would be improper to limit the claims to a preferred embodiment disclosed in the specification. See Phillips, 415 F.3d at 1323; Chamberlain Group, Inc. v. Lear Corp., 516 F.3d 1331, 1335 (Fed. Cir. 2008); Amgen Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1325 (Fed. Cir. 2003).

Rebtel's proposed construction also seeks to incorporate "correlate to a recipient" into the claim term. As the specification and the claims make clear, the existence of a correlation between a telephone number dialed by the caller and a particular recipient is at the heart of the claimed invention. See, e.g., '156 Patent, col. 3:45-48; 5:32-34. Moreover, including the phrase "correlate to a recipient" serves to clarify that the "assigned incoming telephone number" is the number dialed by the caller that is associated with a recipient and not, e.g., the number assigned by the telephone company from which a caller dials.

Stanacard argues that the inclusion of the phrase "correlate to a recipient" would render the subsequent claim element "identifying a recipient associated with the assigned incoming telephone number" superfluous because both capture the concept of an association between an assigned number and a recipient. However, the phrase "correlate to a recipient" serves only to describe the nature of the incoming telephone number; it does not set forth the separate act, described in the subsequent claim element, of "identifying a recipient" to which the number is correlated.

"[A]ssigned incoming telephone number" is not "insolubly ambiguous," Datamize, 417 F.3d at 1347, and is therefore construed to mean "telephone number correlating to a recipient assigned to initiate calls into a system."
"Assigning"

Defendants contend that the term "assigning" means to specify, select, or designate or to "fix in correspondence or relationship." (Doc. No. 240, p. 4 n.8). Defendants argue that the patent abstracts and figures demonstrate further that such assignment must be accomplished before a caller places a telephone call and that such assignment must be stored in a single look-up table. (Id. at 5-8). Defendants also identify portions of the prosecution history that allegedly show a disclaimer of spacial calculations made after a caller has placed a call and a disclaimer of database structures other than a single look-up table. (Id. at 8-15). In addition, Defendants contend that the Examiner's statements concerning the scope of the disclosure of the '111 Reissue in an unrelated reexamination proceeding supports the conclusion that the claims of the '111 Reissue are limited to single look-up tables. (Id. at 16). The state of the art at the time of the filing of the patent applications, argue Defendants, also supports the limitation of "assigning" to that of a single look-up table. (Id. at 16-18). Lastly, Defendants assert that because Plaintiff omitted any reference to spacial calculations made during a call in an interrogatory response, such omission is evidence of a disclaimer of such calculations. (Id. at 18-19).

800 Adept contends that the abstract, figures and other parts of the patents' specifications do not limit the claimed inventions to a single look-up table. (Doc. No. 268, pp. 3-5, 6-8). On the contrary, argues Plaintiff, the specifications specifically recite multiple embodiments, including relational or hierarchical database structures. (Id. at 4). 800 Adept also criticizes Defendants' reliance on statements made in an unrelated reexamination proceeding by the Examiner concerning the scope of the disclosure of the '111 Reissue. (Id. at 5-6).

Returning to the languages of the claims, Plaintiff asserts that the plain meaning of the term "assign" is not limited to any one methodology. (Id. at 8). 800 Adept avers that every database query is the equivalent of a mathematic calculation, and therefore the database embodiments disclosed in the specifications do require "calculations" to be made after a telephone call is placed by a caller. (Id. at 10-11). Moreover, Plaintiff argues that there is no way in which to perform the "assign" limitation to a caller using a mobile telephone prior to the actual telephone call. (Id. at 11-13). Lastly, Plaintiff argues that the passages from the prosecution history identified by Defendants do not address the "assigning" limitation of the claims and, in any event, do not disclaim calculations made during a telephone call. (Id. at 14). n3

n3 Plaintiff also presents an argument which relies on a portion of the Magistrate's Markman Order which was not adopted by the Court. (See Doc. No. 178, p. 39). Such reliance is misplaced. In addition, Plaintiff improperly attempts to incorporate by reference arguments presented in other documents. (See Doc. No. 268, p. 16). This practice is prohibited by Local Rule 3.01(b) which limits a response to a document to not more than twenty (20) pages.

Based on the above, it is apparent that there are two general disagreements over the construction of this claim term. First, the parties debate whether the claims of the '111 Reissue and '689 Patent are limited to a single look-up table, or in other words whether the applicants disclaimed all embodiments except for a database containing a single table. Secondly, the parties dispute whether the assigning limitation disclaims calculations made during the telephone call.

As to the first issue, the Plaintiff plainly has the better argument. The claims, specification and prosecution history of the '111 Reissue and '689 Patent do not limit the term "assigning" to a single, static look-up table. The claims do not recite the term table; they recite the term database. The specification teaches that the database contains fields which can be used as natural keys and that the database structure may be relational or hierarchal. ('111 Reissue, col. 9, ll. 48-51). Thus, the specification plainly teaches database structures as alternatives to a single table database. Moreover, it is well settled that "the scope of the claims is not limited to particular embodiments depicted in the figures." Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1365 (Fed. Cir. 2004). Therefore, without more, Defendants' arguments concerning Figure 1 from the patents is without merit.

Moreover, the passages selected from the patents' prosecution history do not clearly and unambiguously disclaim alternative
database structures. See Sorensen v. Int'l Trade Comm'n, 427 F.3d 1375, 1378-79 (Fed. Cir. 2005) ("Disclaimers based on disavowing actions or statements during prosecution . . . must be both clear and unmistakable."). In each passage quoted from the prosecution history, applicants speak of a "database," not a table or a single look-up table. (See Doc. No. 240, pp. 10-11, 13).

Lastly, the Court finds no reason to limit the claims to a single look-up table from the statements of the Patent Office Examiner. First, "it is the applicant, not the examiner, who must give up or disclaim subject matter that would otherwise fall within the scope of the claims." Sorensen, 427 F.3d at 1379 (quoting Innova/Pure Water, Inc., 381 F.3d at 1124). Secondly, the Examiner's statements in the '111 Reissue do not refer to a look-up table but rather to the database of the claimed invention. It is of no moment that the Examiner refers to the embodiment depicted in Figure 1. That argument has no more force in this context than when the Court construes the claims. See Lighting World, Inc., 382 F.3d at 1365 ("[T]he scope of the claims is not limited to particular embodiments depicted in the figures."). Further, although the Examiner characterizes the '111 Reissue in an unrelated reexamination proceeding as implementing "a telephone number to telephone number lookup in a single table, or database," it is clear from the context of the statement that the Examiner was discussing the patent's disclosure, i.e., what the '111 Reissue teaches and not the scope of the claimed invention. (See Doc. No. 240, p. 16 n.33 & n.34). "Specifications teach. Claims claim." SRI Int'l v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1121 n.14 (Fed. Cir. 1985).

The parties also dispute whether the assigning limitation disclaims calculations made during the telephone call, and both parties delve into the prosecution history and state of the art to support their positions. The Court addresses this dispute in two parts. First, the Court must determine when the "assigning" step occurs. Then, the Court determines whether there is a disclaimer of the scope of the claims.

The answer to the first question starts with the language of the claims. The claims of the '111 Reissue recite "assigning to [each originating telephone number n4 or the physical location n5] of said potential first parties a telephone number of a service location of a second party that will receive calls originating from within the boundary of a geographic area." Similarly, claim 1 of the '689 Patent recites "assigning to the telephone number of each potential first party a telephone number of a specific location of the second party that will receive calls originating from within a geographic area of each first party."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

N4 This is the language used in claim 1 and claim 9 of the '111 Reissue.

n5 This language is used in claim 17, claim 29, and claim 41 of the '111 Reissue.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

"Assigning" is a commonly used and widely understood word. See Phillips, 415 F.3d at 1314. It means "to set aside for a particular purpose" or "designate." WEBSTER'S II NEW RIVERSIDE UNIVERSITY DICTIONARY 131 (1994). It is clear upon review of the specification that the patent uses the term in a manner consistent with its ordinary meaning without providing a more specialized meaning. See Phillips, 415 F.3d at 1316.

As discussed above, the term "potential first parties" refers to individuals who can place a telephone call but have not done so. The use of the term "potential first parties" strongly suggests that the assignment occurs prior to the caller placing a telephone call. In addition, each and every one of the claims uses the future tense, i.e., "the second party that will receive calls." The use of the future tense in the claims also suggests that the event described by the verb, i.e., the call, has not happened yet.

A review of the specification also supports the conclusion that the assignment occurs prior to the placement of the telephone call. The '111 Reissue teaches that once a telephone call has been placed by an individual, a local exchange carrier contacts a long distance carrier ("LDC") for routing instructions. ('111 Reissue, col. 4, l. 60 to col. 5, l. 20). The LDC retrieves the routing instructions from its own network control point ("NCP") and passes those instructions back to the local exchange carrier. (Id.). The specification teaches that the NCP contains "all of the direct routing instructions for the WATS number." (Id.; see also id., col. 5, ll. 24-51; id., col. 5, ll. 45-53; id., col. 8, ll. 14-22; id., col. 8, ll. 39-48; id., col. 8, l. 64 to col. 9, l. 6;
id., col. 9, ll. 23-32).

The specification also teaches the steps required to prepare the NPC for its role in this system. The written description discloses that "[a]fter defining the trade areas, assigning the corresponding NPA-NXX (or NPA-NXX-XXXX) combinations and submitting the appropriate direct routing information to the chosen LDC, the system (network) is activated." (Id., col. 12, ll. 38-41, emphasis added). In other words, the LDC does not receive the routing instructions that are stored in the NCP until after the assignment step is complete.

The abstract also supports this claim construction. It discloses:

Once these coordinates are assigned to each of the potential callers, the second party's criteria is applied to assign the potential caller to a second party. . . . Once all such assignments have been made, a database is assembled to be used by a long distance carrier for direct routing of telephone calls from callers to an assigned second party.

(Id. at face page, emphasis added).

Consequently, the language of the claims when read in light of the specification refers to "a designation made prior to the telephone call of the first parties."

The Court also considers whether the applicant disclaimed calculations made after the telephone call. Nothing in the above analysis indicates that the applicant must have disclaimed further calculations. Indeed, the specification contemplates further processing where the call is placed from a mobile telephone. n6 (Id., col. 6, l. 59 to col. 7, l. 2).

n6 Plaintiff's argument concerning the "cell phone embodiments" supports only the proposition that further calculations were contemplated once the technology was available.

Additionally, the prosecution history does not expressly and unambiguously disclaim all calculations made after a telephone call is placed. In distinguishing a prior art reference, the applicant stated:

A second major distinction between Finucane, et al. patent and Applicant's system is that Finucane, et al. requires that a computer perform "point of origin" to "point of termination" calculations while the caller is on the line . . . .

On the other hand, Applicant's Direct Routing Telephone System performs all such calculations prior to the call even being made and, in fact, prior to the delivery of the data base [sic] to the Long Distance Carrier (LDC).

(Doc. No. 240, Ex. C, pp. 123). Similar statements are quoted by Defendants on pages 9 to 13 of docket number 240. These statements are, at best, ambiguous. They might refer to the timing of the "assigning" step or they might refer to the disclaimer of post telephone call calculations. The Court finds the former is the better view in light of the disclosure of the specification as a whole. In any event, such ambiguity prevents the applicant's statements in the prosecution history from serving as a disclaimer of claim scope.

GO BACK

4. Assigning

After considering the arguments of counsel and the intrinsic record, the court construes "assigning" in accordance with its ordinary meaning. The term means "to fix or specify in correspondence or relationship." Webster's Ninth New Collegiate Dictionary (1991).

GO BACK
4. "assigning a secret code to activate the multi-function card"

Step 3 of Claim 1 provides for "assigning a secret code to activate the multi-function card." 311 patent, col. 10, lns. 63-64. Plaintiff argues that this term should be construed as:

a step of the method recited in claim 1 that means selecting a code that must be entered before it is possible to activate the multi-function card. The activation enables the user to access the data set of a particular single purpose card, document, key or the like in order to convert the multi-function card in form and function to that particular single purpose card, document, key or the like.

Joint Stmt. at App. A, p. 4. Defendants, on the other hand, argue that the term should be construed as "inputting a code through a separate electronic device into the electronic multi-function code." Id. (emphasis added). The Court finds that a separate electronic device is not required by the patent.

a. Separate Electronic Device to Assign Secret Code

In the "Description of the Embodiments" section of the specification, the patent provides two examples for how a user assigns a secret code to the card. The first example describes the use of a "master unit." The user "determines a secret code which will be required later to activate the electronic multi-function card. This secret code is known to nobody else but the user and may be input in the electronic multi-function card, for example via the master unit." 311 patent, col. 6, lns. 56-61. The second example for how a user would assign a code is through the use of a personal computer. In this scenario, the user would "enter the secret code via the computer keyboard . . . ." Id., col. 9, lns. 6-8.

Defendants contend that because the specification also states that "the secret code can be determined only if a master unit according to Fig. 3 is available, as only the master unit is provided with means for entering figures or alphanumerical information, as shown in Fig. 3," this means that only a master unit in the form of a unit designed for the multi-function card or a master unit in the form of a computer can be used to assign a secret code. 311 patent, col. 7, lns. 56-65; Def. Resp. at 21. Defendants' conclusion is overreaching.

The language that defendants rely upon to reach this conclusion appears under the "Description of the Embodiments" section, and follows the example of how the "master unit 15" is one example of how the user may assign a code. The specification then provides a second example of how a user could enter in the code through a computer keyboard. Thus, the language that defendants cite to imply that a master unit is the only means for assigning a code ("The secret code can be determined only if a master unit according to Fig. 3 is available . . . "). is simply hypothesizing a situation where the master unit 15 is the unit being used, rather than another example like the computer keyboard. The patentee does not limit himself to one form of assigning the code over another.

Although the specification does provide two examples of how a user could assign a secret code, the language used makes it clear that these are just possibilities. The suggestion of using the master unit to assign the code says that the code may be input, "for example, via the master unit 15." 311 patent, col. 6, lns. 58-61 (emphasis added). This is non-exhaustive language. Likewise, the suggestion of using a computer to assign a code is prefaced with the language "in this case, too," thus making it clear that the computer is just another option for assigning the code, rather than the exclusive means for assigning the code. Id., col. 9, lns. 6-8.

It is true that the only two examples describing how a user would assign a secret code do require assignment via a separate electronic device; thus, the only examples comport with defendants' proposed construction. Nevertheless, the patent does not exclude the possibility of the user assigning the secret code through the multi-function card itself. In fact, the Claim 1 of the patent provides that the multi-function card will have a keyboard for entering in the secret code, 311 patent, col. 10, lns. 65-66, although the patent does not state that this same keyboard can be used for assigning the code. Again, the non-exhaustive language in the specification suggests to the Court that assigning a secret code can be done in more ways than described in the preferred embodiment, even including through the electronic multi-function card itself.
Looking to the prosecution history for further guidance is unavailing. The prosecution history cited by both parties merely indicate that a secret code "is assigned," and that the card remains inactive until this point. The prosecution history does not provide any insight as to how the user assigns the secret code.

Furthermore, defendants cites no extrinsic evidence in support of their proposed construction. Defendants merely state that there is "possible inventor testimony" and "possible expert testimony" to support their construction, but do not submit such testimony. Joint Stmt. at App. C, p. 15. Defendants do, however, cite the Hennerg Invention Disclosure Statement, which provides that "one can only be determine [sic] this PIN code if one has a master device." Inv. Dis. Stmt. at p. 10. This exclusive language contradicts the non-exclusive language of the patent; the patent states that the master device is just one example of how a user can enter in his identification code. Because the cited extrinsic evidence contradicts the language of the patent specification, this extrinsic evidence cannot be used to support defendants' proposed construction. See Georgia Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1332 (Fed. Cir. 1999).

Based on this lack of extrinsic evidence, as well as a general disfavor of using Preferred Embodiment language to limit the construction of broader claim language, the Court construes "assigning a secret code to activate the multi-function card" as:

"The user assigns a secret code by entering a code through a separate electronic device or through an alphanumeric keyboard or keypad on the card."

235

2. STEP OF ASSIGNING (a UID to each LICENSE FILE)

The analysis here is similar to that in the preceding section. The function of the claim is "assigning a UID." As already noted in section III(C)(1), herein, reference to the specification reveals that the assignment of a UID is accomplished by the operating system, however, no description is provided as to how the assignment is accomplished. Because this element is introduced with "step of" rather than "step for," and because there is no indication in the claims or in the specification that "assigning a UID" is truly a "step" in the sense intended by § 112 P 6, the Court believes that "assigning a UID" should be given its plain meaning.

"STEP OF ASSIGNING A UID TO EACH LICENSE FILE," refers to the act of specifying a correspondence between each license file and respective UIDs, where "license file" is an area of memory on a disk capable of storing at least one LICENSE.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

17 The discussion in the preceding section specifies that a license file by definition contains a UID. The clear meaning of the second element of Claim 18 is that a UID is assigned to a license file which, until that instant, does not contain a UID. By analogy, if the patent were for a house and the definition of "house" was "four walls and a roof," the Court would not interpret "step of adding a roof to the house" to mean "the addition of a second roof to a structure already consisting of four walls and a roof." The Court recognizes that this interpretation implies a certain lack of precision on the part of the patent drafter, but is unwilling wholly to abandon common sense and clear meaning in the pursuit of strict consistency.

236

5. "assigning and displaying a device symbol" (claims 1 and 6)

The plaintiff proposes the following construction: "setting aside for a particular purpose and making available for viewing a representation of a device." The defendant asks the court to construe the term to mean "setting aside for a particular purpose and visually presenting a persistent representation of a storage device." The parties' disagreement centers around the persistent representation of a device and whether the device must be visually represented or simply capable of being
visually represented. The relevant claim language provides:

... wherein said data processing system assigning and displaying a device symbol for said external storage device and processing the operation request in magnetic disk format issued from users upon plug said external storage device into said USB or IEEE 1394 interface of said data processing system.

The only mention of "displaying" in the specification occurs in a discussion of a preferred embodiment in col. 4 of the '672 patent. Specifically, the patent states that "the driver coordinates with the firmware to accomplish the initialization of the device and notifies the operating system to assign and display a device symbol for the external storage device. . ." '672 Patent at 4:48-51. This use of "displaying" confirms the plain and ordinary meaning of "displaying" as used in claim 1.

The claim language does not limit or modify "display." The plain meaning of displaying within the context of claim 1 is visually representing a symbol for the external storage device. Nothing in the patent specification suggests that "displaying" means "capable of being displayed" or "making available." Grammatically, "displaying" is present tense active voice of the verb "to display."

The parties also disagree as to the duration of the visual display. The defendant asks the court to read into the claim the limitation that the display must be "persistent" while the plaintiff argues that it is incorrect to add that limitation. There is no support in the intrinsic record for requiring the display to be persistent or indefinite.

The court defines "assigning and displaying a device symbol" to mean "setting aside for a particular purpose and visually presenting a representation of a storage device."

4. "Assigning Attractant and Repellant Vectors" ('053 patent, claim 3)

The next phrase in dispute is "assigning attractant and repellant vectors." Plaintiff's construction is "providing information for influencing the movement of one object towards or away from another object." Defendant's proposed construction is "associating objects with attractor and repulsive values that can be mathematically combined."

Defendant's construction is supported by the specification of the '053 patent (and the corresponding specification of the '132 patent), which provides that "[o]bject avoidance is accomplished by equipping each object with a small repulsive force vector and monitoring the vector sum." '053 patent at 8:17-19; see also '132 patent at 8:20-22. Defendant's construction replaces the word "equipping," which appears in the above-quoted language, with the word "associating," but the Court credits Dr. Booth's testimony that "[a]ssociating . . . is more consistent" than "equipping" "with the usual terminology that you would find in computer science, where you associate properties with objects." See Tr. at 129. In any event, Dr. Booth noted that defendant "would be satisfied by either" "associating" or "equipping," see Tr. at 129-130, and both "associating" and "equipping" are preferable to the word "providing" in plaintiff's construction because, as Dr. Booth testified, the word "providing" "blurs the distinction between the object that is being influenced and the object which is doing the influencing," see Tr. at 130.

Further, the Court is persuaded by Dr. Booth's testimony as to why the phrase "that can be mathematically combined" should be included in the construction. Dr. Booth explained that people in computer graphics "use vector mathematics to describe the locations of objects in three-dimensional space" and occasionally "slip into the fantasy . . . that [the objects'] locations actually are vectors instead of points." See Tr. at 158. However, "you cannot mathematically combine two points," so that "even someone who is well practiced in the art at the time of the patent might appreciate the reminder that these are real mathematical vectors, not the sort of pretend ones that we all the time use in computer graphics and in animation." See Tr. at 158. In any event, plaintiff's own expert essentially conceded that the vectors "the patent is talking about are vectors that can be mathematically combined." See Tr. at 78.

Accordingly, the Court hereby adopts defendant's construction of "assigning attractant and repellant vectors."
e. Assigning the process steps to the machines

ITI proposes that the limitation "assigning the process steps to the machines" should be construed as designating the operations that a particular machine, machines, or workstation will carry out during manufacturing. Defendants argue that ITI's meaning is incorrect, as the patent requires that each machine perform a single fundamental operation and that each machine must be assigned a process step. Thus, defendants' proffered construction of the phrase involves specifying the fundamental operation (for example, in semiconductor manufacturing: depositing, patterning, etching, or doping) performed by each machine in the model.

The specification defines a process step as "the fundamental operation performed on a machine." U.S. Patent No. 4,796,194, col. 11, lines 29-30. The term "operations," however, is used interchangeably with "process steps." See id., col. 11, lines 23-25 ("In this embodiment each workstation is qualified to perform only a specified set of process steps or operations."). Defendants aptly note that "the fundamental operation performed on a machine" might indicate that each machine performs only one fundamental operation. But the language is also open to the interpretation that each machine performs a fundamental operation, but is not limited to only that operation.

Defendants' reading does not find support in the claims or specification; the patent nowhere specifies that each machine is limited to one operation. ITI's interpretation, however, is consistent with the specification. Example two provides a representation of two simplified semiconductor wafer fabrication processes. In describing the process, the patent states that "real semiconductor fabrication sequences may have 250 process steps using 50 workstations and 200 pieces of equipment." If 200 machines are capable of performing 250 process steps in one embodiment of the invention, it would appear that some machines must be capable of performing multiple process steps. Similarly, the specification indicates that workstations are groupings of like machines. Id., col. 11, lines 16-17. It further states that "workstations may perform more than one step in a single process sequence." Id., col. 8, lines 30-32.

In addition, defendants have provided no intrinsic support for their contention that each machine must be assigned a process step. Indeed, the specification clearly contemplates that certain machines might be unavailable for processing as a result of planned downtime or random failures. See id., col. 12, lines 21-26. And figure 1 demonstrates that a fabrication sequence can skip certain machines.

The Court is unwilling to adopt defendants' proposal that providing examples of fundamental operations within the definition will aid the jury's understanding of the meaning of fundamental operations. The cited operations apply to only one embodiment of the invention. The Court therefore adopts the following interpretation of the limitation: designating the fundamental operation or operations that a machine will carry out during manufacturing.

3. "Associate"

Plaintiff argues that the ordinary and customary meaning of the term "associate" is "relate." (Pl.'s Mot. 7-8; Pl.'s Opp'n 6.) Defendant, however, contends that the specification of the '837 Patent demonstrates that the proper construction of the term is: "'to directly connect,' such that a separate association is created between each selected requirement-primitive pair ('associating' means 'directly connecting,' 'associated' means 'directly connected')." (Def.'s Mot. 11-12; Def.'s Opp'n 13-14.)

a. The Claim Language

Neither party refers to the claim language to support its argument as to the proper construction of the term "associate." The claims repeatedly include phrases such as "associating the one or more primitive with the one or more requirements" (Claim 1), "displaying an association between a primitive and a selected requirement" (Claim 2), "associating the one or more primitives with the one or more statements" (Claim 10), and "displaying an association between a primitive and a selected
statement" (Claim 12). See, e.g., U.S. Patent No. 7,349,837 col.83 l.51-54, col.83 l.57-60, col.84 l.53-56, col.84 l.61-65 (filed Jan. 22, 2004). This claim language does little more than establish that an association involves some type of interaction between a primitive and a requirement. Nevertheless, the Court notes that some of the claim language implies that an "association" between a primitive and a requirement is non-visual. Specifically, Claim 1 states "associating the one or more primitives with the one or more requirements such that a primitive displayed in the programming area is visually associated with a displayed requirement of the requirements area." U.S. Patent No. 7,349,837 col.83 l.51-54 (filed Jan. 22, 2004); see Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005) (finding that use of the phrase "steel baffles" in the claim "strongly implies that the term 'baffles' does not inherently mean objects made of steel").

b. The Specification

In support of its interpretation of the term "associate," Defendant points to the '837 Patent specification's description of how to create an association between a requirement and a primitive:

To create an association between a requirement and a primitive:

1) Click on the Requirements tab in the project browser
2) Click on the desired requirement, using the (+) symbol to expand the parent classifications if necessary.
3) Right click on the primitive to be associated with the requirement.
4) Select Associate from the context menu.

U.S. Patent No. 7,349,837 col.82 l.45-52 (filed Jan. 22, 2004); see Def.'s Mot. 11-12; Def.'s Opp'n 13-14. Defendant argues that this description demonstrates that the "association" between a primitive and a requirement is between the "actual requirement itself" and the primitive, i.e., that the association is "direct." (Def.'s Mot. 11; see Def.'s Opp'n 13.) In other words, the procedure shows "that the text of a requirement is directly connected, via the 'Associate' action selected from the context menu, with the primitive." (See Def.'s Opp'n 13.) The Court, however, does not find Defendant's narrow construction convincing. This portion of the '837 Patent specification describes, with reference to the preferred embodiment, see U.S. Patent No. 7,349,837 col.61 l.48-50 (filed Jan. 22, 2004), how to create an association between a requirement and a primitive but it does not specify that an association must necessarily be directly between the actual requirement and the primitive. Moreover, Plaintiff correctly points out that the term "direct" is vague and unclear, leading to an improper and ambiguous claim construction. See Pl.'s Opp'n 6; see also Chimie, 402 F.3d at 1377 (internal citation omitted).

Plaintiff stresses other portions of the specification in support of its construction of "associate" as "relate." (See Pl.'s Mot. 7-8; Pl.'s Opp'n 6-7.) The '837 Patent describes Figure 20, the preferred embodiment in "Meta mode," see U.S. Patent No. 7,349,837 col.16 l.26-29 (filed Jan. 22, 2004), as such:

FIG. 20 shows the simulation in Meta mode and highlights the relationship between the requirements and their associated user interface components. For example line 432 highlights the relationship between the list page (with superscript 1) and the requirement numbered 1. Similarly, for example, line 433 highlights the association between the user interface element superscripted 13 with the requirement number 13.

U.S. Patent No. 7,349,837 col.72 l.21-29 (filed Jan. 22, 2004) (emphasis added). This portion of the '837 Patent specification demonstrates that the terms "relationship" and "association" are used interchangeably, as line 432 "highlights the relationship" between a certain primitive and a certain requirement, whereas line 433 "highlights the association" between a certain primitive and a certain requirement. Similarly, the specification explains that users may "$[d]eclar[e] relationships between requirements and instances of IRM primitives." U.S. Patent No. 7,349,837 col.19 l.54-55 (filed Jan. 22, 2004). Again, given that the claim language describes an "association" between a requirement and a primitive, this portion of the specification, referencing a "relationship" between a requirement and a primitive, implies that "association" and "relationship" are used interchangeably.

Because the specification of the '837 Patent uses the terms "association" and "requirement" interchangeably, the Court finds that the specification supports Plaintiff's definition of the claim term "associate" as "relate," rather than Defendant's
interpretation, i.e., "to directly connect."

c. Extrinsic Evidence

Although the Court does not find the intrinsic evidence on the term "associate" to be entirely unambiguous such that reference to extrinsic evidence is appropriate, the Court again notes that the extrinsic evidence on the issue, limited to expert depositions, declarations, and reports, is not particularly useful for purposes of construing the term "associate." Both parties' experts merely repeat the arguments made in their respective parties' briefs. (See Alexander Infringement Report 8; Locke Decl. P 26; Locke Opp'n Decl. PP 16-20.) Nevertheless, Plaintiff's expert, Locke, does contend that Plaintiff's construction comports with the plain and ordinary meaning of the term. (See Locke Decl. P 25; Locke Opp'n Decl. P 11.)

d. Conclusion

Particularly in light of the specification's interchangeable use of the terms "relationship" and "association," the Court finds that the proper construction of the term "associate" is "relate."

5. "Associating"

<table>
<thead>
<tr>
<th>Claim Language</th>

<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;associating&quot;</td>
<td>Plain and ordinary meaning.</td>
<td>specifically and uniquely relating</td>
</tr>
<tr>
<td>&quot;associate&quot;</td>
<td>Plain and ordinary meaning.</td>
<td>specifically and uniquely relate</td>
</tr>
<tr>
<td>&quot;associated with&quot;</td>
<td>Plain and ordinary meaning.</td>
<td>specifically and uniquely related to</td>
</tr>
</tbody>
</table>

The dispute here is similar to the "uniqueness" argument surrounding the "identifier" term. The defendants argue that the URL sent out to the viewer has to be specific and unique. Therefore, the defendants argue that if the association between an identifier or URL and a particular image or display is not specific and unique, the identifier or URL would not be able to perform its purpose, namely, enabling access to a specific image or display. Defendants contend that the specification repeatedly describes the relationship between the identifier and an image or display as specific and unique.

Fotomedia's argument is that the term "associate" is used in the specification in its ordinary meaning - to mean "relate." Therefore, Fotomedia urges that the Court should avoid construing it further. Fotomedia argues that the specification discloses an "identifier" that is unique, and Court should not introduce this limitation to the "associating" terms. The Court agrees. The Court has already construed the term "identifier" as being unique. Therefore, there is no need to further import such a limitation into the "associating" terms.

The Court concludes that "associate" means "to relate."
Plaintiffs contend that the term “song associated pictorial graphics” means “visual images associated with songs.” Opening Brief at 13. Defendants contend that the term means “graphics that are linked by the song record to a particular song.” Resp. Brief, Ex. E at 2. Plaintiffs base their proposed construction on standard definitions of “pictorial” and “graphic.” “Pictorial,” they contend, means “suggesting or conveying visual images,” and “graphic” means “[a]ny computer-generated pictures produced on a screen, paper, or film ... [g]raphics range from simple line or bar graphs to colorful and detailed images.” Opening Brief at 13. They also contend that “song associated” needs no interpretation because it simply means something associated with a song.

Defendants' proposed construction is based on language in the specification stating that the “graphics address field” in the catalog “contain[s] the beginning address in the bulk storage unit of the compressed digital data of a graphics image, if any, to be associated with the song.” Id., Ex. 2 at 3:48-51. The Court disagrees that this language in the specification “defines” the term as defendants suggest. Rather, defendants' proposed construction is an effort to import into the claim a limitation from a preferred embodiment, which is inappropriate in this situation. The Court construes the term as meaning “visual images associated with songs.” The same construction applies to the term “song associated pictorial graphics” in the 189 patent.

6. Associated therewith or having.

Relying on the plain meaning of the terms, Intergraph argues "associated therewith" means "related to, but not necessarily embedded within." Intergraph supports this position with language from the '028 patent's specifications which states, "we use the word 'associated' herein to designate the concept that the pipeline and group identifiers are not required to have a fixed relationship to the instruction words. That is, the pipeline and group identifiers need not be imbedded within the instructions themselves as shown in FIG. 7. Instead they may arrive from another means, or on a different cycle." '028 patent at 8: 20-26. Intel, however, relying on communications with the patent examiner during prosecution, claims that pipeline and group identifiers must be "embedded" or "encapsulated" within each individual instruction. Thus, Intel contends "associated therewith" or "having" requires that the identifier be embedded within the instruction. However, as discussed above, Intergraph's acceptance of an "embedded" limitation in the prosecution of some claims, claims that issued with the term "embedded" included, does not limit all claims issued.

Thus, the Court construes "associated therewith" or "having" as logically related to or logically connected, but not necessarily embedded. '028 patent at 8: 20-26.
M. "associated with"

<table>
<thead>
<tr>
<th>Term</th>
<th>Plaintiff's Definition</th>
<th>Defendants' Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;a payer obtaining a document containing document information, the document information being associated with a debt incurred by the payer or for goods or for services to be paid for or purchased by the payer&quot;</td>
<td>Identified with or having a connection to.</td>
<td>Plain meaning; alternatively, identified with or pertaining to.</td>
</tr>
</tbody>
</table>

This term appears in claim 28 of the '148 patent and claims 7 and 41 of the '302 patent. The parties dispute whether "associated with" can "have some connection to" or can "pertain to."

Plaintiff argues that its proposal is consistent with "customary definitions" as found in dictionaries. According to Plaintiff, "pertain" is defined as "to belong as an adjunct, part, holding, or quality," which is narrower than "associated with." Plaintiff explains that "associated with" is used to describe the relationships between a party and account or credential information, and between a VAN and a transaction. A VAN has a connection to a transaction, according to Plaintiff, and does not belong as an adjunct. Defendants argue that "having some connection to" is too broad.

Although some portions of the specification support Defendants' argument, the claim languages is broadly written to embrace document information "associated with" the debt. There may be document information that "has a connection to" a debt but does not necessarily "pertain to" a debt. For example, the debtor's account number pertains to the debtor, but has only a connection to the debt. **Plaintiff's proposal is more consistent with the language of the claim, and the Court adopts it.**

D. "associated with"

Stanacard proposes that "associated with" be given its plain and ordinary meaning, while Rebtel argues that "associated with" be given the definition "preprogrammed by the caller to correlate to."

Rebtel argues that given the computerized context of the claimed invention, the association between the incoming telephone number and the recipient number must, in fact, be "preprogrammed." Further, Rebtel asserts that because the specification only discloses embodiments in which the caller preprograms the system, the claims are properly limited to the single disclosed embodiment. See, e.g., Toro Co. v. White Consolidated Indus., Inc., 199 F.3d 1295, 1301-02 (Fed. Cir. 1999); Ormco Corp. v. Align Tech., Inc., 498 F.3d 1307, 1316 (Fed. Cir. 2007).

However, the specification, including the passages cited by Rebtel, do not establish that "associated with" has the same meaning as "preprogrammed." See Vitronics, 90 F.3d at 1582. Things can be "associated" with each other by an individual without being preprogrammed by the individual, as the specification of the '156 Patent makes clear. Compare '156 Patent, col. 4:18-23 ("In one embodiment, the call connection module 360 selects a particular recipient based on the profile information associated with the caller. For example, the caller programs the system 300 to connect with a particular recipient when the caller dials one of the assigned incoming telephone numbers.") with col. 7:1-5 ("In another embodiment, the recipient is determined, in part, by the recipient selected by the caller to be associated with the specific assigned incoming telephone number as shown in the recipient field 430 within the caller's profile."). Because the specification discloses embodiments in which the caller may select the recipient of a call without actually engaging in preprogramming the system to dial the selected recipient, it cannot be said that the specification discloses only a single embodiment of the invention in which the caller preprograms the system. As a result, Rebtel's proposed definition would improperly impose a
new limitation to the claim term "associated with."

Finally, Rebtel's definition would introduce unnecessary verbiage to claim language that a jury would understand. See Alcatel USA, 2008 U.S. Dist. LEXIS 64351, at *30-31 (holding that "associating" did not require construction because "a lay jury will understand the term").

"Associated with" is given its plain and ordinary meaning.

1. Term 1 ('645 Patent, Claim 1)

<table>
<thead>
<tr>
<th>Term</th>
<th>Court's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>... a given object of a participating content provider is associated with an alphanumeric string ...</td>
<td>... a particular object of a participating, content provider is associated with an alphanumeric string that includes the URL used to identify the object in the absence of a content delivery network ...</td>
</tr>
</tbody>
</table>

Akamai's suggestion that the term "associated" be given its dictionary meaning ignores the Federal Circuit's warning in Phillips that "[t]he risk of systematic overbreadth is greatly reduced if the court [] focuses at the outset on how the patentee used the claim term in the claims, specification, and prosecution history, rather than starting with a broad definition and whittling it down." Phillips, 415 F.3d at 1321. The '645 Patent specification describes as the present invention a single embodiment in which the Uniform Resource Locator ("URL") used to retrieve an embedded object from the content provider's server(s) in the absence of a content delivery network is modified by prepending it with a virtual server hostname:

According to the present invention, a given Web page (comprising a base HTML document and a set of embedded objects) is served in a distributed manner. . . . To serve the page contents in this manner, the URL associated with an embedded object is modified. As is well known, each embedded object that may be served in a page has its own URL. . . . According to the invention, the embedded object URL is first modified, preferably in an off-line process, to condition the URL to be served by the global hosting servers 2 . . . . Thus, according to the present invention, a virtual server hostname is prepended into the URL for a given embedded object . . . ." ('645 Patent, col.6 1.35 - col.7 1.40 (emphasis added).)

1 (See Akamai's Claim Construction Mem. (Docket # 67) at 9 (citing the definition of "associated" from Merriam-Webster's Collegiate Dictionary).)

2 The '645 Patent specification uses the terms "ghost," "ghost server" and "hosting server" interchangeably to describe the service provider's servers which replicate and deliver a participating content provider's content to the user. (See '645 Patent, col.5 11.65-67.) The claims, however, use the term "content server(s)," a term which does not appear in the specification, to describe these servers. (See, e.g., '645 Patent, Claim 1 (claiming "a method of content delivery wherein participating content providers identify content to be delivered by a service provider from a set of content servers that are distinct from the participating content provider sites and associated with the service provider").) The court construes "ghost(s)," "ghost server(s)," and "hosting server(s)" to refer to "content server(s) distinct from the content provider server(s)."

The specification then continues on to describe "the inventive global framework" in the context of a specific example. (Id. col.7 11.50-53 (emphasis added).) At step 5 of the example, a copy of the object is retrieved from a content delivery provider ("ghost") server. The specification goes on to explain:
Step 6: If, however, no copy of the data on the ghost exists, a copy is retrieved from the original server or another ghost server. Note that the ghost knows who the original server was because the name was encoded into the URL that was passed to the ghost from the browser.

(Id. col.12 11.54-58 (emphasis added).)

Here, the specification describes the invention as associating a particular object of a content provider with an alphanumeric string consisting of a virtual server hostname prepended onto the URL for the object. The URL of the object is necessary to the inventive global framework in order to retrieve the object from the content provider's server if no copy exists on a ghost server. The specification discloses no other way that an object is associated with an alphanumeric string, nor is there any suggestion or teaching that an association which did not include the URL for the embedded object could be used in an embodiment of the invention. Therefore, Akamai's proposed construction is overly broad and the court declines to adopt it. Rather, the court adopts a construction that incorporates the association described in the specification as "the . . . invention." (Id. col.7 ll.36-40.)

--- Footnotes ---
3 Limelight's proposed construction requiring the alphanumeric string to include "the domain name conventionally used . . . to identify the object," is excessively limiting. (See Docket # 90, 1.) Neither the specification nor the claim requires the domain name to be a part of the object URL. (See '645 Patent, col.6 11.51-54 ("Typically, the URL has a hostname identifying the Content Provider's site from where the object is conventionally served . . . .") (emphasis added).)

--- End Footnotes ---

B. "associated with at least one patron"

Claim 5 sets forth, in relevant part, "[a] system for assigning and managing patron reservations to one or more of a plurality of attractions, comprising: at least one personal communication device (PCD), each PCD associated with at least one patron. . . ." (col. 27, ll.26-29) (emphasis added). The specification indicates that each PCD is "associated with a patron or group of patrons visiting the park." (col. 5, ll. 60-61.) Consistent with this, the Plaintiff contends that the ordinary meaning of "associated with at least one patron" is simply "in an identifiable relationship with at least one patron." In proposing this construction, the Plaintiff relies on the dictionary definition of "associated" as "closely connected, joined, or united with another (as in interest, function, activity or office)." Webster's Third New International Dictionary (Unabridged) 132 (1993). The Defendants argue that the Plaintiff improperly relies on a dictionary definition to establish the ordinary meaning of the term. However, while cautioning against excessive reliance on dictionaries, the Federal Circuit has stated that the use of dictionaries is not precluded. Pfizer, Inc. v. Teva Pharms., USA, Inc., 429 F.3d 1364, 1375 (Fed. Cir. 2005); Phillips, 415 F.3d at 1321-22.

The Defendants also argue that because the personal communication device is inherently "in an identifiable relationship with at least one patron," the Plaintiff's construction is unduly broad and renders the "associated with" portion of the phrase meaningless. Instead, the Defendants propose the following construction: "for at least one customer of a group assigned to the PCD, there is a unique information record for the customer stored locally in the PCD." Neither the claims nor the specification supports this limiting construction. The Defendants point to several instances in the specification that discuss how patrons may input into the PCD various information describing their groups. (See col. 2, l. 63 to col. 3, l. 2; col. 6, l. 67 to col. 7, l. 8.) However, these portions of the specification simply describe the manner in which patrons may initiate use of the PCD. They do not limit the ordinary meaning of "associated with at least one patron." Finding no support for the Defendants' proposed construction, the Court finds that the ordinary meaning of "associated with at least one patron" is "in an identifiable relationship with at least one patron."
a. "at least one data storage assembly associated with said local processor assembly"

The parties' dispute concerning this limitation focuses on a single word: Citrix proposes that the "data storage assembly" is a structure for holding data, while Rothschild contends it is a place for holding data. While Rothschild claims that its construction is supported by the specification of the '534 Patent, Rothschild does not explain how the specification supports its construction and the basis for Rothschild's proposed construction is not clear.

Citrix, on the other hand, claims that its proposed construction is supported by the claims, the patent specification, and the ordinary meaning of "assembly," which, as defined in the dictionary, is a structure of some kind, i.e., a collection of parts. For example, in relevant part, the American Heritage Dictionary defines "assembly" as follows:

assembly: 4a. The putting together of manufactured parts to make a completed product, such as a machine or electronic circuit. 4b. A set of parts so assembled.

Citrix also suggests that the ordinary definition of "assembly" is consistent with the patent's use of the term. Citrix notes that each of the examples of a "data storage assembly" in the '534 Patent contemplates a structure, such as an internal hard drive, CD-ROM or DVD disk. For example:

Preferably, the data storage assembly 30 includes a computer readable medium, and in the preferred embodiment of FIG. 1 preferably includes a computer hard drive or other fixed data storage assembly wherein a large quantity of data may be stored and contained. As will be described in further detail subsequently, however, the data storage assembly may also include a portable and/or interchangeable assemblies such as compact discs or other such writable and non-writable assemblies and the accompanying drives.

The Court concludes that Citrix's proposed construction is supported by the relevant intrinsic and extrinsic evidence. Rothschild identifies no basis for construing an assembly to be a "place" rather than a structure, and such a construction would contradict both the '534 Patent and the ordinary meaning of the word. Moreover, it is not clear what Rothschild's proposed construction means: for example, Rothschild's construction could encompass a location, such as a court room, rather than the structure storing the data. Accordingly, the Court construes "at least one data storage assembly associated with said local processor assembly" as "the local processor assembly includes at least one structure for holding data."

b. "said auxiliary site date being associated with said primary site data"

Claim 1 further requires that the claimed "auxiliary site data be associated with said primary site data." Citrix suggests that this term is properly construed as "[t]he auxiliary site data concerns the same subject matter as the claimed primary site data and provides additional information on that subject matter. For example, if the primary site data concerns a particular real estate space, the associated auxiliary site data may include video images of that particular real estate space." Rothschild contends that the term should be construed as "auxiliary site data is capable of interacting with the primary site data."

Because Citrix's position is contradicted by its own expert and because Rothschild's proposed construction is consistent with the language of the '534 Patent, the Court construes "said auxiliary site data being associated with said primary site data" to mean: auxiliary site data is capable of interacting with the primary site data.
F. "a plurality of media player devices associated with the user account" / "a plurality of media player devices as being authorized with the user account"

This disputed term appears in claim 7 of the '704 patent: "A media asset management system comprising: . . . a plurality of media player devices associated with the user account. . . . " Likewise, claim 4 of the '414 patent states, "A media asset management system comprising: . . . a server application accessible over a network and capable of recognizing a plurality of media player devices as being authorized with the user account. . . . " Zapmedia believes that this term means "two or more 'media player devices' associated with the user account." Alternatively, Zapmedia contends that the term should be defined as "two or more media players specified in the user account, whereby referenced media assets can be copied and/or used by the aforementioned media players." The defendant's proposed construction is "a set of two or more permitted media players that are specified in the user account, whereby referenced media assets can be copied and used exclusively by media players in the set."

The primary difference between the plaintiff's alternative definition and the defendant's definition is whether the associated or authorized media player devices are the "exclusive" set of media players that may copy and use media assets. Apple argues that prosecution disclaimer prevents Zapmedia from contending that the associated or authorized set of media players is non-exclusive. In distinguishing the Milsted reference, the applicants pointed to the "associate a plurality of media player devices with the user account" limitation. (Dkt. No. 84, Ex. F, at 6). According to Apple, the following statements to the PTO distinguish Milsted on the basis that Milsted did not require an exclusive set of media player devices:

"And although Milsted does indicate that assets can be copied to another player device, the use of the asset is governed by licensing rights that are embedded in the asset itself without regard to the device being associated with the user account." Id. at 7 (emphasis added).

"Rather than associating the end user devices with a user account as recited in claim 84, Milsted describes embedding usage conditions within an asset. Thus subject to the usage conditions, the assets can be copied and used by ANY player device, not a subset of player devices that are associated with a user account." Id. at 8 (emphasis added).

"[T]he media assets are referenced in the media asset library associated with a particular user account. The user account specifies the plurality of media player devices that may access the media assets." (Dkt. No. 84, Ex. L, at 11).

In response, Zapmedia asserts that there was no "clear and unmistakable" disavowal of access by media player devices not associated with the user account. See Omega Eng'g Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). The plaintiff admits that the patentees distinguished Milsted on the basis that the Milsted prior art did not teach the association of media player devices with a user account. But, according to Zapmedia, the patentees did not disclaim prior art methods of media asset distribution, such as taught in Milsted. In one of the responses to a PTO rejection, upon which Apple relies, the patentees state, "Although the embodiments that are covered by claim 84 do not preclude technology such as described in Milsted, the applicants point out that the Milsted reference does not disclose the invention as recited in claim 84 . . . ." (Dkt. No. 84, Ex. F, at 8). This statement indicates that the patentees did not disclaim the prior art, but merely distinguished Milsted from their improvement. Zapmedia argues that the '414 and '704 patents teach a hybrid of the prior art DRM techniques (watermarking, encryption, encapsulation) and the allegedly novel registration/authorization of media player devices. (See '704 patent, 11:28-31 ("The system and method of the present invention optionally allow for security against asset piracy by one or more methods: watermarking, encryption, and object encapsulation.").) In support of this argument, Zapmedia points to the following passage from the specification:

Furthermore, with the permission of a digital media asset owner or licensor, a user may be granted the right to loan or forward his or her licensed media assets to another person that is not a registered user of the system. The forwarded asset is encapsulated in an executable file that allows for the object's integration into the recipient's media players . . . .

(704 patent, 11:61-66). Thus, the media players associated with the user account are not the exclusive set of media players that are permitted to access the media assets. As such, the court construes the terms "a plurality of media player devices associated with the user account" and "a plurality of media player devices as being authorized with the user account" to mean "two or more media players specified in the user account, whereby referenced media assets can be copied and/or used by the aforementioned media players."
C. "Associates the Valid Logon Command with the Remote Computer Unit"

The term "associates the valid logon command with the remote computer unit" appears in claims 3, 4, and 5 of the '945 patent. 128 ABC contends that the term means "to connect or bring into relation a valid logon command with one or more computers that are to be remotely controlled from a remote location using a local computer/interface unit." 129 WebEx asserts that the term means "uses the valid logon command to connect to the remote computer unit that is associated with the valid logon command." 130

128 The term "associates the valid logon command with the remote computer unit" literally appears only in claim 1 of the originally issued version of the '945 patent. Claims 3, 4, and 5, however, are written in dependent form, and all depend on claim 1. As explained above, ABC canceled claim 1 during reexamination, but claims 3, 4, and 5 survived reexamination without amendment. Therefore, the text of claim 1, including the term "associates the valid logon command with the remote computer unit," remains part of the '945 patent because it is incorporated by dependent claims 3, 4, and 5.

129 ABC's Brief, Docket Entry No. 154, at 15.

130 WebEx's Brief, Docket Entry No. 156, at 27.

The context within which the disputed phrase appears makes clear, 131 and the parties agree, that the website performs the function of associating the valid logon command with the remote computer unit. The parties disagree, however, as to what is communicated by the term "associates." In other words, they do not agree as to precisely what the website actually does when it "associates" the valid logon command with the remote computer unit. The parties also disagree as to whether the phrase "remote computer unit" requires further explanation or definition, and if so, whether "remote computer unit" refers to only a single remote computer unit, or whether it can be interpreted to refer to one or more remote computer units.

131 Claims 3, 4, and 5 of the '945 patent are method claims. The first four steps are common to all three asserted claims:

[1] operating a website capable of allowing and facilitating communication between a remote computer unit and an interface unit via an internet;

[2] receiving, by a website, a valid logon command from the interface unit whereby the website associates the valid logon command with the remote computer unit;

[3] receiving, by the website, data signal instructions from the interface unit; and

[4] sending the data signal instructions from the website to the remote computer unit whereby the data signal instructions act to remotely operate the remote computer unit . . . .

'945 patent, claims 3, 4, 5 (emphasis added).

1. "Associates"

ABC contends that "associates" should be given its ordinary and customary meaning, which -- because "associates" is not a technical term -- can be ascertained from general purpose dictionaries. 132 The first dictionary cited by ABC explains that
the verb "associate" means "to connect; combine; join" or "to connect in the mind." 133 The second dictionary cited by ABC similarly defines "associate" as "connect in the mind" or "join or combine." 134 Accordingly, ABC begins its proposed definition with the phrase "to connect or bring into relation . . . ."

WebEx argues that the verb "associates," in this context, means "uses . . . to connect to." WebEx asserts that the claim language of the '945 patent supports this definition because the step immediately following the step of receiving and validating the logon command involves the website receiving data signal instructions from the interface unit (the local element) and sending the data signal instructions on to the remote computer unit. 135 WebEx also points to the specification of the '945 patent, which states that the computer service control unit "connects the [customer interface unit] to the [multiple computer system] . . . when an encrypted valid PIN is received." 136

135 See '945 patent, claims 3, 4, 5.

136 '945 patent, col.4 ll.46-48 (emphasis added).

The court notes that the word "connect" is included in both parties' proposed definitions, but appears to carry a slightly different connotation in each. In WebEx's definition the term "connect" apparently refers to establishing a link or means of communication between two physical objects: the remote computer unit and, presumably, the website itself. In ABC's definition the term "connect" conveys the more abstract concept of identifying a relationship or correspondence between two things: the logon command and a particular remote computer unit.

The court is persuaded that this aspect of ABC's proposed definition is preferable for several reasons. It is more consistent with the ordinary and customary meaning of "associates." Moreover, the cited excerpts from the claim language and specification do not necessarily suggest that the website "uses" the logon command to connect -- i.e., establish a link for communication -- to the remote computer unit. Nor are the cited claim and specification excerpts inconsistent with ABC's proposed definition. In other words, neither the claim language nor the specification indicates that the website cannot or does not, in the abstract, "connect or bring into relation" the logon command with a particular, corresponding remote computer unit. Accordingly, the court concludes that the term "associates" means "to connect or bring into relation."

2. "Remote Computer Unit"

ABC's proposed definition describes the remote computer unit as "one or more computers that are to be remotely controlled from a remote location using a local computer/interface unit." WebEx does not seek to further define this phrase, but objects to this aspect of ABC's definition because it suggests that a remote computer unit can consist of more than one computer.

As explained above in the discussion of the term "logon command," the asserted claims unanimously and unambiguously speak in terms of a single remote computer unit and, therefore, cannot be interpreted to ambiguously refer to one or more computer units as ABC suggests. Also, ABC has not presented any evidence to show that the "remote computer unit" is necessarily equivalent to a "computer." Similarly, ABC has not shown that the "interface unit" disclosed in the '945 patent claims is necessarily equivalent to a "local computer." The court agrees, however, with ABC's description of the remote
computer unit as a computer unit "that [is] to be remotely controlled from a remote location using a[n] . . . interface unit."
This description is consistent with the claim language and specification of the '945 patent, and WebEx does not contend or present evidence to the contrary.

3. Conclusion

For the reasons explained above, the court concludes that the term "associates the valid logon command with the remote computer unit" means "to connect or bring into relation a valid logon command with a particular computer unit that is to be remotely controlled from a remote location using an interface unit."

K. Independent Claim 50 - "associating a UTID with the electronic transaction"

The magistrate judge recommended that the phrase "associating a UTID with the electronic transaction" in independent claim 50 should be construed as: "the party originating the transaction connecting or linking up the unique transaction identifier created by the originating party to the transaction." First Report at 10. Plaintiffs object to the magistrate judge's recommended construction, arguing that independent claim 50 was purposefully drafted to claim the alternative embodiments where the UTID may be generated by a party other than the originator. Plaintiffs' proposed claim construction in place of the magistrate judge's is: "connecting or linking up the UTID to the transaction." Pl. Obj. to First Report at 15. Once again, Plaintiffs contend that the magistrate judge's recommended claim construction is contrary to the specification and that the magistrate judge erred in relying on the prosecution history to find that the originator must generate the UTID. Plaintiffs contend that the limiting statements in the Petition Statement, properly interpreted, taught "one of the ways the invention can be practiced[.]") Id. at 16. The court overrules Plaintiffs' objections. The magistrate judge's recommended construction is correct based on the Petition Statement, wherein VIMachine distinguished its invention over prior art because its invention requires that the originator generates the UTID. Plaintiffs' argument that the Petition Statement merely stated a preference or one way the invention can be practiced is not persuasive. The Petition Statement is "clear and unmistakable" in distinguishing "the pending claims" and "claimed invention" from prior art based on the UTID generated by the originator. That an alternative embodiment in the specification allows a UTID to be generated by a TA does not sway the court otherwise. See Rheox, 276 F.3d at 1327 ("[W]here the prosecution history requires a claim construction that excludes some but not all of the preferred embodiments, such a construction is permissible and meets the standard of highly persuasive evidentiary support.").
associating of the data terminal including:

   means for entering the security number;

   means, operative during any initial transaction and any recharge transaction, for entering any monetary amount
   corresponding to the amount of call authorization;

   means for connecting to the host computer to transfer the security number and the call authorization amount; and

   means responsive to the transfer for receiving a verification message from the host computer authorizing receipt of the
   monetary amount to thereby associate at the host computer the call authorization amount to the security number, wherein
   the calling card does not store the call authorization amount; and

   wherein the database includes a record for each calling card security number having a call authorization amount
   associated therewith, the record including a balance; and

Claim 1 from the ' 68 patent:

activating the particular pre-paid calling card account in the database of prepaid [sic] calling card accounts in response to
receipt of the activation information by associating an active call authorization amount with the particular pre-paid calling
account;

for each pre-paid calling card account that is activated, maintaining in the database information sufficient to identify: (i) a
date on which the particular pre-paid calling card account is activated, (ii) a particular point-of-sale location at which the
particular pre-paid calling card account is activated, and (iii) the active call authorization amount that was associated with
the particular pre-paid calling card account when activated on said date and from said point-of-sale location;

At the hearing the parties agreed generally that:

1. The "data terminal" is the terminal at which the calling card is swiped or data is otherwise entered at the point of sale
   where the customer obtains the card or recharges the card. Tr. p. 13-14; and

2. The "host computer" is the central computer, or a system of networked computers, that keeps track of all the cards or
   card accounts. Tr. p. 14-16.

The parties also agreed that, at a minimum, the three terms in dispute describe variable amounts selected by the customer.
The real question is whether these terms can also be defined as including a pre-set amount, say $ 5.00 or $ 10.00. Tr. p. 11-
13, p. 34-35. TGIP says they can. Tr. p. 21. The Defendants argue they can not. Tr.22.

TGIP points, among other things, to '114 patent col. 2, 11. 52-54, which describes using a keypad at the point of sale or
recharge "for entering any monetary amount corresponding to an amount of call authorization associated with a particular
calling card . . . " TGIP also relies upon its request for reexamination of the '768 patent in which it stated that "[a]n active
call authorization amount means a call amount that is then useful for obtaining the call service . . . a call authorization
amount (albeit inactive) may be associated with the account prior to the user purchasing the calling card account because
the calling card account is not associated with an 'active call authorization amount' until an active, or usable, amount is
joined with the account. . . . ." Request for Reexamination, 7/6/2000, p. 3, Ex. E to TGIP's Opening Claim Construction Brief
[Doc. # 200, Attachment # 5, p. 3 of 24]. Additionally, during the reexamination process, the Board of Patent Appeals stated
that claim limitations of an "active call authorization amount" "do not require (but do not exclude) point-of-sale activation
of varying call amounts . . . . The active call authorization amounts could be a limited number of predetermined values as in
[Doc.# 200, Attachment # 8, pp. 11 of 31].

The court does not discount TGIP's statement in reexamination proceedings out of hand, but recognizes that it was
submitted to the PTO after some years of disputes concerning the patents. The court must be careful about allowing
statements made during a reexamination to enlarge the patent's scope, or to recapture scope which had been earlier
surrendered when limiting arguments made to obtain the patent have not been retracted and brought to the attention of the new examiner. See Creo Prods. v. Presstek, Inc., 305 F.3d 1337, 1344 (Fed. Cir. 2002); Hakim v. Cannon Avent Group, PLC, -- F.3d --, 2007 U.S. App. LEXIS 3926, 2007 WL 542697, *3 (Fed. Cir. 2007). This would seem especially true when the statement in question was peripheral to the issues being addressed by the examiner and the Board of Appeals.

Of course, TGIP also relies upon the familiar cannons of construction that a patent is defined by its claims, that claims should be given their full scope, and that limitations should not be imported from descriptions of preferred embodiments.

Defendants rely heavily upon statements in the specification such as: "The present invention relates to . . . activation and recharging of calling cards in customer defined amounts." ‘114 patent, col.1., 11. 6-9. Defendants also argue that TGIP disavowed all cards issued in fixed or pre-set amounts pointing to statements distinguishing prior art such as: "The most significant drawback is the requirement that pre-paid calling cards be issued in fixed or preset amounts."' 114 patent, col. 1, 11. 46-48, and '768 patent, col. 1, 11. 51-53.  See Astrazeneca AB v. Mut. Pharm. Co., 384 F.3d 1333, 1340 (Fed. Cir. 2004).

It appears to the court that nothing in the claim language itself eliminates all cards with a pre-set amount. n3 The first use of the disputed phrase is in Claim 1 of the ‘114 patent: "associating, at the host computer, an amount of call authorization to a security number of a calling card . . .” "114 patent, col. 6, 11. 14-16. In Claim 1 of the ‘768 patent Reexamination Certificate ("Reexam Cert") we see: "activating the particular pre-paid calling card account in the database of pre-paid [sic] calling card accounts in response to receipt of the activation information by associating an active call authorization amount with the particular pre-paid calling card account." ‘768 patent Reexam Cert, col. 1,11.33-37. The statements in the specification and prosecution history of each patent establish that the intent was to go beyond the previous fixed limit card, but they do not eliminate the possibility that what is claimed is a new system which describes: (1) an "open ended" card (or one with a high upper limit) so the customer picks any amount (or any amount less than the high limit); and (2) a card with an amount preprinted on the card, or alternatively two or more amounts, one of which must be selected by the customer.

--- Footnotes ---

n3 The record contains a much more detailed exposition on this issue, including the responses of the parties to various hypotheticals. See Tr. pp. 10-60.

--- End Footnotes ---

Whether the claim language can be defined as including this second type of card is the real dispute. See Tr. p. 11-13. Both patents use the indefinite article "an" when referring to the call authorization amount or the amount of call authorization. The specification describes an embodiment in which there is "an amount of call authorization associated with a particular calling card . . ." '114 patent, col. 2, 11. 53-54. The court concludes that the claim language describes at least some types of cards with a pre-printed amount, or perhaps a limited choice of amounts. To this extent,"call authorization amount" and "active call authorization" simply mean a monetary amount assigned to the card or account.

But the analysis does not end there. Two systems or scenarios for use of cards with pre-set dollar amounts are technically feasible. Tr. p. 16-18, 42.

Scenario 1: Cards of say $ 5.00 or $ 10.00, etc., where the security number is pre-associated with that amount at the host computer, but the card is not valid until it is "swiped" at the point of sale so the host computer knows it is activated. (In other words the host computer database already "knows" the security number of the card, and the amount of the card, and all that is needed is to validate or activate the card.)

Scenario 2: Cards of say $ 5.00 or $ 10.00 etc., where a security number is not associated with a particular card or amount until the card is swiped. This could include a card with a limited number of choices available, say a choice between $ 5.00, $ 10.00, or $ 15.00. (In other words the host computer database has a list of security numbers, and when a card is activated at the data terminal the amount printed on the card is associated with one of those security numbers.)

Comparing these scenarios illuminates the importance of the term "associating" and illustrates why it must be construed in conjunction with the three terms originally submitted. n4
n4 Of course, with a "variable" or pure "customer choice" card, no dollar amount can be associated with a security number until the customer selects an amount and activates or recharges the card for that amount. As noted, the parties do not dispute that the patent terms define this type of transaction.

Claim 1 of the '114 patent states that as part of the system there is a host computer with an input port, and a data terminal "connectible to the input port for associating, at the host computer an amount of call authorization to a security number of a calling card . . . ." '114 patent, col. 6, ll. 13-16 (emphasis added). Similarly, Claim 1 of the '768 patent describes a method in which calling card account in the database is activated "by associating an active call authorization amount with the particular pre-paid calling card account." '768 patent Reexam Cert, col. 1, ll. 35-37(emphasis added).

"Associating" is an active verb, which must mean something. If, as TGIP argues, cards could have a preset amount printed and coded on the card, along with that card's identifying or security number, then what is left to associate by the host computer or the data terminal? After Claim 1 of original application for the '114 patent had been rejected as obvious in light of two earlier patents, the applicant stated:

 Amendment to First Office Action, 5/18/1995, p. 8 (Bates No. TGIP 006428), Ex. 7 to Defendants' Responsive Brief [Doc. # 207, Attachment # 7, p. 9 of 11].

To define the terms at issue so broadly as to encompass the system of scenario 1 above, would simply ignore this statement to the PTO, and would define "authorizing" as simply meaning "validating." The prosecution history makes it clear that such a construction was rejected by the PTO. n5 The court will define these related terms as follows:

"Call authorization amount" as used in the '114 patent, Claims 1, 6, and 7, and "amount of call authorization" as used in the '114 patent, Claims 1 and 6, mean: "a monetary amount to be used to pay for call service."

"Associating, at the host computer, an amount of call authorization to a security number" as used in the '114 patent Claims 1 and 6, means that as part of the activation process, and not before, the amount of call authorization is linked in the host computer database to a security number for that card.

"Active call authorization amount" as used in the '768 patent, Claims 1-3, and 5-11 means: "a monetary amount to be used to pay for call service."

"Associating an active call authorization amount with the particular pre-paid calling card account" as used in the '768 patent, Claims 1-3, and 5-11, means that as part of the activation process, and not before, the active call authorization amount is linked in the remote location database, to the pre-paid calling card account.

n5 TGIP tries to get around the statements it made to the PTO to obtain approval of the patent by now arguing that the security number (or other card identifier) and the monetary amount could be combined on the card but not really be "associated" until transmitted to the host computer or database. This is just a fancy way of saying "validating."

TGIP points out in its Supplemental Claim Construction Brief ("Supp. Br."), Claim 7 of the '114 patent does not include the term "associating." See TGIP's Supp. Br., p. 2[Doc. # 229-1, p. 3 of 12]. Claim 7 was added during prosecution after Claim
1 was rejected. See TGIP's Supp. Br., p. 2 [Doc. # 229-1, p. 3 of 12]. After explaining (as set out above) that amended Claim 1 could be distinguished from Schilling and Kamil, because the data terminal associated an amount of call authorization to a security number of a calling card using the data transmitted between the terminal and the host computer, the patentee stated to the PTO:

Independent Claim 7 is directed to a system wherein a "plurality of data terminals" are used to provide the on-site card activation capability. For the reasons set forth above with respect to Claim 1, Claim 7 is also patentable.

Amendment to First Office Action, 5/18/1995, p. 9 (Bates No. TGIP 006429), Ex. 7 to Defendants' Responsive Brief [Doc. # 207, Attachment # 7, p. 10 of 11](emphasis added). However, the effect of these statements to the PTO on the interpretation of Claim 7 is not before the court at this time.

The parties initially stated that the primary dispute between them involves these three related claim terms. TGIP proposed: "a call amount that is useful for obtaining call service." Defendants suggested "any customer defined variable (i.e. not fixed or pre-set) amount, assigned to a calling card at the time of activation or recharge." A candid discussion between the court and the parties at the Markman hearing revealed that the more important issue is how the term "associating" applies to, and affects, these three terms.

To assist in the analysis, the relevant portion of the first claim of each patent is set out with these terms in bold:

Claim 1 from the '114 patent:

at least one data terminal located at a predetermined location remote from the host computer and connectable to the input port for associating, at the host computer, an amount of call authorization to a security number of a calling card using data transmitted between the data terminal and the host computer during one or more charging transactions, the means for associating of the data terminal including:

means for entering the security number;

means, operative during any initial transaction and any recharge transaction, for entering any monetary amount corresponding to the amount of call authorization;

means for connecting to the host computer to transfer the security number and the call authorization amount; and

means responsive to the transfer for receiving a verification message from the host computer authorizing receipt of the monetary amount to thereby associate at the host computer the call authorization amount to the security number, wherein the calling card does not store the call authorization amount; and

wherein the database includes a record for each calling card security number having a call authorization amount associated therewith, the record including a balance; and

Claim 1 from the '68 patent:

activating the particular pre-paid calling card account in the database of prepaid [sic] calling card accounts in response to receipt of the activation information by associating an active call authorization amount with the particular pre-paid calling card account;

for each pre-paid calling card account that is activated, maintaining in the database information sufficient to identify: (i) a
At the hearing the parties agreed generally that:

1. The "data terminal" is the terminal at which the calling card is swiped or data is otherwise entered at the point of sale where the customer obtains the card or recharges the card. Tr. p. 13-14; and

2. The "host computer" is the central computer, or a system of networked computers, that keeps track of all the cards or card accounts. Tr. p. 14-16.

The parties also agreed that, at a minimum, the three terms in dispute describe variable amounts selected by the customer. The real question is whether these terms can also be defined as including a pre-set amount, say $5.00 or $10.00. Tr. p. 11-13, p. 34-35. TGIP says they can. Tr. p. 21. The Defendants argue they can not. Tr. p.22.

TGIP points, among other things, to '114 patent col. 2, 11. 52-54, which describes using a keypad at the point of sale or recharge "for entering any monetary amount corresponding to an amount of call authorization associated with a particular calling card . . . ." TGIP also relies upon its request for reexamination of the '768 patent in which it stated that "[a]n active call authorization amount means a call amount that is then useful for obtaining the call service . . . a call authorization amount (albeit inactive) may be associated with the account prior to the user purchasing the calling card account because the calling card account is not associated with an 'active call authorization amount' until an active, or usable, amount is joined with the account. . . ." Request for Reexamination, 7/6/2000, p. 3, Ex. E to TGIP's Opening Claim Construction Brief [Doc. # 200, Attachment # 5, p. 3 of 24]. Additionally, during the reexamination process, the Board of Patent Appeals stated that claim limitations of an "active call authorization amount" "do not require (but do not exclude) point-of-sale activation of varying call amounts . . . . The active call authorization amounts could be a limited number of predetermined values as in the prior art." See Board of Patent Appeals Decision of 9/26/2003, Ex. H, p. 11 to TGIP's Opening Claim Construction Brief [Doc.# 200, Attachment # 8, pp. 11 of 31].

The court does not discount TGIP's statement in reexamination proceedings out of hand, but recognizes that it was submitted to the PTO after some years of disputes concerning the patents. The court must be careful about allowing statements made during a reexamination to enlarge the patent's scope, or to recapture scope which had been earlier surrendered when limiting arguments made to obtain the patent have not been retracted and brought to the attention of the new examiner. See Creo Prods. v. Presstek, Inc., 305 F.3d 1337, 1344 (Fed. Cir. 2002); Hakim v. Cannon Avent Group, PLC., -- F.3d --, 2007 U.S. App. LEXIS 3926, 2007 WL 542697, *3 (Fed. Cir. 2007). This would seem especially true when the statement in question was peripheral to the issues being addressed by the examiner and the Board of Appeals.

Of course, TGIP also relies upon the familiar cannons of construction that a patent is defined by its claims, that claims should be given their full scope, and that limitations should not be imported from descriptions of preferred embodiments.

Defendants rely heavily upon statements in the specification such as: "The present invention relates to . . . activation and recharging of calling cards in customer defined amounts." '114 patent, col.1., 11. 6-9. Defendants also argue that TGIP disavowed all cards issued in fixed or pre-set amounts pointing to statements distinguishing prior art such as: "The most significant drawback is the requirement that pre-paid calling cards be issued in fixed or preset amounts." '114 patent, col. 1, 11. 46-48, and '768 patent, col. 1, 11. 51-53. See Astrazeneca AB v. Mut. Pharm. Co., 384 F.3d 1333, 1340 (Fed. Cir. 2004).

It appears to the court that nothing in the claim language itself eliminates all cards with a pre-set amount. n3 The first use of the disputed phrase is in Claim 1 of the '114 patent: "associating, at the host computer, an amount of call authorization to a security number of a calling card . . . ." '114 patent, col. 6, 11. 14-16. In Claim 1 of the '768 patent Reexamination Certificate ("Reexam Cert") we see: "activating the particular pre-paid calling card account in the database of prepaid [sic] calling card accounts in response to receipt of the activation information by associating an active call authorization amount with the particular pre-paid calling card account." '768 patent Reexam Cert, col. 1,11.33-37. The statements in the specification and prosecution history of each patent establish that the intent was to go beyond the previous fixed limit card, but they do not eliminate the possibility that what is claimed is a new system which describes: (1) an "open ended" card (or one with a high upper limit) so the customer picks any amount (or any amount less than the high limit); and (2) a card with
an amount preprinted on the card, or alternatively two or more amounts, one of which must be selected by the customer.

n3 The record contains a much more detailed exposition on this issue, including the responses of the parties to various hypotheticals. See Tr. pp. 10-60.

Whether the claim language can be defined as including this second type of card is the real dispute. See Tr. p. 11-13. Both patents use the indefinite article "an" when referring to the call authorization amount or the amount of call authorization. The specification describes an embodiment in which there is "an amount of call authorization associated with a particular calling card . . . ." '114 patent, col. 2, 11. 53-54. The court concludes that the claim language describes at least some types of cards with a pre-printed amount, or perhaps a limited choice of amounts. To this extent,"call authorization amount" and "active call authorization" simply mean a monetary amount assigned to the card or account.

But the analysis does not end there. Two systems or scenarios for use of cards with pre-set dollar amounts are technically feasible. Tr. p. 16-18, 42.

Scenario 1: Cards of say $ 5.00 or $ 10.00, etc., where the security number is pre-associated with that amount at the host computer, but the card is not valid until it is "swiped" at the point of sale so the host computer knows it is activated. (In other words the host computer database already "knows" the security number of the card, and the amount of the card, and all that is needed is to validate or activate the card.)

Scenario 2: Cards of say $ 5.00 or $ 10.00 etc., where a security number is not associated with a particular card or amount until the card is swiped. This could include a card with a limited number of choices available, say a choice between $ 5.00, $ 10.00, or $ 15.00. (In other words the host computer database has a list of security numbers, and when a card is activated at the data terminal the amount printed on the card is associated with one of those security numbers.)

Comparing these scenarios illuminates the importance of the term "associating" and illustrates why it must be construed in conjunction with the three terms originally submitted. n4

n4 Of course, with a "variable" or pure "customer choice" card, no dollar amount can be associated with a security number until the customer selects an amount and activates or recharges the card for that amount. As noted, the parties do not dispute that the patent terms define this type of transaction.

Claim 1 of the '114 patent states that as part of the system there is a host computer with an input port, and a data terminal "connectible to the input port for associating, at the host computer an amount of call authorization to a security number of a calling card . . . ."' 114 patent, col. 6, 11. 13-16 (emphasis added). Similarly, Claim 1 of the '768 patent describes a method in which calling card account in the database is activated "by associating an active call authorization amount with the particular pre-paid calling card account." '768 patent Reexam Cert, col. 1, 11. 35-37(emphasis added).

"Associating" is an active verb, which must mean something. If, as TGIP argues, cards could have a preset amount printed and coded on the card, along with that card's identifying or security number, then what is left to associate by the host computer or the data terminal? After Claim 1 of original application for the '114 patent had been rejected as obvious in light of two earlier patents, the applicant stated:

Claim 1 has been amended to further emphasize several of the above-identified features and concepts that are neither described nor obtained by Schilling, taken by itself or in combination with Kamil . . . For example, Claim 1 now describes . . . The data terminal is now described as the device in the system which is used to associate an amount of call authorization to a security number of a calling card using the data transmitted between the terminal and the host computer.
Amendment to First Office Action, 5/18/1995, p. 8 (Bates No. TGIP 006428), Ex. 7 to Defendants' Responsive Brief [Doc. # 207, Attachment # 7, p. 9 of 11].

To define the terms at issue so broadly as to encompass the system of scenario 1 above, would simply ignore this statement to the PTO, and would define "authorizing" as simply meaning "validating." The prosecution history makes it clear that such a construction was rejected by the PTO. n5 The court will define these related terms as follows:

"Call authorization amount" as used in the '114 patent, Claims 1, 6, and 7, and "amount of call authorization" as used in the '114 patent, Claims 1 and 6, mean: "a monetary amount to be used to pay for call service."

"Associating, at the host computer, an amount of call authorization to a security number" as used in the '114 patent Claims 1 and 6, means that as part of the activation process, and not before, the amount of call authorization is linked in the host computer database to a security number for that card.

"Active call authorization amount" as used in the '768 patent, Claims 1-3, and 5-11 means: "a monetary amount to be used to pay for call service."

"Associating an active call authorization amount with the particular pre-paid calling card account" as used in the '768 patent, Claims 1-3, and 5-11, means that as part of the activation process, and not before, the active call authorization amount is linked in the remote location database, to the pre-paid calling card account.

--- Footnotes ---

n5 TGIP tries to get around the statements it made to the PTO to obtain approval of the patent by now arguing that the security number (or other card identifier) and the monetary amount could be combined on the card but not really "associated" until transmitted to the host computer or database. This is just a fancy way of saying "validating."

--- End Footnotes ---

TGIP points out in its Supplemental Claim Construction Brief ("Supp. Br."), Claim 7 of the '114 patent does not include the term "associating." See TGIP's Supp. Br., p. 2 [Doc. # 229-1, p. 3 of 12]. Claim 7 was added during prosecution after Claim 1 was rejected. See TGIP's Supp. Br., p. 2 [Doc. # 229-1, p. 3 of 12]. After explaining (as set out above) that amended Claim 1 could be distinguished from Schilling and Kamil, because the data terminal associated an amount of call authorization to a security number of a calling card using the data transmitted between the terminal and the host computer, the patentee stated to the PTO:

Independent Claim 7 is directed to a system wherein a "plurality of data terminals" are used to provide the on-site card activation capability. For the reasons set forth above with respect to Claim 1, Claim 7 is also patentable.

Amendment to First Office Action, 5/18/1995, p. 9 (Bates No. TGIP 006429), Ex. 7 to Defendants' Responsive Brief [Doc. # 207, Attachment # 7, p. 10 of 11](emphasis added). However, the effect of these statements to the PTO on the interpretation of Claim 7 is not before the court at this time.

---

9. Associating the DR and the referenced record ('321 patent, claims 47, 185, 190 and 193)

The parties agree that "associating the DR and the referenced record" creates a relationship between the DR and the referenced record and that the term "associating" is broader than "linking." Although defendant argues that this relationship must be "unambiguous and defined" in order to "facilitate the principal goal of the '321 patent," I will not read such a limitation into the disputed claims. See also Webster's Ninth New College Dictionary 110 (1983) (defining "associate" as "to bring together or into relationship in any various and tangible ways"). Accordingly, "associating the DR and the referenced record" in claims 47, 185, 190 and 193 of the '321 patent creates a relationship that is broader than linking.
4. "associating roles"

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>FotoMedia's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;associating the roles with individual metadata elements&quot;</td>
<td>No construction necessary</td>
<td>for each of a plurality of metadata elements, assigning a list of roles to the metadata element</td>
</tr>
</tbody>
</table>

The dispute here is similar to the preceding one. The defendants argue that the intrinsic record requires that roles must be associated with more than one metadata element and that the association be done on an "individual" basis. This plurality is reflected in the claim language. The defendants argue that the plain meaning of the phrase "individual metadata elements" requires associating the roles with the metadata elements on an individual basis, i.e., roles must be associated "for each of a plurality" of metadata elements. 10 The defendants also point to following section of the specification for support:

[after] defining metadata elements for an image file, particular roles (e.g., job roles) are then associated with the individual metadata elements defined for the image, and each role is assigned certain access privileges for the metadata element to which they are associated.

'231 patent, at 3:54-60.

Footnotes

10 The defendants also point to an office action response wherein the applicants differentiated a prior art that allowed associating access rights with sets of images, such as photo albums. This prosecution history, however, is irrelevant to the issue of associating metadata elements of a single image.

FotoMedia responds by arguing that the claim only requires associating roles with metadata elements, and that there is no support for a specific type of association such as assigning a list of roles to each of at least two metadata elements.

As with the "associating users" term, a key feature of the invention claimed by the inventors is the ability to discriminate between various types of users and roles in providing access to the various elements of the image data. As such, the Court adopts defendants' proposed construction for this term.

"Associating the roles with individual metadata elements" means "for each of a plurality of metadata elements, assigning a plurality of roles to the metadata element."

A. Claim Construction

Before turning to the parties' contentions about the proper construction of the asserted claim, it is important to review some basic principles of claim construction. First, and most importantly, the language of the claim defines the scope of the protected invention. Yale Lock Mfg. Co. v. Greenleaf, 117 U.S. 554, 559, 29 L. Ed. 952, 6 S. Ct. 846 (1886) ("The scope of letters-patent must be limited to the invention covered by the claim, and while the claim may be illustrated it cannot be enlarged by language used in other parts of the specification."); Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384
F.2d 391, 396, 155 U.S.P.Q. (BNA) 697, 701 (Ct. Cl. 1967) ("Courts can neither broaden nor narrow the claims to give the patentee something different than what he set forth [in the claim]."). See also Continental Paper Bag Co. v. Eastern Paper Bag Co., 210 U.S. 405, 419, 52 L. Ed. 1122, 28 S. Ct. 748 (1908); Cimiotti Unharring Co. v. American Fur Ref. Co., 198 U.S. 399, 410, 49 L. Ed. 1100, 25 S. Ct. 697 (1905). Accordingly, "resort must be had in the first instance to the words of the claim," words to which we ascribe their ordinary meaning unless it appears the inventor used them otherwise. Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759, 221 U.S.P.Q. (BNA) 473, 477 (Fed. Cir. 1984). Second, it is equally "fundamental that claims are to be construed in the light of the specifications and both are to be read with a view to ascertaining the invention." United States v. Adams, 383 U.S. 39, 49, 15 L. Ed. 2d 572, 86 S. Ct. 708 (1966). See also Markman, ___ F.3d at ___, 34 U.S.P.Q.2D (BNA) at 1329-30 ("Claims must be read in view of the specification, of which they are a part. . . . For claim construction purposes, the [specification's] description may act as a sort of dictionary, which explains the invention and may define terms used in the claims.").

We construe claim preambles, like all other claim language, consistently with these principles. Much ink has, of course, been consumed in debates regarding when and to what extent claim preambles limit the scope of the claims in which they appear. See, e.g., 2 Donald S. Chisum, Patents § 8.06[1][d] (1993); 1 Anthony W. Deller, Patent Claims §§ 78, 163-83 (2d ed. 1971); Willis Higgins, The Significance of Preambles in Chemical Composition Claims, 49 J. Pat. & Trademark Off. Soc'y 337 (1967); Vincent Millin, PTO Practice: Preamble--Prelude to Patentability, 72 J. Pat. & Trademark Off. Soc'y 348 (1990); David R. Pressman, Note, Patents--Claim Construction, 30 Geo. Wash. L. Rev. 380 (1961); Alton D. Rollins, Is It New or Not?, 68 J. Pat. & Trademark Off. Soc'y 89 (1986). These debates center, however, on particular arts and claiming styles and do not call into doubt the general principle, as well-settled as any in our patent law precedent, that a claim preamble has the import that the claim as a whole suggests for it. In other words, when the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects. In re Paulsen, 30 F.3d 1475, 1479, 31 U.S.P.Q.2D (BNA) 1671, 1673 (Fed. Cir. 1994) ("Terms appearing in a preamble may be deemed limitations of a claim when they give meaning to the claim and properly define the invention.") (internal quotation omitted); London v. Carson Pirie Scott & Co., 946 F.2d 1534, 1539, 20 U.S.P.Q.2D (BNA) 1456, 1459 (Fed. Cir. 1991) ("The shank is defined in the preamble as that portion of the hanger 'between the supporting hook for the hanger and the support for the garment.' This is not merely a suggested use or 'clarifying language,' as London argues, but rather a limitation supported by structure which must be satisfied by Samsonite's clamp, either literally or equivalently[,] if infringement is to be found."); In re Stencel, 828 F.2d 751, 754, 4 U.S.P.Q.2D (BNA) 1071, 1073 (Fed. Cir. 1987) ("Whether a preamble of intended purpose constitutes a limitation to the claim is, as has long been established, a matter to be determined on the facts of each case in view of the claimed invention as a whole."); Loctite Corp. v. Ultraceal Ltd., 781 F.2d 861, 866, 228 U.S.P.Q. (BNA) 90, 92 (Fed. Cir. 1985) ("Although it appears in the preambles of the '012 patent claims, the term 'anaerobic' breathes life and meaning into the claims and, hence, is a necessary limitation to them."); Perkin-Elmer Corp. v. Computervision Corp., 732 F.2d 888, 896, 221 U.S.P.Q. (BNA) 669, 675 (Fed. Cir.) ("The system of claim 1 is one of unity magnification and is image forming. Those limitations appear in the preamble, but are necessary to give meaning to the claim and properly define the invention.").

the preamble has been denied the effect of a limitation where . . . the claim or [interference] count apart from the introductory clause completely defined the subject matter [of the invention], and the preamble merely stated a purpose or intended use of that subject matter. On the other hand, in those . . . cases where the preamble to the claim or count was expressly or by necessary implication given the effect of a limitation, the introductory phrase was deemed essential to point out the invention defined by the claim or count. In the latter class of cases, the preamble was considered necessary to give life, meaning and vitality 1 to the claims or counts.

--- Footnotes ---

1 This particular phrase originates in Schram Glass Manufacturing Co. v. Homer Brooke Glass Co., wherein the court observed that a claim preamble "may entirely fail to supply a necessary element in a combination, yet it may so affect the enumerated elements as to give life and meaning and vitality to them, as they appear in the combination." 249 F. 228, 232-33 (7th Cir.), cert. denied, 247 U.S. 520 (1918).

--- End Footnotes ---
Id. at 152, 88 U.S.P.Q. (BNA) at 480-81. Preamble construction thus presents no deeper mystery than the broader task of claim construction, of which it is but a part.

B. Claim 6 of the '080 Patent

Claim 6 of the '080 patent recites a "method for transmitting a packet over a system comprising a plurality of networks . . . said packet including a source address and destination address," as its preamble indicates. It then recites, inter alia, the steps of "assigning, by said source device, one of said trees to broadcast said packet and associating with said packet an identifier indicative of said one of said trees." (Emphasis added). These two steps of the claimed method, by referring to "said packet," expressly incorporate by reference the preamble phrase "said packet including a source address and a destination address." As a result, only a method for transmitting packets that have both source and destination addresses can literally infringe Claim 6.

Bellcore contends, as it did before the district court, that one ought not to accord "definitional status" to the phrase "said packet including a source address and a destination address" because it appears in the claim's preamble, relying primarily on our decision in DeGeorge v. Bernier, 768 F.2d 1318, 226 U.S.P.Q. (BNA) 758 (Fed. Cir. 1985), for the proposition that "the preamble to a claim does not limit the claim." Bellcore likely maintains this position on the mistaken belief that to do otherwise would be to concede its case against Vitalink. In any event, however, Bellcore's position is untenable. In DeGeorge, we noted that "generally, and in this case, the preamble does not limit the claims." Id. at 1322 n.3, 226 U.S.P.Q. (BNA) at 761 n.3. As the preceding discussion of our cases on claim preambles makes clear, this observation in DeGeorge can only have been descriptive, rather than prescriptive. We have long eschewed the use of an absolute rule according or denying all preambles limiting effect, having recognized that one cannot determine a preamble's effect except by reference to the specific claim of which it is a component. Claim 6, as drafted and in light of the specification, is plainly limited such that it literally reads only on methods that transmit packets having both source and destination addresses. 2

The district court further concluded that the above limitation regarding the contents of the packet compels one to construe the step of "associating with said packet an identifier" to require that the identifier be separate and distinct from the destination address. Vitalink urges us to affirm this construction of the claim. In other words, Vitalink would have us read the phrase "associating with said packet an identifier" as if it were "inserting into said packet a separate identifier." This construction of the claim is, however, no more tenable than Bellcore's. For, while nothing within Claim 6 considered in isolation impeaches the construction that Vitalink prefers, it is legal error to construe a claim by considering it in isolation. A claim must be read in view of the specification of which it is a part. Adams, 383 U.S. at 49; Markman, __ F.3d at __, 34 U.S.P.Q.2D (BNA) at 1329-30. The specification of the '080 patent makes it clear to one of ordinary skill in the art that one can "associate" an identifier with a packet within the meaning of Claim 6 either explicitly (e.g., by the insertion of an additional "tree number" field into the packet) or implicitly (e.g., by the insertion of a destination address field from which a tree number can be determined). Thus, the associating step of Claim 6 covers both an implicit or an explicit approach. The district court, by construing it to cover the explicit approach alone, read an additional limitation into the claim, an error of law. See, e.g., Specialty Composites v. Cabot Corp., 845 F.2d 981, 988, 6 U.S.P.Q.2D (BNA) 1601, 1606 (Fed. Cir. 1988).

Bellcore also contends that the district court erred when it interpreted the assigning step of Claim 6 to require that the source device assign the packet to be broadcast along one and only one spanning tree, on which the packet would travel to its destination without any mid-course changes in tree assignment. We, however, share the trial court's view of the assigning step's proper construction. The claim first recites the step of "assigning, by said source device, one of said trees to broadcast said packet." Although this clause appears to include no limitation regarding the possibility that mid-course changes in tree assignment might occur, the remainder of the claim renders such a construction of Claim 6 unworkable. First, the broadcasting step, according to which the packet is sent "through the system on said one of said trees," strongly suggests that the packet travels on the same tree, assigned at the outset, from its source to its destination. Second, and more importantly, the claimed method whereby the gateways execute their store-and-forward protocol precludes mid-course changes in tree assignment. According to the claim, each gateway receiving the packet "determines for each said packet . . . said packet identifier"—that is, the identifier associated with the packet that is "indicative of said one of said trees" on which
the packet has been broadcast. Each gateway then executes its first inhibit-or-forward decision according to whether it "processes packets having said identifier"—again, the identifier associated with the packet that is "indicative of said one of said trees" on which the packet has been broadcast. Thus, the identifier that indicates the "one of said trees" along which the packet is broadcast "through the system" remains the same throughout the packet's trip from its source to its destination. As a consequence, in the claimed method, the tree on which the packet travels must also remain the same: if the packet were assigned to a new tree mid-course, the gateways along that new tree would not forward it, inasmuch as they do not process packets having the identifier, indicative of a different tree, that was associated with the packet prior to its broadcast. The district court properly construed Claim 6 to require that the source device assign, prior to transmission, the one spanning tree along which the packet travels to its specified destination.

3. "associating users"

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>FotoMedia's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;associating users who will access the image with roles&quot;</td>
<td>No construction necessary</td>
<td>For at least two roles, assigning a list of users who will access the image to the roles</td>
</tr>
</tbody>
</table>

Fotomedia proposes that no further construction is necessary for this term. Fotomedia argues the patent teaches that users are assigned roles, and there is no support in the intrinsic record for defendants' proposed construction, assigning a "list of users" to "roles."

The defendants contend that this term should at least be limited to its plural form. As part of their proposed construction, defendants also suggest that the term "associating" be interpreted as "assigning." For this, defendants point to the specification that reads "[a]ll users who will access the image are assigned particular roles." See '231 patent, col. 3, ll. 61-63.

In this context, the specification uses the terms "assign" and "associate" synonymously. Therefore, the Court finds that the scope of the claim should be limited to a system wherein users are indeed assigned roles. The defendants' proposed requirement of a plurality of roles is also supported by the claim language and the specification. One highlighted feature of the invention over the prior art is that it is able to intelligently discriminate between users based on these roles. See '231 patent, col. 1, 50-60. There can be no discrimination between users if there is only a single role defined.

The Court, therefore, adopts the defendants' proposed construction. "Associating users who will access the image with roles" is construed as follows: "For at least two roles, assigning a plurality of users who will access the image to the roles."

4. ASSOCIATION

The parties apparently have been unable to agree upon the meaning of the word "association" as used in the phrase "computers each in association with one of said license storage keys," in Claim 1. Defendants maintain that the phrase means each computer must be "connected to an associated peripheral storage device containing one of the license files . . . ." Plaintiff's opt for a straightforward dictionary definition.

The Court has found the dictionary to be a convenient reference tool for discovering the meaning of common English words. Accordingly, reference to Webster's Ninth New Collegiate Dictionary, Merriam Webster (1984), yields an appropriate definition for "association" for purposes of construing the '297 Patent. The relevant dictionary entry for association reads "the state of being associated." In turn the pertinent entry for "associate" reads "to join or connect
together." It follows directly from the preceding that "association" refers to the state of being joined or connected together.

Additionally, because Claim 2, which is dependent upon Claim 1, adds only that "communications between a license storage key and a computer are encrypted," the Court is of the opinion that association contemplates communication, even in Claim 1. That is, "communications" are referred to in Claim 1 as though they are a pre-existing aspect of the relationship between license storage keys and computers in the computer network with encryption thereby being the only new element of the dependent claim. In light of the above, the following definition is appropriate.

**ASSOCIATION** is the state of being joined or connected together such that communication is possible as between the joined or connected components.

---

**12. Associative crossbar/ associative crossbar switch.**

Borrowing from Intel's practice of incorporating claim elements into the definition of a term, Intergraph defines "associative crossbar" as a first set of connectors coupled to the super scaler storage for receiving each of the software-scheduled instructions therefrom, and a second set of connectors coupled to the plurality of instruction pipelines. Intel's proposed construction is addressed above, as it views the terms "crossbar" and "associative crossbar" to be synonymous. The Court construes "associative crossbar" and "associative crossbar switch" as a crossbar in which the data being routed includes the routing instructions. '028 patent at 3:11-17; 10:10-21.

---

**260**

E. To Assume a Proper Configuration (Claim 1)

PCTEL contends that the term requires no construction. Agere and USR state that the term means "to assume a proper hardware configuration."

The Court agrees with Agere and USR. Agere and USR base their interpretation on the relation of this term to the remaining language in claim 1. The only configuration that is identified in claim 1 is a "hardware configuration." In fact, the term in context reads "to cause said means for changing the hardware configuration to assume a proper configuration." '561 patent, col. 11:52-54. Thus, it appears to the Court that the "proper configuration" in this claim obviously refers to the hardware configuration term that proceeded it. Accordingly, the Court construes "to assume a proper configuration" as to assume a proper hardware configuration.

---

**261**

c. The '064 Patent

The disputed claim terms in the '064 Patent are "interworking unit" (which, again, the parties seem to agree means the same thing as the "interworking device" disclosed in the '294 Patent) and "asynchronous communication." With respect to the claim term "interworking unit," the parties once again incorporate their arguments as to the same claim term in the '294 Patent. For the same reasons, the court also construes the claim term "interworking unit" in the '064 Patent to mean ATM interworking multiplexer, grants Vonage's motion for summary judgment on the issue of literal infringement as to this claim limitation, and denies Vonage's motion as to the issue of infringement of this claim limitation under the doctrine of equivalents.

The only new issue presented with respect to the '064 Patent is the disputed claim term "asynchronous communication." Vonage asks the court to construe this claim term to mean ATM communication. To help understand the distinction, "asynchronous" is a term of art in the communications field that refers to communications where the transmitting and
receiving devices do not communicate based on a synchronized clock. A declaration submitted by Sprint's expert, Dr. Wicker, is helpful to an understanding of the relevant technology underlying the distinction between "asynchronous communication" and ATM communication. Dr. Wicker explains that one of skill in the art recognizes "asynchronous" as a term of art in the communications field that refers to communications where the transmitting and receiving devices do not share a common clock to facilitate communication. This is opposed to synchronous communications such as the PSTN in which time synchronization is required to identify data and ensure delivery to its proper destination. To put the matter in context, Dr. Wicker asserts that asynchronous communication in the '301 Family Patents is descriptive of packet communication including ATM, IP, and other well known packet technologies. Such packets are generally communicated without a timing relationship (or synchronized clock) between the sender and receiver. Thus, packet technologies are asynchronous. Consequently, Vonage's argument that the court should construe the claim term "asynchronous communication" to mean ATM communication is essentially an attempt to limit the claim term to one particular type of packet communication and, in particular, to the exclusion of the IP packet technology used in the Vonage system.

As Sprint points out, the doctrine of claim differentiation is once again pertinent to the court's construction of this claim language. Dependent claim 6 claims a method "wherein the asynchronous communication is in asynchronous transfer mode [ATM]." '064 Patent, col. 23, ll. 56-57. Thus, a presumption arises against construing the claim term in the manner suggested by Vonage.

Vonage has not directed the court's attention to any disclosure in the specification which suggests that the court should construe the specific claim term "asynchronous communication" in the manner urged by Vonage.

Instead, Vonage relies on its overriding theory that the written description establishes that the inventions disclosed in the '301 Family Patents generally relate to ATM technology. In the absence of some type of link to the disputed claim language at issue, however, these generalized disclosures are insufficient to overcome the presumption created by the doctrine of claim differentiation. As such, the court declines to construe the claim term in the manner urged by Vonage.

5. "At a later timepoint determined by a fixed period of time predefined at a beginning of the handover" (Claim 1)

The full phrase of this limitation states: "at a later timepoint determined by a fixed period of time predefined at a beginning of a handover, deleting the link data from the first base station and freeing up the resources of the firstbase station . . . ." '830 Patent at 8:25-29. The specification explains:

It is therefore proposed that in the case of a handover the base station initially continue to hold the data and resources. To accomplish this a timer, for example, is started when the old base station asks the mobile station to look for a new base station (or when the mobile station confirms this). The base station holds the resources of the mobile station in reserve until it receives the request to redirect the links or until the timer runs out. During this time the mobile station has time to look for a new base station that is capable of carrying the traffic. If the search for a new base station is unsuccessful, the [mobile station] re-registers at its old [base station] and keeps its previous settings. If the [mobile station] does not [re-]register within the time defined by the timer the old base station frees up the resources and deletes the [mobile station] from its lists.

Id. at 7:41-54.

HTC proposes that the cited limitation be construed to be "the base station deleting the link data and freeing up the link resources if a predetermined time passes after the mobile station began searching for a new base station." This defines more than the limited phrase, quoted above. IPCom prefers, "when the time, which has been preset and initiated before handover, expires." The Court adopts IPCom's more limited definition. The phrase "at a later timepoint determined by a fixed period of time predefined at a beginning of a handover" means "when the time, which has been preset and initiated before handover, expires."
C. "each of said plurality of student terminals . . . at a pace controlled by teacher" (Pacing)

Claim 1 also requires, in part, "allowing the teacher to initiate and terminate said student tasks on said interactive electronic classroom system, such that each of said plurality of student terminals provides said responses to said student tasks at a pace that is under the control of the teacher." (emphasis added). Better Education's proposed construction is "the teacher may set a time limit or control the pace by starting, stopping, or advancing to the next instructional activity, question, or set of questions which the students may provide responses to on their student terminals." The defendants assert that this term means "the teacher has the ability to set separate time limits for when different student terminals send responses to the student tasks." The primary dispute is whether the system must be capable of setting different time limits for individual students.

The defendants first argue that the system must permit separate time limits because the claim language states that "each of said plurality . . . is under the control of the teacher." (emphasis added). According to the defendants, Better Education's proposed construction reads "each of" out of the claim language by not requiring individual control. But, even with a system having a single aggregate timer, each individual student terminal provides responses; thus, the "each of" language is not rendered superfluous. Next, the defendants cite to a portion of the Summary of the Invention, which states:

The inventive system also involves a combination of software and hardware to accomplish the following: . . . a timing environment . . . for allowing each of the terminals to proceed . . . either at each student's own pace, or in lockstep with all other students in the class. If the teacher assigns different tasks to different groups of students in the class, then students within each group may proceed either individually or in lockstep with others in that group . . . .

('491 patent, 4:26-27, 39-52). Thus, according to the defendants, the claimed system must permit individual timers. In response, Better Education argues that the language of the dependent claims supports its asserted construction. Claim 28, which depends upon claim 1, "allows each of said plurality of student terminals to receive and respond to said student tasks at each student's own pace." The Federal Circuit has explained that "the presence of a dependent claim that adds a particular limitation raises a presumption that the limitation in question is not found in the independent claim." Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004). As claim 28's pacing limitation is nearly identical to the defendants' proposed construction of claim 1, the doctrine of claim differentiation counsels against the construction asserted by the defendants. The court is not persuaded that the specification requires the narrow reading of this limitation that is advanced by the defendants. Therefore, the court construes "each of said plurality of student terminals provides said responses to said student tasks at a pace that is under the control of the teacher" to mean "the teacher may set a time limit or control the pace by starting, stopping, or advancing to the next instructional activity, question, or set of questions which the students may provide responses to on their student terminals."

12. "at a time requested by the user"

Claim 19 provides in pertinent parts:

A distribution method responsive to requests from a user identifying items in a transmission system containing information to be sent from the transmission system to receiving systems at remote locations, the method comprising the steps of:

- sending a request, by the user to the transmission system, for at least a part of the stored information ...

- sending at least a portion of the stored information from the transmission system to the receiving system at the selected remote location;
receiving the sent information by the receiving system at the selected remote location;

storing a complete copy of the received information in the receiving system at the selected remote location; and

playing back the stored copy of the information using the receiving system at the selected remote location at a time requested by the user.

The Court finds that the "time" in the phrase "at a time requested by the user" refers to the time the user wants to receive the information at a device, such as a TV or VCR. This method gives the user the ability to designate a playback time. In this regard, the parties raise two issues: 1) whether designation of a playback time is optional or mandatory; 2) when, i.e., at what point is the playback time designated.

With respect to the first issue, to determine the optional or mandatory nature of the playback time, Court examines Figure 3, which is a flowchart of an embodiment of a distribution method practicing the claimed invention. Step 3090 of Figure 3 provides: "User may enter time and destination." The use of the word "may" suggests that the playback time is optional rather than mandatory. However, the specification does not contain the optional language of "may:"

The user then indicates whether the confirmation performed in step 3070 is correct (step 3080). If the confirmation performed in step 3070 is correct, the user so indicates and then inputs a desired delivery time and delivery location (step 3090).

('992 Patent, Col. 14:29-33.) The specification does not disclose a means for the user to communicate with the transmission system after making the request for transmission of the information. This leads the Court to the second issue--at what point is the playback time designated.

First, a reasonable interpretation of the phrase "at a time requested by the user" is one in which "at the time" the user makes a request to the transmission system to transmit the information, the user designates a playback time which is at the time of the transmission or at a time later than the time of the transmission. While the transmission request and the playback time request must be made by the user to the transmission system at the same time, the actual playback time may be later than the transmission request time. This interpretation is supported by the specification. Figure 6 is a block diagram of an embodiment of the reception system. The specification of Figure 6 discusses playback time as follows:

In the reception system 200 of the present invention, the user may want to playback the requested item from the source material library 111 at a time later than when initially requested. If that is the case, the compressed formatted data blocks from receiver format converter 202 are stored in storage 203. Storage 203 allows for temporary storage of the requested item until playback is requested.

When playback is requested, the compressed formatted data blocks are sent of [sic] data formatter 204. Data formatter 204 processes the compressed formatted data blocks and distinguishes audio information from video information.

('992 Patent, Col. 18:14-26.) It is apparent that the user would be required to specify a playback time as part of the initial request. However, the user could specify a playback time which is later in time than the time when the request for transmission itself is being made. After the material is transmitted, it would be stored automatically in "storage 203" in the reception system. When the specified delayed playback time arrives, the system would automatically output it in real time. Although a delay in output would occur, the time for output would have been specified at the time of the initial request. There is no means disclosed in the specification by which the user can communicate with the transmission system to modify the designated delayed output time.

Second, there is support in the specification for an embodiment in which the user initiates playback after the information has been received by the reception system. The specification discloses an embodiment in which the user is able to request a particular song, for example, directly from the information "buffered" n10 in the reception system:

For example, a user may desire to listen to a particular song. They may preferably enter the song number either when requesting the item from the compressed data library 118 and only have that song sent to their receiving system 200 or they may preferably select that particular song from the items buffered in their receiving system 200.
In another provision, the specification discloses an embodiment in which the reception system has playback controls which would allow the user to communicate a playback request directly to the reception system:

The reception system 200 has playback controls similar to the controls available on a standard audio/video recorder. These include: play, fast forward, rewind, stop, pause, and play slow.

The Court interprets "buffered," in this context, to mean "temporarily stored." There is no mention in the specification of what kind of a buffering device a user would have in such a receiving system.

These embodiments in which the user is able to communicate a playback request directly from storage in the reception system are described in the specification as direct connection configurations in which the reception system is located at the user's premises:

In direct connection configurations, such as reception system 200 shown in FIGS. 1e and 1f, the user preferably select the reception system 200 to which the requested material is sent, and optionally selects the time playback of the requested material as desired. Accordingly, the user may remotely access the transmission system 100 from a location different than the location of receptions system 200 where the material will be sent and/or played back. Thus, for example, a user may preferably call transmission system 100 from work and have a movie sent to their house to be played back after dinner or at any later time of their choosing.

In non-direct connection reception systems such as shown in reception system 200 of FIG. 1f, intermediate storage device 200c may preferably include, for example, sixteen hours of random access internal audio and video storage. A reception system with such storage is capable of storing several requested items for future playback. The user could then view and/or record a copy of the decompressed requested material in real time, or compressed in non-real time, at a time of their choosing. Accordingly, the user would not have to make a trip to the store to purchase or rent the requested material.

There is no detail for these embodiments. In any event, neither of these references to user controls at the reception system lead the Court to come to a different conclusion that the phrase "at the time requested by the user" should be construed to require that a playback time must be designated at the time of the initial transmission request.

The Court defines at "a time requested by the user" as follows:

In a distribution method as disclosed in Claim 19 of the '992 Patent, in which a transmission system sends information to receiving systems at remote locations in response to a user's request, in a nondirect connection configuration, the phrase "at a time requested by the user" means "at the output time specified by the user when the user makes the request to the transmission system to transmit information." At the time the user makes a request to the transmission system to transmit information, the user must designate an output time. At the time of the transmission request, a user may designate a delayed output time. If so, the information is transmitted to the receiving system where it is stored and at the pre-designated time, the information is automatically output by the receiving system.

The specification states that there can be "storage" in the reception system in a direct connection configuration: "Since items are preferably stored on random access media...."
4. "at a time when" (1[f], 6, 11[b])

(i) Claim Construction

Claim 1 explains that "actuation of said [vend selection] switch means at a time when the amount accumulated in the accumulator means at least equals the vend price" will energize the first portion of the selection monitor. '903 Patent col. 8, lines 45-47 (emphasis added). In a similar vein, claim 6 describes how a selection monitor designed with an optical isolator "includes means responsive to the light produced when said photo-diode is energized by operation of the switch means in the vend selection means at a time when the accumulator has an amount accumulated therein at least equal to the vend price." '903 Patent col. 8, lines 14-19 (emphasis added). Claim 11 also uses this language, describing a means to inhibit the accumulator "until after the customer has actuated one of the product selection switches at a time when the amount accumulated in the accumulator at least equals the selected vend price." '903 Patent col. 9, lines 59-63 (emphasis added).

Mars urges the Court to interpret these phrases so that the patent does not cover the situation where actuation of the switch means energizes the first portion regardless of whether or not the amount accumulated at least equals the vend price. Coinco urges the opposite interpretation, and suggests that the patent covers the situation where the closing of the selection switch may enable the first portion regardless of whether or not the amount accumulated at least equals the vend price.

Words in a patent must have meaning. Ethicon Endo-Surgery v. United States Surgical Corp., 93 F.3d 1572, 1582 (Fed. Cir. 1996); see also Chef Am. v. Lamb-Weston, Inc., 358 F.3d 1371, 1373 (Fed. Cir. 2004) (explaining that words "mean exactly what they say."). Coinco's position, as demonstrated by Mr. Upchurch, is that the "at a time when" language only requires that the selection monitor be capable of working at a time when the amount accumulated at least equals the selected vend price; according to this interpretation, it is irrelevant, according to the claim language, whether or not the selection monitor also operates at a time when sufficient money has not been accumulated in the accumulator. (Tr. vol. 30, 112 (Mr. Upchurch explained that the statement regarding when actuation should occur "is true whether the amount accumulated in the accumulator equals the vend price or not."); Tr. vol. 30, 134 (disclosing the same testimony for claim 11.)) If the Court were to accept Coinco's argument, then claims 1, 6, and 11 would have exactly the same meaning even if the language specifying "at a time when" were removed from the text of those claims. The Court rejects Coinco's argument for three reasons.

First, construing the claims in the manner requested by Coinco would have the result of effectively excising these words from the claims. Second, the specification does not support Coinco's argument because the specification contains no indication that the selection monitor's operation does not depend upon sufficient accumulation. Third, figures that are part of a patent cannot be used to directly contradict the language of the claims. Coinco argues that Figures 1-5 of the '903 Patent do not show any direct connection between the selection monitor and the accumulator, and that without this connection the selection monitor cannot be dependent upon the accumulator. Although Coinco is correct that the figures do not show any direct connection between the selection monitor and the accumulator, requiring the selection monitor to be dependent on the accumulator -- as urged by Mars -- would result in a working vending machine that used the teachings of the '903 Patent's claims. The interpretation requested by Mars would certainly not result in a nonsensical patent. Because "[e]ven a nonsensical result does not require the court to redraft the claims of the . . . patent," and the specification does not show any indication that the drafter intended anything other than what the words say, the law is clear that the words "at a time when" must be given meaning. See Chef Am., 358 F.3d at 1373-74 (citation omitted). Therefore, the Court accepts Mars' interpretation, and the patent does not cover the situation where actuation of the switch means energizes the first portion regardless of whether or not the amount accumulated at least equals the vend price.

GO BACK

6. "at all times not admit for storage in said buffer any cells on said virtual channel connections for which since the previous indication of said end of transmission on said virtual channel connection there has been any rejection of cells for storage"

The plaintiff again argues that all of the agreed technical terms have been defined; therefore, no further construction is needed. In the alternative, the plaintiff argues that the phrase as a whole means "whether or not buffer overflow is
threatened, not admit for storage in the buffer any cells on the virtual channel connection for which since the previous indication of the end of transmission there has been any rejection of cells for storage."

Under the plaintiff's construction, the cell rejection that occurs as a result of the fourth step of the method is tied to and follows the rejection of the first cell of a frame in a threatened buffer overflow situation following the admission of an end-of-transmission cell, as specified by the third step of the method. As a result, under the plaintiff's proposed construction, the only cell rejection required by the fourth step is the rejection of the remaining cells in a frame whose first cell was not admitted under the threat of buffer overflow as a result of the third step.

The defendants propose that the phrase as a whole means "at all times, if there has been any rejection of cells on a VCC since receipt of a cell on that VCC that contains an end-of-frame designation, reject all cells arriving on that VCC for storage in the buffer." Under the defendants' construction, the terms "at all times" and "any rejection of cells" language operates to include not only the rejection of cells because of threatened buffer overflow, but also the rejection of cells for violation of the preferred embodiment's "pre-storage scheduling check." The defendants point to Figure 9 and observe that Figure 9 describes a second method for rejecting cells, based on the pre-storage scheduling check. See Fig. 9, Step 110.

In addition, the defendants argue that the, "said end of transmission" language cannot refer to the same "end of transmission" indication called out by step 3. If this were the case, then once a cell on a VCC has been rejected after the admission of an end-of-transmission cell, all subsequent cells must also be rejected, thus shutting down that VC. According to, the defendants, this would render the claim indefinite or useless.

The claim language at issue is not a model of clarity; nevertheless, the court disagrees that the claim is indefinite and incapable of construction. The court construes this limitation to mean "at all times, if there has been any rejection of cells on a virtual channel connection since the receipt of a cell on that virtual channel connection that contains an end of transmission indication, not admit any cells arriving on the virtual channel connection for storage in said buffer."

Despite the plaintiff's arguments to the contrary, the language "at all times" and "any rejection" are broad terms that suggest that the claim limitation encompasses rejections for reasons unrelated to buffer overflow. As a consequence, the court rejects the plaintiff's alternative construction that "at all times" means "whether or not buffer overflow is threatened."

The Court issues this supplemental claim construction order in light of Defendant Nortel Networks, Inc.'s (“Nortel”) argument during trial regarding the meaning of a term in the Court’s January 10, 2007, claim construction order. The claim language at issue is “at all times not admit for storage in said buffer any cells on said virtual channel connections for which since the previous indication of said end of transmission on said virtual channel connection there has been any rejection of cells for storage.” The Court previously construed this limitation to mean “at all times, if there has been any rejection of cells on a virtual channel connection since the receipt of a cell on that virtual channel connection that contains an end of transmission indication, not admit any cells arriving on the virtual channel connection for storage in said buffer.”

Nortel has suggested that this construction requires that, after any rejection of a cell on a virtual channel connection, all future cells arriving on that virtual channel connection cannot be admitted for storage in the buffer. The Court did not intend this construction, and Nortel did not suggest this construction in its Markman briefing or at the Markman hearing.

Claim construction is an issue of law for the court to decide. Markman v. Westview Instruments, Inc., 52 F.3d 967, 970-71 (Fed. Cir. 1995) (en banc), aff’d, 517 U.S. 370 (1996). The Court must construe claims in the context of the entire patent. Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) (en banc). One of ordinary skill in the art, after reading the entire patent, would understand that this claim limitation is focused on cells in a given frame. See 5,689,499 Patent, Fig. 9, 9:53-10:6. Accordingly, the Court construes this limitation to mean “at all times, if there has been any rejection of cells from a particular frame on a virtual channel connection since the receipt of a cell on that virtual channel connection that contains an end of transmission indication, not admit any other cells from that particular frame arriving on the virtual channel connection for storage in said buffer.”
Rodime is the owner of the reexamined '383 patent, which issued on November 29, 1988. The reexamined '383 patent is directed to a micro hard-disk drive system (3.5 inch drive) suitable for use in portable computers with performance parameters comparable to those available in 5.25 inch disk drive systems. Quantum, the plaintiff in this declaratory judgment action, is the manufacturer of disk drives which, Rodime alleges in its counterclaim, infringe its patent.

The claim limitation at issue in this appeal relates to the storage capability of the hard-disk. The storage capability of a hard-disk is a function of the track density; the greater the track density, the more data that can be stored in a given area of the disk. Track density may be defined in terms of "tracks per inch" (tpi), calculated based on the number of concentric tracks present within an inch along the radius of the hard-disk.

On November 19, 1985, James G. McGinley and Roderick M. Urquhart, two engineers at Rodime, filed a patent application for the invention described above. Claim 1 of this application recited, inter alia, a track density of "approximately 600" tpi. The examiner, in a first office action, rejected all the claims as obvious under 35 U.S.C. § 103. With respect to the track density limitation in Claim 1, the examiner stated:

The art described in the preceding paragraph [regarding 5.25 inch disks] demonstrates that such a density is within the state of the art. Such a density would seemingly be achievable on a [3.5 inch] disk in the same manner by which it was achieved on a larger disk. Consequently it would seem that the subject matter of claim 1 - which is seemingly quite general - should not be considered patentable.

In a response dated May 23, 1986, applicants cancelled the original claims and inserted new claims some of which recited a track density of "at least 600" tpi. Although applicants had replaced "approximately" with "at least" in the track density limitation of these new claims, they made no reference to this in their response, but instead focused on the difference between the size of their disks (3.5 inch) and those in the prior art (5.25 inch) as a basis for overcoming the examiner's rejection. The examiner subsequently allowed these new claims, and the patent issued on January 20, 1987, as U.S. Patent No. 4,638,383 (the original '383 patent). Claims 4, 6, 7, 9, and 14 of the original '383 patent all recited a track density of "at least 600 concentric tracks per inch."

On September 28, 1987, Rodime, the owner of the original '383 patent pursuant to an assignment from the inventors, requested reexamination of its patent. Finding a substantial new question of patentability, see 35 U.S.C. § 303, the United States Patent and Trademark Office (PTO) granted Rodime's request for reexamination of all 16 claims in the original '383 patent. In an office action dated April 19, 1988, the examiner rejected all but two of the original claims. Rodime responded by cancelling certain claims, amending others, and adding dependent Claims 17-31. With respect to the claims at issue in this appeal, Rodime made substantial amendments including changing the track density limitation from "at least 600" tpi to "at least approximately 600" tpi. These claims were allowed, as amended, and the '383 reexamined patent issued on November 29, 1988, as U.S. Patent No. B1 4,638,383. As issued, independent Claims 4, 6, 7, 9, and 14 of the reexamined '383 patent all recite a track density of "at least approximately 600" tpi, and the newly added dependent claims which are at issue in this appeal, i.e. Claims 19-27, either explicitly contain this limitation or incorporate it through their dependency.

--- Footnotes ---

2 Illustrative of the amendments made is Claim 4 with the sections within the brackets being the matter that was deleted and the underlined sections indicating the additions made to the claim during reexamination:

4. A computer disk drive system [for operating a micro hard-disk, said disk drive system] comprising:

   a sealed housing;

   at least [one] two micro [hard-disk] hard-disks each having a diameter of between 92 and 96 millimeters and each having a plurality of concentrically adjacent tracks on both planar sides thereof, said micro hard-disks fixedly mounted in [a] the
sealed housing;

means for rotatably supporting said [hard-disk] micro hard-disks;

means for rotating said [hard-disk] micro hard-disks;

first and second transducer means [having two

read/write heads] for writing digital information on and reading digital information from said [hard-disk] micro hard-disks on both planar sides of [said] each micro hard-disk in a format so that [said] each micro hard-disk has digital information stored on [concentric] said concentrically adjacent tracks at a density providing at least 5 Megabytes of storage per [disk] micro hard-disk with the digital information being stored at a density of at least [6000] approximately 600 concentric tracks per inch, said first and second transducer means each comprising two read/write heads; [and,]

positioning means for moving said first and second transducer means between the concentrically adjacent tracks on said [hard-disk] micro hard-disks, said positioning means including:

a positioning arm disposed within the sealed housing and mounted for movement relative to said micro hard-disks;

a pivot shaft coupled to one end of said positioning arm and supporting said positioning arm for rotational movement relative to said micro hard-disks, four support arms, each supporting one of said heads at one end and each connected to said positioning arm at its other end; and

means for moving said positioning arm including a stepper motor having a shaft extending into said sealed housing and means for operating said stepper motor in step increments, each increment causing [said transducer means] said read/write heads to move from one track to the next adjacent track on said [hard-disk] micro hard-disks.

B.

Quantum filed the present action in the United States District Court for the District of Minnesota on February 26, 1993, seeking a declaration that the reexamined '383 patent is invalid, unenforceable and not infringed. Rodime subsequently filed an answer and a counterclaim for infringement. On February 22, 1994, Quantum filed a motion for summary judgment that Claims 4, 6, 7, 9, 14, and 19-27 of the reexamined '383 patent are invalid under 35 U.S.C. § 305 for being impermissibly broadened by Rodime during reexamination. According to Quantum, Rodime's amendment during reexamination of the track density limitation from "at least 600" tpi to "at least approximately 600" tpi broadened the scope of the claims to cover certain disk drives with approximately but less than 600 tpi that were not covered by the original '383 patent claims, and therefore these claims are invalid under 35 U.S.C. § 305.

The district court, in an order dated April 11, 1994, granted Quantum's motion for summary judgment. The court, after examining the claims, specification, and prosecution history, concluded that the addition of the word "approximately" to the track density limitation during reexamination was not a mere clarification, as Rodime argued, but was instead a substantive change that expanded the scope of the claims at issue in violation of 35 U.S.C. § 305, and that no reasonable juror could have found otherwise. In support, the court relied on the difference in the ordinary meaning of the disputed claim limitations: a track density of "at least 600 tpi" indicates densities starting at, but greater than 600 tpi, whereas the addition of "approximately" in the track density limitation of the reexamined '383 patent modifies the 600 tpi value, thereby eroding the "not less than" meaning of "at least." Based on these definitions, it followed, according to the court, that the claims had been broadened during reexamination since the reexamined '383 patent covered devices with track densities less than 600 tpi that were not covered by the original '383 patent. The court then concluded, without analysis, that the improperly broadened claims were invalid.

Since the district court's ruling disposed of all the claims which Rodime in its counterclaim had alleged Quantum to infringe, the district court, on April 26, 1994, ordered that final judgment be entered under Fed. R. Civ. P. 58 in favor of Quantum for a declaratory judgment of nonliability and against Rodime for its counterclaim of infringement of the
reexamined '383 patent. This appeal followed.

II. DISCUSSION

There are two issues in this case: first, whether Rodime broadened the scope of the claims at issue during reexamination in violation of 35 U.S.C. § 305 by changing the track density limitation from "at least 600 tpi" to "at least approximately 600 tpi," and, second, assuming the claims were impermissibly broadened, the legal effect of violating section 305. We review the district court's grant of summary judgment in favor of Quantum on these issues -- that the claims were broadened and are therefore invalid -- to determine whether any genuine issues of material fact are in dispute, and whether any errors of law were made. London v. Carson Pirie Scott & Co., 946 F.2d 1534, 1537, 20 U.S.P.Q.2D (BNA) 1456, 1458 (Fed. Cir. 1991).

A. 35 U.S.C. § 305 states, in relevant part, that "no proposed amended or new claim enlarging the scope of a claim of the patent will be permitted in a reexamination proceeding." An amended or new claim has been enlarged if it includes within its scope any subject matter that would not have infringed the original patent. In re Freeman, 30 F.3d 1459, 1464, 31 U.S.P.Q.2D (BNA) 1444, 1447 (Fed. Cir. 1994). "A claim that is broader in any respect is considered to be broader than the original claims even though it may be narrower in other respects." Id. (quoting Tillotson, Ltd. v. Walbro Corp., 831 F.2d 1033, 1037 n.2, 4 U.S.P.Q.2D (BNA) 1450, 1453 n.2 (Fed. Cir. 1987)). Accordingly, the claims at issue have been improperly broadened in violation of 35 U.S.C. § 305 if the track density limitation in the claims of the reexamined '383 patent -- "at least approximately 600 tpi" -- is broader than the track density limitation in the claims of the original '383 patent -- "at least 600 tpi."

Whether claims have been enlarged is a matter of claim construction, a question of law subject to complete and independent review on appeal. Id. at 1464, 31 U.S.P.Q.2D (BNA) at 1447. When construing the meaning of disputed terms in a claim, we look to the claims, specification and prosecution history. Carroll Touch, Inc. v. Electro Mechanical Sys., Inc., 15 F.3d 1573, 1577, 27 U.S.P.Q.2D (BNA) 1836, 1839-40 (Fed. Cir. 1993). Although a patentee can be his own lexicographer, the words of a claim will be given their ordinary meaning to one of skill in the art unless the inventor appeared to use them differently. Hoganas AB v. Dresser Indus., Inc., 9 F.3d 948, 951, 28 U.S.P.Q.2D (BNA) 1936, 1938 (Fed. Cir. 1993).

Rodime's principle argument on appeal is that the addition of the word "approximately" to the track density limitation only made explicit what was already implicitly included in the claim, and therefore did not expand the scope of the claims at issue. In support of this proposition, Rodime cites Laitram Corp. v. NEC Corp., 952 F.2d 1459, 1464, 31 U.S.P.Q.2D (BNA) 1276 (Fed. Cir. 1992); Tennant Co. v. Hako Minuteman, Inc., 878 F.2d 1413, 11 U.S.P.Q.2D (BNA) 1303 (Fed. Cir. 1989); and Kaufman Co. v. Lantech, Inc., 807 F.2d 970, 1 U.S.P.Q.2D (BNA) 1202 (Fed. Cir. 1986). Specifically, Rodime asserts that to one of skill in the art the term "600 tpi" means "approximately 600 tpi." In support, Rodime proffers the testimony of various technical experts who maintain that, because of manufacturing tolerances and variations inherent in rotary actuator drives, industry literature referring to a specific track density value is understood by those skilled in the art to represent a range. This interpretation, according to Rodime, is consistent with the specification which uses the terms "600 tpi" and "approximately 600 tpi" interchangeably. Since "600 tpi" means "approximately 600 tpi" to one of skill in the art, it necessarily follows, Rodime argues, that one of skill in the art would interpret "at least 600 tpi" to mean "at least approximately 600 tpi." Accordingly, Rodime concludes that the district court erred in not granting summary judgment to their advantage, or, at a minimum, concluding that this evidence created a genuine issue of material fact to be resolved at trial.

We disagree. The major flaw in Rodime's argument is that it focuses solely on the term "600 tpi" instead of the claim limitation as a whole, in context. See United States v. Telelectronics, Inc., 857 F.2d 778, 781, 8 U.S.P.Q.2D (BNA) 1217, 1219-20 (Fed. Cir. 1989), cert. denied, 490 U.S. 1046, 104 L. Ed. 2d 423, 109 S. Ct. 1954 (1989). Even if "600 tpi" means "approximately 600 tpi," as Rodime argues, it is unnecessary to read in an implicit range when interpreting "at least 600 tpi" because this limitation as a whole already expressly represents an open-ended range, i.e. 600 tpi and up. Therefore, that one skilled in the art understands "600 tpi" to connote a range is irrelevant because the limitation in dispute is "at least 600 tpi," and Rodime offered no evidence to show that one skilled in the art understood "at least 600 tpi" to be the same as "at least approximately 600 tpi" or that the patentee defined it as such in the patent or during prosecution.

Absent such a definition or evidence that the claim limitation as a whole has a special meaning to one of skill in the art, we
To give meaning to the phrase "at least one light source," we must construe claim 1 to cover a device that has only one light
source or a device that has more than one light source, assuming that the "device" is a "flashlight," as that term is used in the claim. According to the written description, the flashlight 8 is a light that is bright enough "to illuminate a small room or to otherwise serve satisfactorily as a flashlight." Col. 2, ll. 46-53. The face illuminator 9, in contrast, is a light that "enables reading the time without turning on [the flashlight] 8 if desired." Col. 2, ll. 58-62. According to the written description, the flashlight 8 and the face illuminator 9 are different elements. However, the written description further explains that light from the flashlight 8 can be used to illuminate the watch face 4 in the absence of a distinct face illuminator. See col. 2, ll. 49-54 ("The brightness of lamps 8 and the disposition of lamps 8 about case 3 should be arranged to illuminate timepiece face 4 so that the watch hands can be seen in the absence of otherwise provided light and so that the time indicative numbers and dots are also then visible."). Therefore, properly construed, the flashlight limitation is met by a wrist watch whose only light source illuminates both the watch face and a significant area beyond the watch face. This definition is consistent with the term's ordinary meaning. See American Heritage Dictionary 511 (2d College ed. 1982) (defining "flashlight" as a "small, portable lamp usually powered by batteries").

Casio argues that the claim cannot cover a watch without a separate face illuminator because the preferred embodiment includes one. However, "particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments." Electro Med. Sys. S.A. v. Cooper Life Sciences, 34 F.3d 1048, 1054, 32 U.S.P.Q.2D (BNA) 1017, 1021 (Fed. Cir. 1994). Because claim 1 does not recite a face illuminator, it is broader than the embodiment referenced by Casio. Moreover, because the written description does not require that the watch include a face illuminator, this "limitation should not be read from the specification into the claim[]." Specialty Composites v. Cabot Corp., 845 F.2d 981, 987, 6 U.S.P.Q.2D (BNA) 1601, 1605 (Fed. Cir. 1988).

Casio also argues that, under our construction, claim 1 is invalid because the recited combination is obvious. This argument is premature. Casio cannot avoid a full-blown validity analysis by raising the specter of invalidity during the claim construction phase. Although the court appeared to believe that several pieces of prior art, when viewed in combination, disclose all the limitations of claim 1, it did not conduct a validity analysis. See Graham v. John Deere Co., 383 U.S. 1, 17-18, 148 U.S.P.Q. (BNA) 459, 467, 15 L. Ed. 2d 545, 86 S. Ct. 684 (1966). Specifically, it did not identify any motivation to combine the references, see In re Fine, 837 F.2d 1071, 1074, 5 U.S.P.Q.2D (BNA) 1596, 1598-99 (Fed. Cir. 1988), or consider objective evidence of nonobviousness, see Custom Accessories, Inc. v. Jeffrey-Allan Indus., Inc., 807 F.2d 955, 960, 1 U.S.P.Q.2D (BNA) 1196, 1199 (Fed. Cir. 1986). Moreover, Rhine alleges that he was denied the opportunity to conduct discovery on the secondary considerations. Therefore, we remand the case so that discovery can proceed, if necessary, and the court may fully evaluate the strength of the invalidity case.

270

A. "At least one of . . . and . . ."

The first and most interesting disputed term is the phrase, "At least one of . . . and . . ." The phrase is used throughout the patent, in the same manner each time:

"Wherein the limitation or restriction prohibits a withdrawal from at least one of a checking account, a savings account, and an automated teller account, or prohibits use of at least one of a checking account, a savings account, and an automated teller machine account." ("725 patent, Claims 108, 135, 138 and 164);

"Wherein the banking transaction is at least one of a clearing transaction, a check clearing transaction, an account charging transaction, and a charge-back transaction." (Id., Claim 118);

"Wherein the apparatus is programmed for at least one of automatic activation, self-activation, automatic operation, and self-operation." (Id., Claims 128 and 157); and

"Wherein the banking transaction is at least one of a clearing transaction, a check clearing transaction, an account charging transaction, a charge-back transaction, and an account settling transaction." (Id., Claim 148).

Plaintiffs urge that the disputed phrase, when used in connection with a list of items (which is the way it is used in the patent in suit) means, "Only one item from the list or any combination of items in the list." Using the phrase, "At least one of A, B
and C," as an example, plaintiffs say the claim means only A, or only B, or only C, or any combination of A, B and C.

Defendants argue that the phrase means, "One or more of each of the items contained in the list." Using the same example, defendants contend that the phrase, "At least one of A, B and C," means, "One or more of A, one or more of B, and one or more of C."

I construe the phrase "at least one of . . . and . . ." in connection with a list of items to mean, "One or more of one or more of the items contained in the list."

If I were to look only to the plain meaning of the language, defendants would be indisputably correct. This is a simple matter of good English grammar (admittedly, a lost art). According to William Strunk, Jr. and E.B. White's classic authority on grammatical construction, THE ELEMENTS OF STYLE, 27 (4th ed. 2002), "An article of a preposition applying to all the members of the series must either be used only before the first term or else be repeated before each term." Here, the preposition "of" (or, rather, the phrase "one of") appears only before the first term in the sequence. It thus applies to every individual term that follows -- to A, and to B, and to C. Or, to put it in the context of the claims in suit, the phrase "at least one of a clearing transaction, a check clearing transaction, an account charging transaction, and a charge-back transaction" means at least one of each kind of transaction. The construction favored by plaintiffs would, as a matter of proper grammar, read, "at least one of a clearing transaction, a check clearing transaction, an account charging transaction, or a charge-back transaction." Use of the disjunctive preposition "or," rather than the additive preposition "and," makes a tremendous difference if all I care about is the grammatically correct construction of the phrase.

Use of the grammatically correct interpretation of the disputed language -- which I will call the "plain meaning" of the language -- was endorsed by the Federal Circuit in the recent case of SuperGuide Corporation v. DirectTV Enterprises, Inc., 358 F.3d 870, 885 (Fed. Cir. 2004). Applying an Occam's Razor approach to claim construction, I am tempted to follow suit.

However, in SuperGuide, interpreting the phrase in the grammatically correct fashion made sense in the context of the patent specifications. Reading the phrase in the same way here would render the claims utter nonsense.

Take again the phrase, "wherein the banking transaction is at least one of a clearing transaction, a check clearing transaction, an account charging transaction, and a charge-back transaction." A single banking transaction cannot be all four, so reading the disputed phrase additively -- while grammatically correct -- means it does not make any sense. That suits defendants' purposes nicely, of course, but it does not comport with the rules for proper claim construction.

One of the things I have learned in my brief but intensive introduction to patent law is that plain English grammar and syntax are not always endorsed by either patent examiners or courts interpreting patents. My personal favorite example of this phenomenon is the word "one," which in plain English means "one and no more than one" but which in patent English means "one or more than one," or "at least one." I do not understand why this is so, but I know that it is so, and I have applied that principle on more than one occasion -- indeed, I will apply it again later in this opinion. So I accept the proposition that it is perfectly proper to ignore English grammar and syntax when interpreting patent claim language -- at least, when context renders a different reading more sensible.

Here, it is far more sensible to read the disputed phrase as though plaintiffs had used the word "or" in place of "and." Indeed, that is what plaintiffs do in the specifications. They substitute either the word "or" or the phrase "and/or" for the word "and" every time they describe an embodiment of the claim. For example, despite phrasing their claims as "at least one of a checking account, a savings account and an ATM account," they state, "FIG. 4 illustrates a block diagram of an alternate embodiment of the apparatus of the present invention which is utilized in conjunction with a checking account, savings account and/or ATM account and/or transaction (hereinafter referred to as a 'banking transaction')." "725 patent, col. 20, line 63 - col. 1, line 10. Or, despite the use of the word "and" in the phrase "at least one of a clearing transaction, a check clearing transaction, an account charging transaction, and a charge-back transaction," the specifications state, "The apparatus and method of the present invention may be utilized to obtain account owner authorization in a banking and/or financial transaction." The specification continues in this vein, making repeated references to "a savings account or a checking account number," "determining the status of the account" and "the transaction," as in "...the account owner may either utilize the reply or two-way pager feature on the communication device 104 in order to either approve or authorize the transaction or disapprove of, or void, the transaction." (the relevant portions of the specification are found at col. 24, line 49 - col. 28, line 5).
Ironically, SuperGuide offers further support for adopting the ungrammatical but sensible reading of the disputed phrase. In that case, the disputed phrase was "at least one of selection and storage of program start time, program end time, program service and program type." In the first instance, the Federal Circuit concluded that the grammatically correct reading of the phrase "at least one of...and..." was the "plain and ordinary meaning of the disputed language." SuperGuide, supra, 358 F.3d at 885. But the court then looked to the specification, to see if anything therein "rebuts the presumption that the patentee intended the plain and ordinary meaning of the language." Id., at 887. What it learned from the specification was that, "Every disclosed embodiment teaches that the user must choose a value for each designated category," and that Figure 4a -- the only Figure in the specifications that explains how transmitted schedule information is stored -- likewise showed that the system's user had to choose at least one value for each designated criterion. Id.

I agree with defendants that the plain meaning of the language is conjunctive, not disjunctive. But when I go on to test that proposition by referring to the specifications -- as I must, under the teaching of Hoechst-Celanese, supra, 78 F.3d at 1578 -- it becomes clear that the patentee did not intend to use the phrase in its plain and ordinary way. Rather, the language used in the specifications is either disjunctive ("or") or both conjunctive and disjunctive ("and/or"). And unlike Figure 4a in SuperGuide, Figure 4 in the '725 patent plainly diagrams a transaction that supports a disjunctive, rather than conjunctive, reading of the relevant term. In short, the specification rebuts the presumption that the language should be given its plain and ordinary meaning.

Therefore, in the context of the '725 patent, I define the phrase "at least one of...and..." in connection with a list of items to mean "one or more of one or more of the items contained in the list." I hasten to add that this definition is adopted solely to square the claim language in the '725 patent with the patent's specifications. Thus, this decision has absolutely no precedential value for any other patent.

Touchtunes contends that the conjunctive language in this claim term requires that the song record include at least one of each of the categories of information listed, whereas Arachnid contends that the song record only requires at least one of the categories of data.

The plain meaning of "at least one of...and..." is conjunctive and requires at least one of each category unless the intrinsic records requires a departure from such plain meaning. See, e.g., SuperGuide Corp. v. DirecTV Enters., Inc., 358 F.3d 870, 885-87 (Fed. Cir. 2004); cf. Joao v. Sleepy Hollow Bank, 348 F. Supp. 2d 120, 123-26 (S.D.N.Y. 2004) (the phrase "at least one of...and..." should be construed to require the presence of all listed items unless doing so would contradict the specification or "render the claims utter nonsense").

Arachnid cites the '575 Patent specification as evidence in the intrinsic record of a departure from a conjunctive interpretation of the disputed claim term. Arachnid characterizes the '575 Patent specification as explaining that a song record is "a collection of song data representing one or more identifying characteristics of a song." (Arachnid Resp. 20(emphasis in original).) However, nothing in the cited specification indicates that song data consists of "one or more" of the characteristics, as opposed to at least one of each. The only indication that certain fields may be blank is in the description of the "graphics address field," which is used for "a graphic image, if any, to be associated with a song." '575 Patent 3:48-53. But the "if any" language does not make the inclusion of graphics address data optional, but rather allows for the possibility that the data might indicate that no graphic image is associated with the song.

Arachnid also argues that Touchtunes' proposed construction would render the phrase "at least one of" superfluous because the song record would always include data in each of the listed categories. This argument is incorrect, because even if data were always included in each of the listed categories, the phrase "at least one of" allows for the inclusion of more than one piece of data in some of the categories.

The Court therefore adopts Touchtunes' proposed construction.
The relevant portion of claim 1 with the disputed claim language underlined reads as follows:

An online television program schedule system comprising:

first means for storing at least one of a desired program start time, a desired program end time, a desired program service, and a desired program type;

means for receiving television program schedule information, said television program schedule information comprising at least one of program start time, program end time, program service, and program type for a plurality of television programs;

second storing means, connected to said first storing means and said receiving means, for storing selected portions of received television program schedule information which meet at least one of the desired program start time, the desired program end time, the desired program service, and the desired program type; and . . . .

'211 patent, col. 8, ll. 4-27 (emphases added).

SuperGuide generally argues on appeal that the district court's interpretation of the disputed language in claim 1 is inconsistent with the claim language, the specification and the prosecution history. 7

B. "At least one of"

The phrase "at least one of" also appears in claims 2, 5 and 6. 8 SuperGuide does not dispute that this phrase should be construed to have the same meaning in each instance. In interpreting this phrase, the district court concluded that the term "a desired," which precedes "at least one of," is repeated for each category and because the final category in the criteria list is introduced by "and a desired," the list is conjunctive. SuperGuide Corp., 169 F. Supp. 2d at 517. The court also concluded that accepting SuperGuide's position that "at least one of" refers only to one category of the criteria would contradict the purpose of the invention as described in the written description, as depicted in Figure 4a and recited in claim 1. Id. Thus, the court construed the phrase "at least one of . . . and" as meaning "at least one of each desired criterion; that is, at least one of a desired program start time, a desired program end time, a desired program service and a desired program type. The phrase does not mean one or more of the desired criteria but at a minimum one category thereof." Id.

8 We note that the district court stated that SuperGuide withdrew allegations that the defendants' products infringe claims 2, 5 and 6. DirecTV, however, does not contest that claims 1, 2, 5 and 6 have been asserted in this case.
addition, SuperGuide contends that the district court erroneously relied on Figure 4a in its analysis because that figure does not cover the asserted claims. SuperGuide lastly emphasizes that during prosecution the patentee repeatedly characterized the invention as requiring the presence of one or more of the four listed criteria and interchangeably used the terms "or" and "and."

DirecTV counters that the district court's construction is supported by the patentee's use of the conjunctive word "and" and by the grammatical rule requiring that the phrase "at least one of" be applied to each category in the list. Moreover, it disputes SuperGuide's arguments that the patentee used "and" out of necessity and that it could not introduce relevant evidence on that point. With respect to the specification, DirecTV contends that every disclosed embodiment of a desired criteria list, including Figure 4a, teaches a conjunctive list that is consistent with the plain meaning of the claim language. Responding to SuperGuide's argument, DirecTV maintains that even though Figure 4a relates to a data structure involving the transmission of data in packet form, claim 1 is written to also cover such a system. DirecTV lastly argues that accepting SuperGuide's prosecution argument would improperly allow the prosecution history to enlarge the claim scope beyond its ordinary meaning. DirecTV also points out that the '211 patentee never explicitly stated that "and" should be interpreted as "or" in the claim language and they did not refute the Examiner's characterization of the criteria list as being conjunctive.

We conclude that the plain and ordinary meaning of the disputed language supports the district court's construction and that the phrase "at least one of" means "one or more." Rhine v. Casio, Inc., 183 F.3d 1342, 1345 (Fed. Cir. 1999). The issue here is: what does "at least one of" modify? The criteria listed in the claim at issue consist of four categories (program start time, program end time, program service, and program type). Each category is further comprised of many possible values. SuperGuide contends that the phrase "at least one of" modifies the entire list of categories, i.e., selection and storage of one or more values for one or more of the four listed categories is required. DirecTV, on the other hand, argues that the phrase "at least one of" modifies each category in the criteria list, i.e., one or more values in each category are required.

We agree with DirecTV. The phrase "at least one of" precedes a series of categories of criteria, and the patentee used the term "and" to separate the categories of criteria, which connotes a conjunctive list. A common treatise on grammar teaches that "an article of a preposition applying to all the members of the series must either be used only before the first term or else be repeated before each term." William Strunk, Jr. & E. B. White, The Elements of Style 27 (4th ed. 2000). Thus, "in spring, summer, or winter" means "in spring, in summer, or in winter." Id. Applying this grammatical principle here, the phrase "at least one of" modifies each category of the list, i.e., each category in the list. Therefore, the district court correctly interpreted this phrase as requiring that the user select at least one value for each category, that is, at least one of a desired program start time, a desired program end time, a desired program service, and a desired program type.

10 Indeed, SuperGuide does not articulate its argument that "at least one of" means "one or more of the four listed criteria" without using the term "or" to separate the four listed categories. See Brown v. 3M, 265 F.3d 1349, 1352 (Fed. Cir. 2001) (interpreting the phrase "at least one of two-digit, three-digit, or four-digit year-date representations" as "only two-digit, only three-digit, only four-digit, or any combination of two-, three-, and four-digit date-data").
different elements. If two equivalent parts are referred to as "rods" or "bars," the alternative expression may be considered proper.

MPEP § 706.03(d) (1990). According to SuperGuide, at least some of the criteria referred to in the claims at issue, such as "program start time" and "program type," are not equivalent in the same sense that a "rod" may be equivalent to a "bar." SuperGuide's argument lacks merit for three reasons. First, the cited MPEP rule only states that the given example "may make a claim indefinite," it does not absolutely preclude such alternative expression. Moreover, the example given is distinguishable from the language the '211 patentee could have arguably used here because the modifying phrase "at least one of" does not precede the alternatives in the example. The use of the phrase "at least one of" in the claims at issue provides definiteness that is not present in the example provided in the MPEP rule. Lastly, even assuming arguendo that the patentee drafted the claim at issue in response to the PTO's instructions on avoiding indefiniteness, we fail to see how this instruction compels us to construe the term "and" as "or."

--- Footnotes --

11 Having concluded that the '211 patentee was not precluded from using the term "or," we do not address SuperGuide's argument that the patentee was also precluded from using a "Markush" format.

--- End Footnotes ---

We further conclude that nothing in the specification rebuts the presumption that the '211 patentee intended the plain and ordinary meaning of this language. See Tex. Digital, 308 F.3d at 1204. Every disclosed embodiment teaches that the user must choose a value for each designated category. See, e.g., '211 patent, fig. 1. The written description explains that in this embodiment "the [predetermined] selection criteria 17 may include a desired service list 17a, a desired types of programming list 17b, desired times of listings 17c and other criteria 17d." Id. at col. 4, ll. 23-26. SuperGuide points to another part of the written description, describing the same embodiment, which states the following:

for example, if a user is only at home in the evening he may only wish to view listings from 6 p.m. to 11 p.m. Other criteria 17d may also be selected or provided.

Id. at col. 4, ll. 49-52. This description, however, does not teach that a value for less than all the designated categories can be chosen. Further, "other criteria" refers to either another category or another list of categories that require values. In other words, it explains that other categories, besides the ones specified, are possible.

--- Footnotes ---

12 DirecTV contends that 17a-d in Figure 1 are "alternative lists of categories of criteria," whereas SuperGuide contends that they are "alternative criteria." We find it unnecessary to resolve this dispute. In either case, the figure does not teach a conjunctive list of categories.

--- End Footnotes ---

We also conclude that Figure 4a of the '211 patent supports the plain and ordinary meaning of the asserted claims. This figure and its corresponding explanation are the only parts of the specification that explain how only certain portions of the transmitted schedule information are stored. The figure consists of a flow chart describing a method for storing portions of the received schedule information according to the chosen criteria. The method compares the received information to determine whether the information "meets" all the criteria chosen by the user. Importantly, the flow chart uses a conjunctive criteria list, i.e., the system's user must choose at least one value for each designated criteria, or the logic would be inoperable. '211 patent, fig. 4a.

--- Footnotes ---

13 The meaning of this term is discussed below.

--- End Footnotes ---
SuperGuide argues that Figure 4a is inapplicable to the construction of the disputed language because the figure relates to the processing of received information that has been transmitted in group format whereas the asserted claims do not require such a group format. We disagree. The asserted claims do not require the transmission of schedule information in any particular format. Thus, the asserted claims could cover a system with schedule information that is transmitted in group format. There is also no suggestion in the specification that Figure 4a is applicable only to the transmission format disclosed in the figure. Indeed, the specification states that Figures 4a-4c "are a block diagram illustrating the logic and sequence of operations for storing broadcast TV program information according to the present invention." Id. at col. 3, ll. 41-44 (emphasis added).

Lastly, we decline to enlarge the claim scope from its plain and ordinary meaning based on the prosecution history in this case because the ’211 patentee did not clearly and explicitly define the term "and" in the covered criteria list as "or." 14 See N. Telecom, 215 F.3d at 1295 (holding that vagueness and inferences in the prosecution history do not rebut an ordinary meaning of a claim term).

--- Footnotes ---
14 SuperGuide argues that the district court erred by failing to consider the ’211 prosecution history. However, because the claim construction is unaffected by the prosecution history, any error was harmless. See Lemelson v. United States, 752 F.2d 1538, 1550 (Fed. Cir. 1985) (holding that the district court properly interpreted the claim at issue, and the court's failure to consider the prosecution history was therefore harmless error not meriting reversal).

--- End Footnotes ---

Step 2

The parties' next dispute is with the claim construction of Step 2's phrase "content profiles indicating at least one of the presence and the degree of." As explained, the court accepts Pinpoint's argument that the '257 patent claim term "degree" was intended to include "presence" and that the claim term "presence" was later added to the'722 patent for clarification purposes. The court need only consider whether the disputed phrase requires that content profiles indicate either presence or degree (Pinpoint's proposed construction), or both presence and degree (Amazon's proposed construction). Def. Mem. at 33; Pl. Opp. Mem. at 25. According to Amazon, Superguide Corp. v. Directv Enters., 358 F.3d 870, 886 (Fed. Cir. 2004), instructs that the phrase "at least one of" before "the presence and the degree of" requires the disputed phrase be construed to mean that both presence and degree are included in the content profile. Amazon is mistaken. Superguide is inapplicable because the prosecution history supports Pinpoint's proposed construction. Not only does file history reveal that the '722 patent inventors explicitly asserted that the phrase meant that "the content profiles indicate either the 'degree of content' or the 'presence' of predetermined characteristics in the data," but the patent examiner later confirmed this reading. See Pl. Mem. at 25-26, App. 8 (AMZN 002688); App. 11 (HH 0002402). The inventors' construction, as it appears in the prosecution history, controls. See Golight, Inc. v. Wal-Mart Stores, Inc., 355 F.3d 1327, 1332 (Fed. Cir. 2004) ("an inventor . . . may be his own lexicographer if he defines the specific terms . . . in the written description or in the prosecution history"); Superguide, 358 F.3d at 888 ("lastly, we decline to enlarge the claim scope from its plain and ordinary meaning based on the prosecution history in this case because the '211 patentee did not clearly and explicitly define the term 'and' in the covered criteria list as 'or'). The court construes "content profiles indicating at least one of the presence and the degree of" as "content profiles indicate either the presence or the degree of predetermined characteristics."

---

1.1.5 “Wherein the Routing Means Comprises at Least One of"

Claim 25 claims a routing means, wherein the routing means comprises at least one of:
**means for** sending at least a portion of a credit application to more than one of said remote funding sources substantially at the same time;
**means for** sending at least a portion of a credit application to more than one of said remote funding sources sequentially until a funding source returns a positive funding decision; and
**means for** sending at least a portion of a credit application to a first one of said remote funding sources, and then, after a predetermined time delay, sending to at least one other remote funding source, until one of the funding sources returns a positive funding decision or until all funding sources have been exhausted.

(’403 Patent, 34:38-56.) Defendants construe “at least one of” in this clause to mean “each and every” of the following three “means.” Plaintiff construes “at least one of” to mean “at least one of.” The Court agrees with Plaintiff. The ordinary meaning of the term supports Plaintiff’s construction, and none of Defendants’ arguments convince the Court that the ordinary meaning of the term should not apply.

Defendants rely on SuperGuide Corp. v. DirecTV Enterprises, Inc., 358 F.3d 870, 885-88 (Fed. Cir. 2004), to argue that the ordinary meaning of this disputed term is “each and every one of the means listed below.” But the reasoning in that case does not apply here. In that case, the court found that the phrase “at least one of [A], [B], [C], and [D]” meant “at least one of [A], at least one of [B], at least one of [C], and at least one of [D].” The court cited a “common treatise on grammar” for the principle that “in spring, summer, or winter” means “in spring, in summer, or in winter.” Id. at 886. That principle is inapplicable here for two reasons. First, the structure of the clause is different in our case. In that case, [A], [B], [C], and [D] were elements of a series, separated by commas. Here, in contrast, “at least one of” is followed by a colon, and then a list separated by semicolons. This grammatical structure implies that the “at least one of” means “at least one of the elements listed below.” Second, in SuperGuide, the construction “at least one of [A], at least one of [B], at least one of [C], and at least one of [D]” made sense, because [A], [B], [C], and [D] were categories with elements that users of the patented technology could choose “at least one of.” Here, in contrast, to construe this claim as “at least one of [A], at least one of [B], and at least one of [C]” would not make sense. Accordingly, the ordinary meaning of this claim term is “wherein the routing means includes at least one of the elements listed below.”

Defendants’ other arguments do not convince the Court that its construction should stray from the ordinary meaning of the claim term. Accordingly, this claim term is construed as “wherein the routing means includes at least one of the elements listed below.”

### Claim Term

(’861 Patent, claim 1); (’465 Patent, claim 1)
"floor terminal . . . operative for at least one input of codes of destination call reports and recognition of identification codes of passengers"

('861 Patent, claim 11)

"operative for input of destination call reports or recognition of identification passengers"

To the extent these claim terms can be construed, the floor terminal must perform both the functions of inputting destination call reports and recognizing identification codes; and the computing unit must perform both the functions of evaluating destination call reports and associating destination floors with recognized identification codes.

"floor terminal . . . for at least one of the input of destination call reports and for recognition of identification codes of users"

('465 Patent, claim 1)

"for the input of destination call reports or for recognition of identification codes of users"

Here, the parties have not submitted identical terms, however, the terms sought to be defined are similar. More importantly, the Court's interpretation of these terms will produce a single result - namely, these terms will be construed either in the disjunctive or the conjunctive.

"computing unit . . . for at least one of evaluating the destination call reports and association of destination floors with recognized ones of the identification codes"

('465 Patent, claim 1)

"for evaluating the destination call reports or for association of destination floors with recognized ones of the identification codes"
Plaintiff argues in favor of the disjunctive interpretation on the basis that the specification does not disclose a single embodiment in which both of the stated functions are required and application of the conjunctive formulation does not make grammatical sense. Plaintiff concedes that the prosecution history indicates that the original submission to the PTO stated a claim for "installing at least one floor terminal at each floor served by an elevator controlled by an elevator control for the input of destination call reports or for recognition of identification codes of users." (Pl.’s Opening Markman Br. 20) (emphasis added). The Patent Examiner rejected Inventio’s original claims as indefinite because the "or" terminology made the claim alternative. (See Defs.’ Opening Markman Br. Appx. 278.) Plaintiff amended its claim to include language of "at least one of [A] and [B]" in order to overcome this rejection for indefiniteness. (See id. 267, 271.) (emphasis added). Plaintiff argues that this amendment was not intended to substantively narrow the scope of its claim, but rather it was intended merely to overcome the Patent Examiner’s formalistic objection to the use of the term "or."

Plaintiff further contends that the specification for the ’465 Patent supports the disjunctive formulation. Specifically, Plaintiff cites to the following statements:

. The floor terminals . . . each comprise at least one manual input means . . . for input of a destination call report or at least one recognition device . . . for the recognition of at least one identification code. (’465 Patent, col. 6:8-10.)

. A user inputs, at a boarding floor, a destination call report by way of the manual input means . . . or the user carries the identification 10 transmitter . . . and communicates an identification code to the recognition device. (Id. col. 8: 7-14.)

. The floor terminal . . . communicates to the computing unit 30 by way of the data bus 37 a conveying signal corresponding with the destination call report or an identification signal corresponding with a recognized identification code. (Id. col. 8:15-19.)

. The computing unit 30 executes at least one computer program product for the evaluation of destination call reports or for the association of recognized identification 30 codes with destination floors. (Id. col. 6:27-30.)

. The computing unit 30 executes the computer program product and ascertains at least one conveying result for the conveying signal or for the identification signal. (Id. col. 8:20-23.)

Plaintiff posits that these statements clearly convey that the functions performed with respect to the call reports and identification codes are exclusive of one another, and therefore this language militates in favor of applying the disjunctive construction.

Plaintiff distinguishes the instant case from the decision of the Federal Circuit in Superguide Corp. v. Directv Enterprises, Inc., 358 F.3d 870, 885-888 (Fed. Cir. 2004), in which the court held that the phrase "at least one of" modified each component of the qualified list enumerated in the patent. Superguide involved patents for interactive electronic television programming guides and the "at least one of" language addressed different categories of program information (e.g., start time, end time) that needed to be included for an online television system. Id. at 885. In Superguide, the Federal Circuit determined that the "plain and ordinary meaning" of the phrase "at least one of [A], [B], [C], and [D]" is the conjunctive formulation, and that there is a rebuttable presumption that the plain and ordinary meaning should apply. Id. at 886-87. The court concluded that nothing existed in the patent specification that served to rebut the presumption, and relied upon the fact that under the particular patent embodiment, a value had to be assigned for each category in the list. Id. at 886-87.

Plaintiff argues that the presumption for application of the plain meaning is rebutted in this circumstance because every embodiment disclosed in the ’465 Patent’s specification indicates that only one of the enumerated requirements (i.e., call reports or identification codes) needs to be present.

Similarly, Plaintiff contends that if the conjunctive formulation adopted in Superguide is applied here, it would not make grammatical sense based on the linguistic structure of the instant claims. Plaintiff emphasizes that unlike Superguide, in which there could conceivably be more than one entry within each enumerated category, the Patents-in-Suit do not refer to different categories but are independent types of action that cannot occur simultaneously. In other words, Superguide addressed a television system that allowed a user to input a start time, end time, and program type into the system, whereas, the Patents-in-Suit would only allow for a user to manually input a destination call report or have one automatically generated by an identification code at a single time, i.e., the use of one method would render the other superfluous for that

- 728 -
passenger. Plaintiff argues that applying the "at least" language to each clause would create an absurd grammatical result, and therefore, the conjunctive formulation is appropriate here. See Joao v. Sleepy Hollow Bank, 348 F. Supp. 2d 120, 124 (S.D.N.Y. 2004) (analyzing the phrase, "wherein the banking transaction is at least one of a clearing transaction, a check clearing transaction, an account charging transaction, and a charge-back transaction," and concluding that because a single banking transaction cannot be all four, a conjunctive reading would be nonsensical). 7

7 Certain courts that have addressed the holding in Superguide have found that it does not dictate a bright-line rule, but rather the phrase "at least one of" must be read in light of the specification to ensure an appropriate grammatical result. See Rowe Int'l Corp. v. Ecast, Inc., 500 F. Supp. 2d 891, 909 (N.D. Ill. 2007); Joao, 348 F. Supp. 2d at 124; Power-One, Inc. v. Artesyn Techs., Inc., No. 05-463, 2007 U.S. Dist. LEXIS 20458, 2007 WL 896093, at *14 (E.D. Tex. Mar. 22, 2007).

Defendants counter that the prosecution history indicates an express renunciation of the interpretation that Plaintiff now seeks to apply. Defendants argue that the conjunctive interpretation is more consistent with the scope of the Patents-in-Suit. Defendants emphasize that the language cited by Plaintiff in the specification contemplates that the floor terminal or computing unit must be able to accomplish both of the enumerated functions. In other words, Defendants do not contest Plaintiff's point that the individual actions of a manual input and the recognition of an identification code are mutually exclusive with respect to an individual passenger (i.e., the elevator would not perform more than one function for a passenger at a given time). Rather, Defendants argue that both functions must be available to a particular passenger. Defendants stress this point by noting that in practical terms, an elevator system could not be limited to recognition of identification codes alone because this would only permit a passenger to travel to the pre-determined floor associated with that identification code.

The court in Automotive Technologies Int'l v. BMW of N. Am., No. 01-71700, 2004 U.S. Dist. LEXIS 30593, 2004 WL 5465964, at *10 (E.D. Mich. Mar. 31, 2004), addressed a similar argument. There, the court addressed the means for mounting a vehicle sensor "onto at least one of a side door of the vehicle and a side of the vehicle between the centers of the front and rear wheels." Id. The court rejected the plaintiff's argument that the term "and" could be interpreted in the disjunctive. 2004 U.S. Dist. LEXIS 30593, [WL] at *11. Instead, the court determined that the plain meaning militated in favor of interpreting the language as requiring that the sensor "must be capable of being mounted on one of the side doors of the vehicle and one of the sides of the vehicle." Id. The court concluded that this language did not require that the sensor be mounted at both locations at the same time, but only that the sensor have the capability to be mounted at either location. Id. Similarly here, Defendants argue that the Patents-in-Suit need not perform both functions simultaneously, but rather that the device be capable of performing both functions when required.

In light of the existing case authority, the Court disagrees with Plaintiff's arguments on both grounds. First, the Court rejects Plaintiff's contention that it intended only a formalistic amendment when it changed the claim language from "or" to "and" to overcome the Patent Examiner's indefiniteness rejection. Plaintiff's reliance merely on its subjective intent that it did not intend a substantive change by submitting the altered language is inapposite. See Seachange, 413 F.3d at 1375 ("Courts must 'view [ ] the prosecution history not for . . . applicant's subjective intent, but as an official record that is created in the knowledge that its audience is not only the patent examining officials and the applicant, but the interested public.'") (quoting Biogen, Inc. v. Berlex Labs., Inc., 318 F.3d 1132, 1139 (Fed. Cir. 2003)); Markman, 52 F.3d at 985 ("The subjective intent of the inventor when he used a particular term is of little or no probative weight in determining the scope of a claim (except as documented in the prosecution history"). There is nothing from the face of the prosecution history itself to indicate that the change submitted by Plaintiff should be construed merely as formalistic rather than substantive. Without a more detailed explanation as to the basis for submitting the altered claim language to the PTO, the prosecution history indicates that Plaintiff has waived the disjunctive interpretation it now seeks to assert.

Even if the Court accepted Plaintiff's contention that the claim amendment in the prosecution history did not serve to limit the scope of the claims, the Court disagrees with Plaintiff's construction of the disputed claim language. In accordance with the teachings in Superguide, the Court concludes that Plaintiff has presented insufficient evidence in the record to rebut the presumption that the disjunctive construction was intended for the Patents-in-Suit. It is true that the statements in the specification cited by Plaintiff indicate that a passenger would utilize only a manual call report or identification code at a
single time, however, these statements are not inconsistent with the construction that the Patents-in-Suit must still be capable of performing both functions.

The Court recognizes that the stated functions pertaining to call reports and identification codes in the above-referenced claims are mutually exclusive, meaning that only one is capable of being performed at a given time. This fact alone, however, does not lead to a grammatically absurd result. The critical distinction for purposes of this case is between the performance of both functions simultaneously and the capability to perform both functions. The Court finds that this conjunctive construction is most consistent with the language and scope of the Patents-in-Suit.  

8 The conjunctive interpretation is particularly compelling in this case because, as Defendants point out, applying the disjunctive construction would create an incongruous result because the elevator system using only identification codes would not let a passenger travel to a destination floor other than that pre-determined floor associated with that passenger's identification code.

GO BACK

15. "at least one of . . ." followed by an enumerated list

For illustration sake, the Court will consider this phrase as "at least one of X, Y, and Z." Essentially, Artesyn contends that this phrase means "at least one X, at least one Y, and at least one Z." Power-One, on the other hand, argues that the listing of "X, Y, and Z" composes a group (i.e., the group includes X, Y, and Z) from at least one is selected. The Court finds Artesyn's position to be inconsistent with the specification. For example, Artesyn contends that in the sole example in the '999 patent specification where a control unit in a POL regulator calculates the period of time recited in the claim, the calculation is made using data from all three of the relevant data categories (turn-on data, slew rate data, voltage set-point data) in claims 3, 4, 27 and 30:

Alternatively, a POL regulator may generate a one volt output one millisecond after receiving activation data if it received voltage set-point data, slew rate data and turn-on data corresponding to two volts, one volt per millisecond and three milliseconds respectively.

See Col. 4:37-41. However, the passage immediately preceding describes a scenario where a turn-on period is determined without turn-on data or slew rate data.

For example, a POL regulator might generate a one volt output for five milliseconds after receiving activation data if it received voltage set-point data and sequencing data corresponding to one volt and five milliseconds, respectively.

See Col 4:33-36. Another embodiment in the specification only mentions voltage set-point data and enable data when it speaks of output data. '999 patent, col. 3:63-65, while another includes output timing data as output data, col. 4:16-19. Further, claim 2 of the '999 patent describes a control unit adapted to determine at least one timing parameter of said output in accordance with said output data wherein said output data further comprises at least one of turn-on data . . . and turn-off data." Artesyn's proposal would require the output data to include both "turn-on" data and "turn-off data even though the control unit need only determine "at least one timing parameter." Finally, Artesyn's proposed construction would require "slew rate data" and "sequencing data," even though the specification makes clear that these types of data are optional:

the POL control unit receives output timing data, which may include slew-rate data, sequencing data, termination data, etc.

See '999 patent, col. 7:1-3.

Artesyn cites Superguide Corp. v. Direct TV Enterprises, Inc., 358 F.3d 870, 886-87 (Fed. Cir. 2004), arguing that Superguide requires an "at least one of X, Y, and Z" term be construed "at least one X, at least one Y, and at least one Z."
However, even if the Court were to agree that Superguide holds that the ordinary meaning of "at least one" is as Artesyn suggests, nothing in Superguide dictates that this term must be construed in this manner no matter what the specification teaches. In Superguide, the specification taught that the user must choose a value for each designated category. Id. at 887. Here, as noted above, the specification teaches embodiments that do not require each category of the enumerated set. Thus, the Court holds that although one of each of the enumerated data categories may be used, the "at least one" language only requires that one of the categories be selected. See Orion IP, LLC v. Staples, Inc., 406 F.Supp.2d 717, 726 (E.D. Tex 2005).

Once again, the plain meaning of the words used in the limitation dictates the construction to be given by this Court. The phrase "at least one" does not, as IBM urges, mean "one and no more than one." Rather, as TM notes, it means "one or more than one." Therefore, the claim limitation teaches that the multi-unit memory system should have one or more than one "spare" memory unit, with "spare" used in its ordinary dictionary sense (a la "spare tire").

G. "At Least One Switch Operable To Optically Couple the Second Optical Line Interface To (a) the First Optical Line Interface Through At Least the Optical Demultiplexer, and Alternatively (b) the Second Transponder"

For the following reasons, this court construes the claim term "at least one switch operable to optically couple the second optical line interface to (a) the first optical line interface through at least the optical demultiplexer, and alternatively (b) the second transponder" in claim 1 to mean:

At a minimum, one switch can at least both: (a) optically couple the second optical line interface to the first optical line interface through at least the optical demultiplexer; and alternatively (b) optically couple the second optical line interface to the second transponder. 1

Footnotes

1 The term "optically couple" contained within this claim term and throughout the '772 patent should be interpreted consistent with section I.A., supra, of this memorandum opinion.

Inclusion of the word "and" in the term "and alternatively," indicates that the switch must be able to optically couple "the second optical line interface" to at least both (a) and (b). Inclusion of the word "alternately" indicates that the switch can only couple the "the second optical line interface" to one of at least (a) or (b) at any particular time. The switch therefore must be able to optically couple "the second optical line interface" to at least (a) and (b) but can only couple "the second optical line interface" to only one of (a) or (b) at any particular time.

The specification supports this understanding and explains that an OLT contains a switch that allows an individual wavelength to either be passed through to a peer OLT via a pass-through port or to client equipment via a transponder. ('772 patent, col. 3:22-29.) For example, when transmitting a wavelength to or from a peer OLT, the patent '772 specification describes how any two or three WDM systems "may be interconnected by connecting respective OLTs of separate WDM system back-to-back at respective pass-through ports." ('772 patent, col. 5:22-27; see col. 5:11-6:51; Figs. 5-8) And when transmitting a wavelength to or from a client apparatus, the specification explains that demultiplexed signals are sent "to client equipment via a transponder and a local port." ('772 patent, col. 2:46-48; col. 2:66-3:1; col. 3:45-50; see Fig. 1.)
4. "At least partially concurrently": "To some extent, occurring at the same time." No guidance in the intrinsic record is provided; the court's construction tracks the ordinary meaning of "concurrently" consistent with the evidence of record. (D.I. 387, ex. 130 (MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY (10th ed. 1998))

3. "ATA register address"

Claim 3 recites "an ATA register address at which to receive data addresses and commands from said host computer and transmit data to said host computer, and a multibyte command packet buffer operable to sequentially store a packet of contiguous bytes of command information received through the ATA register address." 527 patent at 30:9-12. Although defendants agree that the claim language requires one ATA register address to receive data addresses and commands, transmit data and receive command information, they contend that the term should be construed such that all command information, whether single-or multi-byte, be received through a single ATA register address. Plaintiffs, on the other hand, argue that the claim language only requires that one ATA register address receive multi-byte command information, but that another ATA register address may receive single-byte commands.

The claim language does not refer to single-byte commands. It requires only an ATA register address "at which . . . commands" are received and through which "contiguous bytes of command information" are received. There is no disclosed embodiment in the specification that includes an ATA register address that receives single-and multi-byte commands from the host computer and transmits data to a host computer. "A patent claim should be construed to encompass at least one disclosed embodiment in the written description portion of the patent specification." Johns Hopkins University v. Cellpro, Inc., 152 F.3d 1342, 1355 (Fed. Cir. 1998). Because the claims do not address single-byte commands, the court concludes that the ATA register address of claim 3 is not required to receive both single-byte and multi-byte commands from the host computer.

(3) "Attaching" and "Detaching"

For purposes of efficiency, the following analysis will focus on the term "attaching" but is meant to apply to the converse term "detaching" as well. EMC contends that the term "attaching" means making a device logically available, i.e. by setting that device to a "ready state." HP, however, asserts that the term "attaching" means establishing an actual and complete connection between the two data storage facilities such that, in the context of the second command, the second application can read and write to the second data storage facility without any additional "bookkeeping operations," i.e. without any further commands or instructions by the host computer. The parties do not dispute that an attachment may be physical or logical, but rather whether the subject attachment must be, in HP's jargon, "complete".

The claim language is particularly instructive here. Although the parties focus primarily on the use of the term "attaching" in the context of the second command, Claim 1 of the '497 Patent uses the term "attaching" twice and, because the term is used similarly in both instances, it must be construed uniformly. In describing the first command, Claim 1 states,

establishing . . . in response to the first application and in response to a first command, a copy of the data set in the second data storage facility as a mirror for the first data storage facility by attaching the second data storage facility in parallel with the first data storage facility . . . .

'497 Patent, Col. 31, ll. 9-14 (emphasis added). In describing the second command, Claim 1 states,

in response to a second command . . . attaching the second storage facility to be addressed by the second application
whereby the first and second applications thereafter can access the data sets in the first and second data storage facilities respectively and concurrently . . . .

‘497 Patent, Col. 31, ll. 15-25 (emphasis added).

With respect to the second command, the italicized language implies that the term "attaching" does not denote a "complete" attachment after which the second application can, without additional steps, access the second data storage facility. In fact, such language specifically implies that the purpose of the "attaching" function is to allow the second storage facility "to be addressed," i.e. at some time in the future perhaps after other steps have been completed, by the second application. "Thereafter," i.e. after that attachment, the first and second applications can access the data sets in both data storage facilities.

Nor does the language with respect to the first command imply that the term "attaching" requires a "complete" attachment. Although the language of the first command seems to suggest that the direct result of the subject "attaching" is the establishment of a mirrored copy of the data in the second data storage device, that language must be read in light of the preamble to Claim 1 which states, in relevant part,

[a] method for controlling access to a data set . . . wherein the data set is stored in a first data storage facility that is addressable by the first application . . . .

‘497 Patent, Col. 31, ll. 3-6. At the outset of this method claim, therefore, the patentee acknowledges that the first application already can address the data stored in the first data storage facility and no further "bookkeeping operations" are needed to make the first data storage facility available to it. Consequently, the attachment of the first and second data storage systems can, without further ado, "establish" a mirrored copy of the data in the second data storage facility. Use of the term "attaching" in the context of the first command, therefore, does not require that term to be defined as a "complete" attachment.

Moreover, the language of dependent Claim 9 of the ‘497 Patent unambiguously suggests that the term "attaching" can be defined as, at least, "producing a ready status." Claim 9 states

[a] method as recited in claim 1 wherein each of the first and second data storage facilities comprises first and second logical volumes on first and second disk drives, respectively, each of the disk drives connecting through a corresponding device controller to be attached to the first and second data storage facilities by producing a ready status to the first and second applications . . . .

‘497 Patent, Col. 32, ll. 29-38 (emphasis added). Because similar claim terms, comparably used, must be construed uniformly within the same patent, Claim 9 provides some evidence that the term "attaching" ought to be defined as making a device physically or logically available by, for example, producing a ready status. As illustrated above, the language of Claim 1 does not hinder that construction.

Although the Specification of the ‘497 Patent does not specifically refer to the term "attaching," it clearly describes that process in terms of making a device physically or logically available by producing a ready state. Indeed, with respect to the first command (called "the establish command"), the Specification states

the ESTABLISH command effectively connects the BCV [Business Continuation Volume] device 226 as an M3 mirror volume to define a BCV pair with the mirrored storage Volume A. Now the BCV device 226 status as seen by the Volume B application 221 is Not Ready (NR). The status as seen by the Volume A application 222 and copy program is Ready.

‘497 Patent, Col. 17, ll. 58-64 (emphasis added). 14 The plain and ordinary meaning of the term "attach" is to "make fast or join." Webster's Third International Dictionary, 140 (1981). Although the quoted portion of the Specification uses the term "connect" rather than its synonym "attach," it clearly illustrates that such "connection" is marked by a device status of "Ready" or "Not Ready", depending upon the subject application. Moreover, although the phrase "bookkeeping operations" is mentioned with respect to the first command, it appears wholly unrelated to the function of establishing a mirrored copy and, in any event, the Specification clearly states that such operations "do not form part of this invention." See ‘497 Patent, Col. 18, ll. 26-28.
14 A Business Continuation Volume is described in the Specification of the '497 Patent as a device comprised of a standard disk controller and related disk storage devices especially configured to independently support applications and processes. See '497 Patent, Col. 16, ll. 8-15.

Likewise, in the context of the second command (also called "the split command"), the Specification implies that the term "attaching" includes making a device physically or logically available by producing a ready state. In fact, in describing the first response to the split command the Specification states:

\[n\]ext the status of the BCV device 226 in the context of its mirror operation is discontinued by setting the device to a Not Ready (NR) state with respect to the system responsive to the Volume A application 221.

'497 Patent, Col. 19, ll. 8-12. Later, in describing the second response to the split command, the Specification states,

\[s\]tep 262 then sets the BCV device 226 to a ready state with respect to the Volume B application 222. In step 263 the device controller posts a complete status as a return message. The host adapter [which is part of the data storage system and not affiliated with the host computer], in step 264, receives that status and reconnects. When this occurs, the Volume B application 222 now accesses the data set as it stood at the instant of the SPLIT command.

'497 Patent, Col. 19, ll. 56-62 (emphasis added). Each of the prior descriptions related to the dual prongs of the split command reinforce EMC's contention that the term "attaching" includes making a device, such as a BCV, physically or logically available to a particular application (by setting the device to a ready state) and contradicts the supposition that it includes any additional "bookkeeping operations" on the part of the host computer. Thus, although the Specification mentions that other "bookkeeping procedures" may be required, such as updating device records on the data storage system, such procedures "do not form part of this invention." See '497 Patent, Col. 18, ll. 26-28.

In conclusion, both the claim language and the language of the Specification support EMC's construction of the term "attaching" and "detaching". Consequently, the term "attaching" will be construed to mean making physically or logically available such as by producing a ready state. Conversely, the term "detaching" means to make physically or logically unavailable such as by producing a not ready state.

2. Attachment Unit Interface

The AUI mentioned in the preamble of Claim 6 is not part of the claim nor defined by it. It simply gives context to the claimed MAU. Both parties agree that its definition should come from the IEEE 802.3 Standard. The disagreement stems from how much of the 802.3 Standard should be used.

Level One proposes using the one-line description of an AUI found in the "Definitions" section of the 802.3 Standard, which reads: "In a local area network, the interface between the medium attachment unit and the data terminal equipment within a data station." Guy Decl., Ex. H at § 7.1.1.

In addition to the above definition Seeq suggests adding the phrase, "The AUI interfaces three data sources, data out (DO), data in (DI) and collision presence (CP)." Seeq derives this language from the "Description of the Preferred Embodiment" and from the language of claim 6 itself. '183 Patent at 3:35-40. Seeq would also incorporate the description of the AUI from the section of the 802.3 Standard entitled, "Functional Description of Interchange Circuits," which states that "the AUI consists of either three or four differential signal circuits, power, and ground. Two of the circuits carry encoded data and two carry encoded control information. Circuits DO (Data Out) and CO (Control Out) are sourced by the DTE, and circuits DI (Data In) and CI (Control In) are sourced by the MAU. The interface also provides for power transfer from the DTE to the..."
MAU. The CO circuit is optional." Guy Decl., Ex. H at § 7.5.1.

Given that the patent does not even claim an AUI, it seems unnecessary and imprudent to construe the preamble term beyond the basic definition in the 802.3 Standard. This functional description of an AUI is not necessary to understanding the disclosed MAU. In fact, neither is it necessary to understanding the AUI itself, if it were, it would be incorporated into the Standard's own definition. For the same reasons, the court is not inclined to incorporate the unattributed phrase Seeq proposes. Accordingly, the court construes AUI as defined by the 802.3 Standard: In a local area network, the interface between the medium attachment unit and the data terminal equipment within a data station.

3. AUI Port

The language of Claim 6 defines an AUI port simply as "having data out, data in, and collision presence circuits for coupling said attachment unit interface to said media attachment unit." '183 Patent at 7:31-33. Level One proposes that the court adopt a construction of AUI port that defines it as "the portion of the media attachment unit (MAU) that (1) allows the communication of data between the AUI and MAU on "data out," "data in" and "collision presence" circuits and (2) may be placed in a high impedance condition." Level One would also add to its definition that the DO, DI and CI circuits can encompass the AUI transmit-receiver, the AUI receiver-driver, the collision driver or any equivalent structure.

Seeq protests that Level One's proposed definition is purely functional and, more importantly, runs contrary to the plain language of the claim by covering "covering structures in which the AUI and the twisted pair MAU are not distinct devices." Instead, Seeq suggests that the definition include the relevant language of the claim and a description of the AUI port in the preferred embodiment which comprises an AUI transmit-receiver, an AUI receiver-driver and a collision driver. '183 patent at 3:58-64. In addition, Seeq would incorporate the definitions of data in circuit, data out circuit and collision presence found in the 802.3 Standard.

While it seems evident that each party is attempting to expand or contract the scope of the claim to suit its purposes, the court fails to see the ambiguity in the language of the claim itself. First, although Seeq stresses that Level One's proposed construction fails to include the fact that the circuits of the AUI port "couple" the AUI to the MAU, it does not appear necessary for the definition of the AUI port to explicitly clarify whether the MAU and the AUI are two distinct devices. Rather, what sorts of configurations of a MAU might infringe this element is a question for a jury.

On the other hand, Level One correctly argues that Seeq's proposed construction incorporates limitations from the preferred embodiment that are not present in or necessary to the claim language. See Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988). There is no indication that data in circuit, data out circuit or collision presence are terms that need to be each fully defined in order to construe "AUI port." As Seeq itself states, "the language of the IEEE 802.3 standard is not the language of the claim and cannot be used to broaden the claim beyond its plain meaning." Defendant. Opp'n at 5. Nor can it be used to narrow the claim beyond its plain meaning. The parties seem to agree that the data in circuit transfers signals to the AUI from the MAU, the data out circuit transfers signals to the MAU from the AUI and the collision presence detects the simultaneous transmission of data in both direction.

Accordingly, the court rejects both proffered definitions and construes AUI port just as it is defined in Claim 6, as having data out, data in, and collision presence circuits for coupling said attachment unit interface to said media attachment unit.

1. "ATTENUATED AND FILTERED FROM"

The phrase "ATTENUATED AND FILTERED FROM" (Claim 1) is construed by the Court to mean reduced and removed. This Court declines to adopt Nellcor's interpretation of the limitation, which is "reduced in comparison to the desired information." Accepting Nellcor's interpretation would oblige this Court to construe the claim in a way such that "no
removal or reduction" of any aperiodic information (that is, noise) is required. See Nellcor Opp. at 2. Nellcor asserts, instead, that aperiodic information is "spread across the time frame of the composite waveform," thus "reducing in comparison" its magnitude to that of the "desired, periodic information." Id. at 3. This Court finds that such an interpretation is contradictory to both the terms of the patent and the file history.

a. Ordinary and Customary Meaning

Webster's dictionary defines "attenuate" as "to lessen the amount, force or value of" (Webster's Third New Int'l Dictionary ("Webster's"), Lateef Decl., Ex. 9 at 3); the IEEE Dictionary defines "attenuate" as "a decrease in signal magnitude between two points or between two frequencies." The Authoritative Dictionary of IEEE Standards Terms ("IEEE Dictionary"), Lateef Decl., Ex. 10 at 3 (emphasis added).

Similarly, Webster's dictionary defines "filter" as "a device or material for suppressing or minimizing waves or oscillations of certain frequencies passing through it without greatly altering the intensity of others." Webster's at 3. The IEEE Dictionary defines filter as (1) "a transducer for separating waves on the basis of their frequency . . .:" and (2) "a device or program that separates data, signals, or materials in accordance with specified criteria." IEEE, Ex. 10, at 5. The IEEE Dictionary also provides a definition requiring that a filter "eliminate a portion of the signal." Id.

In deciding which dictionary definition to apply, the Federal Circuit instructs this Court to look at the intrinsic evidence and decide which definition best fits within the context of the patent.

Nellcor claims that its purported interpretation of "attenuated and filtered from" as "reduced in comparison" is "consistent with the ordinary meaning of those terms to one of ordinary skill in the art." Nellcor Opp. at 12. To prove this, Nellcor relies upon the IEEE definition for the meaning of "attenuate." See IEEE Dictionary, Ex. 10 at 3 ("a decrease in signal magnitude between two points or between two frequencies"). Nellcor asserts that attenuation is used in the '372 patent to explain the process whereby the "aperiodic information is decreased in magnitude in relation to the periodic information." Nellcor Opp. at 12.

Masimo contends that by inserting the words "in relation to" into their application of the definition to the '372 patent, Nellcor has altered the IEEE Dictionary definition to support its own "reduced in comparison" language. Masimo asserts that such a manipulation is neither supported by case law nor by the patent itself. Instead Masimo claims this Court should rely more heavily upon Webster's definition of attenuate, which is "to lessen the amount force or value of." Masimo Mot. at 11.

This Court finds that both the IEEE Dictionary and the Webster's definitions are relevant in construing the term "attenuate" given the context of the '372 patent. Regardless of the source this Court chooses to apply, the result is the same, as both definitions indicate that "attenuate" implies reduction -- and perhaps even "reduction in comparison." Nonetheless, this Court does not adopt Nellcor's construction of reduced in comparison, because doing so would render this claim construction analysis incomplete, as only one of the two terms would be construed.

In construing the word "filter" Nellcor relies upon the Webster's definition of "filter" as "a device or material for suppressing or minimizing waves or oscillations of certain frequencies passing through it without greatly altering the intensity of others." Webster's at 3. Nellcor explains that this definition is consistent with the use of the term "filtered" in the '372 patent because "aperiodic information [is] being spread across the frequency spectrum, such that its magnitude is decreased or minimized, in relation to the periodic information." 3

3 Further, Nellcor rejected Masimo's use of the IEEE Dictionary definition of filter -- as meaning "eliminate a portion of a signal" -- explaining that since no reduction or removal of aperiodic information occurs, that definition is irrelevant. See Nellcor Opp. at 14.

Again, Masimo objects to Nellcor's insertion of the words "in relation to" into the interpretation. Masimo, instead asserts that
"filter" means "removed." In coming to this conclusion, Masimo relies heavily upon Webster's definition of the verb "to filter." Masimo Mot. at 11. Webster's defines "to filter" as "to remove . . . by means of a filter." Webster's, Lateef Decl., Ex. 9, at 5.

This Court was not immediately convinced that "filter" means "remove." First, as Nellcor points out, the definition upon which Masimo relies reads in full: "to remove from a fluid by means of a filter." Webster's, Lateef Decl, Ex. 9, at 5 (emphasis added). Thus, as Nellcor asserts, this definition may not be completely relevant to the technology at issue in this case. Second, none of the definitions mentioned above clearly indicates that filter means "remove."

Nonetheless, in considering the complete picture -- including the claim language, the specification, and the file history -- this Court ultimately agrees with Masimo and concludes that filter in this context means remove, and that the phrase "attenuate and filter" means reduce and remove.

b. Claim Language

The language at issue claims a process whereby "aperiodic information present in the time-measure is attenuated and filtered from the composite." '372 patent, col. 1:38-40. The law assumes that Nellcor chose those particular words in the claim for a particular purpose. The fact that Nellcor chose to use both attenuate and filter -- side-by-side, in the same phrase -- to describe this process indicates that these words carry unique meanings. If this Court were to adopt Nellcor's construction, then the words "attenuate" and "filter" would lose their individuality and purpose, since either word, taken on its own, could be construed to mean "reduce in comparison."

Similarly, Nellcor's interpretation is incomplete. The words "attenuate" and "filter" and the phrase "attenuated and filtered from" need to be considered within the context of the language of the claim. Claim 1 of the '372 patent claims (in pertinent part): "processing the time-measure collectively to determine a composite . . . so that the aperiodic information present in the time-measure is attenuated and filtered from the composite; and thereafter calculating . . . ." '372, col 59:34-40.

In breaking down the language of the claim, Nellcor appears to be claiming a two-step process: (1) the formation of the composite and (2) the calculating step. Nellcor itself does not contest the fact that aperiodic information is removed prior to the calculating step. See Nellcor Opp. at 2 ("Desired periodic portions of the composite signal are selected for further processing and used in calculating oxygen saturation, thereby removing the aperiodic information from the composite signal.") (emphasis added).

Thus, as Nellcor explains, the aperiodic information must be removed at some point between the formation of the composite and the calculating step. The claim language itself only leaves one point at which that removal could occur: filtration. Therefore, the claim language read in context clearly supports a construction of "attenuated and filtered" that means reduced and removed.

Further, by adopting Masimo's interpretation of "reduce and remove" both attenuate and filter retain meaning and purpose. The two words work in conjunction to describe a complete process whereby aperiodic information is attenuated (reduced) and filtered (removed).

Finally, the placement of the word "from" - in the phrase "attenuated and filtered from" - is quite telling as well. Nellcor's word choice implies that something is taken or removed from, rather than merely reduced in comparison. This notion is further explained and clarified when viewed in the context of the language in the specification as well as the file history.

c. Specification

For additional support of the "reduced and removed" construction, Masimo cites several parts of the '372 patent specification where the terms "attenuated" and "filtered" mean reduced and removed. For example, column 7 of the patent states that the process creates a composite waveform "from which noise, spurious signals, and motion artifact, have been filtered out." '372 at 7:33-38. "Filtered out" in this context clearly supports a construction that implies removal.

d. File History:
The file history of '372 patent provides the strongest support for the conclusion that "attenuated and filtered" means reduced and removed. The record of the prosecution clearly indicates that one of the characteristics distinguishing the '372 patent from the prior art (the New, Jr. Patent) is that the '372 patent requires the removal of aperiodic information prior to the calculation of oxygen saturation in the blood, while the prior art did not. See Examiner's Report, Lateef Decl., Ex. 1 at 208-211.

Specifically, Nellcor argued to the PTO: "In contrast to the New[, Jr.] patent, [Nellcor's] application teaches that by collecting and collectively processing time-measures to obtain a composite waveform from which aperiodic information is removed . . . one does not need to examine pulse against confidence criteria or to determine whether that pulse is a periodic or aperiodic pulse before the blood constituent can reliably and accurately be determined." Id. at 210-11 (emphasis added).

The prior art required the examination of each pulse against confidence criteria; Nellcor urges that the importance of its argument to the PTO was not to emphasize the removal of aperiodic information, but rather to claim the improvement of a "composite waveform." Nellcor adamantly contends that the prosecution history should not be read to limit the '372 patent to require "removal," instead Nellcor explains that the term "removal" should be read as a proxy for "reduced in comparison."

This Court should not be convinced by Nellcor's alternate interpretation. Nellcor cannot argue one meaning to the PTO to distinguish itself from the prior art, and then argue a different meaning to this Court to prove infringement. Thus, this Court should find that in light of the surrounding evidence, the most appropriate interpretation of "attenuated and filtered" is "reduced and removed."

II

Nellcor first contends that the trial court improperly interpreted "attenuated and filtered" to mean "reduced and removed." We agree with Nellcor that the district court's interpretation is incorrect.

The '372 patent describes two embodiments of the invention in detail. The patent first describes a time domain method, which it characterizes as the preferred embodiment of the invention. The time domain method begins with a trigger that is related to the patient's heart beat and thus indicates the beginning of an arterial pulse. The device then detects optical data from the photodetector for both the red and infrared sources throughout the duration of the pulse. That data is digitized and then moved to a buffer that collects data for the red and infrared signals over time. With each subsequent pulse, new data is gathered and stored in a "new data" buffer. In the preferred embodiment, the value of each data point in the new data buffer is divided by 6, and the values for each of those data points are added to 5/6 of the value of the corresponding data points in the data collection buffer. '372 patent, col. 6, line 20, to col. 8, line 49.

Each set of new data contains information from the pulse of interest, together with aperiodic noise. Because the data in the data collection buffer is weighted five times as heavily as the new data that is introduced with each pulse, and because the aperiodic data does not share the same characteristics for each pulse (and thus does not accumulate overtime), the effect of using this method of data accumulation is to reduce the effect of the aperiodic data in each pulse by 5/6. Additionally, the effect of older aperiodic data on the cumulative data is reduced at each triggering event by 1/6. Thus, the aperiodic data is not eliminated altogether, but it is continuously reduced in magnitude in comparison to the desired, periodic data.

A second embodiment of the invention described in the '372 patent is a frequency domain method that can be used with or without a separate pulse-identifying event. '372 patent, col. 11, line 12, to col. 12, line 60. In that embodiment, the output of the photodetector for each of the red and infrared signals is digitized at a rate of 57 samples per second for about nine seconds. In the time domain, the amplitude of that data is represented as a function of the time at which the data was sampled. The resulting 512 data points for each wavelength are then averaged; the resulting value represents the average background intensity for each wavelength. That average value is then subtracted from each of the 512 data points for each wavelength. The resulting data is then transformed to the frequency domain using a mathematical operation known as a Fourier transform. The transformation of the data to the frequency domain produces a value for each of a number of
frequencies above zero for both the red and infrared wavelengths. The average background intensity of the detected optical signals at the red wavelength and at the infrared wavelength is the amplitude at zero frequency for each of those wavelengths. When the data is transformed to the frequency domain, the amplitude of the pulse data for each wavelength can easily be detected because it is the value located at the pulse frequency.

Because the aperiodic noise has components at many frequencies, the aperiodic noise "appears spread across the frequency domain spectrum." '372 patent, col. 11, ll. 53-54. The frequency domain embodiment, however, uses data at only two of the 512 frequencies for each wavelength—the heartbeat frequency (which contains the most useful data for determining blood constituents) and zero frequency (which contains the background level of the optical signals). Accordingly, while some noise still remains at those two frequencies, the noise is not concentrated at those frequencies. The relative impact on the selected data is therefore considerably reduced.

Nellcor contends that the district court erred by construing the term "filtered" to require that the aperiodic signal data be removed rather than simply reduced in comparison to the desired periodic signals. Nellcor submits that the district court's interpretation is not supported by the ordinary meaning of the claim language to one of skill in the art, and that it is not supported by the specification or the prosecution history of the '372 patent.

A standard dictionary prepared by the Institute of Electrical and Electronics Engineers ("IEEE") provides eight different meanings for the noun "filter." Those definitions include a device "that separates data, signals, or material in accordance with specified criteria" and a circuit "that eliminates certain portions of a signal, by frequency, voltage, or some other parameter." IEEE, Authoritative Dictionary of IEEE Standard Terms 435 (7th ed. 2000). It is reasonable to characterize the disclosed processes as involving the separation of signals "in accordance with specified criteria," including their frequency, and it is fair to characterize the process of reducing the relative magnitude of aperiodic noise as the elimination of "certain portions of a signal, by frequency ...or some other parameter." Thus, two of the definitions of the term "filter" given in the standard dictionary of electrical engineering and electronics are consistent with the definition proposed by Nellcor; in any event, the IEEE definition certainly does not compel rejection of Nellcor's proposed construction of the term.

The meaning that the patentees intended to accord to the claim phrase "attenuated and filtered" is made clear from an examination of the specification of the '372 patent. In the Background of the Invention portion of the specification, the patent describes one of the objects of the invention as being to "provide enhanced periodic information from which the patient's blood constituent can be accurately determined" by "collecting successive portions of detected optical signals encompassing periodic information for more than one heartbeat and processing the collected portions to attenuate and filter therefrom aperiodic signal waveforms." '372 patent, col. 4, ll. 28-35. That passage summarizes the cumulation technique described in more detail later in the patent as resulting in the attenuation and filtering of aperiodic signals. As such, it indicates that the words attenuated and filtered are used to describe the relative reduction in the significance of aperiodic noise that results from the cumulation technique described in the patent.

The same is true of the more detailed description of the invention in the Summary of the Invention portion of the specification. There, the patent describes the relative reduction of the impact of aperiodic noise on the composite signal through non-synchronous (and thus canceling) addition and through the spreading of noise signals across the relative time frame of the composite signal. '372 patent, col. 7, ll. 3-9. The patent describes that effect, and in particular the small relative weight given to new information as compared to the prior composite, as resulting in new aperiodic information being "quickly and effectively attenuated, and thus filtered out of the resultant additive portions." Id., col. 7, ll. 21-22. The patent then summarizes the process as follows: "The collective additive sum having synchronized periodic information waveforms thus presents enhanced periodic information that is a composite data set that corresponds to a composite optical pulse from which noise, spurious signals, and motion artifact, have been filtered out." Id., col. 7, ll. 33-38. Because the disclosed process does not actually remove data, but merely results in the suppression of aperiodic noise relative to the periodic signal, it is clear from those passages that the patent uses the terms "attenuated and filtered" to refer to the process of reducing the effect of the aperiodic noise as compared to the periodic signal. Thus, the specification confirms that the claim phrase "attenuated and filtered from the composite" is used to refer to what the patent at one point calls "effective removal" of data, id., col. 8, line 28, rather than the absolute removal of unwanted data, as held by the district court.

Apart from the manner in which the term "filtered" is used in the patent, construing the term "filtered" to require removal of the aperiodic noise would have the effect of excluding all the embodiments described in the specification. That is because none of the embodiments actually "remove" the aperiodic noise from the data used for calculations, as opposed to reducing...
its relative impact on that data. As this court has explained, a construction that excludes all of the embodiments of an invention is "rarely, if ever, correct." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996). The fact that the construction adopted by the district court and advocated by Masimo would have the effect of placing all the embodiments of the invention outside the scope of the claims is powerful evidence that the court's construction is incorrect.

Masimo argues that the district court's construction would not mean that the claims would fail to read on all the embodiments set forth in the written description, but we disagree with that contention. The claim language in question provides for "obtaining a time-measure of the absorption signal including periodic information and aperiodic information," and processing that data "to determine a composite waveform" so that "the aperiodic information present in the time-measure is attenuated and filtered from the composite." The portions of the specification that describe that claimed process disclose the use of various means to reduce the impact of the aperiodic data on the resulting composite waveform. In each instance, the aperiodic data is reduced in impact but is not altogether removed from the composite. Thus, in the time domain embodiments of the invention the data is manipulated so that the periodic data cumulates, while the aperiodic data does not. As a result, the relative impact of the aperiodic data is constantly reduced in comparison with the impact of the periodic data. Similarly, in the frequency domain embodiment the selection of only the zero frequency and the heartbeat frequency as the frequencies from which data is obtained has the effect of substantially reducing the effect of aperiodic noise, which is spread across many frequencies, but it does not remove the noise altogether. From the context of the patent, it is clear that those processes are what the patent refers to as attenuation and filtering. See '372 patent, col. 11, ll. 43-58. While it may be that, in hindsight, the patentees would have been wise to choose a word other than "filtered," it is clear that they meant for that term to describe the "relative reduction" processes set forth in the specification. The use of the term in that fashion is not at odds with the understanding of the term "filtered" in the pertinent art, and in the absence of a clear contrary directive in the patent, we decline to give that term a definition that would exclude the preferred embodiments from inclusion within the language of the claims.

In construing the phrase "attenuated and filtered from the composite," the district court relied heavily on the prosecution history of the '372 patent. The portion of the prosecution history on which the court relied was the applicant's discussion of a prior art patent to New (U. S. Patent No. 4,653,498), which the examiner had cited against the application in an office action. The New patent disclosed a pulse oximeter in which the instrument tested each pulse-like signal against certain parameters to determine whether the signal was related to a heartbeat and therefore should be used in making the blood constituent measurement. The applicants argued that the method used to identify the proper source of meaningful data in New was quite different from the method set forth in the application. In particular, the applicants noted that the New patent disclosed a method consisting of "detecting an absorption signal and determining a related maximum and minimum value in the absorption signal corresponding to a pulse." New's method then evaluated each maximum and minimum "using preselected confidence criteria to determine whether or not they correspond" to a periodic pulse or an aperiodic event unrelated to the patient's heartbeat. In New, the applicants explained, "[a] pulse history is formed based on accepted maximum and minimum signal values that are averaged to smooth out small deviations in pulse rate and oxygen saturation due to physiologic and artifactual noise variations."

The applicants argued to the examiner that the New patent described calculating blood constituents "in a manner that is fundamentally different from, and which does not teach or suggest applicants' claimed invention." In contrast to the New patent, the applicants claimed that their invention "teaches that by collecting and collectively processing time-measures to obtain a composite waveform from which aperiodic information is removed, and which yields a composite relative maximum and minimum, one does not need to examine each pulse against confidence criteria or to determine whether that pulse is [a] periodic or aperiodic pulse before the blood constituent can be reliably and accurately determined."

The district court seized on the applicants' characterization of their invention as one in which "aperiodic information is removed" from the composite waveform, and concluded from that statement that the reference to aperiodic information being "attenuated and filtered" should be construed to mean that aperiodic information is removed altogether. In context, however, the prosecution history does not support that interpretation. The distinction that the applicants sought to draw between the method described in the New patent and the method used in their invention was between (1) testing each pulse-like event to determine whether it was related to the patient's heartbeat, and (2) using a cumulation technique to separate synchronous pulse events from aperiodic events unrelated to the patient's heartbeat. Their method, the applicants pointed out, reduced the relative amplitude of the aperiodic events through processing and thus effectively removed those events from consideration in the blood constituent measurements. The applicants' reference to the "removal" of aperiodic noise thus must be interpreted to refer to a reduction in the aperiodic noise relative to the desired signal, so that the aperiodic noise
does not materially affect the composite waveform generated by the patented method. Accordingly, we do not regard the prosecution history as providing support for the district court's construction of the claim phrase "attenuated and filtered from the composite waveform." For that reason, and because Nellcor's proposed construction of that phrase as meaning "reduced in comparison to the desired information" is consistent with the written description of each embodiment of the invention, we hold that the district court erred in its construction of that critical claim language and that "attenuated and filtered from the composite waveform" means "reduced in comparison to the desired information."

(b) "Attenuating" means "reducing in force, value or amount,"

E. "VAN . . . attesting to the authenticity of the instrument"

<table>
<thead>
<tr>
<th>Term</th>
<th>Plaintiff's Definition</th>
<th>Defendants' Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;including the VAN with the instrument for subsequent use in attesting to the authenticity of the instrument&quot;</td>
<td>The VAN evidencing that the instrument has not changed.</td>
<td>The VAN verifies that the information in the instrument as a whole has not changed and verifies the identity of the party who created the instrument.</td>
</tr>
</tbody>
</table>

This phrase appears in claim 34 of the '148 patent. The parties again dispute whether the VAN "evidences" or "verifies" authenticity, and whether "authenticity of the instrument" requires verifying the identity of the payor as well as confirming that the instrument has not changed. As discussed above, verifies is the appropriate verb.

Plaintiff argues that this claim requires only that the instrument has not changed and that it does not need to verify the identity of the party. Plaintiff relies upon claim differentiation to explain that the originating party is not required to be authenticated in all claims. Defendants argue that an instrument is authentic if the information has not changed and the payor authorized the payment. Defendants further argue that the "instrument as a whole" must be authentic because, "[a]n instrument cannot be authentic . . . if any aspect of the instrument has changed." Def. Brief at 19.

The Court is of the opinion that an instrument is authentic if it has not been forged. As discussed above, there are two types of forgery: creating an unauthorized check and altering an otherwise authorized check. If the instrument is created fraudulently, even if there are no changes to it, it would not be an authentic instrument. The claim requires authenticating the instrument, not merely the transfer information, as in Claim 28. Therefore, authentication should include verifying on some level that it is an authorized instrument. Plaintiff need not be concerned that using the word "verifies" would impose greater authenticity restrictions on the claim. The claim recites "for subsequent use in attesting," which only requires that it be helpful to attesting to authenticity. Therefore, the Court construes the phrase to mean "including the VAN with the instrument for subsequent use in verifying that the information in the instrument has not changed and verifying that the instrument originated from the first party."

D. "the VAN being used for attesting to the authenticity of the payor and document information"

<table>

</table>
number (VAN) on a computer using at least a portion of the document information, and a secret key of the payor, the document information including an amount, and information for identifying the payee, the VAN being used for attesting to the authenticity of the payor and document information"

The disputed phrase appears in claim 28 of the '148 patent. First, the parties dispute whether "attesting" means that the VAN "verifies" or "evidences." Second, the parties dispute whether "attesting to the authenticity of a payor" requires confirming the identity of the payor or merely that the document originated with the payor.

Plaintiff argues that the invention only gives indications of authenticity and does not exactly "verify" authenticity. Pl. Brief at 18. According the Plaintiff, the invention authenticates that the instrument is not forged and did in fact originate with the payor. The plaintiff also argues that "it is axiomatic that the VAN verifies only the portion of the 'document information' that was used to create it." Pl. Brief at 19. Therefore, as the VAN is only created using "at least a portion of the document information," the VAN can only attest to that portion of the document information.

With respect to the authenticity of the payor, Plaintiff argues that the VAN does not confirm the originator's identity. Rather, according to Plaintiff, "the VAN in the funds transfer embodiments is used to confirm that the payor originated, or authorized, the funds transfer instructions." Pl. Brief at 19. Under Plaintiff's construction, the "information extracted from the VAN" needs only match "the information included on the payment instrument." Id. Defendants argue that Plaintiff's proposal is inconsistent with the definition for VAN and inconsistent with the specification.

Defendants also argue that the invention confirms identities of parties, so the VAN must be used to confirm the identity of the payor in claim 28. See Def. Brief at 16-17. Defendants point to the "numerous references to [the invention's] authentication process involving a verification of a party identity."

The Court construed VAN such that it "can be used in verifying the identity of a party or the integrity of information or both." Furthermore, as Defendants point out, the specification repeatedly uses the word "verify" and never uses the word "evidences." The Court is of the opinion that the VAN gives more than just an "indication." Moreover, while an accurate VAN may be only an indicator that a document is not forged, the claim does not require that the VAN verify the document. Rather, the VAN verifies--not merely indicates--that at least some document information is unchanged and that the payor is authentic.

The Court does not agree that payor authenticity is the same thing as identity verification. The specification does indeed recite that the originator's bank verifies the originator's identification, but this is not in connection with a VAN. The bank authenticates the identity of the party at enrollment, not as part of a transaction. The party's identity is presumed to be authentic through the use of the secret PIN, but that identity need not be verified as part of the transaction. The VAN merely confirms that the account holder originated the instrument. The VAN does not confirm that the account holder is who he says that he is. The Court construes the disputed phrase to mean: "The VAN being used to verify that the instrument originated from the payor and that the at least a portion of the document information used to create the VAN has not changed.

1. attribute

Hyperion contends that an attribute is "an identifier used to classify financial data." OutlookSoft contends that attribute is
"an identifier used to organize financial data." Thus, the debate is simply whether an attribute classifies or organizes data.

While Hyperion cites to one example in the prosecution history to support its construction, OutlookSoft proposes the correct construction. In the 141 patent, claim 1 recites "financial data is organized in accordance with at least the attributes. . . ." Thus, the claim language itself supports OutlookSoft's construction. Accordingly, the Court adopts OutlookSoft's construction. "Attribute" means "an identifier used to organize financial data."

290

First, MercExchange challenges the construction of the term "auction," asserting that the district court erred in construing the term as "a process over a trusted network, or with a trusted intermediary." MercExchange argues that the district court should not have required a "trusted" element. We disagree. The district court's construction is supported by the language of the specification, which states that the purpose of the patented system is "to provide a trusted network of consignment nodes that act as brokers to provide a means to electronically present a used good or collectable to an electronic market." '051 patent, col. 2, ll. 12-14.

291

1. "auctioneer in control of the auction event"

The parties dispute whether the term "auctioneer in control of the auction event" appearing in the preamble to claims 1, 2, and 3 serves as a limitation on the claims, and thus, whether that term must be construed at all. Manheim and LGB contend that the term serves as a limitation on the claims and should be construed to mean "auctioneer in complete control of all changes in the state of the auction, including which bids are accepted and rejected." AMS contends that this term is not limiting, and thus needs no construction; or, in the alternative should be construed to mean "an auctioneer is able to exercise authoritative influence over the auction event."

There is no litmus test for determining whether to treat a preamble as limiting the scope of the patent claims. Catalina Mktg. Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002). Rather, "a claim preamble has the import that the claim as a whole suggests for it." Pitney Bowes, Inc. v. Hewlett Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999). Thus, "whether to treat a preamble as a claim limitation is determined on the facts of each case in light of the claim as a whole and the invention described in the patent." Bicon, Inc. v. Straumann Co., 441 F.3d 945, 952 (Fed. Cir. 2006) (quoting Storage Tech. Corp. v. Cisco Sys., Inc., 329 F.3d 823, 831 (Fed. Cir. 2003)); see also Catalina Mktg., 289 F.3d at 808 ("Whether to treat a preamble as a limitation is a determination 'resolved on review of the entire[] . . . patent to gain an understanding of what the inventors actually invented and intended to encompass by the claim.'" (quoting Coming Glass Works v. Sumitomo Elec. U.S.A., Inc., 868 F.2d 1251, 1257 (Fed. Cir. 1989))).

In general, [i]t the body of the claim 'sets out the complete invention,' the preamble is not ordinarily treated as limiting the scope of the claim. Catalina Mktg. v. CoolSavings.com, 289 F.3d 801, 808 (Fed. Cir. 2002). Rather, "a claim preamble has the import that the claim as a whole suggests for it." Pitney Bowes, Inc. v. Hewlett Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999). Thus, "whether to treat a preamble as a claim limitation is determined on the facts of each case in light of the claim as a whole and the invention described in the patent." Bicon, Inc. v. Straumann Co., 441 F.3d 945, 952 (Fed. Cir. 2006) (quoting Storage Tech. Corp. v. Cisco Sys., Inc., 329 F.3d 823, 831 (Fed. Cir. 2003)); see also Catalina Mktg., 289 F.3d at 808 ("Whether to treat a preamble as a limitation is a determination 'resolved on review of the entire[] . . . patent to gain an understanding of what the inventors actually invented and intended to encompass by the claim.'" (quoting Coming Glass Works v. Sumitomo Elec. U.S.A., Inc., 868 F.2d 1251, 1257 (Fed. Cir. 1989))).

Conversely, a preamble will be regarded as limiting if it is "necessary to give life, meaning, and vitality' to the claim." Catalina Mktg., 289 F.3d at 808 (quoting Pitney Bowes, 182 F.3d at 1305). "That is, if the claim drafter 'chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects.' Bicon, 441 F.3d at 952 (quoting Bell Comm'n's Research v. Vitalink Comm'n's Corp., 55 F.3d 615, 620 (Fed. Cir. 1995)) (emphasis in original). In such situations, "there is no meaningful distinction to be drawn between the claim preamble and the rest of the claim, for only together do they comprise the 'claim.'" Pitney Bowes, 182
AMS contends that the preamble term "auctioneer in control of the auction event" merely states "the purpose of the claimed invention" and that the term should not be read as a limitation because "the body of each of the '612 patent claims fully recite[s] an invention that achieves the purpose set forth in the preamble"--i.e., "to allow the auctioneer to remain in control of the auction." (AMS Br. at 6-7.) In contrast, Manheim and LGB contend that AMS clearly and repeatedly relied on the element of auctioneer control in distinguishing prior art, and that such reliance renders the preamble term "auctioneer in control" limiting. (See Manheim Br. at 11-13; LGB Br. at 9-11.) After reviewing the prosecution history of the '612 patent, the Court agrees with Manheim and LGB and concludes that the term "auctioneer in control of the auction event" appearing in the preambles into a claim limitation because such reliance indicates use of the preamble to define, in part, the claimed invention." Catalina Mktg., 289 F.3d at 808-09.

The file history reveals that the examiner repeatedly rejected AMS's patent claims as anticipated or obvious in light of two prior art auction systems disclosed in the Friedland and Dinwoodie patents. In response to the examiner's rejections, AMS clearly and repeatedly relied upon the aspect of auctioneer control to distinguish that prior art. For example, in response to the examiner's initial § 102(e) rejection as anticipated by Friedland, AMS attempted to distinguish that art, arguing that "the claimed invention is not fully disclosed in Friedland" because "Friedland does not disclose a system that allows the auctioneer to remain in control of the auction." (AMS Br. at 6-7.) In contrast, Manheim and LGB contend that AMS clearly and repeatedly relied on the element of auctioneer control in distinguishing prior art, and that such reliance renders the preamble term "auctioneer in control" limiting. (See Manheim Br. at 11-13; LGB Br. at 9-11.) After reviewing the prosecution history of the '612 patent, the Court agrees with Manheim and LGB and concludes that the term "auctioneer in control of the auction event" appearing in the preambles into a claim limitation because such reliance indicates use of the preamble to define, in part, the claimed invention." Catalina Mktg., 289 F.3d at 808-09.

The auctioneer being in control of the auction event is a key element for the integration of remote bidders into the live auction. The auctioneer needs to have control over which bids are accepted, which bids are rejected, when the bidding is going to be closed, when the next lot is put on the block, when the lot is moved into a pre-sold state, etc. . . . For the auctioneer to maintain such control, the various events (i.e., the transition from a bidding state to a sold state) must be conducted under the control of the auctioneer rather than some external force. If such transitions are controlled by external events, the auctioneer is stripped of some level of control.

(Id.) Additionally, after pointing out that Friedland disclosed a time-based system wherein auction events such as state transitions from the pre-bid state to the sold state can occur totally autonomous of the auctioneer, AMS argued that "Friedland cannot possibly describe, suggest, or teach the control aspect of the present invention because it explicitly strips the auctioneer of such control." (Id. at 528.) Finally, the examiner allowed AMS's claims over the Friedland and Dinwoodie patents on the sole ground that the clerk and bid systems claimed in the '612 Patent operate subject to the occurrence of only non-time based events. In commenting on the examiner's reasons for allowance, AMS yet again returned to the aspect of auctioneer control, and again attempted to distinguish Friedland on this ground, stating:

It is applicant's position that Friedland et al.'s [sic] system does not leave an auctioneer in complete control of the auction event. Allowing the auctioneer to remain in complete control of the auction event as claimed in the present invention was a technical hurdle that Friedland et al. was not able to clear, and thus, was not described, suggested, or taught by Friedland.

Id. at 616.

This clear and repeated reliance by AMS on the preambles of Claims 1, 2, and 3 to distinguish prior art references on the ground that they did not "leave[] an auctioneer in control of the auction event" indicates that AMS used the preamble to
define, at least in part, its invention. Such reliance is sufficient to render the preambles of those claims limiting. See Catalina Mktg., 289 F.3d at 808-09.

Because the inventors relied on the preambles to distinguish prior art, the preamble terms serve as limitations on the claims, and thus, must be construed. Manheim and LGB contend that the term "an auctioneer in control of the auction event" should be construed to mean "an auctioneer in complete control of all changes in the state of the auction, including which bids are accepted and rejected." AMS counters that this term should be construed to mean "an auctioneer is able to exercise authoritative influence over the auction event." The Court agrees with Manheim and LGB.

The prosecution history shows that AMS clearly and consistently used the terms "complete control" and "total control" to distinguish the prior art Dinwoodie and Friedland patents. (See, e.g., id. at 576 (stating that in the prior art system "the auctioneer remains subservient to the system delays and the processor's bid acceptance algorithm and thus is not in complete control of the auction event"); id. at 617 ("the system described in Friedland et al. is unable to leave an auctioneer in complete control of the auction event"); id. at 373 (explaining that Friedland was distinguishable because in that system "the auctioneer was stripped of some measure of control") (emphases added).) Having previously adopted the position its invention was distinguishable from prior art because it allowed an auctioneer to remain in "complete control" of the auction event, AMS may not now, in litigation, adopt a position contrary to that taken before the PTO. See Torpharm, Inc. v. Ranbaxy Pharm., Inc., 336 F.3d 1322, 1329 (Fed. Cir. 2003). Accordingly, the Court adopts the definition proposed by Manheim and LGB, and the preamble term "an auctioneer in control of the auction event" shall mean "an auctioneer in complete control of all changes in the state of the auction, including which bids are accepted and rejected."

GO BACK

292

9. "the auctioneer manages the psychology and pace of the auction" / "the auctioneer manages the . . . the pace of the auction and the psychology of the auction"

The parties dispute the meaning of the term "the auctioneer manages the psychology and pace of the auction." The Court has considered Manheim's proposed definition, and concludes that it is untenable in light of the specification and prosecution history. The Court therefore adopts the definition proposed by AMS and LGB, and concludes that the term "the auctioneer manages the psychology and pace of the auction" in claim I shall mean "the auctioneer uses a variety of techniques to exert influence over the emotion, enthusiasm, and excitement of remote and onsite bidders and over the speed of bidding to play bidders off each other so that they are more likely to bid on auction items and make larger bids."

GO BACK

293

1. "AUDI0 AND/OR VISUAL SELECTION"

AOL: "An individual work such as a song or a music video."

TWM: No construction required. In the alternative, "Audio and/or visual content of a stream made available to user(s)."

AOL argues that its definition is "consistent with the ordinary meaning of a 'selection' as a 'work.'" (D.E. 68, pg. 6). TWM counters that "nothing in the claim language limits 'selection' to an individual song." (D.E. 69, pg. 7). As described above, the Court is mandated to first examine the claim language and specification.

AOL's proposal is inconsistent with the claim language. The claim language does not intimate that a "selection" consists of a whole "individual" work, as AOL suggests. Instead, the disputed term is preceded by the following: "wherein at least one stream of [p]ackets comprises an audio and/or visual selection." (emphasis added). The claim itself reveals that merely a packet of information, which as recalled from both parties' DVD tutorials, is a digitized part of an audio selection--not the whole selection--constitutes a selection. A stream of packets is short segments of a song. Because those segments are not the entire "individual" song, AOL's proposal does not comport with the claim language.
The Court believes a construction is necessary because the ordinary skilled person in the art understands "selection" differently than laypersons. Specifically, laypersons would read "selection" as an individual work; skilled persons in the field would read "selection" as either an individual work or a selection of data. To prevent any confusion, the Court adopts TWM’s second proposal. So "selection" is construed as "audio and/or visual content of a stream made available to user(s)."

**294**

B. "audio/video source information"

This term as well as "audio/visual source information" appear in each of the four patents-in-suit in a total of over sixty claims. A representative usage is reproduced above in claim 1 of the '995 Patent. The parties agree that "video" and "visual" are equivalent, and that "audio/video source information" denotes a "work" having a "temporal dimension" as opposed to a photograph or text. However, both parties wish to further clarify this construction.

The intrinsic evidence supports Burst's construction of the term as "an audio and/or video work that can be received from one or more sources and that has a temporal dimension." The '995 specification states that the invention is capable of "receiv[ing] an input signal from a source such as a television camera, a conventional VCR, a television tuner, or another VCR, etc." '995 Patent at 7:2-4, see also '995 Patent at 7:23-8:2 (describing other sources of input). Likewise, the prosecution history discusses "an audio/video transceiver having the ability to receive audio/video source information from a variety of signal sources." Amendment "A", '995 File History, Payne Dec., Exh. 9 at ABPU 89. Apple's failure to support its objection to "from a variety of sources" inclines the court to accept Burst's construction of "audio/video source information" as meaning "an audio and/or video work that can be received from one or more sources and that has a temporal dimension."

Though both parties agree to use "work" to define "audio/video source information," they interpret the term differently. Apple insists that "work" means a complete work, i.e. an entire song or video as opposed to a portion thereof. Under Apple's proposed construction, the patents disclose a sequential process such as that in Mantech Envtl. Corp. v. Hudson Envtl. Serv. Inc., 152 F.3d 1368, 1375-76 (Fed. Cir. 1998). There, the claim covered a process for rehabilitating a hydrocarbon-contaminated stretch of ground water. The Federal Circuit found that the claim inherently disclosed sequential steps, where each step necessarily relied upon the completion of the prior. Id. at 1376.

This case differs from Mantech. Though the steps of Burst's patents are necessarily sequential, each step need not be performed on an entire work before commencement of the subsequent step. Rather, the patent covers a sequential and potentially continuous system. The '995 Patent specification states that "[o]nce received in the second VCR-ET's memory . . . the digitized program can then either be viewed directly from memory or transferred to storage . . . either in its entirety or in random segments, based on user preference." '995 Patent at 10:1-5 (emphasis added); see also id. at 9:17-22 (describing interim storage before storage of entire program is complete). Here, a latter step may be initiated on a portion of some "work" that has been processed in a prior step, though the remainder of the same "work" is still being processed in the earlier step. Apple's argument on this issue relies upon its reading of Mantech to insert the term "complete" into the definition of work. However, the intrinsic evidence suggests no limitation that "work" should include only complete works.

The court concludes that "audio/video source information" is equivalent to "an audio and/or video work that can be received from one or more sources and that has a temporal dimension." Additionally, "work" may be a portion of a complete program, permitting subsequent steps to commence before completion of previous steps.

**295**

Second, Lockwood asserts that the term "audio-visual" refers to either video presentations or audio presentations, but not necessarily to both. We disagree. The '115 patent specification states that the unit displays travel documentaries and that a "high-quality audio-visual travelog can utilize practically all the human senses to motivate and influence a customer." During prosecution, Lockwood argued:
Although certain alpha numeric data are presented in the [prior art] reference, and such as in airport terminals which display schedules, etc., these are to be distinguished from applicant's device which actually presents brief travelogues and other movie-quality audio visual presentations to sell a product.

Although Lockwood correctly notes that the disclosed terminal displays an initial selection menu that does not produce any sound, this menu is not referred to as an "audio-visual" presentation. Rather, the selection menu is merely a method used for choosing an "audio-visual" presentation. Examination of the claims, specification, and prosecution history leads us to conclude that the district court correctly interpreted this term as requiring a device that produces both audio and video. It is undisputed that the SABREvision system cannot produce audio presentations.

### C. "Authentication Data"

<table>
<thead>
<tr>
<th>Plaintiff's Construction</th>
<th>Defendant's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Information identifying the user which includes a credit card number, cell phone number, digital encryption on a personal digital assistant, or a single- or multi-dimensional bar code, social security number, phone number, driver's license number, PIN number, or password.</td>
<td>Information that authenticates the bearer as holding a valid ticket.</td>
</tr>
</tbody>
</table>

With regard to the process of "authentication," Plaintiff notes that the specification explains that it can occur via "infra-red wireless scanning," for example by sliding a credit card through an authentication reader or through the use of bar-coded authentication tickets. '809 patent at 5:24-30. Plaintiff further notes that the specification explains that "ownership information" can be a "cell phone number, a digital encryption on a personal digital assistant, or a single- or multi-dimensional bar code." Id. at 5:10-20. From these passages, Plaintiff purportedly draws its proposed construction. However, Plaintiff's proposed construction also refers to items such as a social security number, pin number, password, and driver's license number, which are not mentioned anywhere in the specification. Without a stronger basis in the internal record, the Court is highly reluctant to construe "authentication data" in terms of such items. Furthermore, with regard to items that are explicitly mentioned in the specification, the Court concludes that these are mere examples and should not limit the claims. Thus, the Court will not adopt Plaintiff's proposed construction.

--- Footnotes ---
1 However, as noted above, based on the claim language and prosecution history, the Court excludes this specific embodiment from the scope of the claims.

--- End Footnotes ---

For its part, Defendant points to no evidence - either intrinsic or extrinsic - to support its own proposed construction. Thus, the Court is also reluctant to adopt Defendant's proposed construction. To the extent Defendant addresses this claim term at all, it is mainly to criticize Plaintiff's construction. Specifically, Defendant criticizes Plaintiff's proposed construction as improperly seeking to include "two things that are not intangible: a printed bar code and an encrypted personal digital assistant." (Id.) However, Plaintiff clarifies in its Answering Claim Construction Brief that its proposed construction is intended to refer only to "non-physical" information, (see D.I. 60 at 6), a limitation that is nonetheless manifest in the claims (see, e.g., '809 patent at Claim 1). In this regard, the Court notes that Plaintiff's proposed construction does not include a "printed bar code," but merely a "bar code," which the specification confirms is not necessarily physical. See '809 patent at 5:13-15 ("The two dimensional bar code can be printed by the user in order to provide a physical indication of ticket
ownership."). Likewise, Plaintiff's proposed construction does not, as Defendant contends, include "an encrypted personal digital assistant." Rather, it includes a "digital encryption on a personal digital assistant," which again is not necessarily physical in nature. Thus, this particular criticism of Plaintiff's proposed construction is, in the Court's view, unfounded.

Defendant further criticizes Plaintiff's construction as improperly pertaining to the establishment of the "identity of the person providing the data." (D.I. 50 at 28.) However, Plaintiff has agreed that "authentication data has nothing to do with the name or identity of the person who has the account." (D.I. 60 at 5.) Plaintiff further states that "authentication data" is "information indicating a system user or ownership of a ticket." (Id. (emphasis added).) Thus, Plaintiff appears to agree with Defendant that "authentication data" is, at least in part, related to ticket ownership. However, the claims also state that "authentication data" may be associated with both ticket buyers and sellers, neither of which may, at a particular point in time, actually hold a valid ticket. Thus, the Court will not, as Defendant requests, construe this claim term to refer only to the "holding [off] a valid ticket."

Notably, though criticizing Plaintiff's construction, Defendant actually maintains that the parties propose "similar" constructions. (See D.I. 62 at 9.) Thus, the Court understands Defendant's objections to Plaintiff's proposed construction as being fairly limited. Accordingly, the Court will construe the term "authentication data" in a manner largely consistent with Plaintiff's proposal. Specifically, the Court will construe the term "authentication data" to mean "information indicating a system user or ownership of a ticket, such as a credit card number, a cell phone number, a digital encryption on a personal digital assistant, or a single- or multi-dimensional bar code." This construction clarifies the meaning of "authentication data" without improperly limiting it to examples that are either set forth in the specification or drawn from some other unknown source. In addition, in the Court's view, this construction better expresses the parties' agreement that "authentication data" does not pertain to the name or identity of the system user.

"Authentication server" means a "server that provides session identifiers for service requests." This term is expressly defined in claim 12. Amazon urges the Court to also define "server that provides session identifiers for service requests to multiple servers." Given the Court's constructions of session identifiers and services requests, this is unnecessary.

The district court made several findings with regard to the construction of the term authorization code. We agree with some of these findings, disagree with others, and address them below.

1.

The district court held that an authorization code must "include a code that enables the IMM to decode the information that is to be reproduced in a material object and that was previously stored in encoded form at the IMM." Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1809. The district court reasoned that the "seemingly component" of the disclosed authorization codes was the encoded catalog decipher program that allowed the IMM to decode information. See id. at 1805. Without this component, the district court continued, "the IMM would be unable to convert the information from its encoded, unusable format to its decoded, usable format." Id. Accordingly, the district court held that "the encoded catalog decipher program is the true 'authorizing' mechanism," and the authorization code needs such a component. Id.

IGE argues that an authorization code need only authorize copying and need not provide decoding information. IGE points to the language of the claims to substantiate its argument. The appellees respond that the portions of the specification noted in IGE's asserted definition before the district court require that the authorization code perform a decoding function, and that the specification does not disclose an authorization code without such a function. The appellees also maintain that an
authorization code must include an IMM code, used to identify the IMM intended to receive the authorization code from the ICM. The appellees further respond that the definition of the term authorization code requires that it be transmitted electronically between the IMM and the ICM.

We agree with IGE that the authorization code need only authorize copying. Our holding is based on the claim language and the language of the specification identified in IGE's asserted definition before the district court. First, the language of the independent claims does not require that the information be encoded, much less that the authorization code have decoding information. Encoded information is not claimed until claim 5. Further, the claim language itself suggests that the sole function of the authorization code is "authorizing . . . reproduction." Freeny patent, col. 28, l. 47 (claim 1).

Second, in response to the district court's request for a binding definition of all disputed terms, IGE identified the passage in the Freeny patent at column 6, lines 1-23 as defining the term authorization code. At two points in that passage, the purpose of the authorization code is stated to be providing permission for copying. In the context of the preferred embodiment, it states that "if [the request for reproduction is] approved, [the ICM] provides an authorization code." Id. at col. 6, ll. 4-5. Later, it notes that information is reproduced only with permission, "such permission being indicated by the authorization code." Id. at col. 6, ll. 21-22. The only reference in this passage to decoding information merely states that such decoding occurs in the IMM of the preferred embodiment "in response to receiving the authorization code." Id. at col. 6, ll. 7-8. This simply does not state that the authorization code must include a decoding code. It does indicate a sequence to the events or a causality between reception of the authorization code and the decoding action, but this is expected given that information, which may or may not be encoded, cannot be decoded before permission to reproduce has been received. See id. at col. 6, l. 17.

The appellees' arguments that an authorization code must also include an IMM code and that the authorization code must be transmitted electronically are not persuasive. Neither of these proposed limitations is mandated by the claim language itself or the specification. Although the preferred embodiment routes the authorization code with the use of an IMM code and electronic transmission, these features are not recited in the independent claims and we are not at liberty to read them into the claims. See Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865, 9 U.S.P.Q.2d (BNA) 1289, 1299 (Fed. Cir. 1988) ("References to a preferred embodiment, such as those often present in a specification, are not claim limitations."); SRI Int'l. v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1121, 227 U.S.P.Q. (BNA) 577, 585-86 (Fed. Cir. 1985) (en banc); cf. Toro Co. v. White Consol. Indus., Inc., 199 F.3d 1295, 1301, 53 U.S.P.Q.2d (BNA) 1065, 1069 (Fed. Cir. 1999) ("It is well established that the preferred embodiment does not limit broader claims that are supported by the written description.").

2.

The district court also held that the authorization code is separate and distinct from the request reproduction code. This is clearly correct. First, these codes are separately recited in claim 1. Compare Freeny patent, col. 28, ll. 31-36 (origin of request reproduction code) with id. at ll. 37-41 (origin of authorization code). Second, the specification supports this distinction. In the preferred embodiment, a request reproduction code originates from the user and is passed from the user to the IMM and then to the ICM. See id. at col. 5, l. 60 - col. 6, l. 3. However, an authorization code originates from the ICM and is passed from the ICM to the IMM. See id. at col. 6, ll. 3-7.

3.

As discussed above with respect to the IMM, the district court further held that an ICM must transmit the authorization code to the IMM. This is a limitation associated with the ICM or the IMM and not with the term "authorization code." Because an authorization code need only authorize copying, it would be improper in this case to construe the term "authorization code" to include limitations regarding its origin or its destination. See Intervet, 887 F.2d at 1053, 12 U.S.P.Q.2d (BNA) at 1476; Laitram, 863 F.2d at 865, 9 U.S.P.Q.2d (BNA) at 1299; SRI Int'l, 775 F.2d at 1121, 227 U.S.P.Q. (BNA) at 585-86; cf. Toro, 199 F.3d at 1301, 53 U.S.P.Q.2d (BNA) at 1069.

4.

Accordingly, we hold that: (1) an authorization code must authorize copying but need not provide decoding information; (2) the term "authorization code" is not to be construed to require that it include an IMM code or that it be transmitted
299

G. "entering an authorization code though the keypad for having the computer initiate communication with a host data processor" 7

7 Claim 20, in which the disputed claim term appears, reads:

A method for processing debit purchase transactions, the method comprising the steps of:

- providing a counter-top terminal having telecommunications means operable with a computer, at least one keypad for data entry to the computer, a display responsive to the computer, and a card reader communicating with the computer for modifying purchasing value of a card in response to card use;

- entering sales transaction data to the computer through keypad data entry by a clerk;

- entering confirmation of the sales transaction data by a customer;

- reading a debit styled card through the card reader for providing card data to the computer;

- entering an authorization code through the keypad for having the computer initiate communication with a host data processor;

- electronically transmitting a transaction request to the host data processor through the telecommunications means of the counter-top terminal for requesting a response of approval or disapproval from the host data processor;

- receiving a response from the host computer; and

- displaying the response from the host data processor for the debit purchase transaction on the counter-top terminal display.

('859 patent, col 9 lines 56-67 to col 10 lines 1-15 (emphasis added))

SVS proposes that this disputed term be construed to mean: "the customer enters via the keypad a personal identification number for authorizing access to a customer data base of a host data processor or the clerk enters via the keypad a code which permits the initiation of a debit purchase transaction." (D.I. 43 at 19; D.I. 47 at 27) CAT proposes instead "a series of numbers and/or letters, or a combination thereof, entered via the keypad to establish a communication link with a host data processor." (D.I. 44 at 29) I recommend that the Court adopt CAT's construction.

SVS argues that the only types of "authorization codes" in the '859 patent are the "customer authorization code" and the "clerk authorization code," and, accordingly, this general "authorization code" term should be construed to incorporate SVS's proposed constructions for those two specific types of authorization codes. (D.I. 43 at 19) SVS also points out that certain claims depending from independent claims 20 and 29 -- the claims in which this general "authorization code" term appears -- indicate that the step of entering an authorization code requires entering both a customer authorization code and a clerk authorization code. (Id. at 19-20)

CAT argues that SVS's construction of this general "authorization code" term in claims 20 and 29 wrongly incorporates the limitations SVS proposes for the "customer authorization code" and "clerk authorization code" terms from claims 1 and 10. (D.I. 44 at 29) Specifically, CAT finds three flaws in SVS's construction: 1) it requires that only the customer or clerk enter
the authorization code, 2) it requires that the code is a PIN, and 3) it renders the function of the "authorization code" synonymous with the functions of the "customer authorization code" and "clerk authorization code." (Id. at 29-32) CAT also points out that SVS's construction would improperly read limitations from certain dependent claims into the independent claims from which they depend. (Id. at 32) To CAT, the general "authorization code" and its function are wholly distinct from and broader than either the "customer authorization code" or the "clerk authorization code" terms.

For reasons already given, I recommend that the "code" portion of the disputed term not be limited to a PIN but instead be construed to mean "a series of numbers and/or letters, or a combination thereof." Given the plain language of the claims at issue, the code must be entered "via the keypad." Finally, I agree with CAT that the general "authorization code" language of claims 20 and 29 is broader than the "customer authorization code" and "clerk authorization code" terms. The general "authorization code" language does not specify that any particular party must enter the "authorization code." Also, the function of this general "authorization code"—"for having the computer initiate communication with a host data processor"—is broader than the functions of the "customer authorization code" ("authorizing access to a customer data base of a host data processor") or the "clerk authorization code" ("initiating a debit purchase transaction").

The prosecution history is consistent with this analysis. The examiner initially rejected as anticipated the general "authorization code" term based on the Gutman patent (U.S. Pat. No. 5,221,838), but indicated that the related "customer authorization code" and "clerk authorization code" terms were allowable subject matter. (D.I. 43 Ex. D (March 8, 1999 Office Action) at SVS000190, SVS000193) This implies that the examiner viewed the "authorization code" term as broader than the other (allowable) terms. See In re Skvorecz, 580 F.3d 1262, 1266 (Fed. Cir. 2009).

Accordingly, I recommend that the Court construe the term "entering an authorization code through the keypad for having the computer initiate communication with a host data processor" to mean "a series of numbers and/or letters, or a combination thereof, entered via the keypad to establish a communication link with a host data processor."

2. Authorization data

This term is found in Claim 3 of the '364 Patent, which discloses: "The process of claim 2, further comprising the process of: (g) providing authorization data at selected ones of said points along said route of passage by means of said electronic record." '364 Patent, col. 16, ll. 8-12.

DE proposes that "authorization data" should be construed as "data relevant to obtaining authorized passage through a point." Dell contends that it should be construed as "information required to authorize passage through a point."

DE claims that the data is not required to receive authorized passage through a point, and that the specification provides an alternative approach for obtaining an authorized passage through customs. The specification provides that "rather than providing a hard copy of a commercial invoice, an electronic copy with the authorization of the international carrier can be provided either as an electronic document or a hard copy can be generated and provided ...." '020 Patent, col. 12, ll. 7-10.

The court agrees with DE, and construes "authorization data" to mean "data relevant to obtaining authorized passage through a point."

An authorization procedure

Digital Reg argues that this term does not require construction or alternatively should be construed as "a process which determines whether access should be granted." Defendants contend the term should be construed as "a process that determines whether a transaction is accepted or rejected."
Digital Reg argues that Defendants’ construction improperly imports limitations from the specification into the claims. Specifically, Digital Reg objects to Defendants’ use of the word "transaction," which Digital Reg contends is only used in the specification to describe situations where payment is required. See Abstract ("The payment authorization center approves or rejects the payment transaction, and bills the corresponding account. The authorization center then transmits an authorization signal to the payment server computer indicating whether the transaction was approved."). Digital Reg contends that it is clear from the specification and the claims that either payment or use information can be provided to gain access to content. See col. 4:13-16; claim 20.

Defendants contend that the term's ordinary meaning is a procedure that will either approve or reject the client's requests to access the client, i.e., will authorize the request. Defendants contend that in the step described in claim 13, the external source reviews the information provided by the client, e.g., use and payment information, to determine whether the external source should provide a token to the client that will allow the client to execute an installation process to generate the unique permission for the digital content. See col. 4:30-46. Defendants argue that the specification describes the authorization procedure as occurring at an external source and that the purpose of the procedure is to determine whether the external source should approve or deny a client's request for permission to receive a resource to access the digital content.

As argued by Digital Reg, and as discussed with regard to "token," limiting the term to "transaction[s]" is overly narrow. Defendants' construction is also overly limiting in that it specifies an act of either acceptance or rejection. "Authorization" carries a broader meaning consistent with Digital Reg's proposal of "access should be granted." Claim 13, in view of its dependence on claim 1, connotes granting access to digital content. Inclusion of "acceptance or rejection" is not consistent with the language "based on a result of the authorization procedure" in claim 13. Accordingly, the Court construes "an authorization procedure" as "process which determines whether access should be granted."

A. "Authorization Request"

I adopt the following definition: "a query sent to the central processing computer via a communications medium, seeking approval or disapproval of a transaction or activity."

"Authorization request" appears in two claims-in-suit, 87 and 94.

Defendants offer the following: "a query seeking approval or disapproval of a banking transaction, the query being sent from a banking transaction terminal over a communications medium to the central processing computer for processing the query." Plaintiffs suggest, "an asking for an approval or an allowance of or regarding a transaction or an activity."

At first glance, plaintiffs' definition should be sufficient. "Authorization" and "request" are easily understood terms, both on their own and in connection with the commercial practice of seeking approval from some third party before completing a credit transaction. One might assume that any query "asking for approval… of a transaction," regardless of its source or destination, would constitute such a request.

However, as defendants correctly argue, the patent limits the definition beyond the plain meaning of the words. Many transmissions discussed in the patent may be queries for some kind of approval - a vendor device may contact a central processing device or the account holder directly; the central processing device may contact the account holder; etc. However, the phrase "authorization request" as used in the patent refers only to communications between a vendor device and the central processing device. In the second claim, for example, in which the central processing computer is bypassed and a message to the account holder is sent directly from the transaction processing device at the vendor location, the message is not referred to as an "authorization request," but only as a "first signal." "725 Patent, col. 44:58 - 45:14. Therefore, I conclude that an authentication request is a request for approval by the vendor (or the bank, if we are talking about an ATM transaction) that terminates at the central processing computer.

Footnotes

1 The authorization request may pass through other computer systems in transit to the central processing device. See '725 Patent, col. 21:32-38.
This limitation makes sense in light of what we know about the invention itself. The claims make it clear that the central processing device, not the account holder, either authorizes or blocks a transaction. Its decision may be based on its own internal database of rules or, if the invention works, it may be based on information received from the account holder. Therefore, a request from the central processing computer to the account holder concerning a transaction is not an "authorization request."

However, defendants are incorrect in asserting that the request must originate at a "banking transaction terminal" or be limited to requests concerning banking transactions. I have previously defined a "banking transaction" as, "An activity affecting a deposit account, such as a deposit of funds or a withdrawal" Joao I, 348 F. Supp. 2d at 130. Therefore a banking transaction terminal is a device which engages in activity affecting a deposit account.

The description of the invention, as well as the preferred embodiments, make it plain that authorization requests can be generated by a credit or debit card authorization device ('725 Patent, col. 46:63-65); a smart card authorization device, (Id., col. 47:1-2), a "point-of-sale" transaction (Id., col. 47:4-6) or a cellular telephone (Id., col. 29:10-24). Claim 94 states that the authorization request may originate at "a point-of-sale authorization device, a point-of-sale authorization terminal, and a transaction authorization device." Id., col. 55:15-18. None of these devices necessarily affect deposit accounts. Therefore, the patent does not limit "authorization requests" to those generated specifically by "banking transaction terminals," or limited to those seeking authorization for banking transactions.

Striking unnecessary language from defendants' definition, I adopt the following phrase: "a query sent to the central processing computer via a communications medium, seeking approval or disapproval of a transaction or activity." That is the definition I adopt.

C. "Authorized by the subscriber"

Independent claims 13 and 23 both recite "a set of notification rules . . . authorized by the subscriber" and "a separate set of queue replenishment control rules authorized by the subscriber." '243 patent, 27:18-24, 28:17-23. Plaintiff proposes that the term "authorized by the subscriber" in this context should simply be construed as "permitted or sanctioned by the user," whereas defendants propose that the term be construed more narrowly in light of the specification to mean "a subscriber's election after being presented with a choice among multiple options."

Defendants rely on the fact that all of the disclosed embodiments are directed to user selections that control the management of the subscriber's queue. Defendants argue that plaintiff's construction of the claim language is so broad that it could even encompass a situation in which the subscriber is required to take no particular action to "authorize" the relevant rules. Defendants contend that such a reading is clearly inconsistent with the specification. On the other hand, plaintiff relies on Howmedica Osteonics Corp. v. Wright Medical Technologies, Inc., 540 F.3d 1337, 1345 (Fed. Cir. 2008), to argue that "the fact that the specification describes only a single embodiment, standing alone, is insufficient to limit otherwise broad claim language." However, the Court finds that the intrinsic evidence supports construing the claim language "authorized by the subscriber" to require affirmative selection of an option by the subscriber from multiple options. Specifically, in the background, the '243 patent mentions Netflix's rental queue system as prior art and describes one of its drawbacks as not giving subscribers "any flexible degree of control over their rental selection queue or shipments." '243 patent, 2:20-23. The summary of the invention goes on to state its objects as overcoming the limitations of the prior art, and implementing "an intelligent queue monitoring system that allows subscribers/purchasers to define policies and rules to be used in determining what actions should be taken with respect to particular items in such queue, and at what times." '243 patent, 3:5-9. Accordingly, the Court finds that there is sufficient intrinsic evidence to support construing the term "authorized by the subscriber" to mean "elected by the subscriber after the subscriber is presented with a choice among multiple options."
5. "Authorizing"

**Step (c) of Claim 1 recites: "authorizing beam transport to one of the treatment rooms."** 20 (Rosenberg Decl. Ex. 2, the '581 Patent at 9:10-12.) "Authorizing" is defined in the Oxford English Dictionary as "the giving of authority; sanctioning." Id. Random House gives the following definition: "to give authority for; formally sanction[.]") (Airhart Decl. Ex. H at 121.) The American Heritage Dictionary defines "authorize" as follows: "[t]o give permission for; sanction." AMERICAN HERITAGE DICTIONARY (4th ed. 2000.) Defendant Ion Beam proffers the following construction of the disputed term: "issuance of computer generated data permitting beam transport." However, the court finds no reason to import this limitation to the claim terms.

--- Footnotes ---

20 The entire claim reads as follows: Claim 1 of the '581 patent recites the following: "a switchyard for directing accelerated beam from the accelerator to a selected one of the treatment rooms . . . comprising the steps of:

(a) receiving a beam request signal from one . . . treatment rooms;

(b) verifying the authenticity of one of the beam request signals from one of the treatment rooms; and

(c) authorizing beam transport to one of the treatment rooms.

(Rosenberg Decl. Ex. 2, the '581 Patent at 9:1-12.)

--- End Footnotes ---

Ion Beam offers the following definition, taken from a technical treatise, in support of its construction: "authorization The process of verifying that a user or process has permission to use a resource in the manner requested." (Rosenberg Decl. Ex. 24, IEEE 100 THE AUTHORITATIVE DICTIONARY OF IEEE STANDARD TERMS (7th ed. 2000). But that definition does not mention "issuance of computer generated data." (See id.) Indeed, in the context of the contested claim language, it more closely supports Plaintiff Optivus' construction. Therefore, the disputed claim term is hereby defined as follows: "to permit beam transport to one of the treatment rooms."

Finally, MercExchange asserts that the district court erred in construing the preamble phrases "automated method, performed by a computer-based auction system," and "computer-implemented method of conducting Internet-based auctions" in various claims of the '051 patent. The district court held that those phrases do not require that all steps following the preamble be performed by an automated process, as argued by MercExchange. Rather, only the steps that are claimed to occur automatically are required to be performed in that manner. MercExchange contends that the court's interpretation is inconsistent with the portion of the specification entitled "Computer Implementation," which provides different operating systems and platforms for use in a preferred embodiment of the invention. '051 patent, col. 7, line 59 through col. 8, line 9. That portion of the specification does not support MercExchange's argument, however. Various limitations of the relevant claims require actions by participants and cannot be "automatically performed via an automated process." For example, as the district court stated in its Markman order, claim 1 contains a limitation requiring that the computer system "receive bids on the item from participants." That step requires that participants enter their bids manually and cannot occur automatically. Likewise, one step of claim 12 requires that a seller "establish a seller's account." That step also requires that a seller manually enter relevant information into the system. Accordingly, the district court was correct in holding that not all steps had to be performed by way of an automated process.
J. "automated modification"

Claim 15 contains the term "automated modification": "wherein the redirection server is configured to allow automated modification of at least a portion of the rule set correlated to the temporarily assigned network address." Although the specification does not contain the term "automated modification," the modification of rule sets is discussed, e.g., "[r]ule sets may contain data about . . . when and how to modify the rule set during a session," (118 patent, 4:46-47), and "[t]he redirection server . . . is programmed to implement . . . other attendant logical decisions such as . . . dynamically changing the rule sets based on conditions." (118 patent, 4:59-66). Linksmart asserts that no construction of this term is necessary.

Alternatively, Linksmart proposes the following construction: "a change by the system based on a condition." On the other hand, the defendants contend that "automated modification" means "a change by the system without a request or instruction by a person."

The parties agree that "modification" means "a change by the system" but disagree on the meaning of "automated." Linksmart argues that "automated" means "based on a condition." In support of its proposed construction, the plaintiff cites the above-quoted language from the specification: "dynamically changing the rule sets based on conditions." Linksmart's proposal does not distinguish an automated or dynamic modification from a manual modification, however—the phrase "based on a modification" provides no clarification. On the other hand, the defendants contend that automated means "without a request or instruction by a person." But Linksmart notes that an automated modification may occur in response to a user's action. For example, claim 17, which depends from claim 15, states that "the redirection server is configured to allow modification of at least a portion of the rule set as a function of the data transmitted to or from the user." Thus, user action may prompt an automatic modification. As such, the court adopts the following construction: "a change by the system without a request or instruction to change from a user."

B. "automated negotiations engine for analyzing terms"

As to this term, this Court ordered the following claim construction, which remains unchanged following this Court's analysis of the prosecution history:

Special purpose software that performs the functions necessary to implement multiple rounds of bargaining which allows for an offer and multiple counteroffers between two participants where each round is related to prior rounds without human intervention.

Tr. 14:20-15:4; 19:4-10.

3 The following patents and corresponding claims were identified by the parties in the Joint Claim Construction Chart ("Joint Chart") as relevant to construction of this term: '677 patent (claims 2, 22, 37, 39, 40, 46), '249 patent (claims 1, 2, 6-8, 12, 20, 21, 25, 28, 42-44, 48, 52-54), '698 patent (claims 1-3, 6, 7), and '315 patent (claims 1, 2, 4-8, 10, 12-19, 21-23).
of construction even though the word appears in the preamble of the identified claims? Only if the answer to that question is yes, is it necessary for the Court to construe this term.

Generally speaking, there are three parts to every claim: the preamble, the transitional phrase, and the body. The transitional phrase, e.g., "comprising" or "consisting of," connects the preamble to the body of the claim. The preamble is the portion of the claim that includes everything before the transitional phrase. The body is everything after the transitional phrase. For example, the preamble of claim 2 of the ’677 patent reads:

An automated apparatus for generating a plurality of authorized drafts on financial accounts belonging to a plurality of payors, the drafts payable to one of a fixed set of one or more payees . . . . ’677 patent, claim 2.

With regard to the claims identified as containing the term "automated," almost all of them only use the term in the preamble.

Terms found solely in the preamble are not to be construed if the body of the claim sets forth the complete invention. Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1371 (Fed. Cir. 2003). Thus, if the preamble does not give "life, meaning and vitality to the claim," the preamble is considered to be "of no significance to claim construction because it cannot be said to constitute or explain a claim limitation." Id. In order to determine whether the preamble should constitute a limitation, the Court must look to the "overall form of the claim, and the invention as described in the specification and illuminated in the prosecution history." Id. When the preamble merely states a "purpose or intended use for the invention," it is not limiting. Catalina Mktg. Int'l v. Coolsavings, 289 F.3d 801, 808 (Fed. Cir. 2002).

AutoScribe contends that "automated" is merely an "intended use" of the invention. However, beyond that bald statement, AutoScribe fails to explain why that is the case. That may be because the intended use of the invention is not "automated," but to pay the amount owed to the payee in a more timely, less cumbersome fashion then waiting for a check to be delivered in the mail. The intrinsic evidence reveals that the word "automated" is more than a purpose or intended use for the invention, but describes how the claimed system functions and achieves its purpose. All of the patents are directed towards an "Automated Payment System." See, e.g., ’677 patent, Title of Invention, col. 1, line 1. As the ’677 specification elaborates, an "object of the present invention is to provide a process for receiving payments in which an automated draft production system is provided to produce authorized drafts on the account of a payor, executable by a person other than the payor." ’677 patent, col. 4, lines 40-44 (emphasis added). 4 The claimed invention is also described as follows:

The automated system used to generate the drafts in the preferred embodiment has a simple input screen which receives the necessary information for generation of the draft . . . . The system then immediately verifies the bank and account information by comparing the input information to the data in a bank information database associated with the system. ’677 patent, col. 5, lines 6-14 (emphasis added).

Thus, there is nothing that conveys "automated" amounts to a mere purpose or intended use; on the contrary, it is a limitation that requires construction. Buttressing this conclusion, is the fact that the term "automated" is not always relegated to being used in the preamble. For example, in the ’315 patent, the term "automated" is used in the body of several claims. See ’315 patent, claim 8 ("providing an automated draft production computing system"), claim 10 ("providing an automated payment order computing system"), and claim 12 ("according to automated check clearing house conventions"). Accordingly, the Court shall construe the term "automated."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 Although the Court only cites to the ’677 patent in this instance for support, as explained above, all of the patents in suit contain a similar, if not identical disclosure because they are related patents, derived from the same initial patent application.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -
the Joint Chart, Intell-A-Check proffered a definition for "automated" that included in relevant part "working with little or no human actuation" based on the dictionary definition for "automatic." See The New Short Oxford Dict. 152 (1993). This general dictionary definition appears to be more appropriate and consistent with how the term is used in the identified claims, which require that most elements be performed by the computer system with little human involvement.

Inexplicably, Intell-A-Check then proffered a third construction at the Markman hearing. Recognizing that its first construction, which allowed for no human input, was fatally flawed, and apparently not satisfied with the second construction, Intell-A-Check asked this Court to limit the term such that after the operator has entered the specific payor information, the claimed invention allows for no human involvement. (Tr. at 22:3-8). This construction, however, finds no support in the patents' disclosures. For example, claim 8 of the '315 patent explicitly calls for human interaction after the system operator inputs all of the relevant payor information into the system because it requires that the printed draft be submitted to the automated check clearing system for processing. Further, and perhaps more importantly, even a layperson reviewing the patents in suit would understand that an automated computer system may need some limited amount of human involvement after inputting the relevant draft information in order to ensure the system works correctly. For example, the computer may freeze, requiring the user to reboot the system and reenter the payor information. Or, a printer cartridge may run out of ink and need to be replaced. Because Intell-A-Check's third proposed construction ignores claim language, and ignores the known reality of how a user operates a computer system, it cannot possibly be correct and, thus, must be rejected.

Finally, AutoScribe, relying on its argument that this Court should not look to a dictionary definition to determine the ordinary meaning of the term, argues that "automated" should be construed to mean "the use of a system or apparatus to undertake tasks traditionally performed by human beings." (Tr. at 17:19-18:13). As stated above, this Court will adhere to Texas Digital and its progeny unless and until the Federal Circuit reverses its position on the use of dictionaries in Phillips. But, assuming arguendo AutoScribe is correct, the Court still disagrees with AutoScribe's proposed construction. Using AutoScribe's construction, an "automated apparatus" means "an apparatus used to undertake tasks traditionally performed by human beings." In other words, it does not allow for any human interaction. Obviously, this construction suffers from the same flaw as Intell-A-Check's first proffered construction and, for the same reason, must be rejected.

In summary, the Court adopts the ordinary meaning of the term "automated," which is most consistent with how the term is used in the patents. Accordingly, "automated" means "working with little or no human actuation."

- 757 -

These terms mean a system which is fully automated and completed without human involvement (other than by the applicant). This construction does not exclude systems that allow human involvement after all steps described as being performed without human assistance are completed. In the '007 patent, this means steps d.i. through d.v.

16. "Automatic bridging device"

Defendants argue that the term "automatic bridging device" as used in claim 1 of the '027 patent is a means-plus-function limitation and that the specification fails to recite sufficient structure to perform the automatic bridging function. According to claim 1, the function of the "automatic bridging device" is to "bridg[e] the subscriber on the first circuit to the called party on the second circuit, whereby the subscriber is telephonically linked to the called party without human intervention at the service center." '027 patent, col. 10, 11. 40-42. Cygnus claims that "automatic bridging device" needs no construction and offers expert opinion in support of its position:

The Defendants claims [sic] that this term is a means plus function limitation. It appears to me that claim describes a component in a system. It describes a structure. One of ordinary skill in the art would understand what an automatic bridging device is. There are several examples of such structures in the industry e.g. a dial in bridge service offered by organizations such as AT&T. The mere act of dialing in causes bridging.

Am. Forys Expert Report Claims Constr. (dkt. # 643) at 26. 9 In addition, Cygnus claims that two of its witnesses gave examples of automatic bridging devices. Thomas Thompson testified that Call Interactive used a "telecommunications switch" called the "AT&T Dimension," although he did not specifically state whether "AT&T Dimension" corresponded to the "automatic bridging device" of the '027 patent. See Thompson Decl. at 108-09. 10 James Alleman, the named inventor, explained:

[Q.] Was the 386 system capable of doing that bridging after the person that was being called picked up on the line?

A. I don't believe--I don't know. I don't know that we've--I believe that the bridge prior to, it could have, but we certainly didn't attempt to experiment with that, to the best of my recollection.

Q. Did you have any specific hardware that accomplished the bridging function in the 386 system?

A. Yes. It was from Dialogic, as I had mentioned earlier.

Q. It was one of the Dialogic boards?

A. I believe it truly bridged the two. They were called DX 4 Dialogic boards, and it really, if you think about a computer system, where there's empty slots, the DX 4 board would fit in one slot, and another DX 4 would fit in another slot, just as a second hard drive or serial port would fit in. And to the best of my recollection, the bridge actually fitted on top of those two DX 4 boards. So it didn't have a separate slot of its own in the computer, but it fit on top.

Q. Okay.

Alleman Depo. at 121. 11
9 The court strikes Forys's opinion on whether "automatic bridging device" is a means-plus-function limitation as without foundation and invading the province of the court. 10 Excerpts of the September 20, 2006 deposition of Thomas Thompson, including pages 108 and 109, are attached as Exhibit 297 to the declaration John Sutton (dkt. # 685). 11 " Excerpts of the September 20, 2006 deposition of James Alleman, including page 121, are attached as Exhibit 298 to the declaration John Sutton (dkt. # 685).

--- End Footnotes ---

Defendants argue "automatic bridging device" is a means-plus-function limitation and that it is fatally indefinite. Defendants point to two portions of the description of the preferred embodiment which they claim are inconsistent. First, "DTMF Generator 26 recognizes the called party number DTMF digits entered by the subscriber and out pulses those digits over the second seized circuit. DTMF generator 26 activates bridging function 29 to bridge the subscriber onto the second outbound circuit." '027 patent, col. 7, 11. 54-57. Second, "When a second outbound circuit is seized, as described at 62 in FIG. 4, CRU 20 out pulses the called party number at 70, and bridges the subscriber onto the second outbound circuit to monitor call progress tones at 71." Id., col. 9, 11. 28-31. The patent appears to recite in different places that bridging is performed by different components, either the "DTMF generator 26 activat[ing] bridging function 29" or the "CRU 20." However, it is not clear from the '027 patent whether the components along the right edge of Figure 1 are intended to be subparts of the "CRU 20" or whether they are distinct from it. In places, the specification treats them as distinct. See, e.g., '027 patent, col. 7, 11. 25-28 ("At the same time the CRU 20 delivers the DID digits to the subscriber table server 21, it also delivers call detail information to the system message detail recording database (SMDR) 24."). In another portion, however, it would appear that at least some of these right-side components are subparts of "CRU 204":

CRU 20 is a computer, or switch, that is connected to the LEC 15 central office and consisting of integrated components that permit the system to perform a number of functions integral to this invention. This includes switching functions to handle line (circuit) connections; interactive voice response operations; database controller for subscriber identification; and a system message detail recording (SMDR) unit 24 to provide information necessary to create call records.

'027 patent, col. 6, 11. 59-67.

When a claim limitation does not contain the word "means," the limitation is "presumptively not a means-plus-function limitation." Mass. Inst. of Tech. v. Abacus Software, 462 F.3d 1344, 1355 (Fed. Cir. 2006). "However, a limitation lacking the term 'means' may overcome the presumption against means-plus-function treatment if it is shown that the claim term fails to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function." Id. at 1353 (some quotation marks omitted). "The generic term[] 'device[]' typically do[es] not connote sufficiently definite structure" to avoid treatment as a means-plus-function limitation. Id. at 1354. The Federal Circuit has contrasted a pair of examples:

Claim language that further defines a generic term like "mechanism" can sometimes add sufficient structure to avoid 57 Ore. 541, 112 P 6. For example, in Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580 (Fed. Cir. 1996), which involved a mechanical device, we held that 57 Ore. 541, 112 P 6 did not apply to the term 'detent mechanism," because "the noun 'detent' denotes a type of device with a generally understood meaning in the mechanical arts, even though the definitions are expressed in functional terms." Id. at 1583. The court recited several dictionary definitions for "detent," including "a mechanism that temporarily keeps one part in a certain position relative to that of another, and can be released by applying force to one of the parts." Id. (internal quotation marks and citations omitted). These definitions connoted sufficient structure to avoid 57 Ore. 541, 112 P 6. We also concluded that "the fact that a particular mechanism--here 'detent mechanism'--is defined in functional terms is not sufficient to convert a claim element containing that term into a 'means for performing a specified function' within the meaning of 57 Ore. 541, 112 P 6" because "many devices take their names from the functions they perform." Id. 12

In contrast, the term "colorant selection," which modifies "mechanism" here, is not defined in the specification and has no dictionary definition, and there is no suggestion that it has a generally understood meaning in the art. We therefore agree with the district court that "colorant selection mechanism" does not connote sufficient structure to a person of ordinary skill in the art to avoid 57 Ore. 541, 112 P 6 treatment.' 13

Mass. Inst. of Tech., 462 F.3d at 1354 (original bracket removed; footnotes renumbered).
I. Term Relating to All Patents: "automatic call distributor"

Rockwell proposes that the term "automatic call distributor" or "ACD" means "a system that receives incoming calls, then routes the calls (e.g., by queuing incoming calls to put them 'in line' until they are able to be answered), so as to distribute each call to a selected one of a set of agents at the call center." This definition comprehends a system that is software-based rather than requiring a hardware apparatus called a central processing unit or "CPU." Apropos proposes that ACD means "a device that receives incoming telephone calls and automatically distributes those calls, which is comprised of an integrated 2 telephone switch and computer apparatus, in communication with one another through a specialized proprietary software interface." Rockwell, noting that ACD is not specifically defined in the patent specifications, relies on a broad, functional definition such as is found in dictionaries. 3 It relies on testimony of its expert, John E. MacCrisken, as well as the testimony of Leonard J. Forys, Ph.D., that the ordinary English meaning of ACD is "an apparatus that connects calls to agents in some automatic fashion," (Tr. of Markman Hr'g, Feb. 12-14, 2001 ("Markman Tr.") at 83, l. 17), and points to the testimony of Patrick Kevin Brady, Apropos' founder and former chief technology officer, that ACD means "a device, not an operator, that automatically distributes calls" and other extrinsic evidence from which such a functional definition might be drawn. 4 Apropos, on the other hand, contends that ACD, at the time of the filing of the 059 patent application (1996), 5 was understood in the industry as consisting of an integrated telephone switch and a computer that, together, performed the function of call distribution. It points to the specification of the 059 patent which states that an ACD "... generally includes a multiport switch controlled by a central processing unit (CPU) to interconnect the customers and the agents..." col. 1, l. 22-23. Apropos also cites the 117 patent, which refers to ACD as a "switch," col. 2, l. 23-24, fig. 1, and the reference in the 070 patent which describes existing (unsatisfactory) telephone systems as "hard-wired by the manufacturer," col. 1, l. 4-16, and col. 2, l. 26-27: "The telephone switching system 12 has a network 14 which is connected to a switching system such as an Automatic Call Distributor (ACD) ...") as evidence that Rockwell understood at the time it filed these applications that an ACD was an integrated telephone switch and computer using proprietary software. 6

2 Apropos' expert, Leonard J. Forys, Ph.D., explained that "integrated" in this context means "that the switch and the software associated with the switch were integrated together." (Tr. of Markman Hr'g, Feb. 12-14, 2001 ("Markman Tr.") at 182).

3 See Interactive Gift Express, Inc. v. Compuserve, Inc., 231 F.3d 859, 866 (Fed. Cir. 2000) ("Dictionaries, which are a form of extrinsic evidence, hold a special place and may sometimes be considered along with intrinsic evidence.")
256 F.3d 1323, 1327 (Fed. Cir. 2001); IIEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONIC TERMS 6th ed. 58 (defines an ACD as "the facility for allotting incoming traffic to idle operators or attendants."); IBM
DICTIONARY OF COMPUTING 43 (defines an ACD "in telephony, [as] a service that allows incoming telephone calls
directed to the same dialed number to be routed to one of multiple agents, all of whom can provide the same service to
the calling party and all of whom are assigned to the same ACD group."); NEWTON'S TELECOM DICTIONARY 87 (defines
an ACD as "[a] specialized phone system originally designed simply to route an office's incoming calls to all available
personnel so that calls are evenly distributed.").

4 (Brady Dep. at 94) (Brady agreed to a functional definition of "Automatic Call Distributor"). Rockwell also cites the
following Brady Dep. at 105-06 (Brady agreed with Rockwell that an "ACD" need not be "in one box": "it doesn't matter
how many cabinets that device is in."); Brady Dep. at 266-67 (Brady agreed with Rockwell that an "ACD" need not have
a switch that is "integrated" with a computer apparatus: "they [ACDs] were not integrated."); Brady Dep. at 261 (Mr. Brady
testified that the term "automatic call distributor" did not necessarily require that the device contain "specialized proprietary
software interface" and Brady agreed with Rockwell and Apropos that the 059 patent at Col. 1, l. 20-24 gives a brief but
accurate description to a person of ordinary skill in the art of the term "automatic call distributor."); Brady Dep. at 101-02
(Brady agreed that the individual words in the phrase "automatic call distributor" describe the function being performed by
the device.); Brady Dep. at 236-38 (Brady agreed that ACDs did in fact contain "general purpose computers" such as the
Intel 80386, and that the Opinion Letters stating the opposite should be rephrased in that regard.).

5 "In the past, telephone call centers have been provided with two major systems, an [ACD] and a business data system
comprising a host computer. (Markman Tr. at 180-82) (Forys) (In the time frame that the applications for the patents-in-suit
were filed, Forys had seen or inspected 12-15 models of ACDs manufactured by separate companies and all were integrated
systems. In that time frame, an automatic call distributor was "an integrated system which distributed calls. . . . Proprietary
protocols were used for the communication"), and at 455 (Forys) (an ACD "was integrated with this hard wired switch with
it, switch fabric together with the computer. Very rigid kind of thing. That's what's back then.").

6 A propros cites other evidence as well: 394 Patent, col. 3, l. 37-44 and Fig. 1 ("The ACD 116, or alternatively a private
branch exchange (PBX), operates in a well-known manner to connect an agent telephone … to external telephonic units
. . ."); Competitive Flash, Ex. 116 to the MacCrisken Dep., R006356-6359, attached as Ex. A to the Decl. of Chris
Rechtsteiner ("While not a true ACD, Apropos [Call Link] is positioned as a robust, call handling system"); Decl. of Chris
Rechtsteiner, PP 2, 5, 11 and 12 (stating that he prepared Ex. A when he was a Rockwell employee, and that the statement
that Apropos' product was not a "true ACD" reflected the perception both at Rockwell and throughout the industry that
products such as Apropos' Call Link were not ACDs, because they were not hardware-based products; the prevailing
mindset at Rockwell and in the industry was that software-based solutions such as Apropos' Call Link were not automatic
call distributors); MacCrisken May Dep. at 657-62 (MacCrisken admitting that the phrase "while not a true ACD" in
reference to Apropos' product is a statement that Apropos' product is not an ACD); MacCrisken May Dep. at 661, l. 21-662,
l. 7 (Richard McLaren, Rockwell's counsel, contending that the "not a true ACD" language must have been written by an
Apropos employee, thus implying that if it were written by a Rockwell employee, it was an admission by Rockwell that
Apropos' product was not an ACD); Brady Dep. at 105, l. 13-23 ("I think we're leaving out that the industry has seen many
call distributors, and . . . they come in certain configurations and . . . the term 'automatic call distributor' . . . implies this
mating of a computer or embedded CPU with the switching hardware. And you run wires to it, for instance, and . . . it has its
own phones, et cetera."); id. at 109, l. 14-110, l. 10 ("by implication your question lumped the Apropos product in with the
other devices, which have a CPU and a switch which is controlled directly by the CPU, not just interfaced to it, and has
phones wired up to it, and I can't agree with that"); id. at 111, l. 9-20 (ACDs control the switching matrix itself); id. at 265, l.
10-17 ("It's not really that important whether its control computer is on a shelf in a rack or if it's sitting next to it. If it's
sending the same kind of information and doing the same types of control of the hardware that comprise that switching
device, then . . . it's an integrated, all-in-one, stand-alone unit.").

- - - - - - - - - - - End Footnotes- - - - - - - - - - -

The court finds Apropos more persuasive than Rockwell. The inventor, as well as those ordinarily skilled in the art,
necessarily understood the term ACD as a device that existed at the time these patents were being pursued, unless evidence
of foresight exists. See Elekta Instrument S.A., 214 F.3d at 1308 (The prosecution history of the claims must be thoroughly
considered when construing the claims of a patent because the prosecution history makes clear the patent examiner's
understanding of what he or she deemed to be patentable.). Although there may have been other types of ACDs in existence
in 1996, there is no evidence of any ACD that did not consist of an integrated telephone switch and computer using proprietary software (whether or not in a single "box"). Nor is there evidence that the inventor would have foreseen ACDs that were not comprised of these elements. Therefore, the court adopts Apropos' definition of automatic call distributor for the purposes of this case.

313

3. "Automatic ion output current adjustment circuit"

ITW's claim construction is: "a circuit used to increase or decrease the ion output current of the positive and/or negative high voltage power supplies based on the result of the comparison performed by the comparator." Pl.'s Revised Proposed Order Regarding Claim Construction at 5. Ion's proposed construction is: "a circuit under the control of a software routine used to increase or decrease the ion output current by a predetermined amount." Def.'s Proposed Order re Claim Construction for the '756 patent at 6.

The parties agree that the change in the ion output current is based on the result from either the comparison step or the performance of the comparator. Def.'s Opp'n Br. re Claim Construction of the '756 patent at 22. They disagree on the meaning of "circuit." Ion contends that this circuit must be under the control of a software routine. ITW argues that such a construction impermissibly limits the claim language. The dictionary definition of "circuit," in the context of electronics, is: "a closed path followed or capable of being followed by an electric current." American Heritage Dictionary of the English Language (4th 2000). Nothing in the claim language or specification requires that circuit be limited in the manner proposed by Ion.

ITW and Ion also disagree over whether the ion output current must be changed by a "predetermined amount." ITW argues that Ion's proposed limitation would unreasonably preclude ITW's product from employing an electronic circuit to compare two values. I have already defined the comparator and the comparing step for purposes of the '756 patent. Therein, I found that the '756 patent disavowed any balancing or comparing step that was "hardware-based." See supra §§ 1.A.3, 1.B.2. These decisions do not, however, preclude the patent from employing hardware like an electronic circuit. So long as mere use of the circuit is insufficient to render the "comparison" "hardware-based," i.e. the hardware circuit is not a signature feature of the step in question, it can be properly included within the construction for this claim.

The proper construction, consistent with my discussion of claim 17, is: "a circuit used to increase or decrease the ion output current of the positive and/or negative high voltage power supplies based on the result of the comparison performed by the comparator."

314

2. "an automatic message distribution system"

The phrase appears in claims 13 and 21 (and parent claims) of the '414 patent, and claims 1, 2, 15, and 19 of the '399 patent. Claim 15 of the '399 patent is representative (the disputed term is in boldface):

15. A method for automatically distributing digitally-encoded messages that are input to an automatic message distribution system that includes a resource load containing a plurality of resources, comprising the steps of:

(a) storing each of said digitally-encoded messages in one or more distributed message queues;

(b) storing resource information concerning said resources in a resource information table that enables the automatic message distribution system to determine which of said resources is available to a digitally-encoded message stored in said one or more distributed message queues;

(c) storing a set of routing rules in a distribution routing table that control distribution of said digitally-encoded message
Jump to: A B C D E F G H I J K L M N O P Q R S T U V W X Y Z

to the resources; and

(d) automatically routing a digitally-encoded message stored in said one or more distributed message queues.
[paragraphing added by the parties]
a) The Parties' Proposed Constructions
The parties propose the following constructions:

eBay
The system that processes information received in message format that can route messages based on message content.

IDT
A system that processes information received in message format.

*2*See Doc. No. 99 at 66 (JCCC Exhibit 1 at 64).

IDT's current proposed construction was advanced after the parties' briefing. Currently, the only substantive difference between the parties' proposed constructions is that eBay adds "that can route messages based on message content." To the extent that IDT previously argued that eBay's proposed construction excluded making routing decisions on factors other than message content, e.g., the availability of resources, eBay clarifies in its sur-reply that "eBay's construction does not provide that the system must make all routing decisions only on the basis of message content, to the exclusion of all other considerations." (Doc. No. 95 at 8). However, eBay adds that "thus [the claims as construed] [do] not cover systems that do not use content-based routing." Id.

b) Discussion

eBay's proposed construction is taken from the specification, '399 patent, col. 2, lines 51-55, which again, in context, i.e., lines 51-56, provides:

"The AMD of the present invention processes information that is received in message format rather than as a telephone call, and therefore can base routing decisions on message content. Message content information is not available to conventional ACD systems as described above."

While it is true, as discussed above, that AMD systems, as described in the '414 and '399 patents, have the capability of making routing decisions based on message content -- which ACD systems could not -- eBay's arguments seem to gloss over the word "can" (although the word appears in eBay's proposed construction) and seem to contend that routing decisions must be made, at least in part, on message content.

The '414 and '399 patents, however, are generally directed to allocating resources to received messages -- or, as the specification explains, "[u]sing the present invention, message distribution is optimized according to a set of configurable distribution rules." '399 patent, col. 2, lines 43-45. Although, as the specification also says, the system "can base routing decisions on message content," eBay points to nothing in the claims, specification, or prosecution history of the patents-in-suit that requires that routing decisions be made on message content -- in addition to other information.

Based on the foregoing, the Court believes that the proper construction of "automatic message distribution system," in the context of the '414 and '399 patents, is "a system that processes information received in message format that is able to route messages based on message content."

c) Conclusion
In view of the foregoing, the Court concludes that:

The phrase "automatic message distribution system" means "a system that processes information received in message format that is able to route messages based on message content."
2. Automatic Operation

Lectrolarm proposes that "automatic operation" be construed to mean "the automatic reciprocating motion of the camera between defined points." The Defendants would interpret "automatic operation" to mean "movement of the camera base that is not directly responsive to input from a monitoring person (other than initiation of the automatic operation)."

Both Lectrolarm and the Defendants agree that "'automatic operation,' as typically understood in the field of electronics, refers to the operation of some structure without human intervention." (Pl.'s Br. at 53.) Lectrolarm argues that the scope of the definition of "automatic operation" was narrowed in the specification by the language "during automatic operation, the television camera 7 undergoes rectilinear motion between the two points A and B regardless of the path of rotation in scanning...." U.S. Patent 4,974,088, Column 5:57-60.

The court agrees that the specification consistently uses the term "automatic operation" to refer to motion of the camera between pre-set points. This is not, however, the meaning of the definition Lectrolarm has proposed. Lectrolarm's definition includes the term "reciprocating motion." Webster's defines "reciprocating" as "to move forward and backward alternately." Webster's Revised Unabridged Dictionary, 1998. One of the modes of automatic operation described in the specification involves directing the camera to a pre-defined position when an alarm is triggered. U.S. Patent No. 4,974,088, Column 6:28-40. This aspect of the camera's automatic operation does not involve "reciprocating motion."

The parties agree that the plain meaning of "automatic operation" is movement without human intervention. The specification does not limit the plain meaning of the claim in the manner that Lectrolarm proposes. The court construes "automatic operation" as "movement of the camera base that is not directly responsive to input from a monitoring person (other than initiation of the automatic operation)."

X. "An automatic steering and isolation diode network for supplying voltage to said radio from either said AC powered DC power supply or said removable DC power supply, and also for automatically supplying charging voltage from said AC powered DC power supply to said removable DC power supply"

Next, the Court turns to the term "an automatic steering and isolation diode network for supplying voltage to said radio from either said AC powered DC power supply or said removable DC power supply, and also for automatically supplying charging voltage from said AC powered DC power supply to said removable DC power supply" from claim 13 of the '059 patent.

A. The Parties' Proposed Constructions

Black & Decker proposes that the term "an automatic steering and isolation diode network for supplying voltage to said radio from either said AC powered DC power supply or said removable DC power supply, and also for automatically supplying charging voltage from said AC powered DC power supply to said removable DC power supply" means:

At least one diode in conjunction with other components that supplies voltage to the radio from either the alternating current powered direct current power source or the removable direct current power supply. The diode component also supplies the removable direct current power supply with a voltage from the alternating current powered direct current power supply.

Bosch proposes construing the term as:

A first diode that receives a voltage from the AC powered DC power supply, a second diode that supplies an appropriate charge voltage to the removable DC power supply, and a third diode that feeds current from the removable DC power supply.
supply to the radio such that the three diodes operate the radio through the AC powered DC power supply, the removable DC power supply, or to simultaneously power the radio and charge the battery.

B. The Court's Construction

Bosch points to the three diodes in Figures 6, labeled 54, 55, and 56, that perform the three functions of this claim term and therefore require that the Court adopt its proposed construction. Bosch, however, does not point to any portion of the intrinsic record that requires that the Court limit this claim term to the embodiment disclosed in the specification. n11 The Court rejects Bosch's attempt to limit this claim term according to the preferred embodiment disclosed in the specification. SanDisk Corp. v. Memorex Prods., Inc., 415 F.3d 1278, 1286 (Fed. Cir. 2005) ("it is axiomatic that without more the court will not limit claim terms to a preferred embodiment described in the specification"). The plain meaning of the claim does not in any way restrict this claim to the three particular diodes required by Bosch's construction. Further, the specification discloses an alternative embodiment of the claimed invention where the radio uses two diodes for power steering and two diodes for DC/DC converter isolation. (059 patent, col. 5, ll. 6-10.) Therefore, the specification does not limit automatic steering and isolation diode networks to the three diodes, each having a specific function, that Bosch's proposed construction requires. Accordingly, the Court rejects Bosch's construction because it is not supported by the intrinsic evidence and attempts to limit the claims to the preferred embodiment.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

N11 Bosch, in essence, wants the Court to construe this claim as if it were a means-plus-function limitation under 35 U.S.C. § 112, P6, limiting the claimed structure to the disclosed structure in the specification corresponding to the claimed function. But, Bosch fails to argue, or in any way point out, how this claim term invokes § 112, P6. Even if Bosch did make such an argument, that argument would fail. First, because this claim term does not recite the term "means," the Court presumes that this term does not invoke § 112, P6. Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) ("the presumption flowing from the absence of the term "means" is a strong one that is not readily overcome"). Next, this term expressly includes "an automatic steering and isolation diode network," and therefore identifies sufficient structure such that it does not invoke § 112, P6. Id. at 1358-1363.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Black & Decker, on other hand, contends that a "diode network" can simply be "at least one diode in conjunction with other components." The Court finds that this proposed construction is too broad and not supported by the intrinsic record. In the Summary of Invention, the patentee explains that the automatic steering and isolation network has a "plurality of diodes" rather than a single diode. First, the patentee summarizes how one can use a single diode in the claimed invention: "A button causes the power supply to supply voltage through the diode, and the diode feeds current from the power supply to the radio receiver." (059 patent, col. 2, ll.49-52.) Notably, the patentee does not use the term "automatic steering and isolation network" in the context of disclosing the use of a single diode. The patentee then goes on to explain that "alternatively" one could use a "plurality of diodes," which the patentee refers to as "an automatic steering and isolation network." The specification provides: "Alternately, a plurality of diodes may act as an automatic steering and isolation network to supply either AC supplied current, battery power or simultaneous power and battery charging from AC power." (059 patent, col.2, ll. 53-56.) Accordingly, the "Summary of Invention" provides that "an automatic steering and isolation diode network" must have more than one diode. n12 See C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004) (noting that statements that "describe the invention as a whole, rather than statements that describe only preferred embodiments" are commonly found in the "Summary of Invention" section of the specification and "are more likely to support a limiting definition of a claim term"). In addition, there is no teaching in the specification of using a single diode for the purposes required by this claim term. Boss Control, Inc. v. Bombardier Inc., 410 F.3d 1372, 1378 (Fed. Cir. 2005) ("While it is of course improper to limit the claims to the particular preferred embodiments described in the specification, the patentee's choice of preferred embodiments can shed light on the intended scope of the claims"). The Court construes the term "an automatic steering and isolation diode network for supplying voltage to said radio from either said AC powered DC power supply or said removable DC power supply, and also for automatically supplying charging voltage from said AC powered DC power supply to said removable DC power supply" as "a group or system of at least two diodes that supplies voltage to the radio from either the alternating current powered direct current power source or the removable direct current power supply and also supplies the removable direct current power supply with a voltage from the alternating current powered direct current power supply." n13
n12 This understanding is supported by the extrinsic evidence. Various patents in this field from slightly before and after the
time of the invention, use the terms "network of diodes" and "diode network" interchangeably, and therefore indicate that a
"diode network" must contain multiple diodes, rather than a diode in connection with other components. (See U.S. Patent
Nos. 4,492,935, 4,712,184, 6,055,180, and 6,172,383). Although the Court does not give this extrinsic heavy weight, the
Court notes that this extrinsic evidence confirms the understanding of one of ordinary skill in the art based on reading the
intrinsic record.

n13 In addition, there is no teaching in the specification of using a single diode for the specific purposes required by this
claim term.

A. "Automatic Tax Reporting"

Simplification's Construction Block's Construction
Determining and/or reporting Preparing a tax return on a
tax liability, or satisfying computer automatically without
tax reporting obligations, via manual intervention from the
a process in which one or more user.
functions, once initiated, are completed without manual intervention.

The essence of Block's proposed construction appears to be that manual intervention in the preparation of the tax return is
allowed only during an unclaimed initialization step that precedes the initiation of the claimed tax preparation method.
Figure 1 of the specification portrays this initialization step in a flow chart as a box labeled "Provide information on the tax
data providers." The text of the specification refers to this initialization procedure as "step 11" and provides a detailed
description of what it may include. (See '052 patent at 4:34-5:49.) Simplification urges the Court to adopt a broader
construction of "automatic tax reporting." Specifically, Simplification contends that the term simply refers to a process in
which "at least one piece of tax data is handled automatically in accordance with the steps recited in the claims." (D.I. 85 at
11 (emphasis added).) Thus, Simplification's construction would allow for manual intervention at any point in the process.
During the Markman hearing, Simplification clarified that their construction would permit one to "circle back around in the
process" and do additional manual data entry as necessary "throughout" the process. (See, e.g, D.I. 101 at 13:9-14:7, 17:14-
18:7.) Put yet another way, Simplification contends that Block is inappropriately asking the Court to redefine the term
"automatic" to mean "fully automated." (Id. at 7:5-16, 16:21-17:13.)

After reviewing the intrinsic evidence, the Court agrees with Block that the claims are limited to a tax preparation system
that, outside of manual intervention during the initialization process, is "fully automated." Beginning with the specification,
the Court notes that the patent distinguishes the prior art on the basis of it not being "fully automated." Indeed, the
specification explains that despite certain technological advances, "the potential for fully-automated tax reporting has not
yet been realized . . . ." (052 patent at 2:16-18.) Likewise, the specification explains that the "objects and advantages of the
present invention" are achieved through a "fully-automated" tax reporting system. (Id. at 3:21-24 (emphasis added); see also
id. at 4:28-33 (explaining that the figures in the specification portraying the "preferred embodiment" correspond to a "fully-
automated" tax reporting system).) Similarly, the patent explains that "few technological, legal, or practical obstacles exist
for the fully automated preparation and filing of federal and state tax returns . . . ." (Id. at 2:11-15 (emphasis added).) Thus,
the patent characterizes the invention as a "fully automated" system. In fact, although the Court affords this little weight, it
is notable that the '052 parent patent is entitled "Fully-Automated System For Tax Reporting, Payment And Refund."

The substance and structure of the specification comports with the raw textual evidence set forth above. To the extent the
The patent describes manual intervention in the tax preparation process, it is only during an extended description of "step 11" of the method, which is the first step of the disclosed tax preparation process and that pertains to initialization of the process and the provision of information regarding tax data providers. (See id. at 4:34-5:48.) In describing this process, the specification explains that the taxpayer can provide information regarding "special tax cases," such as whether the taxpayer has charitable contributions. (Id. at 4:63-5:2.) The specification further describes an alternative embodiment where, during "step 11," a "tax return preparer ensures that the electronic intermediary receives the appropriate information required . . . ," including information pertaining to "special tax cases." (Id. at 5:43-49.) Such manual intervention is not described as being part of subsequent steps in the automated tax preparation process. On the contrary, in discussing "step 12," the patent unambiguously explains that "the invention eliminates the current requirement that a taxpayer manually collect the tax data, eliminates the current requirement that a taxpayer manually enter such tax data onto a tax return or into a computer, and eliminates the need for all, or virtually all, intermediate hard copies of tax data, thereby saving paper, time, and cost." (Id. at 6:23-29 (emphasis added).) Thus, the specification contemplates that during "step 11" the taxpayer and/or tax preparer, in addition to providing rudimentary information such as a social security numbers, will anticipate "special tax cases" so that during "step 12" manual entry of tax data is "eliminat[ed]." In the Court's view, this description does not embrace the notion of "circling back around" to do manual input as the need arises, but is more consistent with the construction advocated for by Block.

To the extent the specification could be understood differently, such interpretations are laid to rest by the prosecution history. Indeed, during the BPAI hearing, counsel for Simplification argued as follows:

JUDGE LEE: The tax preparer ensures that information is collected to determine whether the taxpayer has a special tax case.

MR. SARTORI: Oh, on column 5. Okay, I got you. I'm sorry.

JUDGE LEE: Can you explain that?

MR. SARTORI: Sure.

JUDGE LEE: That sounds like manual intervention.

MR. SARTORI: That is manual intervention. And that has to do with step 11, which is the manual step required to initiate it, to initiate the automatic process. That's taken from column 5, line 45, what you've been focusing on, sir, Your Honor. And that has to do with step 11, which is the manual stuff.

JUDGE LEE: I see. So you're allocating all of these manual input to the category of initiating the process.

MR. SARTORI: Yes, Yes.

JUDGE LEE: If there's any manual input outside of initiation, then it's not covered by the claim.

MR. SARTORI: It's not covered by the claim and it does not anticipate the claim.

(D.I. 79, Exh. F at 30:7-24 (emphasis added).)

This Court is aware that to disavow claim scope during prosecution a patentee must clearly and unambiguously express surrender of subject matter, and the Court is thus cautious in concluding that a patentee has disavowed claim scope. See, e.g., Sepracor Inc. v. Dey, L.P., No. 06-113-JJF, 590 F. Supp. 2d 649, 2008 U.S. Dist. LEXIS 102728, at *17-18 (D. Del. Dec. 18, 2008); Honeywell Int'l, Inc. v. Nikon Corp., No. 04-1337-JJF, 589 F. Supp. 2d 433, 2008 U.S. Dist. LEXIS 99199 (D. Del. Dec. 9, 2008). However, in the Court's view, the above exchange represents a clear and unambiguous disavowal of claim scope. Furthermore, the Court has reviewed the entirety of the BPAI hearing transcript and concludes that this disavowal is not, as Simplification contends, merely taken out of context. Indeed, many other statements during the BPAI hearing confirm the disclaimer. For instance, at one point the following exchange occurred:

JUDGE MEDLEY: So "automatic," what does that - what is your position? What does that mean?
MR. SARTORI: It should mean acting or operating in a manner that is essentially independent of external input or control.

JUDGE MEDLEY: So not manual.

MR. SARTORI: Not manual, yes.

JUDGE MEDLEY: So if you have any kind of manual input from start to end, then, it's no good.

MR. SARTORI: It's no good in the sense of the comprising language, and no good in the sense of the limitations we have in the claims must be performed automatically.

(D.I. 79, Exh. F at 15:8-18.) 2 Counsel for Simplification went on to explain that "step 11" was the point where some data had to be input manually, and that this was the "feature of the invention . . . not recited in the claims." (Id. at 15:21-26 (emphasis added).)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 Simplification argues that Block is misunderstanding this exchange and contends that in referring to the open-ended transitional phrase "comprising," it was clearly advocating for a broader understanding of the claims. (D.I. 85 at 9-10.) However, the Court disagrees, and finds that although the term "comprising" was mentioned, Simplification's position was quite clear that "any kind of manual input from start to end" was "no good."

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Likewise, Simplification analogized its invention to an automatic dishwasher during the BPAI hearing. In so doing, Simplification explained that "once you start that dishwasher or that washing machine, it's going to town," that it was "automatic," and that there would be no need to "add the water" or "tell it when to start the rinse cycle." (Id. at 16:13-18, 17:11-14.) Later in the hearing, Simplification explained that "[s]tep 11 talks about the manual part of it," and that "once it receives the information, it automatically goes through all the steps in the process." (Id. at 21:14-20 (emphasis added).) In the Court's view, none of these statements comports with the meaning of "automatic tax reporting" that Simplification now advocates for.

Simplification raises two main arguments in support of its construction. First, Simplification contends that by using the open-ended transitional phrase "comprising," the claims allow manual input that Block's construction improperly forecloses. (D.I.80 at 13-14.) Second, Simplification relies on the Federal Circuit's decision in CollegeNet, Inc. v. ApplyYourself, Inc., 418 F.3d 1225, 1235 (Fed. Cir. 2005), where the term "automatically" was interpreted to mean "once initiated the function is performed by a machine, without the need for manually performing the function." Though these arguments would normally have force, Simplification's statements during the BPAI hearing change the situation dramatically. Furthermore, this case is not resolved by a straightforward application of CollegeNet, as Simplification contends, because in CollegeNet the specification and prosecution history both supported the proposed construction. See id. at 1235-36. As explained above, the Court finds that this is not the case here, especially when it comes to the prosecution history.

Accordingly, the Court concludes that "automatic tax reporting" means, as Block essentially contends, "preparing a tax return on a computer without manual intervention from the user." Though the Court effectively adopts Block's construction, the Court declines to include in its construction the word "automatically," as Block proposes. In the Court's view, this word is redundant to the phrase "without manual intervention from the user."

On the other hand, though Simplification criticizes Block's construction for using the word "computer" (see D.I. 85 at 5 n.2), the Court concludes that this word clarifies the meaning of "automatic." See CollegeNet, Inc. v. ApplyYourself, Inc., 418 F.3d 1225, 1235 (Fed. Cir. 2005) (defining "automatically," in part, to include the limitation of being "performed by a machine"). Furthermore, it is consistent with the agreed upon definition set forth in the specification for "electronic intermediary," which, in the claims and specification, is the component that carries out "automatic tax reporting." (See D.I. 79 at 5; '052 patent 4:39-42 ("The term 'electronic intermediary' refers to a data processing system comprising a general
D.

In its cross-appeal, ApplyYourself argues that the district court's grant of summary judgment of infringement of the '278 patent was improper, because it was based on an incorrect construction of the term "automatically." However, before reaching the merits of ApplyYourself's appeal, this court must first address whether ApplyYourself waived its right to challenge the construction of this term. Rule 51 of the Federal Rules of Civil Procedure provides that "no party may assign as error the giving or the failure to give an instruction unless that party objects thereto before the jury retires to consider its verdict, stating distinctly the matter objected to and the grounds of the objection." Fed. R. Civ. P. 51 (2002). n2 Though not formally objecting to the jury instruction and risking the loss of a right to appeal, ApplyYourself did flag the instruction in its Joint Submission of Jury Instructions as "disputed." ApplyYourself also referred the court to the Markman ruling, in which the district court rejected ApplyYourself's proposed construction, and to ApplyYourself's construction of "automatic" in the Joint Claims Construction Statement. CollegeNet, Inc. v. ApplyYourself, Inc., Nos. CV-02-484-HU, CV-02-1359-HU (D. Or. Dec. 19, 2002) (Markman ruling). Thus, while ApplyYourself's actions may have been "deficient in terms of the plain language of Rule 51," they "fall within the limited exception we have recognized for a pointless formality." Vohries-Larson v. Cessna Aircraft Co., 241 F.3d 707, 714 (9th Cir. 2001). "Where the district court is aware of the party's concerns with an instruction, and further objection would be unavailing, we will not require a futile formal objection." Gulliford v. Pierce County, 136 F.3d 1345, 1348 (9th Cir. 1998) (citations and quotation marks omitted). Therefore, this court finds ApplyYourself did not waive this argument.

n2 This court is aware of the 2003 amendments to Fed. R. Civ. P. 51. However, because the amendments became effective after the trial in this case, the previous version of Fed. R. Civ. P. 51 applies to this appeal.

Claim 1 uses the word "comprising." "The transitional term 'comprising' ... is inclusive or open-ended and does not exclude additional, unreelcted elements or method steps." Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327-28 (Fed. Cir. 1999). "A drafter uses the term 'comprising' to mean 'I claim at least what follows and potentially more." Vehicular Techs. Corp. v. Titan Wheel Int'l, Inc., 212 F.3d 1377, 1383-84 (Fed. Cir. 2000). Thus, consistent with this court's precedent, the district court correctly adopted CollegeNet's inclusive definition and rejected ApplyYourself's preclusive definition. While claim 1 does not expressly provide for human intervention, the use of "comprising" suggests that additional, unreelcted elements are not excluded. Such elements could include human actions to expressly initiate the automatic storing or inserting, or to interrupt such functions.

This construction does not read "automatically" out of the claims, as ApplyYourself suggests, because a machine still

- 769 -
performs the claimed functions without manual operation, even though a human may initiate or interrupt the process. The district court's automatic dishwasher and auto-pilot examples also support this court's understanding of automatic processes that contemplate human intervention. "Simply because a human has to load [an automatic dishwasher] and press the start button, and has the ability to turn it off mid-cycle, does not mean that the device does not 'automatically' wash the dishes." Markman ruling, slip. op. at 83. Similarly, "an 'auto-pilot' which is turned on by a human and necessarily must be able to be interrupted by a human once the automatic process is engaged ... remains an 'automatic' device." Id. slip.op. at 83-84. Thus, the claim language supports the district court's interpretation.

In addition, the district court's construction of "automatically" is consistent with one of the problems the invention sought to redress: avoiding the manual re-entering of the same information for every college application a prospective student desires to complete. '278 patent, col. 1, ll. 27-30. The '278 patent solves this problem by inserting common information into subsequent application forms, without the human user re-entering it. Adding a human initiation or interruption element would not alter the invention's solution to this problem.

The prosecution history also supports the district court's construction. The system disclosed in U.S. Patent No. 5,640,577 (issued June 17, 1997) (the Scharmer system or reference) obtains data from a database on a mainframe computer and displays it on a display terminal as a database report. The patent applicants explained:

Some of the displayed data is saved in memory at the display terminal on which it is displayed, and is then inserted onto a form. Report data to be saved is identified by its coordinates on the display screen, which coordinates had to have been previously programmed into the saving function. An operator can also enter data into a form before the form is saved, but the information typed in by the operator, although saved as part of the form, is not saved in a database independent of the form. Consequently, the data is not available from such a database for use on subsequent forms. None of the data manually entered by the operator on one form can be used to automatically fill in subsequent forms. Scharmer teaches a one way flow of data from the database into the forms, and nothing the user does can add to or change the data in the database that is the source of information for completing subsequent forms.

Markman ruling, slip. op. at 92-93. The patent applicants then amended claims 1 and 21 to include the term "automatically." The district court correctly concluded that the patent applicants' prosecution-related comments supported its interpretation of "automatically." Markman ruling, slip. op. at 98. The addition of "automatically" to the claim language did not prohibit human interaction; it merely decreased the need for the user to insert information into a form. In addition, the distinction over Scharmer was not that the applicants' invention eliminated the requirement of manual input of data into a form. Rather, the distinction was that instead of a one-way flow of information from a database where a machine inputs information which has previously been stored in the database by some other process, into a form, the claimed invention allows a two-way flow of information in that the user, by filling out and saving an application form, enters data into the database which can then be accessed by the forms engine to allow the forms engine to input that data into a second form.

Id. Thus, the forms engine "automatically", i.e., without human intervention, extracts data from the database and inserts that information into the second form. The patent applicants distinguished the Lextron reference on similar grounds. Therefore, because the district court's claim construction of "automatically" was correct, the district court's grant of summary judgment of infringement was proper.

---

C. Infringement

1. The Chan Patent

SSL argues that the district court erred in construing the "automatically" limitation in claim 1 of the Chan patent to mean "autonomously." SSL contends that the plain meaning of "automatically" is "having a self-acting or self-regulatory mechanism," and that "automatically" does not mean "undertaken or carried out without any outside control." SSL argues that the claim only requires that desaturation and east-west stationkeeping occur simultaneously and without further manual
commands from the ground; it does not preclude such maneuvers from being initiated by ground control commands. SSL further argues that Lockheed's satellites literally infringe claim 1, and that prosecution history estoppel does not preclude infringement under the doctrine of equivalents.

Lockheed responds that SSL's proposed claim construction is inconsistent with the written description, and that the district court properly concluded that the accused satellites do not infringe claim 1, either literally or under the doctrine of equivalents. Lockheed emphasizes the fact that the accused satellites require a ground operator to initiate stationkeeping maneuvers. Lockheed contends that the Chan patent does not disclose manually initiated east-west stationkeeping, and instead discloses that desaturation maneuvers are initiated by the satellite itself, not by a ground operator. Lockheed further contends that SSL failed to present any evidence of any structural equivalence under 35 U.S.C. § 112, P 6, and that the district court correctly concluded that the accused satellites do not perform the same functions as recited in the claim.

In interpreting claims, a court "should look first to the intrinsic evidence of record, i.e., the patent itself, including the claims, the specification and, if in evidence, the prosecution history." Vitronics Corp. v. Conectronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1996). Absent an express intent to impart a novel meaning, "terms in a claim are to be given their ordinary and accustomed meaning." Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249, 48 U.S.P.Q.2D (BNA) 1117, 1121 (Fed Cir. 1998); Carroll Touch, 15 F.3d at 1577, 27 U.S.P.Q.2D (BNA) at 1840 ("The words of a claim are generally given their ordinary and accustomed meaning, unless it appears from the specification or the file history that they were used differently by the inventor.").

As an initial matter, we do not agree with SSL's assertion that the district court erred in construing the term "automatically" to mean "autonomously." The disputed portion of claim 1 reads as follows:

[...]

Chen patent, col. 6, ll. 40-44 (emphasis added). Given its ordinary meaning, the term "automatically" denotes that the claimed apparatus is capable of performing east-west stationkeeping independently, without any external control. See, e.g., Webster's II New Riverside University Dictionary 140 (1988) (defining "automatic" as "1. a. Acting or operating in a manner essentially independent of external influence or control. b. Self-regulating."). The term "autonomously" has a similar ordinary meaning, likewise denoting independent operation. See id. (defining "autonomous" as "1. a. Independent. b. Self-contained."). Thus, the district court's construction is supported by the ordinary meaning of those terms.

The district court's construction is also consistent with the specification. The written description explicitly states that one of the advantages of the present invention is that "all manual east-west stationkeeping maneuvers are eliminated." Chen patent, col. 1, ll. 63-65. Moreover, the abstract indicates that the claimed invention relates to an "apparatus for autonomously performing stationkeeping maneuvers for three-axis stabilized spacecraft." Id., Abstract (emphasis added). 1 The abstract further states that "the invention autonomously performs desaturation of a momentum/reaction wheel . . . while simultaneously accomplishing the preselected compensation of the spacecraft's east-west position." Id., Abstract (emphasis added). Accordingly, given that the elimination of "all manual east-west stationkeeping maneuvers" is one of the stated advantages of the claimed apparatus, and the fact that the terms "automatically" and "autonomously" are used interchangeably in the specification, we conclude that the district court did not err in construing the term "automatically" to mean that the claimed apparatus is "capable of performing multiple, autonomous east-west changes in position over a substantial period of time without ground transmissions concerning the parameters of such movements." Space I, 1998 WL 1045304, at *6 (emphasis added).

--- Footnotes ---

1 Although SSL argues that it was improper for the district court to rely on the abstract in construing the claim, we have previously stated that in determining the scope of a claim, the abstract of a patent is a potentially useful source of intrinsic evidence as to the meaning of a disputed claim term. See Hill-Rom Co. v. Kinetic Concepts, Inc., 209 F.3d 1337, 1341 n.*; 54 U.S.P.Q.2D (BNA) 1437, 1440 n.1 (Fed. Cir. 2000).
A. Automatically

The term "automatically" appears in all claims. Timeline argues that "automatically" should be construed to mean "without the need for human analysis," a term that appears in a number of the same claims as "automatically." In its prior claim construction order, the court construed the term "without the need for human analysis" to mean "not requiring evaluation or choice by a human." 2 (Dkt. No. 173 at 21).

2 The court also noted that "[s]imply because human evaluation or choice is not required would not mean that human evaluation or choice is never allowed." Id.

Timeline argues that the patents expressly define "automatically" to mean "without the need for human analysis." To support this argument, Timeline points to the following sentence from the '511 patent specification:

Preferably, some or all of the analysis involved is performed automatically (i.e., without the need for human analysis), in one embodiment, using a properly programmed computer.

'511 patent, Col. 3:3-5 (emphasis added).

Timeline's argument that "automatically" and "without the need for human analysis" have identical meanings is not consistent with the Joint Claim Chart filed in February 2006, in which Timeline proposed somewhat different constructions of the two terms. As Timeline notes, a patentee may serve as his or her own lexicographer in defining claim terms. However, "[w]hen a patentee acts as his own lexicographer in redefining the meaning of particular claim terms away from their ordinary meaning, he must clearly express that intent in the written description." Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1370 (Fed. Cir. 2005). "[T]he statement in the specification must have sufficient clarity to put one reasonably skilled in the art on notice that the inventor intended to redefine the claim term." Id. Given that Timeline itself previously proposed somewhat different constructions of "automatically" and "without the need for human analysis" in the Joint Claim Chart, it would be difficult to conclude that the written description reflects a clear intent by the patentee to define "automatically" to mean "without the need for human analysis."

The Federal Circuit has also indicated that "[t]he use of [two] terms in close proximity in the same claim gives rise to an inference that a different meaning should be assigned to each." Bancorp Servs., L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367, 1373 (Fed. Cir. 2004); see also Primos, Inc. v. Hunter's Specialties, Inc., 451 F.3d 841, 848 (Fed. Cir. 2006) (holding that "the terms 'engaging' and 'sealing' are both expressly recited in the claim and therefore 'engaging' cannot mean the same thing as sealing'; if it did, one of the terms would be superfluous."). Here, the terms "automatically" and "without the need for human analysis" are sometimes used in close proximity in the same claims. For example, Claim 1 of the '511 patent reads, in part:

[U]sing said first driver to automatically obtain first information about the data structure of said first data source without the need for human analysis of the first data source by automatically accessing content of information…

(emphasis added). There is no apparent reason why the patentee would use "automatically" and "without the need for human analysis" in such close proximity in the same claim if the patentee intended the two terms to have identical meanings.

Defendants' proposed construction of "automatically" is "without user input or analysis." The court finds this construction to be more consistent with the ordinary meaning of the term and the intrinsic evidence. As Defendants note, the claims use the term "automatically" in the context of automatically obtaining information and automatically accessing content of information. Construing "automatically" to mean "without user input or analysis" is sensible in these contexts. Defendants also point to language in the '511 patent specification that contrasts actions that may be performed "automatically" to those that include user "input." See '511 patent, Col. 12:10-16 and Col. 12:27-32.
Therefore, the court adopts Defendants' proposed construction and finds that the term "automatically" means "without user input or analysis."

1. "automatically" or "automated" (claim 1)

Flow argues that this term should be construed as "performed without manual intervention." Omax acknowledges in its Markman brief that "this is generally the ordinary meaning of the term," but argues in the joint claim chart that this phrase "should be construed against Flow depending on the circumstances." In its Markman brief, Omax proposes that the Court find this term to be invalid or adopt a narrow construction of this term: "on-the-fly, in real time."

Omax's arguments for finding the term invalid lack merit. Omax seizes on a number of apparently contradictory references to the claim term to argue that the term is indefinite and therefore the claim invalid. Flow's alleged contradictions, however, would not affect the ability of an individual of ordinary skill in the art to understand the meaning of the term as used in the patent. Moreover, it is far from apparent that Flow has ever defined the term "automatically," as used in claim 1, as anything other than "performed without manual intervention." In light of Omax's acknowledgment that this is how someone of ordinary skill in the art would interpret this term, the Court adopts this construction.

4 Omax's proposed definition for this term seems far more fitting as a definition of "dynamically." This adds credence to Dr. Garris's argument that the prosecution history relied on by Omax refers to the static vs. dynamic issue, not the definition of automatically.

2. Automatic

Claim 1 describes a method for managing projects,

said method to be automatic in nature and with built in triggers which are based on the nature and status of said data without the need for manual project management coordination, said project management coordination to involve all the steps of the project management cycle including planning, resource leveling, status reporting and reminding, tracking and updating plans . . .

Def. Ex. A at col. 8, lines 49-55. Based on this language, Microsoft argues that Claim 1 is limited to a program which can automatically perform all steps of the project management cycle without the need for human intervention.

Again, the patent specifications and prosecution history support this limitation. The Patent Examiner initially rejected inventor Raj's patent application on the basis of obviousness. To distinguish his invention from prior art, Raj emphasized in a later amendment: "The inventor is not aware of any project management system . . . which performed the above 4 [project management] steps automatically, based only on data sent to a server" and that "none of the systems described by Michael Heck are automatic in their behavior with respect to the complete project management cycle." Def. Ex. B at 63-64. Raj further told the Patent and Trademark Office ("PTO") that "the [program] provides a method for hands-off project management. The complaint against project management tools has before this invention [sic] required experts to manage the project management cycle, including coordination, archiving, resource leveling, reminding etc." Def. Ex. B at 64. In particular, Raj noted that his invention improved on commercially available project management software such as defendant's Microsoft Project because, for such programs, "typically a project coordinator is hired by organizations to manually compile input data, run the tools and distribute progress reports." Def. Ex. B at 7. Thus, we conclude from the
inventor's statements that the patented method requires no human inputs in order to perform its specified management roles.

Plaintiffs dispute the notion that Claim 1's use of "automatic" means that the Program was intended to perform all steps of project management without human intervention. Plaintiffs have not offered any evidence drawn from the language of the Patent, its specifications or prosecution history to support their interpretation. Instead, plaintiffs point to Microsoft's use of the word "automatic" in its promotional materials, which we find irrelevant for purposes of this Markman hearing.

Plaintiffs are, however, correct in arguing that use of the Patent involves some human intervention. For example, in its description of the invention, the Patent provides that a human project leader "creates a project plan," containing "information on the project, tasks, dependencies and resources to be used." Def. Ex. A at col.7, lines 32-34; see also Def. Ex. A at fig.3. Similarly, a human manager must assign priorities for multiple projects in order for the Program to perform its algorithm-based function of allocating resources among multiple projects. See Def. Ex. A at col.7, lines 51-54. As discussed above, the periodic basis within which the Program performs specific functions is "as desired by . . . work group members." However, none of these features contradicts the clear language in the patent and its specifications and prosecution history that the Program is to perform all four steps of the project management cycle without human intervention. As the Patent states:

It should be noted that the operations of the 'Auto Multi-Project Server' are automatic (or self-running) and there is no manual intervention. Only at the staff-up stage is there any manual customization of the environment, by changing some of the program variables and setting up the environment file. In general the operation is driven by mail messages received from users. The 'Auto Multi-Project Server' responds to the messages and is thus 'event driven', though the response does not occur immediately but rather batched together for the end of day processing, as explained in the next paragraph.

Def. Ex. A at col.8, lines 7-16.

Accordingly, we find that Claim 1 teaches a method that automatically performs all of the steps in the project management cycle, without the need for manual intervention or supervision, based only on messages sent to the computer. As Microsoft points out, such a claim would not, for example, cover a method in which a human project leader resolved resource conflicts by manually reassigning resources among projects.

**323**

c. "Bus master configuring the bus automatically"

Claim 1 discloses that a "bus master configuring the bus automatically whenever a said instrument is either newly connected or is disconnected from said bus." '286 Pat. col.7 ll.17-19. KSEA argues that this term should be construed as "the bus master identifying and communicating with connected devices." (Proposed Constructions Chart 8.) S&N contends that it should be construed as "the bus master, without manual user intervention, is able to (i) control access to the bus by newly connected stations, and (ii) cease controlling stations disconnected from the bus, without interruption of the operation of the system in either situation." (Id.)

KSEA's proposed construction fails to acknowledge the bus master's expressly-disclosed configuration role and the notion that a bus master controls access to the bus, instead of merely identifying and communicating with stations on the bus. S&N's proposed construction accurately reflects the claim's text and the teaching of the specification.

The Court construes the "bus master configuring the bus automatically" term as "the bus master, without manual user intervention, is able to (i) control access to the bus by newly connected stations, and (ii) cease controlling stations..."
disconnected from the bus, without interruption of the operation of the system in either situation.

9 The Court does not define "without manual user intervention" to exclude, for instance, the possibility that a person connected a device to the bus.

15 Apropos contends that "automatically" as used in the phrase "automatically establishing voice communications," requires that the step of establishing voice communications between a called party and a calling party is initiated and performed without human intervention, i.e., without manual dialing, manual activation or other manual activity. For example, establishing voice communications by manually dialing or manually activating a connection using a button (such as on a phone, mouse, keyboard or other device) to initiate a call is not "automatically establishing voice communications." Additionally, Apropos argues, as used in the patent, "automatically dialing" requires that the step of dialing a telephone number be performed without human intervention, i.e., without manual activity. For example, initiating a call by manually dialing the digits or manually activating a connection using a button (such as on a phone, mouse, keyboard or other device) to initiate a call is not "automatically dialing."
Tr. at 236-37), reading the definition of "automatic" from the IEEE STANDARD DICTIONARY, "Automatic …[pertains] to a function, operation, process or device that … functions without intervention by a human operator." Without detailing all the relevant portions cited, the court, after reviewing the text, discerns that the only human intervention permitted in the "automatically dialing" phrase is the entry by the computer user of the information that permits the call center's telephone switching system to return the call. (Rockwell cites col. 1, l. 8-19, col. 2, l. 17-30, 51-67, and col. 4, l. 51 to col. 5, l. 42, in support of its position). For example, at col. 1, l. 17, the Background of the Invention portion recites, "... The computer user transmits a call request over the computer network to a telephone switching system associated with the agent and, in response to the call request, the telephone switching system calls the computer user and connects the agent to the computer user when the computer user answers the call." (Emphasis added.) The specification recites, "The telephone computer may detect the time to call in the call request and delay transmitting the call request to the ACD until the time to call. ... The ACD would then attempt to dial the telephone number substantially immediately upon receipt of the dial request command." Col. 4, l. 55-62 (Emphasis added). The unambiguous meaning of the text is that the computer detects the information in the call-back request and at the appointed time makes the call which can be routed to any available agent. The term "automatically establishing voice communication" also occurs without human intervention: "When the computer user answers the computer user telephone, the telephone switching system connects an agent telephone associated with the agent to the computer user telephone." Col. 2, l. 27-30 (emphasis added). The word "automatic" may, indeed, be nuanced in that typically some human action in a chain of events sets the automatic function in motion, but the circumstances described in the patent do not admit the notion that human intervention occurs either at the point of dialing or establishing the voice connection, such as an agent making a decision to push a button to activate a call back. The inventor, William Quayle, conceded as much. See (Ex. 23); (Quayle Dep. at 134-35); (Markman Tr. at 257-58) (testifying that "automatically establishing voice communications" does not include "where an agent must manually click on a mouse"). The prosecution history is equally clear. 16 For these reasons, the court accepts Apropos' definition of "automatically dialing" and "automatically establishing." 16 As Apropos pointed out, see discussion note 12, supra, the prosecution history demonstrates that the applicant overcame the initial rejection by asserting that the computer must activate the callback. See A 10052.

The term "automatically adjusting" shall mean: "changing at least one of the high voltage power supplies in a manner independent of external influence or control."
B. The Step-Plus Function Limitation

ICE argues that the remaining terms, "automatically administering credit on a unilateral basis," and "automatically deriving a respective dealable price message," are "step-plus-function Claims" and are limited by 35 U.S.C. § 112 P 6 (the "112(6) limitation"). Section 112 P 6 allows a patentee to "describe an element of the invention by the result accomplished or the function served, rather than by describing the element to be used." Warner-Jenkinson Co., v. Hilton Davis Chem. Co., 520 U.S. 17, 27, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997). According to 35 U.S.C. § 112 P 6:

An element in a claim for a combination may be expressed as a means or a step for performing the specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

35 U.S.C. § 112 P 6 (2000). However, "the price that must be paid for use of that convenience is limitation of the claim to the means specified in the written description and equivalents thereof." Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1208 (Fed. Cir. 2002) (citing to O.I. Corp. v. Tekmar Co., Inc., 115 F.3d 1576, 1583 (Fed Cir. 1997)). As such, the patentee shoulders "the duty to link or associate structure in the specification with the function [as] the quid pro quo for the convenience of employing the [statute]." B. Braun Med., Inc. v. Abbott Lab., 124 F.3d 1419, 1424 (Fed. Cir. 1997). However, if the patentee fails to sufficiently describe the structure, material, or act to which the function corresponds, the claim is overbroad and therefore, invalid. Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1376 (Fed. Cir. 2001) ("Failure to disclose adequate structure corresponding to the recited function in accordance with 35 U.S.C. § 112, paragraph 1, results in the claim being of indefinite scope, and thus invalid, under 35 U.S.C. § 112, paragraph 2.").

In O.I. Corp. v. Tekmar Co., 115 F.3d 1576 (Fed Cir. 1997), the Federal Circuit analyzed whether the 112(6) limitation applies to a "step" or "method" claim as opposed to when it limits an apparatus claim. The Federal Circuit concluded that "the term 'steps' [refers] to the generic description of elements of a process and the term 'acts' [refers] to the implementation of those steps," and that the 112(6) limitation "is implicated only when steps plus function without definite acts are present." See O.I Corp. at 1583 (emphasis added). The Federal Circuit reasoned that: "Claiming a step by itself, or a series of steps, does not implicate section 112, P 6. Merely claiming a step without recital of a function is not analogous to a means plus a function." O.I. Corp., 115 F.3d at 1583 (Fed. Cir. 1997); Cardiac Pacemaker, Inc., v. St. Jude Med., Inc., 381 F.3d 1371, 1382 (Fed. Cir. 2004) (A method claim "necessarily recites the steps of the method.").

The Federal Circuit reviewed a patent which claimed: "A method comprising the steps of: (a) passing an analyte slug through a passage." O.I Corp., 115 F.3d at 1578. The Federal Circuit held that the act of "passing an analyte slug through a passage" did not constitute a function simply because the operative verb was in the imperfect tense, "such as passing, heating, reacting transferring etc." Id. The Federal Circuit noted that if it were "to construe every process claim containing steps described in an 'ing' verb," then every process claim would be subject to the 112(6) limitation. Id.; see also Cardiac Pacemaker, Inc., 381 F.3d at 1371 (Fed. Cir. 2004) ("[A] patentee can define a method or process claim containing steps that begin with a gerund . . . without necessarily subjecting the claim to § 112 P 6 limitations."). While it indicated that verbs in the imperfect tense do not in themselves implicate the 112(6) limitation, the Federal Circuit left it to the trial courts to establish whether a claim element was a function or an act.

The Federal Circuit subsequently clarified when claim language is to be construed as a function as opposed to an act in Masco v. United States, 303 F.3d 1316 (Fed. Cir. 2002). In Masco, the Federal Circuit expanded upon its reasoning in O.I. Corp., and further advised when claim language describes acts or functions:

The "underlying function" of a method claim element corresponds to what the element ultimately accomplishes in relationship to what the other elements of the claim and the claim as a whole accomplish. "Acts," on the other hand, correspond to how the function is accomplished.

Masco, 303 F.3d at 1327 (citing to Seal-Flex, Inc. v. Athletic Track and Ct. Constr., 172 F.3d 836, 849-50 (Fed. Cir. 1999) (per curiam) (Rader, J., concurring) (emphasis in original)). The Federal Circuit held that "where a method claim does not contain the term 'steps for,' a limitation of that claim cannot be construed as a step-plus-function limitation without a showing that the limitation contains no act." Masco, 303 F.3d at 1327 (emphasis added). Indeed, if any act is present in the claim element language, then the 112(6) limitation is inapplicable to the claim element. In Masco the claim language was, "The method comprising the steps of . . . transmitting a force . . . to drive the lever into a position where the protrusion can
contact the surface of the cam wheel," and the Federal Circuit determined that both a function and an act were present. Masco, 303 F.3d at 1327. While the underlying function of "transmitting a force" was "to drive the lever into the cam," the Federal Circuit found that "transmitting" was an act, and "a limitation of a claim cannot be construed as a step-plus function limitation without showing that the limitation contains no act." Id. at 1327-28. Accordingly, under the Federal Circuit's holdings in O.I. Corp. and Masco the 112(6) limitation applies when:

(1) the claim limitation uses the phrase "step for"; (2) the "step for" is modified by functional language; and (3) the phrase "step for" is not modified by sufficient structure, material, or acts for achieving the specified function.

Here, relying on Masco ICE contends, Claim 17 does not contain acts, but rather merely states functions. (Harrison, Att'y for Def., Hr'g Tr. 63: 12.) In other words, ICE asserts that Claim 17 states what the elements of the claim ultimately accomplish (the function), but does not state how the function is accomplished. Id. ICE asks: "Where is the how?" Id. In opposition, EBS asserts that, similar to the language in O.I. Corp., the terms are just a recital of steps that do not state a function. (Siff. Att'y for Pl., Hr'g Tr. 10: 7-8.)

In accordance with Masco and O.I. Corp., the 112(6) limitation does not apply for two reasons. First, the disputed claim does not contain the language "step for" and, therefore, the 112(6) limitation is presumed not to apply. Second, as the Federal Circuit found in both O.I Corp and Masco, the operative verbs "administering" and "deriving" do not themselves indicate the presence of functions.

First, it is undisputed that Claim 17 of the '627 Patent does not contain the language "step for." U.S. Patent No. 6,014,627 (issued January 11, 2000). As noted, the lack of the language "step for" generally signals that an act, rather than a function, follows. See Cardiac Pacemaker, Inc., 381 F.3d at 1382. While not dispositive, "such a grammatical structure indicates that this is not a step-plus function claim," or at least creates a heavy "presumption that each ensuing step is [not] in step-plus function form." Amgen, Inc. v. Hoechst Marion Roussel, Inc., 339 F. Supp. 2d 202, 255 (D. Mass. 2004); see also Cardiac Pacemaker, Inc., 381 F.3d at 1382; Epcon Gas Sys., Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1028 (Fed. Cir. 2002); Seal-Flex, Inc. v. Athletic Track & Ct. Constr., 172 F.3d 836, 850 (Fed. Cir. 1999) (Rader, J., concurring); Supp. Exam. Guidelines for Determining the Applicability of 35 U.S.C. § 112 P 6, 65 Fed. Reg. 38510 (June 21, 2000) ("[A] claim element that does not include the phrase [] "step for" will not be considered to invoke 35 U.S.C. 112, 6.").

Second, as in both the O.I Corp. and Masco, the disputed terms in Claim 17 are steps without functions. The verbs "administering" and "deriving" can be analogized in use and form in their respective claim elements to the verbs "passing" and "transmitting" in O.I Corp. and Masco, respectively. Additionally, as neither the claim language nor dictionaries of the art explicitly ascribe these verbs meanings particular to "traders dealing in financial instruments," they are interpreted according to their ordinary meaning in their respective clauses. According to their ordinary meaning in their respective clauses, the phrases "automatically administering credit on a unilateral basis" and "automatically deriving a dealable price message" do not state "what" is accomplished, but rather state steps as to "how" the ultimate function of Claim 17 accomplishes, the "trading of financial instruments between traders." U.S. Patent No. 6,014,627 (issued Jan. 11, 2000).
As such, the remaining terms do not implicate section 112 P 6. Phrased in the "what" and "how" language of Masco, "administering" in the sense of dispensing, furnishing or tendering, describes how "administering credit on a unilateral basis" is performed. See Webster's Third New International Dictionary of the English Language Unabridged 27 (1993) ("Administer: to mete out, dispense."); see also Webster's Third New International Dictionary of the English Language Unabridged 27 (1993) ("Administration: furnishing or tendering according to a prescribed act."). Additionally, the '627 Patent itself suggests that "administering" means dispensing according to a prescribed act: "Each client site establishes and may subsequently vary or reset a credit limit for each possible counterparty." U.S. Patent No. 6,014,627 (issued Jan. 11, 2000). "Deriving" in the sense of gathering and arriving at a conclusion by deduction, is an act which describes how "deriving a dealable price message" is performed. See Webster's Third New International Dictionary of the English Language Unabridged 608 (1993) ("Derive: to gather or arrive at (as a conclusion) by reasoning and observation; deduce."); see also American Heritage Dictionary of the English Language 489 (4th ed. 2000).

Consequently, the terms "automatically administering credit on a unilateral basis" and "automatically deriving a respective dealable price message" are not subject to § 112 P 6.

1. "Automatically Administering Credit on a Unilateral Basis"

As Claim 17 is not subject to § 112 P 6, I construe the remaining terms in accordance with the claim language in light of the relevant industry standards, the plain language of the terms, and with an eye to what one knowledgeable in the field would find appropriate. EBS avers that consistent with the Claim itself, and the ordinary meaning of the Claim terms, the phrase "automatically administering credit on a unilateral basis" should be construed as:

Keeping track, without user intervention, of whether each trading floor extends credit to the other trading floors, on a one-way basis.

(Siff, Att'y for Pl., Hr'g Tr. 31: 2-4.) ICE, on the other hand, argues that § 112 P 6 applies and does not propose any construction of the terms in the absence of its application.

The term "automatically administering credit on a unilateral basis" consists of four terms, (i) "automatically," (ii) "administering," (iii) "credit," and (iv) "unilateral basis."

First, the parties do not dispute that "automatically" does not have any special meaning, and that it means "without user intervention," (Siff, Att'y for Pl., Hr'g Tr. 27: 12-13), a definition pretty much in line with the American Heritage Dictionary of the English Language, 112 (4th ed. 2000), which defines "automatically" as the adverbial tense of "automatic" meaning: "acting or operating in a manner essentially independent of external influence or control; acting or done as if by machine; mechanical."

Second, "administering," as defined above in Webster's Third New International Dictionary of the English Language Unabridged, 27 (1993), is: "to mete out; dispense." As aforementioned, "administering" is also supported by the Claim language to mean, dispensing according to a prescribed act.

Third, "credit," according to The McGraw-Hill Dictionary of International Trade and Finance, 96 (McGraw-Hill 1994), means "in finance, an agreement to provide money, goods, or services in exchange for a borrower's promise to pay at a future date." Similarly, the Dictionary of Finance and Investment Terms, 117 (4th ed. 1995), defines "credit" as:

Loans, bonds, charge-account obligations, and open account balances with commercial firms. Also, available but unused bank letters of credit and other standby commitments as well as a variety of consumer credit facilities.

Fourth, Claim 17 of the '627 Patent uses the term "unilateral basis" as involving an independent, one-sided action: "From those other trading floors for which bilateral credit currently remains both from and to a particular trading floor." U.S. Patent No. 6,014,627 (issued Jan. 11, 2000).

As such, reading the '627 Patent in light of the relevant industry standards and the ordinary meaning of the terms, at least insofar as current dictionary definitions are concerned, the contested language must follow the EBS construction and be
construed as:

Keeping track, without user intervention, of whether each trading floor extends credit to the other trading floors, on a one-way basis.

5. The Displaying Step

The "displaying step" of Claim 1 provides as follows: "automatically and simultaneously displaying at the programmed computer in real time the current status information of at least a portion of the delegated instructions received from each two-way communication device." '877 Patent col.32 ll.41-45.

Papyrus suggests that the court construe the step as meaning "the simultaneous display at the programmed computer of some current-status information for one instruction and some current-status information for another instruction." Pl. PCCO 2. In effect, Papyrus focuses on the content of the information displayed on the programmed computer and relies primarily on the language in the specification. Pl. MHSP vol. 1 at 25-28. For example, although the claim language itself expressly references the programmed computer as the display location of the current-status information, it makes no reference to displaying on the floor broker's HHD. See '877 Patent col.32 ll.41-45. In addition, the Abstract also discusses displaying current-status information at the programmed computer. '877 Patent Abstract ("A related method enables an operator to delegate instructions . . . by receiving at the operator's computer current-status information on any delegated instructions and automatically displaying that information at the computer." (emphasis added)). In addition, Papyrus contends that the displaying step requires only the "simultaneous display of current-status information for at least two instructions at the programmed computer." Pl. MHSP vol. 1 at 25.

NYSE, however, asks the court to define this step to mean "the current-status information is displayed both on the programmed computer and the two-way communication device at the same time." Def. PCCO 2. Despite Papyrus's argument that the claim language does not make any reference to a display on the HHD, NYSE asserts that the current-status information is displayed simultaneously on the broker's device and the programmed computer. Markman Hr'g Tr. vol. 1 at 123-124. Relying on the prosecution history, 14 NYSE argues that the current-status information is displayed simultaneously on the broker's device and the programmed computer. Markman Hr'g Tr. vol. 1 at 123-124. Relying on the prosecution history, 14 NYSE argues that the current-status information is displayed simultaneously on the broker's device and the programmed computer. 11. The September 8, 2007 amendment is the first time that the phrase "automatically and simultaneously" appeared in the patent. Rule 1.116 Amendment in Application Serial No. 08/309,337 (Sep. 8, 1997), Pl. App. Ex. 12 at 206.

To construe the displaying step, the court must therefore determine whether the examiner's statements reflect express representations made by Papyrus, or whether the statements are evidence of unilateral action on the part of the examiner. Although the prosecution history is intrinsic evidence that aids the court in claim construction, it "cannot enlarge, diminish, or vary the limitations in the claims." Markman, 52 F.3d at 980 (quotations omitted). The prosecution history includes "all express representations made by or on behalf of the applicant to the examiner to induce a patent grant," as well as amendments to the claims and arguments made to convince the examiner. Standard Oil Co. v. Am. Cyanamid Co., 774 F.2d 448, 452 (Fed. Cir. 1985). "Arguments made during the prosecution of a patent application are given the same weight as claim amendments," and both give rise to prosecution history estoppel. Elkay Mfg. Co. v. EBCO Mfg. Co., 192 F.3d 973, 979 (Fed. Cir. 1999). Although "an examiner's reasoning and findings are highly relevant to the validity inquiry . . . they are not beyond challenge and they do not in every case automatically preclude the existence of a dispute of material fact." TorPharm Inc. v. Ranbaxy Pharm., Inc., 336 F.3d 1322, 1329 (Fed. Cir. 2003). Because the Federal Circuit "has recognized that an Examiners Statement of Reasons for Allowance 'will not necessarily limit a claim," an applicant's "silence regarding statements made by the examiner during prosecution, without more, cannot amount to a 'clear and unmistakable disavowal' of claim scope." Salazar v. Procter & Gamble Co., 414 F.3d 1342, 1345 (Fed. Cir. 2005) (quoting 3M Innovative Props. Co. v. Avery Dennison Corp., 350 F.3d 1365, 1373-74 (Fed. Cir. 2003)). Consequently, "the applicant has no obligation to respond to an examiners statement of Reasons for Allowance, and the statement of an examiner will not necessarily limit a claim." Eolas Techs., Inc. v. Microsoft Corp., 399 F.3d 1325, 1337-38 (Fed. Cir. 2005) (quotations omitted); see Acco Brands, Inc. v. Micro Sec. Devices, Inc., 346 F.3d 1075, 1079 (Fed. Cir. 2003). Nevertheless, an applicant or patent owner may commit to a particular meaning for a patent term "through statements made during prosecution" which are then "binding in litigation." CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1158 (Fed. Cir. 1997). Further, "the public is entitled to equate an inventors acquiescence to the examiners narrow view of patentable subject matter with abandonment of the rest. Such acquiescence may be found where the patentee narrows his or her claims by amendment." TorPharm, Inc., 336 F.3d at 1330 (emphasis added).

Here, Papyrus contends that (a) the examiner mischaracterized the displaying step in both the interview summary and the Statement of Reasons for Allowance, and (b) the "automatic and simultaneous display" language was all that was needed to circumvent the prior art. Pl. Reply Br. 5. The court agrees. The record shows no evidence that Papyrus sought to limit the claim in such a way. Neither the proposed Claim 50 (now Claim 1) language attached to the Interview Summary nor the proposed language in the September 8, 1997 amendment contains any reference to information being simultaneously displayed on both the HHD and the programmed computer. See Pl. App. Ex. 11 at 202; Pl. App. Ex. 12 at 206. Indeed, the phrase "both on the floor broker's display [and] the booth operator[s'] display" appears only in documents issued by the examiner. Pl. App. Ex. 11 at 201; see Pl. App. 14 at Ex. 212. Moreover, the text of the amendment, which represents the arguments that Papyrus made to convince the examiner and induce the patent grant, makes no reference to the displaying of current-status information on the HHD. Papyrus therefore did not seek to induce a patent grant based on the content displayed on the HHD, as NYSE alleges. See Standard Oil Co., 774 F.2d at 452. In discussing the real-time nature of the invention in connection with the current-status information, Papyrus specifically stated that "[i]nsofar as the Examiner indicated in the Interview Summary that the automatic and simultaneous display of information in real-time differs over the art of record, the inclusion of the calculating step should not negate allowability." Pl. App. Ex. 12 at 207. Addressing the prior art, the amendment also states that "[t]he [Sisley] patent does not teach the provision of two-way devices nor does it teach the use of, or access to, current-status information as called for in the pending claims. These features provide the operator of the programmed computer with a distinct advantage over prior art schemes . . . ." Pl. App. Ex. 12 at 208 (emphasis added); see Method and Resource Assignment and Scheduling, U.S. Patent No. 5,467,268 Abstract (issued Nov. 14, 1995), Pl. App. Ex. 71 at 917. 16 Because the record evidence shows that Papyrus repeatedly proposed consistent language which made no reference to the HHD display, the examiner's statements were unilateral and therefore do not limit the claim. See Salazar, 414 F.3d at 1345-46. Furthermore, that Papyrus did not respond to the examiner's statements does not indicate acquiescence to the examiner's interpretation, particularly since the language of the September 8, 1997 amendment does not support the examiner's written statements. See Eolas Techs. Inc., 399 F.3d at 1337-38. For these reasons, the court construes the displaying step as meaning "the current status information for one instruction and some current-status information for another instruction may be simultaneously displayed."
1. "automatically answering incoming telephone calls"

Klausner believes this term need not be construed while Vonage contends that this term should be construed to mean "sensing an incoming ring signal on the called party's telephone line and putting the called party's telephone line in an off-hook state." To support its contention, Vonage primarily relies upon Figures 3A and 3B and the corresponding text in the specification, arguing that these figures "illustrate" the "answer mode of the present invention" and not merely an embodiment of the invention. See Col. 3:27-28; Col. 6:10-11. Vonage also contends, essentially, that because the specification describes a single way of "answering incoming telephone calls," the term should be limited to that embodiment. In response, Klausner asserts that Vonage is improperly limiting the phrase to a specific embodiment. The Court agrees with Klausner.

It is important to remember that although the specification often describes very specific embodiments of the invention, the Federal Circuit has cautioned against confining the claims to those embodiments. See Phillips, 415 F.3d at 1323. The roles of the specification are to "teach and enable those of skill in the art how to make and use the invention and to provide a best mode for doing so. One of the best ways to teach a person of ordinary skill how to make and use the invention is to provide an example of how to practice the invention in a particular case." Id. "[T]he claims of the patent, not its specifications, measure the invention." Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1116 (Fed. Cir. 2004) (citation omitted). "Accordingly, particular embodiments appearing in the written description will not be used to limit claim language that has broader effect. And, even where a patent describes only a single embodiment, claims will not be 'restrictively unless the patentee has demonstrated a clear intention to limit the claim scope 'using words or expressions of manifest exclusion or restriction.'" Id. at 1117 (citations omitted).

Vonage argues that, where the patent specification makes clear that what is described is "the invention" rather than simply "an embodiment" of the invention, the claims may be limited to that description. It is true that where a patent clearly indicates that the description is that of "the invention" and not simply "an embodiment," that indication should be taken into account in construing the claim terms at issue. However, as is discussed below, in this particular case, the patent specification is not so clear as to be directing its description, in any aspect, to "the invention" as opposed to an embodiment of the invention.

The Court begins, as it must, with the words of the claim. See Teleflex, 299 F.3d at 1324; see also CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002) ("The terms used in the claims bear a presumption that they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art."). Vonage does not rely on the language of Claim 3 to support its contention. Indeed, Claim 3 cannot be read to define the term as Vonage suggests. Claim 3 simply requires a "method of automatically answering incoming telephone calls and storing and retrieving information from the incoming telephone calls." While not determinative, Klausner presents evidence, which Vonage does not meaningfully dispute, that one skilled in the art would understand "automatically answering telephone calls" as answering telephone calls without human intervention and not limited in the fashion Vonage proposes. See Ex. 25 to Pl.'s Claim Const. Br. PP 26-28.
Vonage argues that Figures 3A, 3B, 4 and 5 are described as "illustrating [various features] of the present invention." According to Vonage, this language clearly indicates that what is shown in these Figures represents the invention itself and is not simply illustrative of an embodiment of the invention. The Figures are first discussed in the section titled "Brief Description of the Drawings." This section begins with the statement that the "above and other objects and advantages will become apparent to those skilled in the art upon reviewing the detailed description of the preferred embodiments in conjunction with a review of the appended drawings." See Col. 3:18-21. These drawings are then further discussed in the section titled "Detailed Description of the Preferred Embodiments." This section concludes with the statement that "[w]hile the embodiments shown and described are fully capable of achieving the objects of the invention, it is to be understood that these embodiments are shown only for the purpose of illustration and not for the purpose of limitation." Col. 12:61-64.

At several points in the discussion of Figures 3A and 3B, the figures are described as "preferably" containing certain characteristics. See, e.g., Col. 6:30-31 ("The microcontroller then preferably multiplies this number by 6 . . ."); Col. 6:44-45 ("The OGM is preferably stored as message # 1 in memory 2."); Col. 6:48-49 ("When the playing of the OGM is completed, the microcontroller preferably waits 5 seconds (block 160).""). While Vonage argues the description of Figures 3A and 3B define what is meant by answering an incoming telephone call, Vonage does not request that other characteristics of the figures be included in the definition of the term. See, e.g., Col. 6:14-24 ("As illustrated in Fig. 3, the TAD first determines if the user has pressed a key on the TAD (Decision Block 100). This is done by means of the microcontroller reading RS232 serial data port connected to the touch screen 5 through connection to determine if the screen has been touched.").

Moreover, Figure 3B includes a "DTMF DECODE ROUTINE 230", which is further described in Figure 5. And, as Vonage points out in its brief, Figure 5 uses the "present invention" language in describing Figure 5 as "illustrating a flow chart illustrating the DTMF decode routine of the present invention." However, at column 9, lines 51-54, the patent specification states that "[i]t is to be understood that any incoming signals over the telephone line with a voice message that is recognizable by the TAD and is generally unique to the caller may be used instead of DTMF tones." Thus, the patent specification is clear that DTMF tones need not be used, and accordingly, the DTMF decode routine of Figure 5, and as shown in Figure 3B, need not be used. Rather, other incoming signals may be used instead. The clear implication of the patent specification, taken as a whole and not focusing strictly on the descriptions of the Figures, is that Figures 3A and 3B illustrate an embodiment of the invention, an embodiment in which DTMF tones, and a DTMF decode routine are used.

Vonage does not cite the Court to a case where the Federal Circuit has held that describing figures as "illustrating . . . the present invention" alone amounts to a clear intention to limit claim scope to a specific embodiment taught in the specification. See Innova/Pure Water, Inc., 381 F.3d at 1117. It is worth noting that the terms "illustrating," "illustrates," and "illustrated" are used throughout the patent. See, e.g., Col. 3:42-43 ("Fig. 10 is an illustration of the display recalling information linked to one of the callers."); Col. 3:44-45 ("Fig. 11 is a flowchart illustrating a typical operation of the present invention."); Col. 3:65-66 (Fig. 1 illustrates the front perspective view of a telephone answering device (TAD) 25 according to the invention."); Col. 6:14 ("As illustrated in Fig. 3 . . ."). Thus, the term "illustrating" would not seem to necessarily lead to the conclusion that claim scope is limited to the "illustrated" embodiments.

The specification does not teach that the specific embodiment described in the figures is somehow important or vital to what is claimed. Put another way, the specification does not teach that this embodiment is the only way to accomplish the answer mode of the invention. Indeed, as already pointed out, Vonage does not request that all features shown in Figures 3A and 3B be incorporated into "the invention" as claimed. If Figures 3A and 3B were considered as illustrating "the invention" instead of simply an embodiment, the Court would not be at liberty to pick and choose which aspects of Figures 3A and 3B to include and which to not include. And the specification does not provide guidance as to how such determinations might be made.

Vonage also asserts that during prosecution of the '576 patent, Klausner expressly distinguished methods of automatically answering telephone calls with a "telephone answering device" from methods using a computer-based voice messaging system. See Ex. 2 to Vonage's Claim Constr. Br. at 12. The Court disagrees. The cited excerpt from the prosecution history shows the inventors arguing that there was no motivation or suggestion to combine a 1981 patent issued to Klausner and U.S. Patent No. 5,003,577 issued to Ertz. The Court does not find this portion of the prosecution history to disclaim computer based voice messaging systems, but rather to be addressing the examiner's conclusion that certain claims were obvious in light of the referenced prior art.

The Court is not persuaded that one skilled in the art would read the intrinsic evidence as containing explicit expressions of
exclusion or restriction such that the answer mode of the invention was limited to the embodiment set forth in Figures 3A and 3B. Cf. Scimed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1342 (Fed. Cir. 2001) (noting that the common specification leads to the "inescapable conclusion" that patents had disclaimed a particular configuration). Further, the Court finds this phrase understandable to a juror in the context of the claims at issue and, therefore, does not require construction.

G. "Automatically apply or compare the internet media venue design or style standards to the information input by the seller or the advertisement" & "Automatically apply or compare the internet media venue distribution factors to the information input by the seller or the advertisement"

Claim 62 of the '025 patent states, "The computer system of claim 45, wherein the presentation rules of the internet media venue comprise design or style standards, further comprising a computer program design filter to automatically apply or compare the internet media venue design or style standards to the information input by the seller or the advertisement to control look and feel of the advertisement to be displayed on the internet media venue." Similarly, claim 90 states, "The computer system of claim 62, wherein the internet media venue presentation rules comprise distribution factors, further comprising a computer program distribution filter to automatically apply or compare the internet media venue distribution factors to the information input by the seller or the advertisement to determine whether to publish the advertisement to the internet media venue." FM proposes that these claims should be defined as "execute a systematic sequence of mathematical and/or logical operations to apply or compare the internet media venue's design or style standards / distribution factors> to the information input by the seller or to the advertisement." Google advances the same indefiniteness arguments that the court rejected in Section F. The court construes the term "automatically apply or compare the internet media venue design or style standards to the information input by the seller or the advertisement" to mean "execute a systematic sequence of mathematical and/or logical operations to apply or compare the internet media venue design or style standards to the information input by the seller or to the advertisement." Likewise, the court construes the term "automatically apply or compare the internet media venue distribution factors to the information input by the seller or the advertisement" to mean "execute a systematic sequence of mathematical and/or logical operations to apply or compare the internet media venue's distribution factors to the information input by the seller or to the advertisement."
i. The Parties' Proposed Constructions

Smiths argues that "automatically control" means "to automatically control in response to a blood glucose reading." (D.I. 165 at 2.) Smiths states that:

in each initial usage of the term "automatic" or "automatically," it is used in the context of operating the infusion pump in response to a blood glucose reading. As such, the term 'automatically controlling' as recited in claims 1 and 19 means to 'automatically control' in response to a blood glucose reading.

(D.I. 190 at 19.) Smiths further argues that where I to construe "automatically controlling" without reference to a blood glucose reading such construction would constitute new matter not disclosed in the '065 patent application. (Id.) Therefore, Smiths argues, its construction is necessary to avoid invalidity of the patent.

MiniMed contends that the term "automatically control" is part of the function of the "controller means" limitation. (D.I. 214 at 17.) Consequently, it contends, adding the "responding to a blood glucose reading" limitation impermissibly adds a functional limitation to the term "control means." (D.I. 214 at 17 (citing Wenger Mfg., Inc. v. Coating Mach. Sys., Inc., 239 F.3d 1225, 1233 (Fed. Cir. 2001)(holding "a court may not import functional limitations that are not recited in the claim").)

ii. The Court's Construction

Contrary to MiniMed's assertion, Smiths is not arguing for the importation of functional limitations into the claim. Smiths is arguing that one of ordinary skill in the art would understand "automatically controlling" to mean "automatically controlling in response to a blood glucose reading." (D.I. 218 at 3.) That being said, I nevertheless reject the argument that one of ordinary skill in the art would understand "automatically controlling" to have that meaning.

"The general rule is that terms in the claim are to be given their ordinary and accustomed meaning." K-2 Corp., 191 F.3d at 1362. Neither party has argued that there is any ambiguity as to the meaning of "automatically controlling." The fact that "automatically" was used in a different context in the prosecution history is of little significance. Smiths does not even argue that the patentee acted as his own lexicographer and redefined the word "automatic" or the phrase "automatically controlling." (D.I. 190 at 18-19.)

I also find unpersuasive Smiths' argument that giving "automatically controlling" its plain meaning would raise issues of invalidity. "Claims can only be construed to preserve their validity where the proposed claim construction is 'practicable,' is based on sound claim construction principles, and does not revise or ignore the explicit language of the claims." Generation II Orthotics, Inc. v. Medical Tech., Inc., 263 F.3d 1356, 1365 (Fed. Cir. 2001). Smiths' proposed construction of "automatically controlling" is not based on "sound claim construction principals," and must be rejected. See id. Consequently, I find the term has its plain meaning.
evaluation," and not a function. For its part, Glory urges this Court to read "automatically denominating" as a "function" that limits these claims, under the step-plus-function doctrine found in 35 U.S.C. § 112(6), to the structure, material or acts identified in the written specifications of the '806 patent necessary to perform that function. After careful review of the disputed claim language in the '806 patent, this Court finds that the term "automatically denominating" is subject to Section 112(6) because it discloses a function without disclosing the structure, material or acts necessary to perform it. 5

5 Hereinafter, the Court will refer to the components necessary to perform the denominating function as a "structure" even though many of these components resemble acts rather than material or a structure made of material. We choose this word, not because it has any special meaning under § 112(6), but because use of the word "acts" -- in the context of the arguments made by Cummins would be confusing.

We begin construction of the disputed claims with the plain and ordinary words of the patent claim itself. Johnson Worldwide Assocs., Inc. v. Zecco Corp., 175 F.3d 985, 989-90 (Fed. Cir. 1999). If the scope of the claims cannot be unambiguously determined by reference to the plain language in the disputed claims, then the Court may interpret the disputed claim language in light of the specifications and prosecution history. Id.

The dictionary meaning of "denominating" (or "denominate") is "to name" or to "designate." MERRIAM WEBSTER'S COLLEGIATE DICTIONARY, at 308-09 (10th ed. 1997). Cummins conceded during oral argument that the word "denominating" in the context of the '806 patent claims at issue means more than "to name" and, instead, embraces both identifying the denomination of a bill of currency (that is, whether a piece of currency is a $1, or a $5, or a $10 bill), and discriminating among spurious or "bad bills" (those that cannot be identified as genuine) and "good bills" (those that can be identified as genuine).

There is no real leap of logic or linguistics in Cummins' concession. Claim 40 refers to the accumulation in the output bin of "a set of bills, all of whose denominations are known, including bills of a plurality of denominations" (here, the word "denominations" may carry its dictionary meaning) (Col. 33, lines 50-52) (emphasis added). Claim 76 refers to delivery of bills to the output bin that have been successfully evaluated" (Col. 36, line 50), and Claim 101 refers to placing bills in the input bin "to be evaluated" (Col. 38, line 40). To perform this evaluation, the currency device must necessarily "know" the bills that it is evaluating. For several reasons, we construe this dual purpose encompassed within the phrase "automatically denominating" as the disclosure of a function rather than a discrete action for performing some other function.

First, to "denominate," in the way the disputed claim term is written, the device must perform multiple acts to achieve the end results of identification and discrimination. For example, the device must optically scan the narrow portion of the bill, compare the scanned data with the correlation data stored in the software, and stop the machine when a bill is identified as spurious, so that it may be removed from the output bin. The term "automatically denominating" is shorthand for this series of acts which result in an "evaluation," and which, in turn, constitutes the underlying function for the entire invention and for the claims at issue. In the words of the Seal-Flex test, the term automatically denominating "corresponds to what that element ultimately accomplishes in relationship to what the other elements of the claim and the claim as a whole accomplish." 172 F.3d at 849-50.

Second, if we accepted Cummins' invitation to construe "automatically denominating" as an "act" for performing the evaluation of U.S. currency, and to stop reading at the literal language, then the '806 patent would achieve a virtual monopoly in the currency evaluation device market (as we understand it), because it would cover any method for evaluating (i.e., identifying and discriminating among) a plurality of U.S. currency and thus any "structure" for achieving that function. A claim "cannot be construed so broadly to cover every conceivable way or means to perform" that function. Mas-Hamilton Group, 156 F.3d at 1214. Moreover, as we discuss below, such a reading also would create serious validity problems with respect to prior art. We decline to read the patent language in a way that likely would invalidate the patent.

Third, both the identification and discrimination aspects of the claimed "automatically denominating" function necessarily require a structure for culling out spurious bills from those that are genuine and thus ultimately "denominated" or named. But, the disputed claims fail to disclose any structure for performing that function. Thus, this Court finds that the claim
language, read plainly, supports the view that disputed claims 40, 76 and 101 are step-plus-function claims subject to the limitations of Section 112(6).

6 The cases Cummins cites to support the notion that "automatically denominating" is an act are inapposite to the disputed claim term in this case. First, we do not accept the proposition that the decision in O.I. Corp. v. Tekmar Co., 115 F.3d 1576 (Fed. Cir. 1997), precludes a finding that a verb ending in "ing" cannot be written as a function subject to § 112(6). We read O.I. Corp. merely to warn against a blanket rule that every "ing" verb used as an element in a method claim is subject to the statute. Id. at 1583. Second, we find Masco Corp. v. United States, 303 F.3d 1316 (Fed. Cir. 2002) and Serrano v. Telular Corp., 111 F.3d 1578 (Fed. Cir. 1997) -- as well as the other cases cited by Cummins in its reply -- inapposite on the issue of whether "automatically denominating" is an act, rather than a function. In Masco, the term "transmitting a force" was construed as an act rather than a function. The federal circuit rejected the argument that the word "transmitting" was too amorphous to be an act and instead used the Seal-Flex test to determine that "transmitting a force" in the context of the disputed claims in that case was an act for performing the function of "driving the lever into the cam." 303 F.3d at 1327. The Court also found that the plain meaning of the word "transmitting" in the dictionary "described an act for accomplishing the identified function." Our case is distinguishable from Masco because "denominating" has a special meaning given to it by the inventor and cannot be reduced to a plain, dictionary definition that discloses an act for performing some other function; "denominating" is, as we explain above, a function (and we think too amorphous to be an act). The Serrano case is also distinguishable because we do not find the term "automatically denominating" to be "practically identical" to the phrase "automatically determining" -- as Cummins contends (Cummins Reply at 31). "Automatically determining," in the context of the Serrano claim, was an act. For the reasons we have explained, we do not find "automatically denominating" to be in the same category, given Cummins' special and conceded meaning for it.

Construing "automatically denominating" in the disputed claims as a step-plus-function claim element means that this element will be construed narrowly and limited in scope to only the structure necessary for performing the denominating (i.e., identification and discrimination) function. See, e.g., Overhead Door Corp. v. Chamberlain Group, 194 F.3d 1261, 1271-73 (Fed. Cir. 1999). Both the written specifications and the prosecution history are consulted to answer the question of scope presented by the step-plus-function claims. See id. There may be only one structure disclosed in the specification and/or prosecution history that performs the claimed function, Cortland Line Co. v. Orvis Co., 203 F.3d 1351, 1357 (Fed. Cir. 2000), or there may be more than one structure disclosed for performing the recited function. Ishida Co. v. Taylor, 221 F.3d 1310, 1316 (Fed. Cir. 2000). The proper claim construction identifies all the relevant and/or alternative structures necessary to perform the function and allows the disputed claim to cover all of them. Ishida, 221 F.3d at 1316.

It is important to remember, however, that "before finally concluding" that a disputed term "encompasses" several alternative meanings and/or structures, the court "must determine whether the specification or prosecution history clearly demonstrates that only one of the multiple meanings [and/or structures] was intended." Inverness Medical Switzerland GmbH v. Warner Lambert Co., 309 F.3d 1373, 1378 (Fed. Cir. 2002). This search for a single limitation is not to be confused with the well-settled rule against incorporating preferred embodiments "such as those often present in a specification" into a claim limitation. Id. (quoting Laitram Corp. v. Cambridge Wire Cloth Co., 863 F.2d 855, 865 (Fed. Cir. 1988)). That rule only applies when the preferred embodiment is being chosen over other disclosed alternatives to limit a claim term with language broader than the limitation imposed by the preferred embodiment. Id. Where there is evidence in the prosecution history, for example, that the inventor intended to limit the claim to the preferred embodiment, or to any embodiment, then that evidence will carry the day on the issue of claim construction. 309 F.3d at 1379-80.

As discussed below, we find that the written specifications do not provide a definitive answer regarding the necessary structure for performing the "automatically denominating" function. But, the prosecution history of the '806 patent and its parent applications tell the tale. The tale told by the prosecution history is that of inventors who may have intended to broaden the '806 patent claims beyond a non-continuous, single-output evaluation device, but who could not accomplish this objective, despite the change to broader language in the '806 patent, because the patent examiner never removed his prior art objections. Specifically, the inventors had to limit the '067 and '951 patent claims, based on the same prior art obviousness objections by the patent examiner, to a non-continuous, single output evaluation device. Based on our review of the entire prosecution history for the '806 patent, we find that the disputed '806 patent claims must be limited in the same way that

- 787 -
Cummins limited the parent claims, because prior art covers the broader claims that Cummins disavowed to obtain the '067 and '951 patents, but now wants to reclaim through litigation.

(a) The Specifications.

The written specifications have several parts: the abstract, the background, the summary, the drawings (and a description of them), and a description of the preferred embodiments. The invention claimed by the '806 patent is titled "Method and Apparatus for Currency Discrimination and Counting." The parties have no issues regarding the apparatus covered by the invention. The only claims at issue, as indicated, are the method claims, and more particularly, the method claims for currency discrimination and identification -- not counting. We therefore focus on those portions of the specifications that regard the structures necessary to perform those functions.

In the abstract, the inventor describes "an improved method . . . for discriminating between currency bills of different denominations [that] uses an optical sensing and correlation technique based on the sensing of bill reflectance characteristics obtained by illuminating and scanning a bill along its narrow dimension." The parties agree that this "optical sensing and correlation technique" is a software system. 7 We will refer to it as software here. The rest of the abstract goes on to describe how this software distinguishes between bills or different denominations and how the software performs "denomination identification" -- identification of a bill "as belonging to the denomination." In other words, the software described in the specifications incorporates a process for identifying "known" (genuine) versus "unknown" (spurious) bills. The abstract speaks of a correlation number system for achieving such identification and/or discrimination, but it does not say what the software does the with the bills that are known and what it does with the bills that are unknown. The claims say what the invention does with the known bills (it stacks them in a "denominated bill output receptacle" ('806 patent, Col. 33, lines 46-47), or "one and only one output receptacle" (Id., Col. 36, line 51); but, it is not clear from the abstract what additional structure is needed for discriminating between the spurious and genuine bills and dealing with the spurious ones.

7 In the background, the inventor states that "optical sensing" is a "commonly used" technique ('806 patent, Col. 1, line 49). Thus, although this portion of the software claimed by the '806 patent is necessary structure for performing the claimed function of evaluation, the inventor is not claiming an "invention" as to this aspect of the software.

The background of the invention describes the invention as "relating, in general, to currency identification" and "more particularly to a method . . . for automatic discrimination . . . of different denominations . . . " ('806 patent, Col. 1, lines 24-27). The background goes on to describe the "related art" and draws a distinction between "systems capable of handling only a specific type of currency" and "complex systems which are capable of identifying and discriminating among and automatically counting multiple currency denominations" (Id., Col. 1, lines 35-40). The '806 patent claims an invention that falls into the latter, more complex system category.

The background section then proceeds to describe the "major obstacle" and "major problem" of conventional currency discrimination systems as being the tension between the desire for speed and accuracy: that is, the need to acquire an amount of data from the scanned bill sufficient to compare to the stored sample patterns in the software program of known bills in order to determine genuineness and denomination (which ordinarily had required scanning on the longer dimension of currency bills), versus the amount of "time required to analyze test data and compare it to predefined parameters in order to identify the currency bill under scrutiny, and the rate at which successive currency bills may be mechanically fed through and scanned" ( '806 patent, Col. 1, lines 63-66). The background describes the problem as being that "systems capable of accurate currency discrimination are costly, mechanically bulky and complex, and generally incapable of both currency discrimination and identification at high speeds with a high degree of accuracy" (Id., Col. 2, lines 30-35).

The summary of the invention picks up from that point, and identifies the way in which the "present invention" solves those identified problems. Specifically, "it is a principal object of the present invention to provide an improved method . . . for identifying and counting currency bills comprising a plurality of currency denominations" ('806 patent, Col. 2, lines 38-41). The summary further calls out some other objectives of the invention, namely, to increase the speed and accuracy of the devices that both count and perform the task of "denomination discrimination" among a plurality of types of United States
currency; and, to be compact in physical form, more economical, and more uncomplicated in construction and operation (Id., Col. 2, lines 45-50).

The "improved method" disclosed as the "principal object" of the invention is comprised of "an improved optical sensing and correlation technique adopted to both counting and denomination discrimination of currency bills" that "is based on" among other things -- "scanning a bill along its narrow dimension, approximately about the central section of the bill" (‘806 patent, Col. 2, lines 57-58). From this disclosure, it appears that the inventors are claiming a structure that comprises an improved software that adds a "correlation technique" that "scans" a bill "along its narrow dimension" (Id., Col. 2, line 57) and also "on the bill surface" (Id., Col. 2, line 61; Col. 3, line 5). The narrow dimension portion is expressly claimed (Id., Col. 33, lines 38, 41-42, 46): the correlation software and scanning on the bill's surface is not. Thus, the summary discloses the structure of the software that the inventors claim will help them achieve the identification aspect of the denominating function, but the summary does not tell us what structure to use for the discrimination aspect of that function because we still do not know what to do with the non-denominated (unknown or spurious) bills.

Thus, we move to the description of the preferred embodiments (and their corresponding drawings) (the "description"). The overwhelming majority of the description (all twelve pages, except for one arguable reference in one sentence in one paragraph, which we discuss below) discloses a currency evaluation device that employs a controlled stopping feature as part of the optical sensing and correlation technique that stops the device after a spurious bill is detected, and deposits the bill into the output bin so that it maybe removed before another bill is deposited on top of it (see, e.g., ‘806 patent, Col. 15, lines 24-30, Col. 16, lines 16-24). The description discloses, in great detail, a device that stops as part of the discrimination step of the evaluation process. Moreover, because the device stops "the transport of a bill that has been identified as ‘spurious’" (Id., Col. 17, line 60), such a device needs only one single stacker bin (or output receptacle) -- which is consistent with the desire, expressed in the summary, for a device that is "compact" (Id., Col. 2, line 49). The drawings for the description only show a device with one output receptacle or stacker (see, e.g., ‘806 patent, Figures 11 and 13-15), and the description -- like the language in Claim 40 -- refers exclusively to "a conventional stacking station where sensed and counted bills are collected" (Id., Col. 4, lines 1-3) (emphasis added) and "the stacker" (See, e.g., id., Col. 17, line 12).

8 We recognize that the articles "a" and "an" are not invariably synonymous with "one," but can mean "more than one, depending on the context in which the article is used," Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 977 (Fed. Cir. 1999); see also Tate Access Floors, Inc. v. Maxcess Technologies, Inc., 222 F.3d 958, 966 n. 4 (Fed. Cir. 2000) (giving "a" and "an" a plural meaning "in view of the embodiment disclosed in the specifications"). For reasons discussed in the text, we read the embodiment, the balance of the specifications and the prosecution history all to suggest that these articles be given their singular meaning.

The only reference in the specifications that may arguably be read as disclosing a multi-output bin device is found in one "fleeting" passage in the description:

Another advantage accruing from the reduction in processing time realized by the present sensing and correlation scheme is that the response time involved in either stopping the transport of a bill that has been identified as 'spurious', i.e., not corresponding to any of the stored master characteristic patterns, or diverting such a bill to a separate stacker bin, is correspondingly shortened. Accordingly, the system can conveniently be programmed to set a flag when a scanned pattern does not correspond to any of the master patterns. The identification of such a condition can be used to stop the bill transport drive motor for the mechanism.

(‘806 patent, Col. 17, lines 57-67) (emphasis added). Cummins argues that the reference a "separate stacker bin" expressly disclosed an invention with two output pockets: one for known bills, and one for spurious or rejected bills (Cummins Reply at 25). Cummins repeated this contention at oral argument, and further argued that the preceding reference to "stopping the transport of a bill that has been identified as 'spurious'" calls out the preferred embodiment disclosed in the description.

This latter interpretation strikes the Court, as implausible, because stopping the transport of a bill that has been identified as spurious is not what the preferred embodiment discloses. Rather, the preferred embodiment discloses an invention that
allows the transport of the spurious bill to continue until it is deposited in the output pocket; then and only then does the transport stop, so that no additional bills will be deposited into the pocket on top of the spurious bill. Thus, we read this language to refer to an approach different from that in the preferred embodiment discussed at length in the description.

Cummins' interpretation of the reference to diverting a spurious bill to a separate stacker bin, on the other hand, is not facially implausible. The word "divert" would suggest redirecting the spurious bill from the path that a known or genuine bill would follow, and the reference to a "separate" stacker could be interpreted as a separate, dedicated output pocket that would receive only spurious or rejected bills. On the other hand, the reference to diverting the spurious bill to a separate stake could be read as expressing in different words the preferred embodiment: the single output pocket which accumulates known currency in substance becomes a reject bin when a spurious bill is deposited into it, and the system then stops so that no other bills -- known or spurious -- can be deposited in that pocket until the spurious bill is removed. During

oral argument, counsel for Cummins conceded that this language could be read as referring to the system of handling spurious bills disclosed in the preferred embodiment.

In the Court's view, the immediately following sentences in Column 17 do not resolve the question. The first sentence, introduced by the word "accordingly," suggests that what follows is the result of either stopping the transport of the bill or depositing it in a stacker bin. But, the sentence that follows the word "accordingly" merely says that the system can be programmed to set a "flag" when a spurious bill is identified -- which would have to be done under any embodiment to ensure that the spurious bill is not commingled with genuine bills. This sentence does not shed light on what method of handling the bills identified as spurious is disclosed in the preceding sentence. And, the next sentence states that identification of a spurious bill "can be used to stop the bill transport drive motor for the mechanism" ( '806 patent, Col. 17, Lines 66-67) that would be necessary to the approach described at length in the preferred embodiment (stopping the transport immediately after the spurious bills is deposited in the output pocket), or in an alternative approach (set forth in Col. 17, lines 59-60) (stopping the transport of the bill that has been identified as spurious, before it reaches the output pocket). But, identification that stops the transport of a spurious bill would not be necessary if there was a separate output pocket dedicated to receiving spurious bills, since in that event there would be no need to stop the transport to avoid commingling known and spurious bills. On the other hand, the fact that this sentence states that identification of a spurious bill "can be used" to stop the bill transport drive can read to mean that it "need not be used" to do that -- which could be consistent with a continuous output system that contains two pockets, one exclusively dedicated to genuine bills and the other to spurious or rejected bills (i.e., the "separate stacker bin").

For these reasons, we find the passage upon which Cummins relies for its disclosure of a multi-pocket continuous operation unit to be ambiguous. Accordingly, we look to the prosecution history.

(b) The Prosecution History.

It is in the prosecution history for the '806 patent, and the history of its predecessor or parent patents, especially the '067 and '951 patents, that we find the answer to our question regarding the proper scope of the term "automatically denoming" in the disputed claims. We focus, in particular, on the discriminating function since the identification function for recognized bills only requires the structure of software identified in the specifications as the "optical sensing and correlation technique." We therefore look to the prosecution history for the sole purpose identifying the structure necessary to perform the discrimination function, and to consider Glory's assertion that Cummins has disavowed any claim to a two-pocket continuous operating unit (Glory Mem. at 45). We review the governing legal principles first.

The relevant legal rule is known as "prosecution history estoppel." "Prosecution history estoppel precludes a patentee from obtaining in an infringement suit patent protection for subject matter which it relinquished during prosecution in order to obtain allowance of the claims." Mark I Marketing Corp. v. R.R. Donnelly & Sons Co., 66 F.3d 285, 36 U.S.P.Q.2d 1095, 1099-1100 (Fed. Cir. 1995). "The standard for determining whether particular subject matter was relinquished is an objective one that depends on what a competitor reasonably would conclude from the patent's prosecution history. The application of prosecution history estoppel is a question of law." Id. (internal citations omitted). The relevant "history" is not limited to the particular patent-in-suit if that patent is part of a "continuation-in-part application." Id. 9 Rather, the prosecution history must be examined with respect to the entire history of the patent-in-suit to determine whether estoppel applies. Id. (citing Jonsson v. Stanley Works, 903 F.2d 812, 818 (Fed. Cir. 1990) (prosecution history of parent application in a continuation-in-part series relevant to understanding claim scope). When viewing this entire history, the examining court must be careful "to determine whether and what subject matter was surrendered to procure issuance of the patent." Id.
Thus, the case law confirms that "any interpretation that is provided or disavowed in the prosecution history . . . shapes the claim scope." See, e.g., Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249 n.3 (Fed. Cir. 1998) (citing Loctite Corp. v. Ultraseal, Ltd., 781 F.2d 861, 867 (Fed. Cir. 1985) (holding that term not limited by the specifications was nonetheless "expressly defined" in a narrow manner in the prosecution history). This rule applies in a step-plus-function method claim where a court is searching for the structure or structures necessary to perform the claimed function. See Personalized Media v. Int'l Trade Comm'n, 161 F.3d 696, 704-05 (Fed. Cir. 1998).

9 "A CIP (continuation-in-part) application contains subject matter from a prior application and may also contain additional matter not disclosed in the prior application." Augustine, 181 F.3d 1291, 1301. "Different claims of such an application may therefore receive different effective filing dates." Id. "Subject matter that arises for the first time in the CIP application does not receive the benefit of the filing date of the parent application." Id. Thus, the decision on the proper priority date -- the parent application date -- for the subject matter claimed in a CIP application depends on when that subject matter first appeared in the patent disclosures. To decide this question, a court must examine whether the "disclosure of the application relied upon reasonably convey[s] to the artisan that the inventor had possession at that time of the later claimed subject matter." Id.

Surrender of subject matter can occur either by the amendments filed or arguments made by an applicant to overcome the patent examiner's objections to the disputed claims. Id. In particular, "the prior art may aid in determining the scope of an estoppel." Id. at 1299. Specifically, during prosecution a patentee cannot add a claim limitation in a parent application to overcome prior art and then later assert in a continuation-in-part application for another patent, which is subject to the same prior art objections, that the prior claim limitation is not binding on the patent-in-suit. Augustine, 181 F.3d at 1298-99.

10 Cummins asserts that this legal principal is limited to parent applications with the same literal language in the disputed claims (Cummins Reply at 26). We disagree. The two cases that Cummins cites to support this proposition, Advanced Cardiovascular Systems, Inc. v. Medtronic, Inc., 265 F.3d 1294 (Fed. Cir. 2001), and Al-Site Corp. v. VSI Inat'l, Inc., 174 F.3d 1308, 1322-23 (Fed. Cir. 1999), are distinguishable from this case. In Medtronic, for example, specific limitations were added to claim terms in the parent application that did not appear, literally or functionally, in the successive patent-in-suit. 265 F.3d at 1305. That is not the case here where the claim terms, although they use different literal language, describe the same function to be performed by device when it discriminates among a plurality of bills. Al-Site is also distinguishable from our case because, there, the court found that claim language in the parent application was different than that found in the patent-in-suit and had a different meaning. Thus, the specific limitations added to the claims in the parent application had no relevance to the claims at issue in the patent-in-suit. As indicated below, we find that the disputed claims of the '806 patent are functionally the same as those that were limited by Cummins to overcome prior art objections to what became the '067 and '951 patents.
the same as those in the '067 and '951 patents (i.e., claims disclosing the identification and discrimination functions that later were reduced to the shortened term "denominating" in the '806 patent).

The patent examiner initially rejected certain claims in the '067, '951 and '806 patents on the grounds that they were obvious over certain prior art in particular, the Jones and the O'Maley patents. Jones discloses a device that counted currency with an apparatus that included an input receptacle; a single output receptacle for receiving evaluated bills; a transport mechanism for transporting bills; a discriminating unit for evaluating the bills; and a means for flagging a bill when the identity of the bill could not be determined by the discriminating unit. However, the Jones device does not determine the denomination of the bill. It is the O'Maley invention that both determines the denomination of a bill and discriminates between genuine bills and spurious bills. But, the O'Maley device discloses a continuous operation that did not count the currency, and "teaches the use of at least two output receptacles" (Cummins Reply, Gatz Dec., Dec., Ex. D, CG0000662); one for rejected or spurious bills and the other for denominated or successfully evaluated bills. Thus, although the patent claims did not literally read on either the Jones or O'Maley patents, the patent examiner initially rejected the disputed claims in the Cummins' patent applications as invalid under 35 U.S.C. § 103, because he thought it was "obvious" to combine the two inventions into one device: the Cummins' invention, as disclosed in the '067, '951 and '806 patents.

It is this Court's view that Cummins persuaded the examiner to issue the claims that were initially rejected based on the Jones/O'Maley prior art by limiting Cummins' claims, including those that are disputed in this lawsuit, to a non-continuous device using a single output receptacle for denominated and non-denominated bills. Our reasons for this conclusion are as follows.

With respect to Application No. 200 (which led to the '806 patent), the examiner rejected all pending claims under 35 U.S.C. § 103 for obviousness in light of the Jones and O'Maley prior art (Cummins Reply, Gatz Dec., Ex. F, CG0000014). To overcome this objection, Cummins argued that the examiner had engaged in impermissible hindsight to combine the two references and that the invention claimed by what is now the '806 patent teaches a device that is distinguishable from the simple note counter invented by Jones and the denomination discriminator invented by O'Maley (Id. at CG0000014-15). Cummins argued that the claims of the '806 patent were distinguishable from the prior art because they contain, among other things, the limitations "automatically denominating bills of a plurality of U.S. denominations," "delivering any bill that has been denominated to one and only one output receptacle," delivering bills which have been evaluated to an output region comprising one and only one stacker wheel containing output receptacle," and "delivering any bill that has been denominated to one and only one output receptacle" (Id. at CG0000015). In other words, Cummins did not provide any arguments outside the claimed language to overcome the examiner's obviousness objections. We, therefore, look to the prosecution history of the parent applications for clues regarding the scope of the disputed claims.

Although the disputed claim language in the application for the '067 and '951 patents is not literally the same as what appears in the '806 patent's disputed claims, the identification and discrimination function claimed by the '067 and '951 patents is the same as that claimed by Cummins in the '806 patent. Thus, we find the prosecution history of the '067 and '951 patents relevant to the determination of what "automatically denominating" in the disputed claim is limited to and thus covers (i.e., what the necessary structure is for performing that aspect of the identification and discrimination function).

It is clear from the prosecution history of the parent applications for the '067 and '951 patents that Cummins limited the scope of the claims regarding the discrimination function in those patents to a non-continuous, single output receptacle. In the face of the Jones/O'Maley prior art objections by the examiner, Cummins distinguished the claims in the '067 and '951 patents by arguing that the inventions did more than combine the teachings of the single output receptacle note counter invented by Jones (an invention with the ability to flag unknown bills, including counterfeit, by stopping the machine, but which could not determine the denomination of the bills it was counting) with O'Maley's multiple output receptacle denomination discriminator (Cummins Reply, Gatz Dec., Ex. E, CG0001552; Ex. D, CG0000662-63). According to Cummins, the claims of the '067 and '951 patents discriminated, denominated and counted using a single-output receptacle and a controlled stopping function, so that spurious or rejected bills could be removed and thus culled out from the genuine bills that would be denominated, counted and deposited in the output receptacle (Id., Ex. D at CG0000662-663; Id., Ex. F., CG0001551-1552).

Specifically, with regard to the '067 patent, Cummins successfully distinguished its claims from the prior art by arguing that it was not obvious to combine a denomination discriminator, which necessarily needed to do something with unknown bills, with a single output receptacle. The invention was the combination of those features, and the combination worked due to the
controlled stopping feature and the software that allowed the unknown bill to be removed without commingling it with the known bills (Id., Ex. D, CG0000662). Cummins further explained to the examiner that this combination of a currency discriminator utilizing a single-pocket satisfied a "long felt need" for a unit that was more compact, lighter and more attributable than previously available systems, and that the single output pocket "contributes to these attributes by reducing the mechanical complexity of the device including a reduction in the number of parts" (Id., Ex. D, CG0000665). This point is consistent with Cummins' stated objective in the summary of the '067 (and '806 patent) that an object of the invention was to create a unit that is "compact, economical, and has uncomplicated construction and operation" (compare '067 patent, Col. 2, lines 41-42; and '806 patent, Col. 2, lines 49-50). As evidence that the '067 patent was not obvious, Cummins pointed to the long coexistence of single pocket note counters and multi-pocket discriminators, without characteristics of a "single pocket" and a discrimination function being combined in one unit (Cummins Reply, Gatz, Dec., Ex. D, GC0000666).

With regard to the '951 patent, Cummins again distinguished its claims from the Jones/O'Maley prior art by arguing that it was not obvious to combine a denomination discriminator that flagged not only unknown bills, but also spurious bills, with a note counter in a single device that contained only one output receptacle for known and unknown bills (Cummins Reply, Gatz Dec., Ex. E, CG0001552). In particular, Cummins argued that the combination of prior art would teach a device that "would detect counterfeit bills and determine their denomination" (as well as, presumably, count the denominated bills), but "it would stop when a suspect bill was detected and also divert it to a separate bin" (Id.) (emphasis added). Because the Cummins' invention "does not do that" Cummins argued that there was "no suggestion that such a combination" could "be made" (Id.). In addition, Cummins distinguished other prior art cited by the examiner (the Glory GFB-200 series) by pointing out that the cited Glory units deposited both a suspect bill and the next bill into the output tray, whereas the Cummins' invention "features stopping the machine such that only the suspect bill is deposited in the output tray for inspection" (Id., Ex. E, 0001553).

The Court finds that these statements by Cummins expressly limited the claims of the '067 and the '951 patents to a currency evaluation device that performed the identification and discrimination function by using a non-continuous, single output receptacle. In overcoming the examiner's objectives, Cummins asserted that this "combination" of features was distinct and not obvious from the prior art because the prior art did not teach the art of discrimination and identification using a single output receptacle; and, the only way such an art could be achieved was by using a stopping mechanism for the discrimination that did not divert the spurious bills to a separate stacker bin or output receptacle. Given this history, which preceded the application for the '806 patent, it is difficult to see how the discrimination step in the denomiating function -- broadly identified as "denomination discrimination" in the same specifications used for the '067 and '951 patents -- can avoid being limited to a non-continuous currency evaluation device comprising a single output receptacle.

In so stating, we acknowledge that Cummins' use of broader claim language in the '806 patent may have been intended to cover a broader range of devices than the non-continuous, single output receptacle evaluation system to which Cummins limited itself in order to overcome the examiner's prior art rejections and obtain issuance of the '067 and '951 patents. And, we further recognize that in responding to the examiner's same prior art rejection in the application leading to the '806 patent, Cummins did not expressly state that its invention was limited to a device with a controlled stopping function and a single output receptacle -- as we believe Cummins clearly did in connection with the '067 and '951 patents. But, at the same time, in addressing the examiner's prior art rejections in the prosecution of the '806 patent, Cummins did not expressly indicate that it was seeking by its new claim language an invention covering the continuous operating machine with multiple output pockets. Rather, Cummins simply pointed the examiner to the new claim language which contained the term "automatically denomiating" -- a term that was used in the prior patents and that Cummins did not explain. Cummins did nothing to alert the examiner that it was seeking to cover by the '806 patent what it had previously disavowed, in order to avoid a rejection due to prior art, in obtaining the '067 and '951 patents. Nor can Cummins point to the brief passage in Col. 17 of the '806 patent to a unit that would "divert [spurious bills] to a separate stacker bin" as revealing this intent; that same passage in the specifications of the '806 patent also appears in the '067 and '951 patents. 11

11 In light of the prosecution history, Cummins' reliance on this language does not carry the day. A fair reading of the prosecution history shows either (a) that this language, which was in the applications for '067 and '951 patents, does not mean what Cummins now claims, or else Cummins would not have told the examiner that its invention was a one output device with a controlled stopping function, or (b) that the cited language means what Cummins claims, but that Cummins disavowed any effort to obtain a patent for a multi-output continuous operation unit when confronted with prior art that
jeopardized the issuance of the patents at all.

The fact remains that the discriminating step in the evaluation function of the '806 patent is functionally the same as that step in the '067 and '951 patents. It stands to reason that the same limitations would apply to that step, despite linguistic differences in the claim language. Otherwise, the broad claims now urged by Cummins would run headlong into the combination taught by Jones and O'Maley, and the Cummins' inventors admitted as much in prosecution of the '951 patent (Gatz Dec., Ex. E, at CG0001552) ("A combination of the machines of O'Maley and Jones . . . would detect counterfeit bills and determine their denomination, as the applicants' machine does. However, it would stop when a suspect bill was detected and also divert it to a separate bin").

In sum, we refuse the invitation to allow Cummins to recapture through litigation subject matter that it surrendered to obtain issuance of the '067 and '951 patents -- and thus the '806 patent. This Court finds that the proper construction of "automatically denominating" in the '806 patent's disputed claims is limited to a non-continuous currency evaluation device that has only one output receptacle.

Automatically Denominating

Much of the dispute in this case centers on the interpretation of the phrase "automatically denominating." That phrase appears in all of the independent claims plaintiff asserts against Glory. (See Nelson Decl., Ex. 1, '806 Patent, Claims 1, 16, 21, 30, 40, 49, 76, 82, 91, 101, 112, 125.) Claim 1, set forth below, is illustrative:

receiving a stack of bills to be evaluated in an input receptacle of the device,

transporting the bills, one at a time, from the input receptacle along a transport path,

automatically denominating bills of a plurality of U.S. denominations,

delivering bills which have been evaluated to an output region comprising one and only one stacker wheel containing output receptacle.

(Id., Claim 1, Col. 30, ll. 34-44) (emphasis added).

Glory contends that the phrase "automatically denominating" must be interpreted as a "step-plus-function" limitation as set forth in 35 U.S.C. § 112 P 6:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

The phrase "steps for" creates a presumption that the recited steps are in step-plus-function form. Masco Corp. v. United States, 303 F.3d 1316, 1326 (Fed. Cir. 2002). A claim that does not contain the "steps for" signal is not construed as a step-plus-function limitation unless the "limitation contains no act." Id. at 1327. If a claim is subject to a step-plus-function limitation, the Court must "look[] to the specification for acts corresponding to the step-plus-function element [that] are necessary to perform the recited function." Micro Chem., Inc. v. Great Plains Chem. Co., Inc. 194 F.3d 1250, 1259 (Fed. Cir. 1999).

Claims 40, 76 and 101, the independent claims at issue in the preliminary injunction proceeding, do not contain the "steps for" signal. (See Nelson Decl., Ex. 1, ‘806 Patent, Claims 40, 76, 101.) Nonetheless, as Glory points out, because those
claims contain the "automatically denominating" function without reciting any acts in support of it, we held that those claims must be interpreted pursuant to 35 U.S.C. § 112 P 6. (See PI Order at 17.) In Glory's view, the Court should extend that construction to every claim in which the phrase "automatically denominating" appears and hold that the acts necessary to perform that function are: (1) scanning standard bills of known denominations to generate master characteristic patterns; (2) scanning unknown bills to obtain a reflected light pattern proportional to the intensity of light from the scanned bills; (3) using a correlation algorithm that requires calculating average values, variances, and normalized values to correlate the reflected light pattern from the scanned bill with the master characteristic patterns; (4) decelerating the transport mechanism upon identification of a no-call bill; and (5) stopping the transport mechanism after scanning the bill following a no-call bill. (Defs.' Mem. Supp. Mot. Partial Summ. J. '806 Patent at 14-15.)

Glory's argument, however, ignores the fact that two of the independent claims that were not at issue in the preliminary injunction proceeding, but are at issue now, recite acts in support of the "automatically denominating" function. Claim 112, for example, recites:

automatically denominating bills of a plurality of U.S. denominations at a rate in excess of 800 bills per minute, the bills being denominated having images associated therewith corresponding to the plurality of denominations, wherein the denoming comprises scanning passing bills using a detector and generating image signals and determining the denomination of the bills based on the image signals.

(Nelson, Decl., Ex. 1, '806 Patent, Claim 112, Col. 39, ll. 17-18, 26-33) (emphasis added). Similarly, claim 125 recites:

automatically processing bills of a plurality of U.S. denominations . . . wherein the denoming comprises scanning passing bills using a detector and generating image signals and determining the denomination of the U.S. bills based on the image signals associated with only the green side of bills.

(Id., Claim 125, Col. 40, ll. 9-10, 19-29) (emphasis added). In addition, Cummins now asserts numerous dependent claims against Glory's machines that recite additional acts in support of "automatically denominating" or "denominating." (See id., Claims 4, 10-11, 15, 18-19, 26-27, 29, 35-36, 39, 44-45, 48, 51-52, 55-56, 61-62, 65, 70-71, 75, 79-81, 86-87, 96-97, 100, 109, 111, 124.) For example, in claim 4, Cummins claims:

The method of claim 1 wherein automatically denominating comprises detecting light reflected off passing bills, generating a reflected light characteristic information output signal in response to detected characteristic information, and generating a denomination signal in response to the reflected light characteristic information output signal.

(Id., Claim 4, Col. 30, ll. 51-56) (emphasis added). Though none of this additional language was analyzed during the preliminary injunction proceeding, Glory makes no attempt to reconcile the language with the preliminary injunction construction of "automatically denominating" that it espouses.

Cummins contends that Glory's view is wrong on all fronts. First, it argues that "automatically denominating" should not be construed as a step-plus-function limitation because it recites a function rather than an act. (Pl.'s Mem. Opp'n Defs.' Mot. Partial Summ. J. '806 Patent at 53); see Seal-Flex, Inc. v. Athletic Track & Court Constr., 172 F.3d 836, 849-50 (Fed. Cir. 1999) (Rader, J., concurring) (stating that the "function" of claim element corresponds to what the element ultimately accomplishes while "acts" correspond to how the function is accomplished). Second, even if it does recite a function, Cummins says that these claims explicitly recite "acts in support thereof," which takes the limitation out of the scope of § 112 P 6. See TurboCare Div. of Demag Delaval Turbomachinery Corp. v. GE, 264 F.3d 1111, 1120-21 (Fed. Cir. 2001) (explaining that "where a claim recites a function, but then goes on to elaborate sufficient structure, material, or acts within the claim itself to perform entirely the recited function, the claim is not in means-plus-function format") (citation omitted). Finally, Cummins contends that even if the "automatically denominating" term is a step-plus-function limitation, Glory overstates the acts that are required to perform that function. (Pl.'s Mem. Opp'n Defs.' Mot. Partial Summ. J. '806 Patent at 59.)
The Court finds Cummins' argument persuasive. None of the claims at issue contain the phrase "steps for," creating a presumption that the claim should not be interpreted under § 112 P 6, unless the claim plainly fails to recite an act. See Masco Corp. at 1327 (noting "where the claim drafter has not signaled his intent to invoke § 112, paragraph 6 by using the 'steps for' language, we are unwilling to resort to that provision to constrain the scope of coverage of a claim limitation without a showing that the limitation contains nothing that can be construed as an act.") In this case, independent claims 112 and 125 explicitly recite acts related to denominating. (See Nelson Decl., Ex. 1, '806 Patent, Claim 112, Col. 39, ll. 16-33, Claim 125, Col. 40, ll. 9-29.) Claim 112, for example, recites, "[a] method of processing currency bills . . . comprising . . . automatically denominating bills . . . wherein the denominating comprises scanning passing bills using a detector and generating image signals and determining the denomination of the bills based on the image signals." (Id., Col. 39, ll. 16-33.)

The acts of "scanning passing bills," "generating image signals" and "determining the denomination of the bills" remove the phrase "automatically denominating" from the scope of § 112 P 6. (Id.; see TurboCare, 264 F.3d at 1120-21. Glory makes no attempt to explain the inconsistency between its proposed interpretation of "automatically denominating" and the language in claims 112 and 125 that describe the automatically denominating function. Accordingly, the Court construes the phrase as falling outside the scope of 35 U.S.C. § 112 P 6, and declines to read in the limitations proposed by Glory.

Even if "automatically denominating" is not a step-plus-function limitation, Glory says the phrase must still be interpreted to require the device (1) to identify "unknown bills . . . using the correlation procedure" described in the patent and (2) "stop[] . . . when a no-call bill is identified" because the specification so requires. (Defs.' Mem. Supp. Mot. Partial Summ. J. '806 Patent at 16.) Though proper claim construction includes an examination of the patent specification, "the appropriate starting point . . . is always with the language of the asserted claim itself." Comark Communications, Inc., 156 F.3d at 1186. The specification may shed light on the meaning of the terms recited in a claim, but "the resulting claim interpretation must, in the end, accord with the words chosen by the patentee to stake out the boundary of the claimed property." Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998). As with the step-plus-function limitation, Glory does not explain how to reconcile its specification-based construction with the explicit language in the claims concerning "automatically denominating."

Interpreting "automatically denominating" in all claims to require bills to be identified according to the correlation procedure set forth in the patent is problematic. First, a number of dependent claims, like claim 4, contain limitations on "automatically denominating" and "denominating." (See Nelson Decl., Ex. 1, '806 Patent, Claim 4, Col. 30, ll. 51-56 (stating that automatically denominating "comprises detecting light reflected off passing bills, generating a reflected light characteristic information output signal in response to detected characteristic information, and generating a denomination signal in response to the reflected light characteristic information output signal").) According to the doctrine of claim differentiation, the limitations on "automatically denominating" that appear in claim 4, the dependent claim, should not he 'read into' claim 1, the claim on which it depends. Liebel-Flarsheim Co., 358 F.3d at 910. Moreover, as Cummins notes, reading additional limitations into the independent claims would make them narrower than the dependent claims that define "automatically denominating" broadly, an interpretation that would violate the patent statute. (Pl.'s Mem. Opp'n Defs.' Mot. Partial Summ. J. '806 Patent at 63); see 35 U.S.C. § 112 P 4 ("[A] claim in dependent form shall contain a reference to a claim previously set forth and then specify a further limitation of the subject matter claimed. A claim in dependent form shall be construed to incorporate by reference all the limitations of the claim to which it refers.").

Interpreting "automatically denominating" as requiring the device to slow and stop when a no-call bill is identified creates similar problems. As discussed in the following section, some of the claims that contain the phrase cannot be limited to a single output pocket and transport path. If the claims extend to an embodiment with two paths and pockets, one path and pocket for denominatied bills and another path and pocket for no-call bills, the patented device would not have to decelerate and stop to perform the automatic denomination function, as Glory contends.

Glory argues that "automatically denominating" must include slowing and stopping because plaintiff made that representation to the PTO. Glory points to an affidavit plaintiff submitted to the PTO to overcome an obviousness rejection of various claims of U.S. Patent No. 5,692,067 ("the '067 patent"), an ancestor of the '806 patent. In that affidavit, plaintiff partially attributes the commercial success of its JetScan currency discriminators, which are covered by the '067 patent and perform the automatic denomination function, to the fact that "the operation of the device is suspended" when "the discriminator is unable to determine the denomination of a bill." (Nelson Decl., Ex. 5, Prosecution History '067 Patent at GL047382.) Having told the PTO that the automatic discrimination includes stopping when a no-call bill is identified, Glory says plaintiff must live with that representation.
Read in context, however, it is clear that the JetScan is just one embodiment of the invention disclosed by the '067 patent. Earlier in that affidavit, plaintiff said that there had been a long-felt need for "a small, light weight, affordable currency discriminator," which the JetScan fulfilled: "The single pocket embodiment of the present invention contributes to a device that can denominate bills and yet is compact, light weight, and more affordable." (Id. at GL047379-80) (emphasis added).

The fact that the JetScan, which stops on no-call bills, is just one embodiment of the invention is also illustrated by the claims of the patent itself. Claim 1 of the '067 patent recites:

A currency evaluation device for receiving a stack of currency bills and rapidly evaluating all the bills in the stack, said device comprising:

an input receptacle for receiving a stack of bills to be evaluated;

a single output receptacle for receiving said bills after said bills have been evaluated;

a transport mechanism for transporting said bills, one at a time, from said input receptacle to said output receptacle along a transport path;

a discriminating unit for evaluating said bills, said discriminating unit including a detector positioned along said transport path between said input receptacle and said output receptacle, said discriminating unit counting and determining the denomination of said bills; and

means for flagging a bill when the denomination of said bill is not determined by said discriminating unit.

(Id., - '067 Patent, Claim 1, Col. 30 ll. 11-27 at GL047180.) Claim 2, which is dependent on Claim 1, claims: "The currency evaluation device of claim 1 wherein said means for flagging causes said transport mechanism to halt with said bill whose denomination has not been determined being the last bill transported to said output receptacle." (Id., Claim 2, Col. 30, ll. 28-31 at GL047180.) As discussed above, under the doctrine of claim differentiation, the presence of the halting limitation in dependent claim 2 creates the presumption that the limitation is not present in claim 1. Liebel-Flarsheim Co., 358 F.3d at 910. Because claim 2 recites an embodiment that stops on no-calls, the JetScan embodiment, claim 1 is presumed to recite an embodiment that is not so limited, i.e. does not stop on no-calls. Because Glory has not rebutted that presumption, plaintiff's statement to the PTO about the JetScan's halting feature cannot be extended to claims and embodiments that do not contain the halting limitation.

In short, the Court holds that "automatically denominated" is not a step-plus-function limitation and does not require that the claimed device identify unknown bills using the correlation procedure described in the patent or decelerate and stop when a no-call bill is identified.

Now that we know what "automatically denominated" does not mean, we must determine what it does mean. Cummins contends that the phrase means determining the denomination of bills by any method known to those skilled in the art at the time the '806 patent application was filed. (Pl.'s Mem. Opp'n Defs.' Mot. Partial Summ. '806 Patent at 61-62.) Construing the phrase so broadly, Glory asserts, creates validity problems. To be valid, a patent must have a specification that:

contain[s] a written description of the invention, and of the manner and process of making and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same, and . . . set[s] forth the best mode contemplated by the inventor of carrying out his invention.

35 U.S.C. § 112 P 1. If "automatically denoming" is construed to mean determining the denomination in any recognized manner, Glory says the specification does not comply with the enablement requirement.

"To be enabling, the specification of the patent must teach those skilled in the art how to make and use the full scope of the claimed invention without undue experimentation." Plant Genetic Sys., N.V. v. DeKalb Genetics Corp., 315 F.3d 1335, 1339
That is not to say that the specification itself must necessarily describe how to make and use every possible variant of the claimed invention, for the artisan's knowledge of the prior art and routine experimentation can often fill gaps, interpolate between embodiments, and perhaps even extrapolate beyond the disclosed embodiments, depending upon the predictability of the art. But it does mean that, when a range is claimed, there must be reasonable enablement of the scope of the range.

AK Steel Corp. v. Sollac & Uigine, 344 F.3d 1234, 1244 (Fed. Cir. 2003) (citations omitted).

Glory argues that the '806 patent enables only a device that denominates according to the correlation procedure disclosed in the patent. The Court disagrees. Though the specification says little about alternate denomination methods, the record establishes that such methods were well known to those skilled in the art of designing currency processing devices in December 1999, when the application for the '806 patent was filed. There is no dispute that currency denominating devices existed in December 1999. (See, e.g., Nelson Decl., Ex. 8, U.S. Patent No. 4,179,685 ("O'Maley Patent"), Col. 2, ll. 3-5 (disclosing "an automatic currency identifying system"); id., Ex. 5, Prosecution History '067 Patent at GL047392 (statement by plaintiff to PTO that De La Rue had been selling multipocket discriminators since 1980); id. (statement by plaintiff to PTO that Glory "was . . . offering a multipocket discriminator in 1986"); Anderson Decl., Ex. T, David Munson Decl. P 14 (stating that "automatic currency identification systems have existed for decades").) Moreover, Glory's own expert David Munson opines that various correlation algorithms for currency discrimination were known to and understood by those skilled in the art well before 1999. (Id., Ex. V, Munson Report at 5-6.) Given this evidence, the Court concludes that the specification of the '806 patent sufficiently enables a device that denominates according to methods other than the correlation procedure disclosed in the patent.

In sum, the Court construes the phrase "automatically denominating" to mean automatically determining the denomination of bills by any method known to those in the art at the time the '806 patent application was filed. See Chiron Corp. v. Genentech, Inc., 363 F.3d 1247, 1254 (Fed. Cir. 2004) (stating that "a patent document cannot enable technology that arises after the date of application"), cert. denied, 160 L. Ed. 2d 770, 125 S. Ct. 870 (2005).

The parties dispute the claims "evaluating," and "about 800 bills per minute," both of which have already been construed above. The only other term the parties dispute is "automatically denominating." Having fully reviewed the parties' briefs on the motion for reconsideration and the briefs on claim construction for the '806 Patent, and having heard testimony on the term "automatically denominating" at the Markman hearing, the Court affirms the '806 Opinion.

In Glory's late 2005 motion for reconsideration, in the second half of its claim construction brief before this Court, and in argument during the Markman hearing, Glory relies primarily on recent cases from the Federal Circuit that Glory believes invalidate the reasoning of the '806 Opinion. Glory cites to Phillips v. AWH Corp., 415 F.3d 1303 (Fed. Cir. 2005) and Honeywell Intl' Inc. v. ITT Industrials, Inc., 452 F.3d 1312 (Fed. Cir. 2006) to support its argument that the '806 Opinion erroneously relied too little upon the terms of the specification, and relies upon Curtiss-Wright Flow Control Corp. v. Velan, Inc. 438 F.3d 1374 (Fed. Cir. 2006) to support its argument that an inventor cannot claim prior art specifically disclaimed in its specification. While the Court respects Glory's arguments that the specification discusses the "optical sensing and correlation technique" that halts whenever a "no-call" bill is discovered, none of the cases cited by Glory refute the basic principles that a court should not import everything in the specification into the claims, or the basic principle of claim differentiation. See Phillips, 415 F.3d at 1315 ("The presence of a dependent claim that adds a particular limitation give rise to a presumption that the limitation in question is not present in the independent claim;"); Varco, L.P. v. Pason Systems USA Corp., 436 F.3d 1368, 1372 (Fed. Cir. 2006) ("In examining the specification for proper context, however, this court will not at any time import limitations from the specification into the claims."). The '806 Opinion explained why "automatically denominating" could not be limited to the specific correlation technique with halting function suggested by Glory because the dependent claims of the '806 Patent describe specific limitations on "automatically denominating" and "denominating," creating the inference that the independent claims may not be so limited. '806 Opinion at 11-13. Additionally, as stated in the '806 Opinion, Glory's own expert testified that correlation algorithms as well as various other denomination techniques were "known to and understood by those in the art well before 1999." '806 Opinion at 15. Therefore, the Court agrees with the '806 Opinion that "automatically denominating" includes any method for automatic denomination known to those skilled
B. The Step-Plus Function Limitation

ICE argues that the remaining terms, "automatically administering credit on a unilateral basis," and "automatically deriving a respective dealable price message," are "step-plus-function Claims" and are limited by 35 U.S.C. § 112 P 6 (the "112(6) limitation"). Section 112 P 6 allows a patentee to "describe an element of the invention by the result accomplished or the function served, rather than by describing the element to be used." Warner-Jenkinson Co., v. Hilton Davis Chem. Co., 520 U.S. 17, 27, 137 L. Ed. 2d 146, 117 S. Ct. 1040 (1997). According to 35 U.S.C. § 112 P 6:

An element in a claim for a combination may be expressed as a means or a step for performing the specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

35 U.S.C. § 112 P 6 (2000). However, "the price that must be paid for use of that convenience is limitation of the claim to the means specified in the written description and equivalents thereof." Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1208 (Fed. Cir. 2002) (citing to O.I. Corp. v. Tekmar Co., Inc., 115 F.3d 1576, 1583 (Fed Cir. 1997)). As such, the patentee shoulders "the duty to link or associate structure in the specification with the function [as] the quid pro quo for the convenience of employing the [statute]." B. Braun Med., Inc. v. Abbott Lab., 124 F.3d 1419, 1424 (Fed. Cir. 1997). However, if the patentee fails to sufficiently describe the structure, material, or act to which the function corresponds, the claim is overbroad and therefore, invalid. Budde v. Harley-Davidson, Inc., 250 F.3d 1369, 1376 (Fed. Cir. 2001) ("Failure to disclose adequate structure corresponding to the recited function in accordance with 35 U.S.C. § 112, paragraph 1, results in the claim being of indefinite scope, and thus invalid, under 35 U.S.C. § 112, paragraph 2.").

In O.I. Corp. v. Tekmar Co., 115 F.3d 1576 (Fed Cir. 1997), the Federal Circuit analyzed whether the 112(6) limitation applies to a "step" or "method" claim as opposed to when it limits an apparatus claim. The Federal Circuit concluded that "the term 'steps' [refers] to the generic description of elements of a process and the term 'acts' [refers] to the implementation of those steps," and that the 112(6) limitation "is implicated only when steps plus function without definite acts are present." See O.I Corp. at 1583 (emphasis added). The Federal Circuit reasoned that: "Claiming a step by itself, or a series of steps, does not implicate section 112, P 6. Merely claiming a step without recital of a function is not analogous to a means plus a function." O.I. Corp., 115 F.3d at 1583 (Fed. Cir. 1997); Cardiac Pacemaker, Inc., v. St. Jude Med., Inc., 381 F.3d 1371, 1382 (Fed. Cir. 2004) (A method claim "necessarily recites the steps of the method.").

The Federal Circuit reviewed a patent which claimed: "A method comprising the steps of: (a) passing an analyte slug through a passage." O.I Corp., 115 F.3d at 1578. The Federal Circuit held that the act of "passing an analyte slug through a passage" did not constitute a function simply because the operative verb was in the imperfect tense, "such as passing, heating, reacting transferring etc." Id. The Federal Circuit noted that if it were "to construe every process claim containing steps described in an 'ing' verb," then every process claim would be subject to the 112(6) limitation. Id.; see also Cardiac Pacemaker, Inc., 381 F.3d at 1371 (Fed. Cir. 2004) ("[A] patentee can define a method or process claim containing steps that begin with a gerund . . . without necessarily subjecting the claim to § 112 P 6 limitations.") While it indicated that verbs in the imperfect tense do not in themselves implicate the 112(6) limitation, the Federal Circuit left it to the trial courts to establish whether a claim element was a function or an act.

The Federal Circuit subsequently clarified when claim language is to be construed as a function as opposed to an act in Mascio v. United States, 303 F.3d 1316 (Fed. Cir. 2002). In Mascio, the Federal Circuit expanded upon its reasoning in O.I. Corp., and further advised when claim language describes acts or functions:

The "underlying function" of a method claim element corresponds to what the element ultimately accomplishes in relationship to what the other elements of the claim and the claim as a whole accomplish. "Acts," on the other hand, correspond to how the function is accomplished.

Mascio, 303 F.3d at 1327 (citing to Seal-Flex, Inc. v. Athletic Track and Ct. Constr., 172 F.3d 836, 849-50 (Fed. Cir. 1999))
and "transmitting" in O.I Corp. and Masco, respectively. Additionally, as neither the claim language nor dictionaries of the "administering" and "deriving" can be analogized in use and form in their respective claim elements to the verbs "passing" Second, as in both the O.I Corp. and Masco, the disputed terms in Claim 17 are steps without functions. The verbs element that does not include the phrase "step for" will not be considered to invoke 35 U.S.C. 112, 6."

First, it is undisputed that Claim 17 of the '627 Patent does not contain the language "step for." U.S. Patent No. 6,014,627 (issued January 11, 2000). As noted, the lack of the language "step for" generally signals that an act, rather than a function, follows. See Cardiac Pacemaker, Inc., 381 F.3d at 1382. While not dispositive, "such a grammatical structure indicates that this is not a step-plus-function claim," or at least creates a heavy "presumption that each ensuing step is [not] in step-plus-function form." Amgen, Inc. v. Hoechst Marion Roussel, Inc., 339 F. Supp. 2d 202, 255 (D. Mass. 2004); see also Cardiac Pacemaker, Inc., 381 F.3d at 1382; Epcon Gas Sys., Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1028 (Fed. Cir. 2002); Seal-Flex, Inc. v. Athletic Track & Ct. Constr., 172 F.3d 836, 850 (Fed. Cir. 1999) (Rader, J., concurring); Supp. Exam. Guidelines for Determining the Applicability of 35 U.S.C. § 112 P 6 is not warranted. n4

Here, relying on Masco ICE contends, Claim 17 does not contain acts, but rather merely states functions. (Harrison, Att'y for Def., Hr'g Tr. 63: 12.) In other words, ICE asserts that Claim 17 states what the elements of the claim ultimately accomplish (the function), but does not state how the function is accomplished. Id. ICE asks: "Where is the how?" Id. In opposition, EBS asserts that, similar to the language in O.I. Corp., the terms are just a recital of steps that do not state a function. (Stiff. Att'y for Pl., Hr'g Tr. 10: 7-8.)

In accordance with Masco and O.I. Corp., the 112(6) limitation does not apply for two reasons. First, the disputed claim does not contain the language "step for" and, therefore, the 112(6) limitation is presumed not to apply. Second, as the Federal Circuit found in both O.I Corp and Masco, the operative verbs "administering" and "deriving" do not themselves indicate the presence of functions.

First, it is undisputed that Claim 17 of the '627 Patent does not contain the language "step for." U.S. Patent No. 6,014,627 (issued January 11, 2000). As noted, the lack of the language "step for" generally signals that an act, rather than a function, follows. See Cardiac Pacemaker, Inc., 381 F.3d at 1382. While not dispositive, "such a grammatical structure indicates that this is not a step-plus-function claim," or at least creates a heavy "presumption that each ensuing step is [not] in step-plus-function form." Amgen, Inc. v. Hoechst Marion Roussel, Inc., 339 F. Supp. 2d 202, 255 (D. Mass. 2004); see also Cardiac Pacemaker, Inc., 381 F.3d at 1382; Epcon Gas Sys., Inc. v. Bauer Compressors, Inc., 279 F.3d 1022, 1028 (Fed. Cir. 2002); Seal-Flex, Inc. v. Athletic Track & Ct. Constr., 172 F.3d 836, 850 (Fed. Cir. 1999) (Rader, J., concurring); Supp. Exam. Guidelines for Determining the Applicability of 35 U.S.C. § 112 P 6 is not warranted. n4

Second, as in both the O.I Corp. and Masco, the disputed terms in Claim 17 are steps without functions. The verbs "administering" and "deriving" can be analogized in use and form in their respective claim elements to the verbs "passing" and "transmitting" in O.I Corp. and Masco, respectively. Additionally, as neither the claim language nor dictionaries of the
art explicitly ascribe these verbs meanings particular to "traders dealing in financial instruments," they are interpreted according to their ordinary meaning in their respective clauses. According to their ordinary meaning in their respective clauses, the phrases "automatically administering credit on a unilateral basis" and "automatically deriving a dealable price message" do not state "what" is accomplished, but rather state steps as to "how" the ultimate function of Claim 17 accomplishes, the "trading of financial instruments between traders." U.S. Patent No. 6,014,627 (issued Jan. 11, 2000).

As such, the remaining terms do not implicate section 112 P 6. Phrased in the "what" and "how" language of Masco, "administering" in the sense of dispensing, furnishing or tendering, describes how "administering credit on a unilateral basis" is performed. See Webster's Third New International Dictionary of the English Language Unabridged 27 (1993) ("Administer: to mete out, dispense."); see also Webster's Third New International Dictionary of the English Language Unabridged 27 (1993) ("Administration: furnishing or tendering according to a prescribed act."). Additionally, the '627 Patent itself suggests that "administering" means dispensing according to a prescribed act: "Each client site establishes and may subsequently vary or reset a credit limit for each possible counterparty." U.S. Patent No. 6,014,627 (issued Jan. 11, 2000). "Deriving" in the sense of gathering and arriving at a conclusion by deduction, is an act which describes how "deriving a dealable price message" is performed. See Webster's Third New International Dictionary of the English Language Unabridged 608 (1993) ("Derive: to gather or arrive at (as a conclusion) by reasoning and observation; deduce."); see also American Heritage Dictionary of the English Language 489 (4th ed. 2000).

Consequently, the terms "automatically administering credit on a unilateral basis" and "automatically deriving a respective dealable price message" are not subject to § 112 P 6.

* * *

2. "Automatically Deriving a Respective Dealable Price Message"

EBS contends that the phrase, "automatically deriving a respective dealable price message" means:

- Deriving a message sent to a trading floor (a potential taker) and indicating a bid or offer originating from another trading floor (a potential maker) with whom the potential taker has credit remaining.

(Siff, Att'y for Pl., Hr'g Tr. 32: 1-4.)

"Automatically deriving a respective dealable price message" consists of (i) "automatically" (ii) "deriving" (iii) "respective dealable price message." As "automatically" and "deriving," already defined above, do not necessitate more attention here.

The term "respective dealable price message" is supported by evidence intrinsic in the '627 Patent. Claim 17 states: "price quotation messages from those other trading floors for which bilateral credit currently remains both from and to a particular trading floor." U.S. Patent 6,014,627 (issued Jan. 11, 2000). In further support, the term "dealable" consists of two conjoined root words, "deal" and "able." To deal means "to buy or sell, or to do business." Dictionary of Banking and Finance, 112 (Standard Chartered Bank 1998). Analogous to the verb "to deal," "deal" as a noun defined by the Handbook of International Financial Terms, 145 (Oxford Univ. Press 1997), is a "colloquial term for transaction." "Able," according to Webster's Third New International Dictionary of the English Language Unabridged, 4 (1993), means, "possessed of needed powers or of needed resources to accomplish an objective."

As such, reading the '627 Patent in light of the relevant industry standards and the ordinary meaning of the terms, at least insofar as current dictionary definitions are concerned, the contested language must follow the EBS construction and be construed as:

- Deriving a message sent to a trading floor (a potential taker) and indicating a bid or offer originating from another trading floor (a potential maker) with whom the potential taker has credit remaining.
Keen has alleged that InfoRocket infringes claims 1-10, 12-19 and 44 of the '165 Patent. (Keen's Mem. Prelim. Inj. at 11).

Claim 1 of the '165 Patent claims:

A method of connecting two parties in real time, the method comprising:

displaying a list of experts to a consumer via an Internet connection with said consumer prior to the consumer submitting a question;

the list indicating individually whether each expert is currently available to telephonically communicate with said consumer at a time when said consumer is viewing the list, said list includes a compensation rate for each expert;

in response to the consumer selecting a displayed icon corresponding to an expert from the list, automatically establishing a telephone connection between the expert and the consumer prior to the consumer submitting a question to the expert; and

said automatically establishing the connection includes a central controller placing a telephone call to said consumer via a connection separate from said Internet connection, and said central controller placing a telephone call to said expert.

('165 Patent, col. 9, ln. 65 to col. 10, ln. 18). Claim 1 is the only independent Claim contained within the '165 Patent that is alleged to be infringed.

In their claim construction arguments, the parties focus primarily on certain phrases contained in claim 1 of the '165 Patent, viz., "automatically establishing" a telephone connection "in response to" the selection of an icon by the consumer. With respect to the claims themselves, InfoRocket argues that the meaning of these phrases is "unequivocal":

"In response to" means exactly what it [says]. Namely, that the telephonic connection is made in response to selecting an icon. The telephonic connection is not made in response to selecting a button. Nor is it made in response to dialing a number. The language "in response to" means that once the consumer merely selects the icon, he does not perform any further manual steps to facilitate the connection.

(InfoRocket's Mem. Summ. J. at 5). In response, Keen asserts that the claims do not require an "instantaneous relationship between selecting the icon and completing the connection, like a switch closing an electrical circuit to turn on a light." (Keen's Opp'n Mem. Summ. J. at 4). Rather, according to Keen, the claims "contain language demonstrating that the process of 'automatically establishing a telephone connection' includes 'manual' steps." (Id. at 5).

With respect to the specification, InfoRocket points to the sole example provided in the '165 patent, which describes a consumer clicking an icon and being connected to an expert:

David clicks an icon in Joe's box and a second or two later, a streaming real-time video of Joe appears on David's PC, and if David's PC is so enabled, Joe sees David in his PC.

(InfoRocket's Mem. Summ. J. at 6 (citing '165 Patent, col. 9, ins. 46-48) (emphasis added)). InfoRocket also highlights the portion of the specification that describes the consumer's "last step" as clicking on the symbol corresponding to the expert--indicating that the consumer need not do anything further in order to be connected to the expert. (Id. (citing '165 Patent, col. 2, ins. 27-31)). Keen responds by asserting that the steps between the consumer's selecting an icon and being connected to an expert are "interactive safety steps" consistent with the '165 Patent's intent to "protect the interests of the consumer."

(Keen's Opp'n Mem. Summ. J. at 6).

With respect to the prosecution history, InfoRocket states that Keen's significant narrowing of the scope of the claims during the application process supports its interpretation of the disputed claim language. (InfoRocket's Mem. Summ. J. at 6). Claim 1 of the originally filed application claimed:

1. A method of facilitating the delivery of advice to consumers, comprising:

providing a server unit with the ability to store the names or identification of two or more experts, said experts coded by
one or more expert characteristics, said server having the ability to detect which experts are online;

said server having the ability to display at least one of said expert characteristics with information-rich graphics or symbols;

said server having the ability to respond to a consumer's selection of expert by either sending the consumer a means to contact expert or by connecting the consumer and expert for real-time communication;

wherein the time-to-connect between consumer and expert is 30 minutes or less.

(Declaration in Support of John A. Bauer, sworn to on February 15, 2002, Ex. 2, at 38 ("Bauer Decl.")). This claim was rejected by the Patent and Trademark Office ("PTO"). (P.I. Hearing Tr. at 71-73). So, too, was the following significantly more narrow claim rejected, in light of the Walker Patent, as obvious:

101. A method of connecting two parties in real time, the method comprising:

displaying a list of experts to a consumer, the list including an indication of each expert's current availability; and,

in response to the consumer selecting an expert from the list, establishing a real time communication connection between the expert and the consumer.

(Bauer Decl., Ex. 2, at 170, 189). Only after this claim was rejected did Keen amend its application to the language as it exists in Claim 1 in the '165 Patent. (Id. at 229). In distinguishing this amended claim from the Walker Patent, Keen asserted:

In addition, Walker does not disclose a central controller automatically placing two independent separate calls to the expert and consumer, in response to the consumer selecting an icon displayed via the Internet. Rather, Walker teaches away from the claimed limitation by only teaching a time consuming and tedious Interactive Voice Response Unit maze, that requires the consumer call into the IVRU and navigate their way into having the expert contacted. (Walker col. 29).

(Id. at 289 (emphasis omitted)). Keen responds to InfoRocket's argument by suggesting that the prosecution history of the '165 Patent does not address the "in response to" or "automatically establishing" language, but rather focused on the differences between the way that the '165 Patent and the Walker Patent taught to select an expert (icon vs. bidding process) and the patents' different usage of telephones (central controller and Internet connection vs. Interactive Voice Response Unit). (Keen's Opp'n Mem. Summ. J. at 9).

I find that InfoRocket's interpretation of the phrases "automatically establishing" and "in response to" in Claim 1 of the '165 Patent is correct and I construe the claims accordingly. The Oxford English Dictionary's first definition of "automatically" includes "by spontaneous, or apparently spontaneous, action," (1 Oxford English Dictionary 805 (2d ed. 1991 (the "Dictionary")), and the second definition includes "without active thought or volition, unconsciously, involuntarily, mechanically," (id.). The Dictionary's definition la of "response" includes "an answer, a reply," and definition 1c includes "the way in which an apparatus responds to a stimulus …."

(8 Oxford English Dictionary 741 (2d ed. 1991)). 4 Using these plain meanings, the stimulus in the '165 Patent is the clicking on the icon. The apparatus or, here, the website, responds to that stimulus by establishing the telephone connection. Use of the word "immediately" as a modifier confirms that the response, that is, the telephone connection, is set up spontaneously or mechanically, without additional volitional acts.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

4 Keen provides no independent definition in the '165 Patent of the term "automatically." Therefore, that term is defined by its ordinary meaning, which may include the use of a dictionary. See CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002) ("Sensibly enough, our precedents show that dictionary definitions may establish a claim term's ordinary meaning."); York Prods., 99 F.3d at 1572-73 (using two dictionaries to construe the term "substantially").

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -
Thus, the plain meaning of the words in claim 1 is that clicking on or selecting a displayed icon corresponding to an expert results in an immediate telephone connection between the expert and the consumer, without a series of intervening manual steps. This construction is confirmed by both the specification (reflecting the consumer's clicking the icon as the "last act" and a connection "a second or two later") and the prosecution history (where Keen's twice-amended application documents attempted to circumvent the prior art by, inter alia, adding the word "automatically" to modify "establishing a telephone connection," (Bauer Decl., Ex. 2, at 229, 289)).

Ultrak, Inc. v. Kustom Signals, Inc., No. Civ. 3:96-CV-1569-H, 1997 WL 528046 (N.D. Tex. Aug. 18, 1997), further confirms this construction. There, plaintiff Ultrak, Inc. ("Ultrak") alleged infringement of claim 1 of its patent entitled "Police Protection Method and Apparatus" against defendant Kustom Signals, Inc. ("Kustom"). Id. at *1. Both Ultrak's and Kustom's systems "enable recording of a police officer's interrogations and interactions by using a wireless microphone transmitter to transmit the officer's conversations to a recording device located in the officer's patrol car." Id. In the patented Ultrak device, when the microphone transmitter is not being used it is stored in a recharging holder in the police car. Id. An officer exiting his vehicle removes that transmitter from its holder—which "automatically initiates transmission and recording"--and places it in his pocket. Id. Further, the transmitter has an "override" provision that enables the officer to remove it from the holder and move without transmitting. Id. In the accused Kustom system, however, "the microphone transmitter is worn continuously on the officer's belt," and the officer must manually turn on the transmitter before it can be used. Id.

Ultrak argued that Kustom's device infringed claim 1 of the patent, which claims "a method for providing the record of interrogation and activity by police officers, . . . including: a. replacement of an automatically activated transmitter in the officer's clothing." Id. Kustom, in turn, moved for summary judgment for noninfringement "on the basis that the accused device does not involve the 'replacement' of an 'automatically activated transmitter' on an officer's person." Id.

With respect to claim construction, the parties presented different interpretations of the phrase "automatically activated." Id. at Kustom asserted that it refers to "the feature of the patented system that the transmitter begins sending a signal to the recorder immediately upon removal from its holder, without the officer having to switch the unit on." Id. Therefore, Kustom's system would not infringe the patent because an officer must manually turn on Kustom's transmitter to start recording. Id. Ultrak, on the other hand, argued that the phrase only means that the officer must push a button to record particular words and that the use of the phrase "automatic" is meant "to distinguish the patented device's "hands-free' transmitter from walkie-talkie-type 'push-to-talk' transmitters that had been the subject of other patents for police devices." Id.

After considering both the patent and its prosecution history, the court agreed with Kustom's claim interpretation:

"Two central features of the "automatic" operation of the transmitter were 1) that the system began to transmit and record immediately, without the officer having to take any special action, and 2) that it did not enable the officer (intentionally or otherwise) to turn the transmitter off and on easily to selectively record. Moreover, considering ordinary meaning of the term, "automatically activated" is naturally construed to mean that a device begins operating without being specially turned on."

Id.

Keen cites Bingo Brain, Inc. v. California Concepts, Inc., 2002 U.S. Dist. LEXIS 1209 (N.D. Ill. Jan. 24, 2002), to support its interpretation of the term "automatically." (Letter from Mark D. Rowland to the Court, dated April 26, 2002, at 2). That case does not support Keen's position. In Bingo Brain, the parties were competitors in the market for hand-held devices that allowed players to use multiple bingo cards simultaneously. Dependent Claim 18 in the patent at issue provided:

18. The method of claim 13 wherein the number configurations for the next game having identification numbers which are displaced in a predetermined relationship from the identification numbers of the previous game are automatically transferred from storage to the calculating unit without entering the identification numbers of the selected number configurations. (151 Patent, Col. 6, lines 40-46).

(Id. at *8 (emphasis added)). Both parties agreed that this phrase meant, at a minimum, that "the device automatically enters the next set of bingo cards at the end of a game." (Id. at *21). But while defendants argued that "the use of the word
'automatically' in Claim 18 precludes any human intervention to initiate the transfer of the number configurations," plaintiff suggested that "this automatic function can also be initiated by the player by pressing a button to signal that the game is over." (Id. (emphasis added)).

The court agreed with plaintiff's interpretation of the claim:

The Patent details a device that is able to determine which sheet of bingo cards follows the sheet just played, and pull that successor sheet from its memory so the player can play this sheet next. No intervention is required for the device to determine which sheet of cards is next. Nor is intervention required for the device to retrieve that sheet from the memory. In other words, the device has a "self-regulating mechanism" that enables it to complete those functions. Only the timing of these processes is initiated by human intervention. Thus, the question becomes whether the fact that this procedure is initiated by an external factor precludes it from being automatic. The court finds that it does not. The device, on its own, ascertains which sheet of bingo cards comes next and makes that sheet available for play -- the player merely prompts the machine to perform this automatic function. An "automatic" garage door opener, similarly, does not sense that an automobile is ready to enter or depart a garage, but performs automatically once it is prompted to do so. Much the same, the device does not sense that a player in the bingo hall has shouted "bingo" and call up the next sheet to be played, but prepares for the next game once the player instructs the device that a new game is starting.

(Id. at *21-*22 (emphasis added)). Therefore, the court concluded, "the word 'automatically,' as used in the '151 Patent, does not preclude human intervention to trigger a process that is, in all other respects, automatic.” (Id. at *24).

In the instant case, however, both parties agree, as they must, that the '165 Patent requires, at a minimum, that a telephone connection between a consumer and an expert is initiated by an external factor--i.e., the clicking of an icon. In other words, neither party suggests that when the consumer sits down at his computer, the computer "senses" that the consumer desires to initiate a telephone connection with the expert and "automatically" facilitates that connection. Rather, the only issue is how much more additional human intervention is needed, beyond the initial clicking of an icon, before InfoRocket is outside the scope of Claim 1's "automatically establishing" language. Therefore, Bingo Brain does not change the result.

<tbody>
<tr>
<td>Automatically forwards</td>
<td>Forwards independent of action by the scribe</td>
</tr>
</tbody>
</table>

The issue regarding this term generally centers on the construction of "automatically." Anthurium argues for the plain and ordinary meaning, including "primarily without human intervention." The defendants argue that "automatically," as indicated by the specification and the prosecution history, means "independent of action by the scribe."

Again, the defendants rely upon the prosecution history of the '124 patent. As indicated above, it is proper intrinsic evidence to consider. The defendants argue that the patentee's statements to overcome prior art during the prosecution of the '124 patent form the basis for their proposed construction. In a Preliminary Amendment, dated February 28, 2001, the inventor attempted to distinguish her alleged invention from the Kikinis patent, by stating the following:

Kikinis does not teach a central computer that automatically selects a scribe from the list of available scribes, and
forwards a job request to a scribe computer associated with the selected scribe. By contrast, Kikinis teaches that the dictation, including instructions is e-mailed to a transcription center. The center pages the "next available transcription person, which then can call in or pick up the emailed information if that person elects to accept the task."

The systems and methods of the present invention eliminate the need for the center to page the transcription person by "automatically selecting a selected scribe from a list of available scribes, and forwarding a job request to a scribe computer associated with the selected scribes." Additionally, unlike the system of Kikinis, the claimed invention does not require the center to scroll through a list of scribes to go to "the next available person until the job is accepted." By maintaining a current list of available scribes, the central computer of the claimed system can select a scribe from the current list, and automatically forward the job request to the selected scribe. Defs.’ Ex. 5 at 118-19 (citations omitted; emphasis added).

In a subsequent Office Action, the patentee again explained the "automatically forwards" aspect of the invention from the prior art. The patentee stated as follows:

As discussed above, both Kikinis and Zebryk disclose making a file available for the scribe to retrieve, rather than automatically forwarding the file to the scribe. . . . By contrast, because the central computer of the claimed invention automatically forwards the job request to the scribe computer, it is desirable for the central computer to ‘know’ that the scribe is available so that the job will be performed when it arrives. Defs.’ Ex. 5 at 177-78 (emphasis added).

As indicated above, the defendants argue that the patentee disavowed any interpretation of "automatically forwards" that would encompass a system where the job packet was not sent from the central computer to the scribe computer until the scribe contacted the central computer.

Anthurium points to one passage in particular for its argument that the patent envisions a scenario in which, after the scribe has been selected, the central computer places the job in the scribe's directory for the scribe to download. '998 Patent, col. 14 ll. 36-42. Anthurium, however, leaves out the subsequent paragraph.

When the Scribe sits down at their computer to begin a work session, they will dial-in to their local internet provider. They will then go to their Scribe Home form where they will click on the ON-LINE BUTTON. The next screen they view is their Directory. Any jobs in the input directory are to be downloaded by priority indicated. They download all files of a job. '998 Patent, col. 14 ll. 36-42.

As the defendants point out, the passage cited to by Anthurium does not support its argument. In fact, as the subsequent paragraph suggests, the jobs have already been sent to the scribe independent of any actions by the scribe.

Anthurium's argument and proposed construction fail to encompass what the specifications and prosecution history envision. It is clear from the prosecution history that, in order to overcome the Kikinis and Zebryk prior art, the present invention had to "automatically forward," absent any "elect[ing] to accept the task." Defs.’ Ex. 5 at 118-19. Additionally, Anthurium's reliance on CollegeNet is misplaced. See CollegeNet Inc. v. ApplyYourself Inc., 418 F.3d 1225, 1235 (Fed. Cir. 2005). The defendants do not intend to preclude human intervention; the defendants merely intend to preclude scribe intervention in the "automatically forwards" aspect of the claim. It is of no effect what the scribe does after the "job step data" is "automatically forward[ed]." It is clear that the prior art required scribe intervention to receive the job file; whereas, in this case the patentee intended to claim an invention to overcome such prior art based on the automatic forwarding absent scribe intervention.

As such, the Court defines "automatically forwards" as follows: "forwards independent of action by the scribe." 5

5 The scope of the claim language includes the situation in which an e-mail is sent to a scribe's e-mail account, even though the e-mail server is not physically close to the scribe. See Tr. of Claim Construction Hearing at 42-44, 87-90.
"automatically initiating the VPN"

The '135 patent, claim 1 contains the phrase "automatically initiating the VPN." VirnetX contends that "automatically initiating the VPN" means "starting the VPN without intervention by a person." Microsoft contends that "automatically initiating the VPN" means "initiating the VPN without the client or target computer requesting such initiation." The parties dispute whether "automatically" refers to not requiring a user or refers to not requiring the client and target computers.

The Court construes "automatically initiating the VPN" as "initiating the VPN without involvement of a user." The specification supports the Court's construction. The specification describes various embodiments of the invention. See Col. 37:63-40:13. In these embodiments, after the user or user's computer makes the initial DNS request, the user is not further involved in setting up the VPN. See, e.g., Col. 39:22-29 (describing that if the user has sufficient security privileges, a secure VPN is established between the user's computer and the secure target website "preferably performed transparently to the user (i.e. the user need not be involved in creating the secure link)"); 38:28-33 (describing that the DNS proxy 2610 determines whether the user has sufficient security privileges to access the required site and if so, the "DNS proxy 2610 transmits a message to gatekeeper 2603 requesting that a virtual private network be created between a user computer 2601 and secure target site 2604"); Figs. 26 & 27. Thus, the specification describes that the VPN is initiated without further user action.

Microsoft argues that "automatically" does not refer to a "user" because claim 1 does not make any reference to a person and instead states "automatically initiating the VPN between the client computer and the target computer." Col. 47:20-32. Microsoft concludes that claim 1 clearly refers to not involving the client and target computers when stating "automatically." However, claim 1 only refers to the client and target computers to indicate where the VPN is being established, "between the client computer and the target computer." This phrase does not disallow involvement of the client and target computers in initiating the VPN. Instead, as discussed supra, the specification shows that "automatically" refers to not involving a user.

Furthermore, the difference between independent claim 1 and dependent claim 2 indicates that the client computer can be involved in step (3) of claim 1, which includes "automatically initiating the VPN between the client computer and the target computer." Claim 2 states "The method of claim 1, wherein steps (2) and (3) are performed at a DNS server separate from the client computer." Col. 47:33-35 (emphasis added). Because claim 2 contains "separate from the client computer" and claim 1 does not, claim 1 presumably does not contain this limitation. This claim differentiation presumption is not rebutted in light of the intrinsic evidence. Thus, the client computer may be involved in initiating the VPN in claim 1. Accordingly, the Court does not adopt Microsoft's construction, but construes "automatically initiating the VPN" as "initiating the VPN without involvement of a user."

4. "automatically provided by a communications network"

The disputed claim term "automatically provided by a communications network" appears in claims 1, 2, 4, 7, 25, 35, 36, 43, and 44 of the '416 Patent and claims 1, 2, 4, 5, 8, 10, 13, 14, 17, 34, and 35 of the '186 Patent. According to Kyocera, "automatically provided by a communications network" should be construed to mean "supplied automatically by the communications network." (Kyocera Br. 24.) Intellect Wireless, in contrast, argues that the proper construction is "supplied by the wireless portable communication device and/or the telecommunications network without manual entry by the message originator." (Intellect Wireless Resp. 21.) According to Intellect Wireless, Kyocera's proposed construction improperly "require[s] that the caller ID information be derived solely from the communications network to the exclusion of any other device or component such as the wireless device itself." (Id.) Instead, "automatically provided by a communications network," Intellect Wireless contends, simply means that "the caller ID information is provided without human intervention" (id.); in other words, when composing a message, the message originator does not need to enter his or her own caller ID information.
Turning first to the claims, the court finds that the plain language of claim 1 of the '186 and '416 Patents supports Intellect Wireless's position that the phrase "automatically provided by a communications network" is describing the transmission of the "caller ID" (i.e., that it is "automatic") as opposed to imposing limitations on the caller ID's origin. Specifically, those claims describe "the message originator sending the caller ID with the picture to the message center." '186 Patent, col.46 ll.51-53; '416 Patent, col.46 ll.46-48. Because the claims expressly recognize that the "caller ID" originates from the "message originator," the court does not believe that one of ordinary skill in the art in the mid-1990s, reading the phrase "automatically provided by a communications network" in the context of all the claim language, would have understood the term as precluding the "caller ID" from emanating from the message originator's device. Rather, the court finds that a person of ordinary skill in the art in the mid-1990s would have interpreted "automatically provided" to mean that the "caller ID" is not manually entered by the message originator.

This interpretation also is consistent with the specifications. First, the Background of the Invention explains that manual entry of caller ID was a disadvantage of the prior art:

One particular problem with conventional paging systems using message center devices is the requirement that a caller must manually enter their call back telephone number. . . . This can be cumbersome particularly if the calling party wishes to also leave a voice message or send some other message data such as a facsimile.

'186 Patent, col.2 ll.19-28. Disparaging the manual entry of caller ID in the prior art likely would suggest to one of ordinary skill in the art that the references to "automatically provided" in the asserted claims indicate that such entry by the message originator is not required. See Hearing Components, Inc. v. Shure Inc., 600 F.3d 1357, 1367 (Fed. Cir. 2010) (relying on "disparag[ing]" discussion of the prior art to interpret claim term).

The specifications also distinguish between caller-identification information and manually entered information. Although Kyocera interprets this distinction as excluding embodiments where the caller ID originates with the message originator's device, the court instead believes that the comparison between automatically transmitted "caller-identification information" or "caller ID" and manually entered "optional data" indicates that the caller ID in the asserted claims is transmitted without manual entry. For example, in discussing Figure 21, the specifications contrast "caller-identification information" that "is automatically transferred to the central office" with "optional data" that the "page-originating communicant enters." '186 Patent, col.42 ll.50-56. The specifications also recognize that "[t]he most common applications of an embodiment requires that the page-originating communicant enter either numeric or alphanumeric data which is identified with the caller-identification information." Id. at col.43 ll.4-7 (emphasis added). In this embodiment, "[u]pon receipt by portable communication device 271, at least one of either the numeric caller-identification information, or the alphabetic caller-identification information, or the optional data entered by the page-originating communicant is compared to one or more data fields in a database . . . ." Id. at col.43 ll.7-12 (emphasis added). The manually entered data, therefore, is distinct from the "caller-identification information" or "caller ID."

Not only do the specifications support Intellect Wireless's position that the message originator does not manually enter the "caller ID" but they also disclose the automatic transmission of the "caller ID" originating with the message originator's device. In one embodiment, "upon establishment of a voice circuit between the telephone unit utilized by the page-originating communicant and the paging center, the caller identification information, if any exists, is automatically transferred to the central office." Id. at col.42 ll.47-51. Similarly, the specifications explain that "[i]n accordance with current Bell standards, caller-identification information may be transmitted, automatically, between call-originator 11 and call receiver 15, through the telephone network 9." Id. at col.34 ll.15-18. (emphasis added). The court accordingly finds that the specifications for the patents in suit support Intellect Wireless's assertion that the phrase "automatically provided by a communications network" simply indicates that the "caller ID" does not require manual entry by the message originator; it does not impose a limitation on the origin of the "caller ID."

The specification for the parent '862 Patent also bolsters Intellect Wireless's position. The court finds that the '862 Patent is relevant intrinsic evidence that one of ordinary skill in the art in the mid-1990s would have reviewed to understand the inventions claimed in the '186 and '416 Patents. See Jonsson v. Stanley Works, 903 F.2d 812, 818 (Fed. Cir. 1990) (recognizing that construction of claim term in parent patent "is relevant to an understanding of" how "that term is used in the [child patent]"). Specifically, the '862 Patent touts the impact of the automatic transmission of the caller ID on "enhancing the efficiency and accuracy of alphanumeric paging networks":

- 808 -
It is another objective of the present invention to provide a method and apparatus for enhancing and improving the communication of information over an alphanumeric paging network, which automatically sends caller identification information, including numeric information and alphabetic information, over the telephone network during interactions between a page-originating communicant and the paging network, thus enhancing the efficiency and accuracy of alphanumeric paging networks, by then automatically transmitting the caller identification information over the wireless communication link between a central office and a page-receiving communicant.

'862 Patent, col.11.65-col.2 1.9 (emphasis added). In addition, according to the '862 Patent, the page-originating communicant's paging request initiates the automatic transmission of caller ID: "The paging request [from the page-originating communicant] automatically transfers caller-identification information . . . from the telephone network to the alphanumeric paging network." Id. at col.2 ll.29-33.

Like the '186 Patent, the '862 Patent also distinguishes between the transmission of the caller-identification information, which occurs automatically, and an "optional message," which requires the page-originating communicant's "input":

Communication is initiated between the page-originating communicant and the alphanumeric paging network over a telephone network. The caller-identification information is automatically passed from the telephone network to the paging network. The page-originating communicant is allowed an opportunity to input an optional message into the paging network.

Id. at col.2 ll.52-58.

Nor does the prosecution history support Kyocera's interpretation of "automatically provided by a communications network." Kyocera relies on the inventor's January 25, 2007 Amendment during the prosecution of the '186 Patent. In that amendment, the inventor added the following phrase which appears (with slight variation) in all of the asserted claims: "the message including a picture supplied by the message originator and a caller ID automatically provided by a communications network that identifies the telephone number of the message originator." (J.A. at 186FH000974.) The phrase's "parallelism," Kyocera contends, "makes clear that one category of information (a picture) is supplied by the message originator, and another category of information (caller ID) is provided by the network." (Kyocera Br. 24.) Again, as explained above, the court believes that this juxtaposition between caller ID and other data such as a picture supplied by the message originator is consistent with Intellect Wireless's assertion that "automatically provided by a communications network" simply indicates that the "caller ID" does not require manual entry by the message originator; the phrase does not exclude the original provision of the "caller ID" by the message originator's device.

Nevertheless, although the court agrees with Intellect Wireless's position that the "caller ID" may originate from the message originator's device and does not involve manual entry by the message originator, the court cannot accept Intellect Wireless's proposed construction for two reasons. First, under one possible interpretation, Intellect Wireless's construction eliminates the phrase "by a communications network" from the asserted claims, replacing it with "wireless portable communication device." Second, the use of the phrase "the wireless portable communication device" incorrectly suggests that the claimed "wireless portable communication device" which receives the message, as opposed to the message originator's device, is sending the "caller ID." For these reasons, the court instead construes "automatically provided by a communications network" to mean "supplied by either the telecommunications network or the telecommunications network via the message originator's device without manual entry by the message originator."

---

10. "Automatically receiving and integrating reports of suspicious activity": n10 Without user intervention, receiving reports of suspicious activity and combining those reports into a different end product; i.e., something more than simply collecting and reiterating data.

n10 '203, '212 and '615 patents, multiple claims.
b.) Automation Boot Sequence Data

The first method step of claim 1 provides that the technology will test for "automation boot sequence data" by examining a boot selection flag. Altiris claims that "automation boot sequence data" is data or computer code from which the computer can be booted up that is separate from the "normal" boot sequence data. Symantec claims that the plain language of the claim suggests that the "automation boot sequence data" must be a particular "known value" of the boot selection flag. The phrase "automation boot sequence data" does not have a customary meaning in the art. As a result of the parties' competing interpretations of the phrase, it would generally be useful to review the specification, however, the phrase "automation boot sequence" does not appear in the specification.

Altiris concludes that because the testing for "automation boot sequence data" is a test for whether an "automation boot" will be implemented instead of a "normal boot," that data is the data or code that will be used to implement the automation boot sequence. However, reviewing the claim language in the context of the entire claim indicates that the "automation boot sequence data" cannot be the automation data or code itself, but something that indicates that the computer should boot in automation mode. Therefore, the court concludes that the proper construction of the phrase "automation boot sequence data" is a particular value assigned to the system ID byte of the first partition which indicates to the custom boot loader that the computer should boot in automation mode.

2. "Automation Code" in Claim 1

The second step of claim 1 requires the "transferring of said computer system to automation code." (Emphasis added.) Similar to the other disputed terms, Symantec argues that this term does not have a clear meaning in the software industry and must be construed by reference to the specification. Symantec claims that according to the specification, the automation code clearly consists of a common operating system, Local Area Network drivers for the Network Interface Card and a program for reading a database on the network server to ascertain the automation commands to be executed.

Altiris rejects Symantec's limitation of "automation code" and argues that the claim language defines "automation code" as any booting code separate from the normal booting code. Altiris further asserts that the specification does not ever expressly "define" automation code in the manner Symantec asserts and, in fact, confirms its interpretation of the claim language by referring to computer code in the automation partition as code from which the computer is "booted up" separate from the"normal" booting. See '593 Patent at col. 6, lines 1-9, 19-21, 47-50, 55-56, 59-61; col. 4, lines 37-41.

The specification provides that "the Installation Utility creates an automation partition on the hard disk populated with a common operating system (such as PC DOS), Local Area Network (LAN) drivers for the Network Interface Card (NIC), and a program for reading a database on the network server to ascertain the automation commands to be executed." Id at col. 3, lines 50-55. The specification also explains that if the testing step indicates that an automation boot should occur, "then the MBR code finds the automation partition on the hard disk, transfers control of the boot process to the code in the automation partition, which then loads the computer operating system. When the operating system has been loaded, the LAN drivers for the resident NIC are loaded, also from the automation partition, and a connection is established across the network to the network server." Id. at col. 6, lines 6-13.

This court concludes that because this phrase is not commonly used in the industry and the claim language is not clear, the phrase should be construed according to what an ordinary person in the field would understand the phrase to mean based upon the information and embodiment contained in the claim specification.
means the code in the automation partition which loads an operating system, LAN drivers for the resident NIC, and a
program for reading a database on the network server to ascertain the automation commands to be executed.

A. Single Self-Contained and Autonomous

Digi proposes that "self-contained" means "providing all networking hardware, networking software, and device interface
elements needed for networked operation of a device." Digi asserts that the term "autonomous" should be construed as
follows: "the module operates independently of the device, does not incorporate any of its functionality or require any
changes to the device, and can if necessary provide all processing power and the network communication capabilities
required to enable networked operation of the device." Further, Digi adds, "No device specific applications run on the
module." Lantronix, on the other hand, contends that the term "self-contained autonomous" "should be defined by the
elements listed after the word 'comprises,' which define what the 'self-contained autonomous' module is 'comprised of.'"
Lantronix asserts that the word "comprises" is "non-limiting and means that a device may be covered by the claim even if it
has additional components or functionality." Finally, Lantronix maintains that "autonomous," as used in Claim 1, does not
mean that the module is located outside the device.

As a preliminary matter, the Court disagrees with two crucial aspects of Lantronix's proposed construction. First, Lantronix
asserts that the claim language to be construed is a single phrase: "self-contained autonomous." Claim 1, however, uses the
language "self-contained and autonomous." (192 Patent C. 18, 1: 41 (emphasis added).) In light of the actual claim
language, the Court will construe the terms "self-contained" and "autonomous" separately. To do otherwise would
inappropriately render one of the terms meaningless. See Cardiac Pacemakers, Inc. v. St. Jude Medical, Inc., 296 F.3d 1106,
1115 (Fed. Cir. 2002).

In addition, the Court finds no support for Lantronix's position that the phrase "self-contained and autonomous module,
followed by the word "comprises," means that the "module" of Claim 1 merely contains the elements that are subsequently
listed in Claim 1. The Court agrees with Lantronix that the word "comprises" acts as a transition, meaning that the claim
language "is inclusive or open-ended and does not exclude additional, unrecited elements or method steps." Georgia-Pacific
Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327 (Fed. Cir. 1999) (citations omitted). However, this transitional
language does not render meaningless the terms that precede the word "comprises." In other words, Lantronix's proposed
construction would inappropriately render the terms "self-contained" and "autonomous" as mere surplusage. The Court finds
that Claim 1 describes a unit that "comprises" the subsequently listed elements, but is also "self-contained" and
"autonomous." (192 Patent c. 18, 11: 41-44.) With this determination in mind, the Court turns to the construction of the
words "self-contained" and "autonomous."

1. Self-Contained

As noted above, Lantronix has not provided the Court with an independent proposed construction for the term "self-
contained." Digi asserts that the term "self-contained" should be construed as "providing all networking hardware,
networking software, and device interface elements needed for networked operation of a device." The Court finds merit in
Digi's construction.

The specification supports Digi's construction. The specification describes a module that provides all of the networking
capabilities needed to operate or monitor a device from a remote location. The specification specifically states:

- the present invention requires only a single, inexpensive integrated circuit chip. Remarkably, this single network interface
  chip provides all the networking hardware, networking software and device interface elements necessary for network
  connectivity and web-based or network-based management of any device.

   (192 Patent c.2, 11: 45-50.) Further, it describes the invention as follows:

   - the network interface chip of the present invention provides complete internet enablement without any expensive web
     server machine. The chip alone is a fully functional internet node, including a web server, and supporting various protocols
and hardware connections.

(Id. at c. 3, 11: 11-16.) Finally, the specification reads:

The network interface chip 36 is a single integrated circuit that connects to the control circuitry 38 of virtually any remote device 34 and implements all networking services required to interface the device with a high performance computer network 32 for remote control and monitoring by one or more clients 30.

(Id. at c. 6, 11: 30-35.) This language supports a construction of "self-contained" as providing all of the hardware and software required to operate a device remotely.

In addition, the prosecution history supports Digi's construction. In their reply to the Office Action dated November 30, 2001, the inventors stated:

The present invention clearly claims and describes in the specification (for example Page 3, lines 23-24; Page 4, lines 22-24; Page 5, lines 1-2) a single module (such as a network interface chip) that provides all the networking hardware, networking software, and device interface elements necessary for network connectivity and web-based or network-based management of any device.

(Reply to Office Action at 5-6 (emphasis in original).) This prosecution history is consistent with the specification and supports Digi's construction.

Thus, the Court construes the term "self-contained" to mean that the module "provides all networking hardware, networking software, and device interface elements needed for the networked operation of the device."

2. Autonomous

As stated above, Digi asserts that "autonomous " should be construed to mean "the module operates independently of the device, does not incorporate any of its functionality or require any changes to the device, and can if necessary provide all processing power and network communication capabilities required to enable networked operation of the device. No device specific applications run on the module." Aside from its arguments noted above, Lantronix offers no independent proposed construction of the term "autonomous." Lantronix disagrees with Digi's construction, however, and asserts that it inappropriately reads limitations into Claim 1.

Digi contends that the specification supports its construction. Specifically, Digi points to the following language:

the present invention requires only a single, inexpensive integrated circuit chip. Remarkably, this single network interface chip provides all the networking hardware, networking software and device interface elements necessary for network connectivity and web-based or network-based management of any device.

(id. at c. 2, 11: 45-50);

the network interface chip of the present invention provides complete internet enablement without any expensive web server machine. The chip alone is a fully functional internet node, including a web server, and supporting various protocols and hardware connections.

(id. at c. 3, 11: 11-16);

The network interface chip 36 is a single integrated circuit that connects to the control circuitry 38 of virtually any remote device 34 and implements all networking services required to interface the device with a high performance computer network 32 for remote control and monitoring by one or more clients 30.

(id at c. 6, 11: 30-36);

The resulting interface to the Device Control Circuitry 38 is a simple, easy to use data exchange. The device 34 is not
burdened with the overhead of network processing.
(id. at c. 6, 11: 41-44);

The chip's complete Internet Protocol implementation offloads the complex network processing and real-time requirements from the device control circuitry.
(id. at c. 7, 11: 23-26); and

As is evident from the description above, the chip 36 is entirely generic and capable of being customized to interface with any device using any of the various device interfaces described above, and with any client via any of the various network interfaces described above. Thus, this single chip can be inexpensively produced in large quantities for a wide variety of potential applications, and then easily customized for use in specific devices.
(id. at c. 16, 11: 23-30).

In addition, Digi asserts that the invention's patentability was initially rejected over prior art that disclosed modules that provided remote monitoring and control of devices but envisioned modification of the devices or running device-specific applications on the module. In reply to the Office Action, the inventors stated:

Important is the partitioning and autonomy of the module wherein the module performs none of the application-specific functions of the host device. The module solely and completely provides the network connectivity function. The same module also enables monitoring and controlling of any device, regardless of its available processing power, code space, or interface pins. Even devices without a CPU or microcontroller are supported.
(Reply to Office Action at 6.)

The Court agrees, in part, with Digi's proposed construction. The Court finds that the specification points to the universal applicability or generic nature of the module, and thus that the module operates independently of the device. In addition, in light of the generic, universally-applicable nature of the module, the Court finds that the specification and prosecution history support that the module does not incorporate any of the device's functionality. If the module were to take over some of the device's functions itself, the module would, in effect, become part of the device control circuitry and not be autonomous. Here, rather, the module simply acts as a conduit between the virtual interface controls of the client machine and the device itself.

The Court finds that Digi's proposed construction goes too far in some respects as well. First, the Court finds no support for Digi's contention that the module "does not require any changes to the device." The Court can contemplate ways in which the universally-applicable module described in the claim language and specification would require a change to the device. For instance, in the hypothetical example often used by Digi in this litigation, the module acts as a link between a host computer and a thermostat via a computer network. Digi's construction does not account for the change that would be required to the thermostat to allow the module to physically connect to the thermostat's circuitry. The Court sees this same issue arising with any device that does not have built-in connection ports. In this sense, the module would require a change to the device in order to allow it to connect to the device. Neither the claim language nor the specification disavows this interpretation.

Digi also asserts that the module can, if necessary, provide all processing power and network communication capabilities required to enable networked operation of the device. The Court agrees that this may be true of the invention based on the specification and prosecution history. But the Court sees no need to incorporate these aspects into the construction of the term "autonomous" because the Court has already construed the term "self-contained" to encompass these elements. Thus, to attach these same definitions to the term "autonomous" would render one of the terms redundant.

Finally, Digi asserts that no device-specific applications run on the module. The Court finds no support in the claim language or specification for this construction. Moreover, the Court finds that the language of the prosecution history (or the inventor testimony) is not sufficient to impart this construction into the definition of the term "autonomous." Specifically, Digi cites to language from the inventors' reply to the Office Action that states that the module "performs none of the
application-specific functions of the host device." (Reply to Office Action at 6.) But this language does not equate to "no device-specific applications running on the module," as Digi contends. Because the claim language and prosecution history contain no clear disavowal of device-specific applications running on the module, this portion of Digi's proposed construction is inappropriate.

With these considerations in mind, the Court defines the term "autonomous" as "the module operates independently of the host device and does not incorporate any of the device's functionality."

**A. Claim Construction**

The parties' dispute whether the auxiliary signal includes the synchronization signal. Philips asserts that the term "auxiliary codes" specifies "control data" that is "distinct from synchronization signals, which contain no information." See Philips Memo. at 40. It states that "synchronization signals are used to indicate that a code word, whether an address or an auxiliary code, will follow immediately." See id. at 40. In comparison, Defendants argue that Claim 20 of '764 does not state that certain types of control information are included within the auxiliary signal, with synchronization signals being excluded from the auxiliary signal. In fact, Claim 20 states that "the auxiliary signal is comprised of address codes and auxiliary codes." See Defs. Memo. at 20. As the patent does not specifically exclude synchronization signals from the auxiliary signal, Defendants argue that those signals are included within the auxiliary signal. See Tr. at 48-49 ("Now, the language of the claim, the '764 patent, states that the auxiliary codes specify control data used for recording information on the carrier. Synchronization codes are used exactly for that purpose, for specifying control data used for recording information on the record carrier.").

The patent specification explains the function of the auxiliary codes. See '764 2: 6-12 ("the auxiliary codes comprise control data for controlling the recording process, wherein the recording device is adapted to control the recording process in dependence upon the extracted auxiliary codes."); '764 2:61-65 ("In such a case, a predetermined address can be assigned to one of the radial positions, while the addresses of track portions having the other radial positions can be indicated by means of auxiliary codes."). The patent differentiates clearly between the auxiliary codes and the synchronization signal. See '764 4: 44-46 ("FIG. 2 provides an example of a suitable auxiliary signal comprising code signals 12 which alternate with synchronized signals [comprising code signals] 11."); '764 59-61 ("The synchronized signals 11 are selected in such a way that they can be distinguished from the code signals 12."); '764 6:64- 7: 6:

As already stated, it should be possible for the auxiliary codes and the address codes to be distinguished from one another. This can be achieved, for example, if the code signals representing the address codes and code signals representing the auxiliary codes are preceded by different synchronization signals 11. A number of different synchronization signals 11 which may be used in conjunction with the code signals 12 described herein are described inter alia in Netherlands Patent Application NL-A-8801275, which corresponds to U.S. Pat. No. 5,060,219.

The plain language of the patent claims and specification indicates that the "auxiliary codes" and the "synchronization signals" are separate and distinct from one another. It would make no sense to contrast the synchronization signal and the auxiliary signal, which encompasses the auxiliary codes, if the synchronization signal was in fact part of the auxiliary signal. As the auxiliary signal is comprised of the address codes and the auxiliary codes, and the synchronization signal is shown to be distinct from the auxiliary signal, and hence cannot be part of either the address codes or auxiliary codes, the Court interprets the disputed term "auxiliary code" as separate and distinct from synchronization signals.
CONSTRUCTION

Auxiliary Device

A playback device, such as another VCR, that is physically separate from the video player that plays back the video program, and is the source of substitute material

A substitute source of video material, where such material may include messages, information, advertisements or other video programs.

Claim 8 uses the term "auxiliary device" in the following context: "sending a signal to an auxiliary device." Claim 19 uses the exact same terminology.

i. Parties' Arguments

The NG Parties argue "auxiliary device" means "a playback device, such as another VCR, that is physically separate from the video player that plays back the video program, and is the source of substitute material." First, the NG Parties rely on the plain meaning of the phrase "sending a signal to an auxiliary device." They believe the verb "sending to" means the auxiliary device is external to the video player because a device cannot send a signal to itself. Second, the Non-Guardian Parties argue the specification exemplifies the "auxiliary device" only by reference to external devices such as "a second video player," "another VCR," or "a VCR."

Guardian believes "auxiliary device" means "a substitute source of video material, where such material may include messages, information, advertisements or other video programs." Guardian believes their construction is consistent with the findings of the PTO's reexamination of the patent. Further, Guardian contends the PTO rejected the definition proposed by the NG Parties.

In its reply, the NG Parties contest Guardian's use of "substitute." They assert the auxiliary device is "the source of substitute material" not "a substitute source of video material." The NG Parties believe Guardian's construction avoids the essence of the claimed invention: replacing material from the main program. Further, the NG Parties argue the auxiliary devices at issue do not replace anything.

ii. Analysis

The first issue is whether the auxiliary device need be external to the video player system. The Court first turns to the language of the claim. Both claim 8 and claim 19 include the phrase "sending a signal to an auxiliary device." Generally, a device cannot send a signal to itself; therefore, the video player and auxiliary device must be separate and distinct components of the system. However, neither claim 8 or claim 19 discusses whether the system must be located either inside or outside of one enclosure. When reasonably read, the claims' limitations would allow both components -- the video player and auxiliary device -- to be housed in same enclosure. The silence of the claims on the issue of physical separation weighs against reading a "physically separate" limitation into the claim.

Moreover, the specification is also silent on the issue of the proposed "physically separate" limitation. According to the specification, the "auxiliary device" provides substitute material to replace material from a main program:

If a REPLACE code is detected, a signal is sent to auxiliary output . . . . On receipt of this signal, an auxiliary device, such as another VCR, responds by playing another recording, and an auxiliary switching device selects the substitute material to be displayed . . .

. . .

When the auxiliary device has finished replaying the substitute program, it sends a signal to auxiliary input . . . which causes replay of the first program to resume.

('158 Patent, at Col. 5:25-41.) Although the specification contains an example of an auxiliary device, "another VCR," it does not explicitly require the auxiliary device be external to the enclosure that contains the video player. Furthermore, after scouring the remainder of the specification, the Court finds no support for the physically separate requirement. Accordingly,
the specification weighs against reading a "physically separate" limitation into the claim.

The NG Parties fail to appreciate the difference between an exemplar and a requirement. The specification includes two exemplars of the "auxiliary device" that are external devices. First, the specification states, "[o]n receipt of this signal, an auxiliary device, such as another VCR, responds by playing another recording . . . ." (The '158 Patent, 5:27-30.) Later, the specification again describes the auxiliary device as an external device, "In this case, the auxiliary device can be a VCR which plays a recording comprising a number of advertisements or messages . . . ." (The '158 Patent, 5:48-50.) Although these examples prove the auxiliary device may be external, it does not necessarily follow that the device must be external. See, e.g., Varco, L.P. v. Pason Systems USA, Corp., 436 F.3d 1368, 1373 (Fed. Cir. 2006) ("In examining the specification for proper context . . . this court will not at any time import limitations from the specification into the claims."). Accordingly, this language does not support the position of the NG Parties.

The second issue is whether the auxiliary device is "the source of substitute video material" or "a substitute source of video material." Despite Guardian's protestations, this is a distinction with a difference. A review of the specification reveals that the sole purpose of the auxiliary device is to provide "substitute video material." The specification states the patent's purpose is "directed to providing means for replacing unwanted program with programme [sic] from another source." (Gresalfi Decl., Ex. 1, at A.9: 5:12-15) (emphasis added). Further, at oral argument, Guardian agreed the auxiliary device provides substitute video material. Guardian's construction improperly implies the auxiliary device is a substitute source, not a source of substitute material. This would mean an auxiliary device could provide the same video material, as long as it was generated from a different source. This would clearly fail to reflect the purpose of "providing means for replacing unwanted program with program from another source." Accordingly, the Court finds the auxiliary device is "the source of substitute video material."

The third issue is whether to include the final sentence of Guardian's proposed construction, in which it defines "video material" as "may include messages, information, advertisements, or other video programs." Turning to the intrinsic record, the specification teaches that substitute material may include "information," "advertisements," "messages," or "substitute programs." (Gresalfi Decl., Ex. 1., at A.9: 5:39, 48, 50-51.) However, because the specification cannot act as a limitation unto itself, the construction should not constrain the term "video material" to these categories. Accordingly, the Court includes the phrase "video material, where such material may include messages, information, advertisements, or other video programs." 3

--- Footnotes ---

3 After oral argument, the NG Parties filed a supplemental letter brief arguing the Court should apply the doctrine of collateral estoppel to determine the proper construction of the term "video program." The NG Parties argue this Court is bound by the Central District's construction of that term in the case Guardian v. Coby, Case No. 2:08cv08439, which also concerned the '158 patent. The Court will not consider this argument, raised by the NG Parties for the first time after extensive briefing and oral argument on the summary judgment motion.

--- End Footnotes ---

iii. Construction

The Court construes the term "auxiliary device" as "the source of substitute video material, where such material may include messages, information, advertisements or other video programs."

346

b. "auxiliary site data"

Claim 1 requires "at least one storage assembly associated with said local processor assembly and structured to contain a quantity of auxiliary site data." Citrix urges the Court to construe "auxiliary site data" as "data that supplements or aids the claimed primary site data." Rothschild proposes that the term be construed as "data on a location on the local processor assembly." "Auxiliary site data" is not a term of art in the computer science field.
Citrix claims that the '534 Patent defines auxiliary site data as a particular type of data and not by its location. For example, Citrix points to the following specification excerpts:

When, however, utilization of the primary site address calls for interactive video and/or graphical displays with associated audio, downloading need not take place, but rather the remote server assembly 50 accesses the [local processor assembly's data storage assembly] and initiates utilization of the auxiliary site data stored thereon by the local processor assembly 25' so as to significantly enhance the on-line experience with added information, graphical display, and advertising clips, if desired.

* * *

The system should also be capable of seamlessly and quickly providing a variety of supplemental and auxiliary information, which can significantly enhance the on-line experience by achieving sophisticated and generally lengthy audio and video segments . . . .

* * *

Preferably, the compact, portable interchangeable, computer readable medium 36 is structured to contain a plurality of separate and distinct video images, audio signals, graphical displays, etc. and various combinations thereof. Indeed, it is seen that the auxiliary site data contained on the compact, portable interchangeable computer readable medium 36 primarily includes data types which are substantially difficult to quickly and effectively download from a remote server assembly . . . .

Citrix also argues that the patent's use of "auxiliary site data" to describe the display data or information meant to supplement or aid the primary site data is consistent with the ordinary meaning of "auxiliary" as defined in the dictionary:

auxiliary: 1. Giving assistance or support; helping. 2. Acting as a subsidiary; supplementary: [e.g.,] the main library and its auxiliary branches. (The American Heritage Dictionary of the English Language, 3d Ed. 1996).

In addition, Citrix points to the testimony of its expert Dr. Newman, who testified at the Markman hearing that "auxiliary site data" is data that "supplement[s] the primary site data." (4/13/07 Hearing Tr. at 78:11-20).

Rothschild contends that the claims and specification support its proposed construction. For example, Rothschild points to language in the specification that indicates that the auxiliary site data is stored on a data storage assembly associated with the local processor assembly. The Court concludes that Rothschild's proposed construction of "auxiliary site data" suffers from the same defect as its construction of "primary site data." By defining "auxiliary site data" merely by its location, Rothschild effectively reads out "auxiliary site" from the limitation. Accordingly, in accordance with the patent's use of the term and the ordinary meaning of "auxiliary," the Court construes the limitation "auxiliary site data" as "data that supplements or aids the claimed primary site data."

II. "AV path" / "data path" / "second path" / "path"

The parties request construction of three different types of "paths," as well as resolution of a global issue pertaining to all "paths" in the asserted claims. The three disputed uses of the term "path" appear in Claim 1 of the '654 patent:

1. A teleconferencing system for conducting a teleconference among a plurality of participants, comprising:

   (a) a plurality of workstations, each workstation having first and second monitors and in communication with audio and video (AV) capture capabilities;
(b) a data path in communication with the plurality of workstations, over which data can be shared among the plurality of participants; and

(c) an AV path in communication with the plurality of workstations, along which AV signals, representing video images and spoken audio of the participants, can be carried;

wherein, the system is configured to reproduce images, based on data signals shared along the data path, on at least two first monitors so as to permit participants associated with the workstations having the two first monitors to interactively share the reproduced images and reproduce participant video images, based on AV signals carried along the second path, on at least two second monitors.

'654 patent at 41:36-55.

A. "path"

Tandberg argues that each type of claimed path must be "defined" or specified before data or AV signals are transmitted. Tandberg argues that the claim language compels this finding. For example, claim 15 states that the data conferencing control establishes "communications with the central control manager to set up requested data paths along a second network over which the data conference can be conducted." '654 patent at 44:3-9. According to Tandberg, once the central control manager has "set up" the path (which occurs before transmission takes place), the path has been defined.

This argument depends on the meaning of "set up." For Tandberg's argument to be valid, "set up" must mean "define." The phrase "set up," however, encompasses other meanings, such as "establish" or "make ready." See, e.g., Webster's Third New International Dictionary of the English Language Unabridged 2079 (1993) ("to put (a machine) in readiness or adjustment"); Random House Unabridged Dictionary 1751 (2d ed. 1993) ("to be assembled or made ready for use") (emphasis added). Moreover, as discussed below, Tandberg's narrow construction would exclude all of the embodiments disclosed in the specification, which unquestionably make use of opportunistic routing and do not require predefined paths.

Tandberg next points to Figure 4 of the patent, which depicts different routes that an AV signal may take through the Wide Area Network ("WAN"). The portion of the Specification corresponding to Figure 4 states that "[t]he system also provides optimal routes for audio/video signals through the WAN. For example, in Figure 4, location A can take either a direct route to location D via path 47, or a two hop route through location C via paths 48 and 49." Spec. at 10:55-59. The fact that data can take one of two routes, however, says nothing about whether the choice of route is predetermined. Indeed, Tandberg observed at argument that in packet-switched networks such as those described in the Specification, the route through the WAN could change during the middle of a transmission, depending on network load and other factors. The routing of each packet through a packet-switched network is individually determined and can change to adapt to changing network conditions. See Spec. at 10:63-66 ("In a more complex network, several multi-hop routes are typically available, in which case the routing system handles the decision making, which for example can be based on network loading considerations.").

Tandberg's remaining arguments in support of its contention that all paths must be predefined relate to a different question—whether the AV and data paths must lie on physically separate wires. The court considers these arguments below. The fact that signals may travel on different wires, however, is not determinative of whether the path for each signal individually is pre-defined. The court will therefore not limit the claim terms as Tandberg requests, and construes "path" to mean "a route or course."

B. "AV path"

CPI argues that the "AV path" should be construed to mean "a route or course over which audio and/or video (commonly abbreviated 'AV') information travels for real-time delivery." Tandberg does not expressly offer a construction of "AV path," but suggests in its papers that the AV path must be physically separate from the data path.

In an earlier litigation involving the '654 and '547 patents, Judge Chesney of this district has already construed the terms "AV path" and "data path" and rejected the very argument which Tandberg advances in this case. Collaboration Props., Inc. v. Polycom, Inc., No. C 02-04591, slip op. at 27 (N.D. Cal. Mar. 23, 2004). The Polycom court reviewed the intrinsic record and concluded that the claimed inventions cover both the preferred embodiment, in which AV and data signals travel over
Finally, Tandberg argues that the Polycom claim construction is inconsistent in that it provides both for paths that are physically separate and paths that are not. The Polycom court only noted, however, that certain claims expressly require...
varying degrees of physical separation while others do not. Nothing about this holding is inconsistent.

The court therefore adopts the Polycom construction; "AV path" means "a route or course over which audio and/or video (commonly abbreviated 'AV') information travels for real-time delivery."

---

348

B. "available for receiving [transmitting] a packet"

At oral argument, counsel for Toshiba argued that affirming the construction of "layer" would not support the noninfringement judgment as to the '710 patent. Even accepting this late-stage contention, it would make no difference. We hold that the district court also properly construed the term "available for receiving [transmitting] a packet," providing another ground for affirming noninfringement of the '710 patent.

The district court construed "available for receiving [transmitting] a packet" as requiring that the virtual connection exists when setting up a bypass pipe. The dispute turns on whether the virtual connection at issue must exist before setting up a correspondence relationship, or only be capable of existing for receiving/transmitting packets.

The claim language uses "available" to describe the virtual connections, a relatively vague term that does not compel either party's position. As Juniper points out, the specification describes a preferred embodiment in which the router will not set up a bypass pipe if the desired virtual connection does not exist. '710 patent, col. 24, ll. 40-50, col. 24, l. 66-col. 25, l. 2. Moreover, Yasuhiro Katsube, a named inventor on the patents, stated in a deposition that "the virtual connection needs to be in existence" before registering the correspondence relationship.

Toshiba urges us to focus on the language of the claims, and provides no other support for its argument that the virtual connections need not exist when establishing a correspondence relationship. Given the ambiguous claim term at issue, we hold that the intrinsic and extrinsic evidence both indicate the virtual connection must exist when setting up a correspondence relationship. We therefore find no error in the district court's construction and affirm the judgment of noninfringement as to the '710 patent.

---

349

B. Proper Construction of "Free Partitions" "Available To Store Data"

NetApp initially proposed construction of the term "free partitions" as "logical cylinders in which all space is free and no data is currently stored." Sun challenged NetApp's initial construction in part because it would preclude a free partition from containing administrative data, which the claims and this Court's Claim Construction Order specifically allow for. See '012 Patent at 18:64-65; 12/22/08 Claim Construction Order. NetApp shifted gears at the second hearing and instead proposed to construe "free partition" as "a portion of verifiable memory space" that is "configured to store verifiable data, such as customer and redundancy data." Sun proposes to construe "free partitions" as "[all or a segment of a memory space] which do[es] not contain customer or redundancy data." Thus, the decisive difference between the parties' current proposed constructions is whether a free partition must be configured to be able to store "customer or redundancy data," or whether it is sufficient if the free partition can contain only administrative data. Resolution of this dispute turns on two questions: (1) what is the correct construction of the term "data" as used in the patent; and (2) how closely must a free partition be associated with a RAID group.

First, with respect to the term "data," NetApp persuasively argues that Sun's infringement theory hinges on an internally inconsistent interpretation of the term "data." Specifically, NetApp points out that Sun's proposed construction of the term "dedicated partition currently storing data" means a partition that "contains customer or redundancy data." Thus, in the context of "dedicated partitions," Sun defines "data" as "customer or redundancy data." In contrast, in connection with "free partitions," Sun argues that "data" can be "administrative data" and need not be limited to "customer or redundancy data." Nothing in the '012 Patent indicates that the term "data" should be interpreted differently with respect to free and dedicated...
partitions, and the patent contemplates the existence of administrative data in both free and dedicated partitions and provides for scrubbing of administrative data in both free and dedicated partitions. Homrig Decl. Ex. 4 at 15:30-44. NetApp is correct that, were Sun to consistently construe "data" so that dedicated partitions could encompass mere administrative data, then it would necessarily follow that the non-filesystem region and spare disks (which Sun admits contains administrative data) would not only be deemed "free partitions," but would necessarily also be deemed "dedicated partitions." This unreasonable interpretation would impermissibly obliterate the patent's distinction between dedicated partitions and free partitions. Further, it would mean that, for the accused NetApp products to infringe, they would need to scrub the administrative data of these "dedicated" partitions, but it is undisputed that the non-filesystem region and spare disks are never scrubbed. Thus, what is significant is whether a partition contains, or is capable of containing, customer and redundancy data, not merely administrative data. The Court therefore concludes that a free partition must at least be configured so that it is capable of containing customer or redundancy data in order to be "available to store data," as required by claim 1.

Second, the '012 Patent discloses a scheme for running a separate periodic scrub for each volume, where "[e]ach volume consists of N+M physical devices forming an N+M redundancy group." Homrig Decl. Ex. 4 ('012 Patent) at 13:34-44. This indicates that the patent only contemplates periodical scrubbing of N+M disks that make up the redundancy, or RAID group. Additionally, the patent states that the periodic disk scrubbing procedure functions by sequencing through all of the device range partitions "on all of the configured volumes for a selected cylinder" before proceeding to scrub the next cylinder. Id. at 14:19-23. This further indicates that the patent contemplates scrubbing configured volumes that are already within a RAID group. Finally, NetApp points out that the claim term "dedicated partition" expressly states that it is "currently storing data." Id. at 17:41-42. NetApp contends that this supports its position that the partitions in the patent change freely from "dedicated" to "free" and vice-versa depending on whether they are "currently" holding data at any given minute, and do not contemplate a situation where a "free partition" would have to undergo a process of being configured to store data and incorporated into a RAID group before it could be a dedicated partition. The Court agrees with these points and construes the term "available to store data" of a "free partition" as "ready and able to store customer and redundancy data." 2

2 NetApp also argues that the '012 Patent discloses the use of a free space directory for "dynamically monitoring" how much data each partition is presently storing. See Opp. at 16 (citing Homrig Decl. Ex. 4 at 8:44-50, Fig. 8). NetApp contends that the claimed invention discloses free and dedicated partitions that can fluidly transform from one to another based on whether they are holding data at a given time, and that dynamic tracking of the available space in each partition is the mechanism by which the patent achieves its claimed performance benefit of knowing what to scrub and not scrub. Sun counters that the Court should not indulge NetApp's attempt to read a "dynamic tracking" limitation into the asserted claims because no such limitation is found in the claim terms and NetApp has not sufficiently shown how or why this limitation should apply. Specifically, Sun argues that claims 1 and 16 do not require that a free partition ever become a dedicated partition (though claim 24 does contemplate this type of transition). The Court does not rely on this assertion by NetApp in granting summary judgment.

Markman Order

By order [138] entered June 15, 2006, this case was referred to Gale R. Peterson, as Special Master, for issues relating to claim construction. Following briefing of the issues by the parties and a hearing, Mr. Peterson submitted his Report and Recommendation (the "R&R") [153] to the Court on April 3, 2007. Following submission of the R&R to the Court, each of the parties filed objections [154 and 155] to the R&R, as well as responses [156 and 157] to the opposing party's objections. As required by Federal Rule of Civil Procedure 53(g)(4) the Court has conducted a de novo review of all of the recommended findings to which objections have been filed. Except as set out below, the Court adopts the findings and conclusions of the R&R. Specifically, the Court adopts the proposed constructions of all terms and phrases as recommended by the R&R, except for the following phrases: "average consumer," "suitable for installation by the average consumer," "can be installed by the average consumer," and "price affordable to an average consumer" (the "average consumer' phrases").

- 821 -
In defining "average consumer" in the "average consumer" phrases, the R&R suggests that because the claimed method in the patent is a "method for providing," the focus of the claim is "the objective characteristics of what is 'provided' rather than the characteristics of an actual purchaser." (R&R at 36) Based on this conclusion, the R&R proposes that these terms be construed as follows:

1. "average consumer" to mean one without special training in stonecutting;
2. "price affordable to an average consumer" to mean that a "pre cut" "non man made" "stone top" in accordance with other terms in the claims does not require a purchaser to incur the additional costs of engaging the services of someone skilled in stonecutting in order to install the top;
3. "suitable for installation by the average consumer" and "can be installed by the average consumer" to mean a "pre cut" "non man made" "stone top" in accordance with other terms in the claims that is "non custom ordered" or "not custom ordered" also in accordance with other terms in the claims, and that product may be installed without requiring the services of someone with special training in stone-cutting.

(R&R at 46.) The problem with this conclusion is that, in defining what is "provided," the patent claim utilizes the characteristics of the purchaser. That is, the counter top must be one that is "pre cut non man made" stone and is "affordable to an average consumer" and is capable of being installed "by the average consumer." ('973 Patent, col. 5, ll 27-28, 32.)

The Federal Circuit has instructed that "claim language should not be treated as meaningless," and "claims are interpreted with an eye toward giving effect to all terms in a claim." Bicon, Inc. v. Straumann Company, 441 F.3d 945, 950, 951 (Fed. Cir. 2006). The construction of these terms in the R&R violates this principle by attributing no meaning to "average consumer" beyond what is otherwise stated in the claim: "a pre cut non man made, non custom ordered stone top." ('973 Patent, col. 5, ll. 27-28.) Plaintiff recognized something more was required to define "average consumer" in its proposed claim construction in which it proposed to define the average consumer, not in terms of the pre cut nature of the top, but in terms of the characteristics of the consumer. Plaintiff's proposed construction of "average consumer" was: "an individual that purchases supplies for a home improvement task from a retail outlet and performs the home improvement task himself or herself, regardless of whether the individual has any professional training in that task." (Joint Claim Construction Statement at A1-1.)

Consistent with the foregoing principles, the Court rejects the construction of "average consumer" in the R&R. The Court finds that Plaintiff's construction of the term "average consumer," with one exception, is consistent with the specification and does not treat a clearly stated characteristic as superfluous. The use of the word "professional" in Plaintiff's proposed definition is not warranted. First, this is a term that may require further definition. Second, the Court finds no support for imposing an additional limitation on the type of training. After reviewing the evidence, the Court concludes that the patent is intended to include tops that can be installed by consumers with no training in counter top installation. The claim provides a method for providing a top that the typical "do-it-yourself homeowner" would be able to install. (973 Patent, col. 2, ll. 18-19.) Therefore, the term "average consumer" shall mean "an individual that purchases supplies for a home improvement task from a retail outlet and performs the home improvement task himself or herself, regardless of whether the individual has any training in that task."

The phrases "AVERAGING THE RESULTING INDICATION . . . OVER TIME" and "AVERAGING OVER A TIME WINDOW" (claims 22 and 24) simply mean that more than one resulting indication, each of which is derived at a different time, is averaged. Additionally, "TIME WINDOW" means a "period of time."
The disputed claim phrase "avoids transfer" appears in claims 1 and 18 of the '051 patent. The parties propose that the disputed claim phrase be construed as follows:

Lexar's proposed constr: - none - [but contests
Toshiba's proposed constr: The controller never transfers the original sectors of the information block during a host rewrite request.
Pretec's proposed constr: Prevents transfer from happening.

For the most part, Toshiba and Pretec agree on the construction of "avoids transfer" and although Lexar disputes Toshiba's construction as the proper one, it does not offer its own proposed construction. The Court finds, however, that Lexar is right in that "avoids transfer" should be construed in accordance with its ordinary meaning. Pretec's proposed construction, "prevents transfer from happening," does not illuminate the meaning of "avoids transfer" in the context of the claim at issue. Toshiba's proposed construction is not consistent with the ordinary meaning of the claim phrase because its use of "never transfers" is likewise inaccurate regarding the meaning of the claim language in context. Claim 1 says that the controller "avoids transfer of a particular information block from one location to another block location each time the host requests that a portion of the information block be re-written." (‘051 patent, 18:54-57 (emphasis added).) The claim language does not say that transfer cannot occur or that it never occurs; it says that transfer is avoided each time the host requests a re-write. That way, as Lexar argued at the claim construction hearing, the invention is more efficient and prevents wearing out the nonvolatile memory device. (Claim Construction Hearing Transcript at 100). Moreover, the description of the preferred embodiment explains that "the overhead associated with an erase cycle is avoided for each write to the memory except for periodically." (‘051 patent, 8:8-10 (emphasis added).) While the court is not to import limitations from a preferred embodiment into the claims themselves, a construction that excludes a preferred embodiment is rarely, if ever, correct. Vitronics, 90 F.3d at 1583-84. Therefore, the court rejects Toshiba's proposed construction. Having considered the claim language in context, the court construes "avoids transfer" to mean: the controller, at times, avoids the transfer of a particular information block during a host rewrite request.

b. Claim 5

Claim 5 of the '892 patent reads (bracketed text and letters provided for ease of reference):

[Preamble] 5. A method of providing a bingo game comprising the steps of:

[A] providing a bingo operator for determining at least one winning bingo pattern;

[B] registering at least one bingo card bearing a plurality of bingo numbers with said operator;

[C] generating a predetermined number of random bingo numbers; and,

[D] identifying all registered bingo cards on which the generated random bingo numbers form one of said at least one [sic] winning bingo pattern and,

[E] awarding the holder of the winning bingo card an award wherein the amount of said award is independent of the number of registered bingo cards on which a winning bingo pattern is formed.

c. Defendant's Proposed Constructions

Defendant contends the Court should give the following terms the meaning they would have had to a person of ordinary skill in the art in light of the intrinsic record. In this regard, Defendant asserts that the following terms should have the following constructions
The term "bingo game" from the preamble: A game of bingo limited by the elements and limitations [A]-[E] from the body of Claim 5.

The term "bingo operator" from paragraph [A]: A person or entity, or a machine or the software in it, that operates a bingo game.

The term "registering at least one bingo card" from paragraph [B]: Assigning each card an identify that will differentiate that card from all the others in play.

The term "a predetermined number of random bingo numbers" from paragraph [C]: The specific and predesignated quantity of random bingo numbers that will be played during a complete bingo game after which the game will end.

The term "an award wherein the amount of said award is independent of the number of registered bingo cards on which a winning bingo pattern is formed" from paragraph [E]: An award of any type in which the value of the award is not based upon how many cards have a winning pattern.

c. Plaintiff's Proposed Constructions

Plaintiff contends that, based upon the general acceptance of certain terms by the public and by using dictionary definitions, the following terms should be constructed as follows:

"Bingo game" - a "traditional" bingo game as that term is understood by the general public. In this regard, Plaintiff suggests that the Court construct the term "bingo game" within Claim 5 as:

a game simultaneously played by multiple players that contains the following elements: (1) displayed cards that bear numbers, (2) which must be daubed on each card when numbers are determined by random means during the game, and (3) which game is won by at least the first person to hold a card on which a previously designated arrangement of numbers has been covered.

"Predetermined number" of random bingo numbers: Plaintiff argues that the term "predetermined number" should be construed in accordance with the dictionary definition of "predetermined." In this regard, Plaintiff argues that the construction should be: "A number or range of numbers that is determined, decided, or established in advance."

"Registered": Plaintiff argues that the term should be constructed as follows:

identifying a discrete bingo card chosen by a player, communicating the pattern of that card to the game operator, and having the game operator record the pattern of the card prior to play of a discrete bingo game.

III. CONCLUSION

Having carefully reviewed the text of Claim 5, the specification, and the prosecution history of the '892 patent, and having considered the parties' arguments presented at the Markman Hearing, the Court finds that the construction proposed by Defendant is, in all respects, proper. The '892 patent was proposed and amended in order to distinguish the patent from prior art. Plaintiff's proposed construction would have the opposite effect. Therefore, the Court finds as a matter of the law that the following terms from Claim 5 shall have the following constructions:

The term "bingo game" from the preamble: A game of bingo limited by the elements and limitations [A]-[E] from the body of Claim 5.

The term "bingo operator" from paragraph [A]: A person or entity, or a machine or the software in it, that operates a bingo game.

The term "registering at least one bingo card" from paragraph [B]: Assigning each card an identify that will differentiate that card from all the others in play.
The term "a predetermined number of random bingo numbers" from paragraph [C]: The specific and predesignated quantity of random bingo numbers that will be played during a complete bingo game after which the game will end.

The term "an award wherein the amount of said award is independent of the number of registered bingo cards on which a winning bingo pattern is formed" from paragraph [E]: An award of any type in which the value of the award is not based upon how many cards have a winning pattern.

IT IS SO ORDERED.

354

1. "Awarding Prize" Step

IGT argues that the "awarding prize" step requires a transfer of legal rights to the prize to the player. Aristocrat contends that simply displaying the amount of the prize won, without a concomitant transfer of entitlement to the prize, suffices to satisfy the "awarding prize" step. Aristocrat's construction is problematic for two reasons. First, this interpretation is contrary to the ordinary and customary meaning of the word "award." "[W]ords in a claim are generally given their ordinary and customary meaning." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). There does not appear to be any evidence in the specification or prosecution history suggesting that the inventor meant to use the term "award" in a manner inconsistent with its ordinary meaning, and Aristocrat seems to agree that "award," as used in the patent, has its ordinary and customary meaning. To award a prize is ordinarily understood to mean to confer rights to a prize, not simply to display for viewing the amount of the prize won, and the dictionary definitions cited by Aristocrat corroborate this understanding. See Dkt. No. 462-1 at 2 (defining "award" as "to grant as legally due").

Second, Aristocrat's proposed construction is contrary to the claim language. The '215 Patent claims a method that includes both of the following two steps: (1) "identifying to the player said one progressive prize from said plurality of progressive prizes that has been won" and (2) "awarding said one progressive prize from said plurality of progressive prizes that has been won." '215 Patent 9:21-25, 10:26-30. In light of this claim language, the "awarding prize" step cannot be met simply by displaying the amount of the prize won, as this would render the "identifying prize" step superfluous. Aristocrat attempts to differentiate between these two steps by contending that the "identifying prize" step indicates to the player that some prize has been won without displaying the monetary amount of the prize, while the "awarding prize" step displays the monetary amount of the prize. This interpretation lacks support in the patent and is contrary to the ordinary and customary meaning of "award." Because a "claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so," Merck & Co., Inc. v. Teva Pharmaceuticals USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005), the court finds that the "awarding prize" step requires more than displaying the amount of the prize won.

It is undisputed that during the testing of gaming machines, legal entitlement to a prize is never conferred upon IGT employees. Since the step of "awarding said one progressive prize from said plurality of progressive prizes that has been won" is not performed during testing, IGT does not perform all of the steps of the claimed method during testing, as required for a finding of infringement. Consequently, the court grants IGT's motion for summary judgment of non-infringement with respect to the '215 Patent.

355

Pursuant to this Court's Markman Order, the term "wafer" means "a thin, generally cylindrical, slice of semiconductor material used as a base for an electronic component or circuit." The term "a first axially symmetric region" means "a region that is symmetric about the central axis of the wafer." The term "substantially free of agglomerated vacancy [or interstitial] defects" means "a concentration of such agglomerated defects which is less than the detection limit of these defects, which is currently about 1000 defects/cm3." The term "agglomerated vacancy intrinsic point defects" means "defects caused by the reaction in which vacancies agglomerate to produce D-defects, flow pattern defects, gate oxide integrity defects, crystal originated particle defects, crystal originated light point defects, and other such vacancy related defects." Finally, "agglomerated silicon self-interstitial intrinsic point defects" means "defects caused by the reaction in which self-interstitials
agglomerate to produce dislocation loops and networks, and other such self-interstitial related defects."

12. **axis of symmetry** ('412 patent)

CEA's proposed construction is "a line relating to the ellipsoid of the indices of a medium corresponding in some way to a symmetric property of the ellipsoid."

Samsung's proposed construction is "the axis in a uniaxial material corresponding to the extraordinary index."

The court adopts Samsung's proposed construction.

CEA's proposed construction, including the language "corresponding in some way to a symmetric property," provides little in the way of defining this claim term. CEA agreed at oral argument that the axis of symmetry corresponds to the extraordinary index. Based on its contention that uniaxial medium does not require the ordinary indices to be equal, however, CEA stated their position is that there is "an axis of rotation" which is an axis of symmetry with respect to the extraordinary index. 39

The specification recites "the compensating medium is a uniaxial medium of negative optical anistropy having an axis of symmetry parallel to the homeotropy direction and an extraordinary axis parallel to said axis of symmetry." 40

Samsung's proposed construction is consistent with the court's construction of uniaxial medium having equal ordinary indices, which would be symmetrical in relation to the extraordinary index.

**Samsung's construction is adopted by the court: "the axis in a uniaxial material corresponding to the extraordinary index."**

1. **Background process** (claim 8)

Plaintiff's Construction: "a process performed automatically while a foreground process, such as reading to or writing from the disc, is not being performed"

Defendants' Construction: "a process performed by the optical disc drive so that another process can be accepted while the background process is being performed"

Although plaintiff argues vigorously in favor of its own proposed definition, the parties' constructions are not that far apart. The parties appear to agree that a "background process" is a lower priority than a foreground process and that the
background process stops while the foreground process is running. At the claim construction hearing, defendants offered no argument on this term.

Plaintiff disputes defendants' use of the word "accepted," which plaintiff says is ambiguous and allows the drawing of an inference that the two processes are occurring simultaneously. One problem with plaintiff's argument is that "accepted" is the word used throughout the patent to describe this process. However, I agree with plaintiff that using the word "accepted" without further clarification leaves the construction ambiguous. Further, defendants did not make an argument in their briefs or at the hearing for keeping that word in the definition, suggesting that they do not object to its omission.

In their response brief (but not at the hearing), defendants included a short discussion questioning plaintiff's use of the word "automatically" because it does not appear in the claim or in any other part of the patent. Dkt. # 183, at 7. In defending the inclusion of "automatically," plaintiff says that "background process" is a term of art in the computer science field and that "automatically" commonly appears in those dictionary definitions. Again, however, it is not enough to point to a dictionary to support a particular construction because dictionaries, even technical ones, do not speak directly to the invention at hand. Phillips, 415 F.3d at 1318-19. The key question is whether the patent itself adopts a dictionary definition or whether it adopts a meaning more tailored to the particular invention. Because plaintiff neither makes a showing that the patent incorporates that definition nor makes any other argument for its inclusion, I will omit it from the construction.

I conclude that this is another term that needs no construction. Again, the parties noted two important aspects of a background process: (1) it can be interrupted by other, higher priority processes; and (2) it is not performed while the high priority process is being performed. These two ideas are already incorporated into the claim itself, which makes clear that the background process is "interrupted" by the request for a recording or reproducing process and that the background process "is resumed" once the other process is finished.

**Court's Construction:** No construction needed
Master does not adopt LPL's construction of "backlight unit" because it does not further define the term. It is axiomatic that a "backlight unit" would include a backlight.

Accordingly, the Special Master's claim construction is as follows:

<table>
<thead>
<tr>
<th>CLAIM TERM</th>
<th>SPECIAL MASTER CONSTRUCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>backlight unit</td>
<td>The layers of the flat-panel display device which illuminate the flat-panel (or liquid crystal) display from behind</td>
</tr>
</tbody>
</table>

The Court construes the term "sufficient bandwidth" to mean "sufficient data transfer capability." In this instance, both parties' proposed constructions improperly include limitations found elsewhere in the claims or specification. For example, ST would include the limitation "that allows real time operation" in the term "sufficient bandwidth." However, the "real time" limitation is found elsewhere in the claim and does not need to be repeated in this term. See '789 Patent, 12:31-32. The Court's construction describes the understanding of one skilled in the art without unnecessary limitations.

4 ST's proposed construction is: "data transfer capability at a rate that allows for real time operation." Motorola's proposed construction is: "equal to greater than the bandwidth required for the decoder to operate in real time without denying the other components on the bus access to memory for an amount of time that would interfere with their operation."

5 ST agreed to the Court's construction at the Markman hearing.

D. Banking Network

Alexsam's Proposal: the Court should adopt the definition provided in section 9 of its Datastream Claim Construction Order (i.e., "a set of interconnected computers used by banks and financial institutions for purposes of conducting and processing financial transactions")

IDT's Proposal: "terminals, computers, and processors of multiple banks, issuers, and third-party processors that are linked together for the purpose of processing financial transactions, and which incorporates and utilizes a bank processing hub"

IDT asks the Court to modify its previous construction for "banking network," which appears in many of the asserted claims. IDT relies on the prosecution history, during which the patentee argued that "a banking network necessarily, by virtue of its being a banking network, incorporates and utilizes a banking processing hub." See Def. Br. at 14. IDT identifies no error in the Court's prior construction, but its argument is nonetheless persuasive. However, the Court disagrees that the banking network necessarily includes a bank processing hub. See '608 Patent, Fig. 2 (processing hub 103 includes three different databases; databases of this type would not ordinarily be found in a bank processing hub). See also '608 patent, 5:4-8 (indicating clearly that the processing hub of the invention is not limited to a bank processing hub). The Court construes "banking network" to mean "a set of interconnected computers used by banks and financial institution for
purposes of conducting and processing financial transactions, and which incorporates and utilizes a processing hub."

361

G. "Banking Transaction"

I define the last disputed term, "banking transaction," as follows: "An activity affecting a deposit account, such as a deposit of funds or a withdrawal."

Again, plaintiffs propose a definition that is vague and overbroad -- "Something carried out or performed with a bank." Defendants' proposed definition, "An activity affecting a deposit account, such as a deposit of funds or a withdrawal, carried out at the request of the account owner," hits closer to the mark, no doubt because that is the definition of "banking transaction" found in the DICTIONARY OF BANKING TERMS. The only problem with the definition is that, as used in the '725 patent, the term "banking transaction" can mean a transaction authorized by the account owner or one that is not authorized by the account owner. The DICTIONARY OF BANKING TERMS limits the definition to an owner-authorized transaction. Such a limitation does not work in connection with this particular patent, which is designed to allow a customer to stop not just transactions that he authorized but has had second thoughts about, but also transactions that he has not authorized, but that are occurring because someone other than the owner has obtained access to the owner's account. In this day and age, where information and identity theft is rampant, it would be foolish to pretend that banking transactions cannot be initiated -- and sometimes completed -- by persons other than account owners. The use of the term "banking transaction" throughout the '725 specifications contemplates the possibility of unauthorized banking transactions. Therefore, the DICTIONARY OF BANKING TERMS definition is too restrictive.

Again, there is an easy fix. Placing a period after the word "withdrawal" in the DICTIONARY OF BANKING TERMS definition, and eliminating the phrase, "Carried out at the request of the account owner," solves the problem while casting the definition in terms that are familiar to one skilled in the art of banking.

362

Base

The Court agrees with Samsung and construes the term "base" in claim 11 of the '339 patent as "a structure on which a multilayer electrical interconnect is fabricated." MEI's proposed construction--"a bottom layer of electrically conductive material"--adds limitations requiring that the base be "electrically conductive" and a "bottom" layer. The specification discloses that the base may be "an organic or inorganic insulator, a conductor, an integrated circuit, or a preceding layer . . . ." '339 Pat. col. 3:24-28 (emphasis added). MEI's narrow construction is controverted by the specification.

363

8. Displaying, with the base map, data that is usable to make a flood zone determination for the real property

This limitation is found in claim 15 of the 698 patent. There are two components to the term. The first is "displaying, with the base map." The second component of the limitation is "data that is usable to make a flood zone determination." The court will address each component.

With respect to the first portion, "displaying, with the base map," the plaintiff suggests that no construction is required. Alternatively, the plaintiff suggests that the court should construe the term to mean "showing, on a CRT or other computer screen to a user, with the base map." The defendants contend that the term "displaying, with the base map" means "showing, on a CRT or other computer screen to a user, with the georeferenced raster topographical map upon which information may be placed." Thus, the defendants contend that the base map must be a georeferenced raster topographical map and that "base" means a map on which information may be placed. The court is persuaded that the term "base map" is the key term
which requires construction. The court defines the term to mean "a map on which information may be placed."

With respect to the second component of the phrase, "data that is usable to make a flood zone determination," the plaintiff contends that the phrase means data which "includes FEMA designations of the same accuracy as a FEMA Flood Insurance Rate Map that may be used to make a flood zone determination for the real property." The defendants contend that the clause means "FEMA designations that may be used to make a flood zone determination for the real property." Although the two definitions are close, the plaintiff's construction is too limiting. The claim language only requires data that "may be used" to make a flood zone determination. As a result, the defendants' construction appears proper, and the court adopts it.

364

3. "a base secret cryptographic value"

A limitation on the "at least one second device" is that it has access to "a base secret cryptographic value" corresponding to said internal secret. The parties dispute the meaning of "base secret cryptographic value."

The language of Claim 1 states that the "base secret cryptographic value" corresponds to "said internal secret state."

The "Detailed Description of the Invention" provides:

The server also obtains the client's base key value K[0] (for example, by retrieving K[0] from the server's memory, by cryptographically deriving K[0] using other secret keys or secret algorithms, by obtaining K[0] from a third party such as a key server, etc.).

('092 Patent, Col. 6:62-66.)

The court construes the phrase "base secret cryptographic value corresponding to said internal secret state" to mean: an initial value sought to be kept secret which is used in the cryptographic method disclosed in Claim 1.

The parties dispute the effect, if any, which step (b) has on the definition of "base secret cryptographic value." In step (b), substep (I), an "updated secret cryptographic value" is derivable. The parties dispute whether this "updated" value 2 is a new value, leaving the "base" value unchanged or whether the "updated" value changes the base value. The Court is requested to indicate in its definition whether the "base" value is "unchanging."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 The dispute also applies to successive "updated" values which are created as step (b) is repeated a plurality of times under step (e).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

A person skilled in the art at the time of the invention would understand from the "Detailed Description of the Invention" that the base value is not retained and used in succeeding processes. Instead, the inventor discloses a method in which the base value is changed in the updating process. Therefore, the Court finds it unnecessary to include the word "unchanging" in its construction of the phrase.

Moreover, the written description discloses an embodiment in which a base cryptographic value may be changed. The specification discloses a state in which "rekeying" could be performed:

Eventually, the client may reach a point at which the entire table has been traversed. For example, the end of the process of FIG. 1 is reached at step 170, where C=60. After this transaction (or at an earlier point if the table length exceeds the maximum number of transactions allowed by the system), the client device could, and might typically disable itself, such as by deleting its internal secrets. However, other actions may be preferable in some cases (e.g., by repeating back to step 110, entering a state in which rekeying is required, etc.).
"Rekeying" could establish a new base cryptographic value. Therefore, the Court declines to include the word "unchanging" in the construction of the phrase because it would eliminate re-keying as part of the process.

A. Parties' Construction Arguments

Plaintiff's original proposed construction seeks "base station" to be construed as "equipment in a wireless communication system that transmits data to a CPE." Plaintiff argues there is language in the specification that supports the "transmits" language. See '759 patent, 2:46-47. At the hearing Plaintiff also proposed a revised construction that reads "a station in a wireless communication system that facilitates communication between a fixed network infrastructure and at least one CPE." Plaintiff provided no briefing on the revised construction, but Plaintiff argued at the hearing that Plaintiff's revised construction is an attempt to bring Plaintiff's construction closer to Defendants' proposed construction in order to focus the Court on the real disputes between the parties.

Defendants seek a construction of "base station" as a "fixed station in a wireless communication system that relays data between a fixed network infrastructure and at least one CPE." Defendants ask the Court to require that the base station be "fixed." For support, Defendants cite to technical dictionaries to show one of ordinary skill in the art would have known that base stations were fixed stations at the time of the filing of the '759 patent. Defendants also point out that the '759 patent incorporates U.S. Patent No. 6,016,311 (filed Nov. 19, 1997) (the '311 patent) by reference, and the '311 patent shows base stations in fixed locations. See, e.g., '311 patent, Figure 4. Defendants' construction additionally requires the fixed station to "relay" data between a fixed network infrastructure and at least one CPE. Defendants' argument relies on the figures and the specification of the '311 patent that show the base station communicating with both the CPEs on one end and network infrastructure on the other end. Id.

B. Analysis

The Court construes the term "base station" as "equipment in a wireless communication system that transmits data to and/or receives data from a CPE." While the Court mostly agrees with Plaintiff's original construction that reads "equipment in a wireless communication system that transmits data to a CPE," the Court believes it is incomplete because it only requires that the base station transmit data to a CPE. Plaintiff supports its construction with the '759 patent specification that describes a method for use in a wireless communication system involving "data transmitted by the base station and subsequently received by the CPE." '759 patent, 2:46-47. But the base station does not only transmit data to the CPEs, it also receives data from the CPEs. See, e.g., '759 patent, 2:19-22 ("a base station having a second modem configured to measure a second link quality for each of the plurality of CPE based on received uplink data"); '759 patent, 2:38-39 ("data transmitted by a CPE and received by a base station"). Therefore, the Court adds the "receives" language to Plaintiff's construction. The Court's construction is strongly grounded in the intrinsic record. See, e.g., '759 patent, 2:52-55 ("receiving a request for the second downlink modulation scheme at the base station, transmitting a third frame of data by the base station to the CPE"); '759 patent, 3:8-40 ("a system where three CPEs . . . are receiving and transmitting data with the base station"); '759 patent, 7:27-29 ("The downlink subframe 302 is used by the base station 102 to transmit information to the plurality of CPEs."). The Court adds the qualification "and/or" to reflect the fact that the specification does not require the base station to both transmit and receive at all times, as in some instances, for example, the specification only discusses the base station transmitting data to the CPEs. See '759 patent, 7:27-29 ("The downlink subframe 302 is used by the base station 102 to transmit information to the plurality of CPEs.").

Defendants' construction is problematic because it imposes an additional limitation that the base station be fixed. "[U]nless required by the specification, limitations that do not otherwise appear in the claims should not be imported into the claims." N. Am. Container, Inc. v. Plastipak Packaging, Inc., 415 F.3d 1335, 1348 (Fed. Cir. 2005). The Court concludes that the '759 patent never limits the base station to a fixed base station, and to the extent Defendants are arguing that base stations are
fixed under the ordinary and customary meaning of that term, the Court disagrees. Nowhere in the '759 patent does the inventor limit the base station to a fixed base station. Defendants point out the '311 patent that is incorporated by reference in the '759 patent, but the '759 patent states that the '311 patent is merely "[o]ne exemplary broadband wireless communications system." '759 patent, 3:29-34. So the '311 patent illustrates a preferred embodiment at best, and it is incorrect for the Court to read in a limitation from a preferred embodiment. Phillips, 415 F.3d at 1323 ("although the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments"). In addition, while the '311 patent clearly shows base stations that are fixed, the '311 patent never explicitly limits or defines base stations as being fixed. Finally, as Plaintiff points out, one of ordinary skill in the art would have known at the time the '759 patent was filed that having mobile base stations was possible. See, e.g., European Patent 0936829A2 (filed Aug. 31, 1998) (describing "mobile base stations"); Patent Cooperation Treaty (PCT) WO 00/36858 (filed Nov. 30, 1999) (describing "mobile base stations"). Thus, contrary to Defendants' argument, the ordinary and customary meaning of base station at the time of the filing of the '759 patent did not require the base stations be fixed.

The Court also disagrees with Defendants' construction as it requires the base station to "relay[] data between a fixed network infrastructure and at least one CPE." The "relay" language does not appear anywhere in the '759 patent, and it is unclear what exactly it means to "relay." In any event, the relationship between the base station and the fixed network infrastructure is not the focus of this invention. The Court "cannot look at the ordinary meaning of a term . . . in a vacuum . . . [r]ather, we must look at the ordinary meaning in the context of the written description and the prosecution history." Medrad, Inc. v. MRI Devices Corp., 401 F.3d 1313, 1319 (Fed. Cir. 2005) (internal quotations omitted). The patent's written description only briefly mentions the fixed network infrastructure—merely to note its existence—when describing the prior art. See '759 patent, 1:13-23 ("A wireless communication system facilitates two-way communication between a plurality of subscriber radio stations or subscriber units (fixed and portable) and a fixed network infrastructure . . . . The key objective of these wireless communication systems is to provide communication channels on demand between a plurality of subscriber units and their respective base stations in order to connect a subscriber unit user with the fixed network infrastructure."). The patentee's invention, as described in the patent, clearly pertains to the relationship between the base station and the CPEs and not any relationship with fixed network infrastructure. See, e.g., '759 patent, FIG. 1 (showing the exemplary wireless communication system that only includes the base station and the CPEs); '759 patent, FIGs. 6a and 6b (describing the invention and focusing only on the relationship between the base station and the CPE). Therefore, it is not necessary to include the relationship between the base station and the fixed network infrastructure because it is not a key part of the invention and consequently it will not be helpful to the jury.

Finally, Plaintiff offered a revised construction at the hearing, but Plaintiff's revised construction suffers the same flaws as Defendants' proposed construction. Plaintiff's revised construction uses the language "facilitates," yet there is not sufficient grounding in the specification for that language as there is for the "transmits and receives" language. The "facilitate" language is only used when describing the prior art in the beginning of the specification. See '759 patent, 1:45-47 ("These broadband networks facilitate two-way communication between a base station and a plurality of fixed subscriber units."). But as noted above, the "transmits and receives" language is located throughout the specification and the claims, so that language is better grounded in the intrinsic record. In addition, as mentioned when discussing Defendants' proposed construction, the Court does not find it necessary to mention the relationship with the fixed network infrastructure because the present invention concerns the relationship between the base station and the CPEs. Therefore, as noted above, the Court construes the term "base station" as "equipment in a wireless communication system that transmits data to and/or receives data from a CPE."

8. "Base station" ('771, Claims 1, 2, 3, 4)

The parties agree that "base station" had a customary meaning to a person of skill in the art at the time of patenting. Agere argues that this meaning is "an interior node used for extending the range of a controller," while Broadcom argues for "an element in a network that repeats data messages and provides access to the infrastructure.

Agere proffers two arguments in support of its construction. First, Agere notes that the patentee explicitly defined "base station" using Agere's definition. ('771 patent, col. 30, ll. 35-36 ("A 'base station' device is used as an interior node for extending the range of a controller.").) This specification, however, appears only in the context of "an alternate preferred
embodiment." (Id., col. 30, l. 29.) 37 In contrast, no other specification makes mention of the alleged "extending the range" function of a base station. For example, Agere cites to the summary of the invention, which states that "base transceiver units" are "linked" to a host computer by a "network controller." (Id., col. 3, ll. 39-44.) Even assuming that "base transceiver units" are "base stations," this language is ambiguous at best. It could mean that the base stations relay messages from the wireless terminal to the wired network (as Broadcom suggests), or, by implication, that the base stations provide added range for the transmissions of the network controller (as Agere argues), or both. This ambiguity is equally evident in the Background of the Invention cited by Agere, which says nothing whatsoever about the "range" of the controller. (See id., col. 1, l. 65-col. 2, l. 9.) 38 Accordingly, there is no basis in the specifications for holding that the broad claim term is defined by its use in a single embodiment because the specifications as a whole show no intent to so define the term.

37 Agere relies upon the "quote/unquote" convention to establish the definitional nature of the quoted language. This argument fails, however, because it would be improper to extend this definition beyond the embodiment in which it appears given that the other uses of the term in the specifications are not necessarily consistent with this definition, as discussed below.

38 A separate portion of the Background of the Invention discusses the range of the base stations, but this is in the context of reducing problems that arise from having too many or too few base stations, rather than of increasing the range of a controller. (See id., col. 2, l. 51-col. 3, l. 32.)

Second, Agere cites Dr. Goodman, who testified that a person of skill in the art would understand the term to have Agere's proposed construction. None of the evidence cited by Dr. Goodman, however, supports Agere's construction. For example, Dr. Goodman cites his own 1991 paper for the proposition that "[a] base station exchanges radio signals with wireless terminals. . . . The cellular switch controls the assignment of radio channels to wireless terminals." (Goodman Rep. P 171.) Several unsupported inferential leaps would be required for this language to lead to the conclusion Agere wishes the Court to adopt, namely that a cellular switch is a "controller" and that the base station "extends the range" of that controller. Similarly, the specification cited by Dr. Goodman stating that "base transceiver units . . . are . . . communicative with [the] network controller" ("771 patent, col. 9, ll. 7-12) does not directly bear on whether base stations extend the range of the controller. Thus, the Court finds that Dr. Goodman's testimony is unsupported by the evidence on which he relies, and therefore the only support for Agere's construction is a definition applicable solely to one preferred embodiment. Accordingly, this construction is rejected as without sufficient basis in the claim language, specifications, or extrinsic record.

In contrast, Broadcom's proposed construction is consistent with the specifications and supported by extrinsic evidence. Indeed, it appears beyond dispute that base stations both relay information to wireless terminals and give those terminals access to the hard-wired portion of the network. (See, e.g., id., col. 2, ll. 54-57 (discussing base station functions in "basic" network configurations), col. 3, ll. 39-44 (describing base stations as "linked" to network and "communicative with" mobile terminals); Acampora Rep. at 8 (citing IEEE dictionary definition of base station as "land-station in land-mobile service carrying on a radio communication . . . with mobile . . . radio stations").) 39 Thus, the Court credits Dr. Acampora's testimony that Broadcom's proposed construction is the customary meaning of "base station" and adopts that construction as consistent with the patent specifications.

39 Agere argues that Broadcom's construction is improper because it defines a base station to be synonymous with a "repeater." This argument, however, is contradicted by Agere's own expert, who opined, in the context of the term "bridging node," that a repeater is a device that "extends the length of the network media." (Goodman Rep. P 133.) Thus, if anything, it is Agere's definition ("a base station . . . extends the range of a controller") that appears similar to the definition of a repeater.
Based on the number of items in the category

The Court agrees with Sklar that the term has its plain ordinary meaning and does not require construction. Microsoft argues the term should be construed to mean "the number of items in a category dictates whether the category is an open category." The parties disagree whether the number of items in a category dictates or is the basis for whether the category is designated as an open category. The claim language is clear on this point: the decision is "based on the number of items in the category." Microsoft's proposed construction seeks to replace "based on" with the term "dictate." The term "dictate," however, does not appear anywhere in the specification or the claims. The term "based on" appears several times in the specification and is used in its plain ordinary meaning. See '843 patent, Cols. 3:32-35, 7:54-57. The term is common and simple, and a lay juror would have no difficulty understanding it. The term is not a scientific phrase and can be easily understood. Substitution of the word "dictate" for the term "based on" is unwarranted and needless. Accordingly, the Court does not construe this term.

GO BACK

A. Based On

The plaintiff contends that "based on" means "taking into consideration." The defendants contend that the term means "in order to fulfill." The specification of the patent states that after receiving transportation requests, "the host then creates a route or route having destinations based on the received transportation requests." Col. 3, ll. 39-40 (emphasis added). This passage implies that the route is created to fulfill the received requests and thus supports the defendants' proposal. Certain claims, however, use the phrase "based on" in a broader sense—a manner consistent with the plaintiff's proposed definition. Claim 12 of the '362 patent, for instance, includes the limitation of "creating new routes based on said received transportation requests and said existing routes." The "existing routes" referenced in dependent claim 12 are stored in memory at the host. '362 patent, claim 12. A definition of "based on" to mean "in order to fulfill" would make little sense in the context of claim 12 because claim 12 would require the creation of new routes "in order to fulfill said received transportation requests and said existing routes." At least in the context of claim 12, the patentee used the term "based on" to mean "taking into consideration." It is presumed, moreover, that the patentee used the terms consistently throughout the claims. "Based on" therefore means "taking into consideration."

GO BACK

"Based on," "dependent on," "depends on," and "function of"

The terms "based on," "dependent on," "depends on," and "function of" appear in many claims within the shock delivery patents. In each instance, the term is used to describe how the defibrillator incorporates a patient-dependent electrical parameter to adjust shock delivery. E.g., 612 Patent Claim 1 ("adjusting the discharge parameter . . . as a function of the value of the electrical parameter"); 454 Patent Claim 15 ("adjusting the tilt of the waveform based on the value of the monitored electrical parameter"); 905 Patent Claim 4 ("shaping the waveform so that an initial parameter of a waveform phase depends on a value of the electrical parameter"). The parties agree that each term means that the shock adjustment is based on the measured parameter; their dispute is over whether the terms require the shock adjustment to be based solely on the measured parameter.

The court finds no reason to limit these terms to require adjustment based solely on the cited parameter. Defibtech points to numerous disclosures in the specification of shock delivery aspects that are "determined by" a measured electrical parameter. It fails, however, to point to a single location where the inventors required that shock delivery be "determined only by" the measured parameter. For that reason, the court declines to impose such a limitation on these terms. Employing Philips' proposed definition ("using") defines these terms just as well as Defibtech's ("determined by"). Neither phrase requires that the patient-dependent electrical parameter be the sole influence on the shock modification, and neither do the
1. The Language of the '839 Patent

The Court first considers the "displayable" language of claim 26 in its immediate context: "the toolbar being displayable based on a location of a cursor in relation to a hyperlink in a first page in a first window of an application." Having done so, the Court finds that claim 26, when properly construed, clearly teaches a toolbar which is "automatically" displayed, insofar as there is no further action required on the part of the user after the cursor is placed in an appropriate location proximate to the hyperlink. This language in Claim 26 means simply that the toolbar is displayable or capable of being displayed, put before the view of the user, or made evident based on the location of the cursor.

2 Indeed, the Court's commonsense understanding of the word "displayable" is supported by the lexicographers at Merriam Webster, who define "to display" as "to put or spread before the view" or "to make evident." <http://www.merriamwebster.com/dictionary/displayable> (last viewed November 30, 2007). Displayable is an adjective. Id. The suffix "-able," forming the adjective, means "capable or worthy of." The American Heritage Book of English Usage: A Practical and Authoritative Guide to Contemporary English, Chapter 8, § 2 (Houghton Mifflin Company 1996), <http://www.bartleby.com/64/C008/002.html> (last viewed November 30, 2007). In other words, a toolbar that is "displayable" is simply one which capable of being displayed, put before the view, or made evident.

3 Having reviewed the patent as a whole, the Court knows that the display of the toolbar in the invention is not the result of some divine providence once the user places the cursor in the vicinity of the hyperlink but is prompted by "detector 70" which "detects the presence of a hyperlink near the location provided by cursor 74" and "sends a toolbar display signal 73 to the display controller 72" whereupon "receipt of a toolbar display signal 73 the display controller 72 sends a signal to the display 11 to display toolbar 20." '839 patent Co. 7:36-43.

Reading further, the Court finds that the '839 Patent extols the benefits of this "automatic" display of the toolbar over earlier conceived methods of displaying a toolbar. The Detailed Description of the Invention provides, in pertinent part, that:

Thereafter, the user selects a hyperlink in block 102 by moving a cursor either "over" or near a hyperlink that the user wishes to select. When the cursor is "over" or near a hyperlink, the program displays a toolbar which illustrates the link enhancements available for that particular hyperlink in block 104. The program may wait a period of time, for example, three seconds, after the pointer is placed 'over' or near a selected hyperlink.

'839 Patent Co. 5:35-43. True, the selection of the hyperlink by the user prompts the display, but the '839 Patent does not contemplate a further action by the user, once the cursor is in the proper location near the hyperlink, to deploy the toolbar. There is no magic here, but there is no right click either, only the positioning of "the cursor in relation to" a hyperlink.

As further explained in the Summary:

Blocks 114 and 116 perform in essence the same functions that are performed when the user places the cursor over a
hyperlink, "right clicks" the hyperlink and selects and clicks on the open new window command from the menu displayed (Netscape Navigator running on Windows 98). The advantage provided by the present invention is that the user can open the new window with just a single click.

While current browsers enable the user to perform a similar function by right clicking on the link and then clicking on the "open in new window" menu selection to display the selected page in a new, browser window, however, the user would then have to manually minimize this browser window. Thus the present application enables the user to accomplish in a single click what might otherwise take three or more user actions. The more user actions taken by the user, the greater the distraction from viewing the current page.

'839 patent Co. 6:22-53.

The abstract of the patent succinctly explains how the invention arrives at this improvement:

This invention permits the user to interact with a hyperlink in a variety of ways without necessarily having to open and/or follow the hyperlink. This is accomplished by detecting the presence of a cursor near a hyperlink. When the cursor has remained near the hyperlink for a predetermined time period, a toolbar is displayed containing one or more link enhancements that a user may select.

'839 Patent Abstract (emphasis added). The same improvement is referenced in the Summary as follows:

First the presence of a pointer near a hyperlink is detected. Next, a toolbar is displayed when the pointer remains near the hyperlink greater than a predetermined time. The toolbar displayed provides at least one choice for a link enhancement.

'839 Patent Co. 2: 55-60 (emphasis added).

An individual using iLOR's invention could not both right click to open a tool bar and then click again to open the new window (or for that matter, select another desired enhancement to a hyperlink) without clicking at least twice. The description of a "single click" does not support iLOR's proposed construction of Claim 26, and it follows that the '839 Patent teaches the "automatic" display of the toolbar based on the presence of the cursor within a certain proximity of a hyperlink as urged by Google to provide the "advantage" claimed in the '839 Patent.

The patent speaks of alternative embodiments of the invention as follows:

The Enhanced Hyperlink toolbar may be designed to appear when a user "mouses-over" a hyperlink. Alternatively, the toolbar may display with the page or the toolbar may appear when the cursor or pointer is in a predetermined area around the hyperlink. Preferably the toolbar is presented to the user instantly on mouse-over, or after the user keeps the mouse pointer on the hyperlink (or banner ad) for a predetermined time, for example one to three seconds. A short time delay prevents the browser from becoming jumbled with too much information if the user simply desires to click through on any given hyperlink.

'839 Patent Col. 3:60 to 4:3. iLOR argues that the "automatic" display of the toolbar upon a mouse-over or detection of the cursor within a certain proximity to the hyperlink is but one embodiment among many contemplated by the '839 Patent. Nonetheless, the Court finds that iLOR's argument that there might be embodiments of its invention without the "automatic" display of the toolbar to be disingenuous, particularly considering that Claim 26 itself includes the only user action required to render the toolbar "displayable" - the location of the cursor proximate to the hyperlink.

No part of the '839 Patent, including Claim 26, suggests the possibility of an embodiment in which the user would "right click" in order to display the toolbar. iLOR may not have needed to explicitly describe every potential embodiment of the invention in order to obtain patent coverage therefor, but it does not change the fact that Claim 26, as well as every other portion of the '839 Patent, predicate the display of the toolbar only upon the placement of the cursor in the vicinity of the hyperlink and not some further action by a user of the invention. That the method of "detection" is taught in other claims is
irrelevant to this Court's decision, because Claim 26 itself places no additional requirements on the user - beyond placement of the cursor - with regard to the display of the toolbar.

Reading the language of Claim 26, both by itself and in the context of the '839 Patent as a whole, this Court is of the opinion that it does not teach a right-click in order to display the toolbar, only the positioning of the cursor over or near the hyperlink. In this sense, the display is "automatic" with regard to the user, and the Court holds that the proper construction of Claim 26 is one in which the toolbar is "automatically displayed" upon the placement of the cursor in proximity to a hyperlink with no further action on the part of a user.

2. Prosecution History

If the Court was left with any doubt as to whether the '839 Patent comprised an embodiment where a right-click by a user was required to display the toolbar, the Court would need only turn to the prosecution history to disabuse itself of that notion. The prosecution history of the '839 Patent plainly shows that iLOR gave up any construction of the display limitation that included a toolbar displayed as a result of a user's right-click. This was done in order to overcome the Patent Examiner's rejections based on the prior art. The "automatic" display of the toolbar was a distinction upon which iLOR relied and which ultimately allowed the '839 Patent to be granted over the prior art.

During the prosecution of the '496 Patent, the parent to the patent-in-suit, iLOR emphasized that the Newfield patent was different than the claimed invention because the user to click on a hyperlink when selecting it, explaining that the Newfield patent "fail[ed] to teach at least five features of claim 178 . . . .[.]" including "detecting a cursor in proximity to said hyperlink [and] displaying a graphical toolbar in proximity to said cursor while said cursor is in proximity to said hyperlink[.]" [Exh. H. to Def. MSJ, 8/24/2006, Amendment, at 9 (emphasis in original)]. Indeed, iLOR relied on specific distinctions between the '496 invention and the invention taught in the Newfield patent:

First, Newfield does not teach detecting a cursor in proximity to a hyperlink. Instead, Newfield teaches that a user must click on or select a hyperlink to access the breadth-first search system of Newfield. See Newfield, e.g., page 5, 3rd paragraph. In contrast, the present invention detects a cursor in proximity to the hyperlink. Therefore Newfield does not teach detecting a cursor in proximity to a hyperlink.

Third, Newfield does not teach a graphical toolbar adapted to provide a plurality of user-selectable link enhancements. . . . The Scratchpad window of Newfield is available to the user after the user selection is made, and not before.

[Id. at 10-11 (emphasis in original).]

In other words, in prosecuting the '496 patent, iLOR relied upon the fact that no "right click" or other action beyond positioning the cursor with the mouse was necessary for the user to prompt the display of the toolbar in its invention and that it was, thus, distinct from the Scratchpad invention of the Newfield patent. The arguments made during prosecution of that parent patent are relevant in determining the meaning of the terms at issue with regard to the patent-in-suit. See Jonsson v. The Stanley Works, 903 F.2d 812, 818 (Fed. Cir. 1990); Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1333 (Fed. Cir. 2003).

Although Claim 26 of the '839 Patent was presented late in the prosecution of the application, it was clearly linked to Claim 9, as iLOR represented to the Examiner that Claim 47 of its Application No. 60/202,029 (ultimately issued as Claim 26 in the '839 Patent) was allowable for the same reasons as Application Claims 22-33 (which included Claim 30, ultimately issued as Claim 9 of the '839 Patent) because Application Claims 34-51 were similar. [Ex. I to Def. MSJ, 11/3/2006 Amendment, at 8.] Application Claims 22-33 were the subject of a Terminal Disclaimer due to their similarity to the claims of the '496 Patent. 5 [Id.]

5 During the prosecution of the '839 Patent, the Examiner rejected Claims 1 and 9, which taught "detecting a cursor in proximity to said hyperlink; displaying a graphical toolbar in proximity to said cursor while said cursor is in proximity to
said hyperlink." The Examiner was concerned with "double-patenting" and the fact that these Claims were not "patentably distinct" from Claims 1 and 9 of the parent '496 Patent. Although not word-for-word identical, the Examiner explained they "contain[] every element of" claims 1 and 9 of the '839 Patent, "and thus [are] anticipated." [Ex. J. to Def. MSJ, 8/7/2006 Office Action, at 2-5.] It was in response to this rejection that iLOR, apparently conceding the point, filed a Terminal Disclaimer without traversing the rejection. [Ex. I to Def. MSJ, 11/3/2006 Amendment, at 8.]

Ultimately, the Examiner allowed the claims, including Claim 26:

…based on [the] Terminal Disclaimer (filed on 11/03/2006) and [because,] in addition [,,] the prior art of record does not appear to teach or render obvious the claimed limitations in combination with the specific added limitations as recited in independent claims and subsequent dependent claims. The prior art of record fails to teach or suggest a method for enhancing a hyperlink by displaying a graphical toolbar in proximity to the cursor while the cursor is in proximity to the hyperlink…

[Ex. K to Def. MSJ, 11/21/06 Statement of Reasons for Allowance, at 2.] It follows that, even at the end of the prosecution, the Examiner relied, however tacitly, upon iLOR's distinction between Newfield and its own invention presented during the prosecution of the '496 Patent - the display of the toolbar as a result of the proximity of the cursor to the hyperlink in place of a right click by the user. 6

--- Footnotes ---
6 If iLOR had not intended this result or believed that the Examiner had improperly construed the distinctions it was making when he allowed these later added claims, iLOR could have challenged the Examiner's grouping of the claims in the Statement of Reasons for Allowance, but chose not to do so. Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 979 (Fed. Cir. 1999).

--- End Footnotes ---

iLOR cannot have it both ways. If similar claims of the '496 and the '839 Patents were allowed, at least in part, because they did not teach a right click, and Claim 26 of the '839 Patent was allowable for the same reasons, it follows that Claim 26 cannot include a right click or, indeed, anything other than a display of the toolbar upon the positioning of the cursor in proximity to the hyperlink. In the course of prosecuting the patents on its invention, iLOR disavowed an interpretation of the "displayable" limitation that would include a display which resulted from a right click. Having relinquished the "right click" in order to successfully prosecute its patents in light of the prior art, iLOR cannot rely upon it now to support its claim of infringement.

Having reviewed the prosecution history of the '839 Patent and its parent, the '496 Patent, the Court is all the more firmly persuaded that Claim 26 does not teach a right-click in order to display the toolbar, only the positioning of the cursor over or near the hyperlink in order that the toolbar be displayed.

GO BACK
claim describes generation of a signal after a person has begun walking or running. Paragraph (c) of Claim 13 describes "analyzing the signal to identify a characteristic in the signal that indicates the person has initially ceased taking footsteps." 314 patent, col. 14, 11. 18-21 (emphasis added). The disputed phrase is found in paragraph (d) of Claim 13, and, logically, "the characteristic" must refer back to "characteristic" in paragraph (c) of Claim 13. "Characteristic" is not used elsewhere in the Claim.

Therefore, the phrase in dispute refers only to the characteristic "that indicates the person has initially ceased taking footsteps," or, as it has been agreed, when the person has stopped stepping. There is no reference to the time the person began stepping. The elapsed time to be measured could be from the point at which the first step was taken. But that is not required by the claim language. It could be from the time the person stopped. Nothing in the claim language would eliminate the second possibility, which might be found in a system which measured a set time after stopping and then started a pulse or blood pressure monitor to determine recovery. (The time it takes the individual to return to the individual's resting pulse rate or blood pressure.)

The specification describes both situations - measurement of time between the first and last steps, and the taking of some action at some time interval after the point at which the characteristic which shows the person first stops. See 314 patent, col. 11, 11. 53-62. ("a timer is stopped or another appropriate action is taken."). Additionally, the specification states that two timers may be involved, which indicates that the "elapsed time period" measured from when the "characteristic" shows that steps have stopped may not be related to the time the steps started. See 314 patent, col. 12, 11. 6-7 (timer stopped when the steps started).

Adidas' strongest argument is based on statements made by the patentee to the Examiner. An Office Action mailed September 15, 2000 rejected Claim 14 (present Claim 13) because it would have been obvious to one of ordinary skill to combine U.S. Patent No. 5,720,200 ("Anderson") and U.S. Patent No. 5,976,083 ("Richardson") to achieve the same result. See Office Action, 9/15/2000, Ex. K to Nike's Opening Claim Construction Brief, [Doc. # 70, Attachment # 1, pp. 18-19 of 50]. The Response to the Office Action used the phrase "and to determine an elapsed time period between when the first and second characteristics appeared in the signal." Response to the September 15, 2000 Office Action, 5/21/2001, p. 18 in Ex. K to Nike's Opening Claim Construction Brief, [Doc. # 70, Attachment # 1, p. 45 of 50]. But that does not accurately describe Claim 13, which does not mention a first characteristic. The Response goes on to state:

the proposed combination of Anderson and Richardson does not disclose or suggest at least one controller, or any other device, that determines an elapsed time period based upon an identified characteristic in a signal that indicates that a person has initially ceased taking footsteps after having been walking or running.

Response to the September 15, 2000 Office Action, 5/21/2001, p. 18 in Ex. K to Nike's Opening Claim Construction Brief, [Doc. # 70, Attachment # 1, p. 45 of 50].

Taken together, these statements in successive paragraphs in the Response are not the most accurate exposition of the claim language. They are also not a clear limitation on, nor a disavowal of, an embodiment of the language in Claim 13 (nor Claims 18, 27, and 31).

The claim language and the specification indicate that the "elapsed time period" may occur before or after the "characteristic" appears. The court will construe this claim term as follows:

- Determining or measuring "an elapsed time period" based on a time at which the characteristic appeared in the signal means: "Using the point at which the characteristic appears to determine or measure an interval of time."

5. Capable of dynamic partitioning based on the elemental width of data received from the data path, the elemental width being equal to or narrower than the data path

For the same reasons advanced above, the court construes "capable of dynamic partitioning based on the elemental width of data received from the data path, the elemental width being equal to or narrower than the data path" to mean "capable of
dividing width-wise into a variable number of elements no wider than the data path, based upon the size of the data elements received from the data path."

C. "Based Upon The Order Of The List," "Based Upon The Desired Order," and "In The Desired Order."

Parties dispute the meaning of the above three terms. Essentially, Blockbuster argues that these three terms are interchangeable in the context of the patents in suit. The first term appeared in claim 14 of the ’381 patent which recited in pertinent part (col. 13:64-14:17):

14. A computer-implemented method for renting movies to customers, the method comprising:

providing electronic digital information that causes one or more attributes of movies to be displayed;

establishing, in electronic digital form, from electronic digital information received over the Internet, a movie rental queue associated with a customer comprising an ordered list indicating two or more movies for renting to the customer;

causing to be delivered to the customer up to a specified number of movies based upon the order of the list, wherein the customer is not required to return the movies within a specified time associated with delivery;

in response to one or more delivery criteria being satisfied, selecting another movie based upon the order of the list and causing the selected movie to be delivered to the customer.

The second and third terms were used in claims 4 and 5 of the ’450 patent (col. 14:64-15:19):

4. A method as recited in claim 1, wherein

the one or more item selection criteria indicates a desired order for the one ore more items that a customer desires to rent,

the step of providing to the customer up to a specified number of the one or more items indicated by the one or more item selection criteria includes providing to the customer up to a specified number of the one or more criteria in the desired order indicated by the item selection criteria; and

5. A method as recited in claim 4, further comprising if a particular item from the one or more items indicated by the one or more item selection criteria is not available, then providing another item from, the one or more items based upon the desired order indicated by the one or more item selection criteria.

Here, Netflix proposes that "based upon the order of the list" should, mean "so as to provide the next-available movie in the order specified by the list." Blockbuster proposes that the same term should mean "in the same sequence as that of the 'ordered list' referred to earlier in the claim." As to "based upon/in the desired order," Blockbuster argues that both terms should have the same meaning, "in the same sequence in which any person wants the items to be provided." Netflix proposes that "based upon the desired order" should mean "so as to provide' the next-available movie in the rental sequence specified by the customer," and that "in the desired order" should mean "in the rental sequence specified by the customer."

The question of whether or not the order in the "list" is the customer's order has already been addressed. As stated above, it may be the customer's order but need not be so restricted. The real dispute is over the meaning of "in" versus "based upon." Had the inventors chosen to do so, they could have used the same term, either "in" or "based upon," in both claims. They did not. The use of two different terms in close proximity gives rise to the inference that two different meanings were intended for the two different terms. Bancorp Serv., L.L.C. v. Hartford Life Ins., 359 F.3d 1367, 1373 (Fed. Cir. 2004). Looking to
commonly-understood meanings, "based upon" allows some deviation from the exact, specified order, while "in" requires that the order must be followed. This inference could possibly be defeated, of course, by showing evidence to the contrary. Blockbuster fails to do so.

The use of the terms in the claims is instructive. Claim 4 of the '450 patent recited "the step of providing to the customer one or more other items indicated by the one or more item selection criteria includes providing to the customer one or more other items indicated by the one or more selection criteria in the desired order indicated by the one or more item selection criteria" (col. 15:8-12). Claim 5 depended from claim 4, and recited "further comprising if a particular item from the one or more items indicated by the one or more item selection criteria is not available, then providing another item from the one or more items based upon the desired order indicated by the one or more item selection criteria" (col. 15:13-18). Here, if the first item on the customer's list was unavailable, the system would select another item from the list. When the provider chooses an item "based upon" the order of the list, the provider does not necessarily follow the list's precise order.

Indeed, if "based upon" and "in" were given the same meaning in these two claims, the provider would have no way to continue renting items to the customer until the first item on the list were available. This reflects the reality that the provider cannot rent what it does not currently have. The specification also supports this construction. The '381 patent stated "[c]ustomers may specify priorities for the items indicated by the item selection criteria. Thus, if a particular customer's first choice is not available, or already rented, then the item having the next highest priority can be rented to the particular customer" (col. 11:18-23). Blockbuster's argument under the written-description requirement of 35 U.S.C. 112, P 1 fails because of this. Blockbuster argues that the specification teaches no other criteria for selecting movies other than those that the customer selected. The above statement shows that this is not the case. The specification explicitly contemplated considering the availability of items before renting them and does not exclude the use of other factors.

The requirement that "based upon" necessarily means the next-available item, however, is without support. Reading this limitation into the definition would render claim 5 redundant because the concept of sending the next-available item was specifically recited.. Accordingly, this order holds that "based upon the order of the list" allows for some deviation from the exact order of the list. "Based upon" need not be strictly based on availability; it could be based on other factors. "In the desired order" refers to the precise order the customer selected, while "based upon the desired order" allows for some deviation from the desired order that need not be solely based on availability.

20. Instruction stream/basic blocks

The plaintiff defines "instruction stream" to mean "a stream of instructions." The defendants contend that the term means "a sequential stream of instructions output from a conventional compiler."

The defendants point to the specification for a definition of "instruction stream." The relevant portion states:

"Processing system 160 operates on standard compiler output 100 which is typically object code or an intermediate object code such as 'p-code.' The output of a conventional compiler is a sequential stream of object code instructions hereinafter referred to as the instruction stream."

'755 patent, col. 6, 1.66-col. 7, 1.5. (emphasis added). Read in context, however, the court believes that the patentees intended in this passage to define instruction stream in the context of features of the preferred embodiment. Given that this is not a means-plus-function term, the court defines "instruction stream" to mean "a stream of computer instructions." It is not necessary for the stream of instructions to be a sequential stream of object code output from a conventional compiler.

ADI proposes a similar limitation to the term "basic block." Biax contends that the term "basic blocks" means "groups of contiguous instructions." ADI contends that the term means "compiler output consisting of blocks of instructions with only one branch at the end of each block." The court adopts Biax's construction. One portion of the specification suggests that basic blocks can be formed in the compiler. The term is therefore not limited to compiler output. E.g., '755 patent, col. 7, 11. 29-31 ("The TOLL software, in this illustrated embodiment of the present invention, is designed to operate on the formed basic blocks (BBs) which are created within a conventional compiler.").
1. "battery compartment"

Claims 1, 3, and 10 of the '571 Patent describe a "battery compartment." Philips asserts that this term should be construed as "a part of an enclosed space within the defibrillator case to hold the battery." Cardiac Science contends that this term should be construed as "a defined space for containing batteries."

Similar to its arguments regarding the electrode compartment of the '969 Patent discussed above, Philips asserts that the battery compartment needs to be enclosed. Cardiac Science notes that the unenclosed nature of the battery compartment is demonstrated by the fact that the battery compartment still remains a compartment even when the AED lid is open.

The specification states that "electrical power is provided by a rechargeable twelve volt lead-acid cartridge battery 80 and a nine volt battery 82 which are removeably positioned within the battery compartment and connected to power generation circuit 84." ('571 Patent at c. 3, ll: 13-16.) Cardiac Science is correct in asserting that neither the claim language nor the specification requires the battery compartment to be enclosed. Consistent with the Court's construction of the term "electrode compartment" discussed above, the Court construes "battery compartment" as "a section within the defibrillator case that contains the battery or batteries."

(1) Bayonet/Bayonet Terminal

The '211 Patent claims:

1. An electric meter for sensing electrical parameters from an electric circuit, the meter including bayonets disposed on the meter, the bayonets mateable with matching jaws of a detachable meter mounting device, the bayonets being used to receive voltage and current signals from the electric circuit to the meter, and one or more sensors coupled with the electric circuit and operative to sense one or more the electrical parameters in the electric circuit and generate one or more analog signals indicative of the electrical parameters, the meter comprising:

   a circuit board with a plurality of openings each adapted to receive the bayonet;

   a plurality of electrically conducting bayonets mounted on the circuit board through the openings to provide at least one of a first voltage bayonet and a first current bayonet, wherein a gap is provided between the openings and the bayonets;

   solder passing through the gap and extending to both sides of the circuit board; and

   a sensor coupled with the electric circuit and operative to assess at least one electrical parameter from the electric circuit and generate an analog signal indicative of the electrical parameters.

The '842 Patent has 48 claims, and the term "bayonet" appears in 22 of those claims. Interestingly, unlike the '211 Patent, the '842 also uses the term "bayonet terminals," but that term appears in just one claim, claim 39, which discloses the following:

39. In an electrical meter for sensing electrical parameters from an electric circuit, said meter including bayonet terminals disposed on said meter mateable with matching jaws of a detachable meter mounting device, said bayonet terminals used to receive signals from the electric circuit to the meter, and one or more sensors coupled with said electric circuit and operative to sense one or more electrical parameters in said electric circuit and generate one or more analog signals indicative of said...
electrical parameters, said meter comprising:

a circuit board with at least one opening adapted to receive a bayonet;

at least one electrically conduct bayonet mounted on the circuit board through said at least one opening wherein a gap is defined between said at least one opening and said bayonet;

a plurality of vias formed around said opening;

solder passing through said vias an extending to both sides of said circuit board through said vias and passing through said gap and extending to both sides of said circuit board through said gap and said solder extending to said bayonet; and

an electrical sensor connected to said at least one electrically conducting bayonet.

U.S. Patent No. 6,186,842 B1, col. 9, line 38 - col. 10, line 15.

The parties seem to use the terms "bayonet" and "bayonet terminals" interchangeably, to mean the same thing. And, indeed, so do the patents. The '842 Patent, for example, as shown above, uses both terms in the claims (though one with much greater frequency than the other); the same is true of the specification. Indeed, the specification's "overview" paragraph discusses "bayonet or blade terminals," then "bayonets," then "bayonet terminals," all seemingly interchangeably. Id., Col 3, lines 49-64. The '211 Patent, which incorporates by reference the '842 Patent, uses "bayonets" exclusively, and the '364 discusses "blade type terminals" and "blades" in the specification and "bayonet terminals" in the claims. Yet they all seem to be talking about the same physical structure or piece. The Court will treat these terms similarly for construction purposes.

Square D initially argued that the claim term "bayonet" means "an electrically conducting blade-type terminal connector that plugs into the jaws of the meter socket on one end and is connected to a circuit board on the other end." EL argued that "bayonet" should be construed to mean "a blade that electrically conducts and mates with the matching jaws of a meter mounting device." At the Markman hearing, Square D offered an alternative construction: "an electrically conducting blade," and EL represented that it did not have any real issue with this alternative definition, though it also opined that this definition would not do much to advance the litigation. Certainly, that is everyone's goal: to advance the litigation. But the Court will not read limitations into claims to do so.

The term "bayonet" is defined in the '211 Patent's specification: "S-base meters feature electronically-conducting bayonets (blade type terminals) disposed on back side of the meter. These electronically-conducting bayonets are designed to align with the matching jaws of a detachable meter mounting device such as a revenue meter socket." U.S. Patent No., 6,983,211 B2, col. 2, lines 49-53. This definition is dispositive. See Vitronics, 90 F.3d at 1582 (when the specification "expressly defines" a term used in the claims, that definition is "dispositive."). Accordingly, the Court construes "bayonet" to mean "a blade type terminal."

Reading the remainder of the proposed constructions would render much of the relevant claim language redundant, which would be inappropriate. See Merck & Co v. Teva Pharmaceuticals USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so."))(citing Elekta, 214 F.3d at 1307 and Gen. Am. Transp. Corp. v. Cryo-Trans, Inc., 93 F.3d 766, 770 (Fed. Cir. 1996)). Construing "bayonet" to mean simply "an electrically conducting blade type terminal" gives meaning to all of the language in the claim, and ensures that limiting language such as "mateable with matching jaws of a detachable meter mounting device" is not just excess verbiage.

Broadcom proposes to construe "beacon" as "a signal sent at predetermined intervals," which Broadcom asserts was the customary meaning of the term in 1991. As evidence, Broadcom provides the testimony of Dr. Acampora, who in turn relies on two allegedly contemporaneous patents and the aforementioned Biba paper. As discussed previously, the Biba paper is
insufficient to determine the customary meaning of an 802.11-related term because it is unclear to the Court whether the paper's definition of such terms was novel or customary at the time of publication. Regarding the two patents cited by Dr. Acampora, one is untimely, having been filed in September 1994. (See U.S. Patent No. 5,606,560.) The other, filed in 1992, states that beacons are transmitted "on a recurring, time intervalled basis." (U.S. Patent No. 5,548,818, col. 3, ll. 51-52). Although this language supports Broadcom's position, the Court finds it insufficient, even when combined with the limited implications of the Bibe paper, to establish that Broadcom's construction was the customary meaning of "beacon" in 1991. Stated differently, a single technical paper of unclear authoritativeness and a single contemporaneous patent, particularly in the absence of a more-broadly applicable reference, such as a dictionary, do not establish to the Court that persons of ordinary skill possessed a common understanding of the claim term. 31 Accordingly, the Court examines the claim context and specifications to determine the appropriate construction.

31 Agere confusingly argues both that there was no customary meaning and that the inventor of the '366 patent, Dr. Robert Meier, testified to not having used the term in accordance with its customary meaning. The Court considers these arguments irrelevant, however, because they are based upon testimony regarding the term "radio beacon," which is not the term at issue. (Goodman Rep. P 149.)

Agere proposes to construe "beacon" as a "packet containing a seed value." The "seed value" limitation, however, is derived from a single embodiment of the beacon in the specifications. ('366 patent, col. 12, ll. 24-25.) The specifications also disclose embodiments wherein the beacons do not contain seed values. ('311 patent, col. 3, ll. 60-63; see also '366 patent, col. 15, ll. 45-47.) Thus, the Court rejects Agere's construction as an improper narrowing of the claim by use of a preferred embodiment.

By contrast, Broadcom's construction is supported by the claim text, which states that beacons are "transmitted at predetermined intervals." ('311 patent, col. 19, l. 67-col. 20, l. 1; '366 patent, col. 20, l. 53.) Because the term "beacon" does not appear in the specifications, and because the "predetermined interval" limitation is the only modifier uniformly used for this term in the '311 and '366 claims, the Court finds that "beacon" is appropriately construed as a "signal sent at a predetermined interval."

Agere argues that Broadcom's construction is overbroad, in that it effectively reads any limitation out of the term because the "predetermined interval" language is already in the claim text. The basis for this argument is claim 1 of the '311 patent, which states that the access point "transmits at predetermined intervals beacons." Agere claims that to use Broadcom's construction would result in the access point "sending signals at predetermined intervals," which in effect simply substitutes the word "signal" for "beacon." This argument, however, neglects the next clause in the claim, which reads, "[beacons] that identify that a message awaits delivery." In total, therefore, the claim as construed by Broadcom reads, "access points . . . transmitting signals at predetermined intervals that identify that a message awaits delivery." Similarly, claim 5 of the '366 patent, as construed, reads "bridging nodes . . . transmitting signals at predetermined intervals that identify . . . wireless terminal nodes operating in the power saving state that have a message awaiting delivery." Thus, each claim itself places a content requirement on the beacon, rendering Agere's concerns about overbreadth misplaced. Accordingly, the Court adopts Broadcom's proposed construction. 32

32 Agere argues, for this term as well as others, that Broadcom's current position is different from that taken in other litigation. The Court finds these arguments irrelevant for two reasons. First, the Federal Rules of Civil Procedure do not prohibit the assertion of contradictory positions in the same lawsuit, much less in different suits. See FED. R. CIV. PROC. 8(a). Second, both parties, within the context of this case alone, assert a multitude of self-contradictory positions (including this one), each time tailoring their arguments to the term at hand. The Court finds nothing problematic in the tailoring of arguments to differing cases and factual scenarios, for this is, of course, a hallmark of effective advocacy.
c. The '545 Patent

The '545 patent recites a flight information communication system with a plurality of wireless ground links that connect respective aircraft resident subsystems with airport-located ground subsystems. Each independent claim of the '545 patent recites an "interrogation beacon." and the parties dispute the meaning of this term. 11 FedEx alleges that the System only operates in the United States, where communication limitations are uniform. (Doc. No. 83 at 12.) As a result, the transmission power level need not be adjusted after installation. Id. In response, Harris maintains that the System meets the "interrogation beacon" limitation under the doctrine of equivalents because the System contains software permitting transmission power levels to be adjusted and has the ability to declare its presence to nearby access points by seeking an open channel for communication. (Doc. No. 87 at 13-14.)
2. "A Beam Request Signal"

Claim 1 sets forth:

a switchyard for directing accelerated beam from the accelerator to a selected one of the treatment rooms, the method comprising the steps of: (a) receiving a beam request signal from one or more of the treatment rooms;

(b) verifying the authenticity of one of the beam request signals from one of the treatment rooms; and

(c) authorizing beam transport to one of the treatment rooms.

(Rosenberg Decl. Ex. 2, the 581 Patent at 9:3-13.)

Plaintiff argues the disputed claim term "a beam request signal" should be construed in light of its ordinary meaning and offers the following construction: "a detectable message indicating a desire for the beam." Defendant Ion Beam, on the other hand, argues the contested claim term is indefinite (Ion Beam P.&A. at 11-12). In addition, Ion Beam offers the following definition for the term "beam request signal": "computer generated data identifying the origin of the request and requesting that a beam be initiated and sent to the requesting treatment room." (Ion Beam P.&A. at pp. 12-13.)

As a preliminary matter, it is not immediately clear why Ion Beam would declare the term "beam request signal" is indefinite. The claim term is made up of three common words. Putting those words together does not obfuscate meaning. The phrase "beam request signal" is not indefinite and Ion Beam does not put forward any justification, aside from the conclusory opinion of its expert, to support the determination that the claim term is indefinite. 18 (See P.&A. at 11-12.)

18 Ion Beam's argument is flawed for several reasons. "Indefiniteness must be determined by the facts in each case, not by some abstract rule. Georgia-Pacific Corp. v. United States Plywood Corp., 258 F.2d 124, 136 (2d Cir.), cert. denied, 358 U.S. 884, 79 S. Ct. 124, 3 L. Ed. 2d 112 (1958). Because the terms at issue in the instant matter are readily understood in the context of their plain and ordinary meaning, it is clear that a person skilled in the art would understand what these words mean. See id. Finally, it would probably be erroneous to allow the conclusory opinions of defendant's expert to trump the plain meaning of claim terms. See Texas Digital Sys., 308 F.3d at 1204.
Accordingly, the court hereby finds ordinary meaning of the disputed phrase to be "a detectable message indicating a desire for the beam."

AMERICAN HERITAGE DICTIONARY (4th ed. 2000); see also OXFORD ENGLISH DICTIONARY (2d ed. 1989).

The definition of "beam path" is straightforward: "a route, course or track upon which the proton beam moves." (See, e.g., Airhart Decl. Ex. H, Random House at 137.) The common dictionary definition of "configuration," according to Random House, is "the relative disposition or arrangement of the parts." (Id. at 127.) Similarly, the Oxford English Dictionary defines "configuration" as an "[a]rrangement of parts or elements in a particular form or figure; the form, shape, figure, resulting from such arrangement; conformation; outline, contour," or an "[a]rrangement of elements; physical composition or constitution." OXFORD ENGLISH DICTIONARY (2d ed. 1989). Parts or elements may also be described as "physical properties." Id. The Oxford English Dictionary explains the term is used in that manner by physicists when describing "configurations" and quantum mechanical relations of sub-atomic matter. Id. The court finds the definition of beam configuration to be the "arrangement of parts, elements or physical properties of the beam." (See id.) Signal means "a detectable message," supra. Accordingly, the plain language of the contested claim term appears to mean "a detectable message indicating the arrangement of beam elements or physical properties of the beam, as well as the course upon which the beam is moving." 22

This meaning is confirmed by reference to the '581 patent specification, which explains a "beam path configuration signal . . . may be generated by detectors or monitors for the various magnets included in the switchyard." (Rosenberg Decl. Ex. 2, the '581 Patent at 5:32-35.) The '581 patent specification elaborates: "[the] switchyard beam path configuration signal is indicative of and provides data corresponding to the path of the treatment beam from the accelerator through the switchyard to one of the treatment rooms." (Id. at 5:39-43.) Further, the patent explains, "if it is so desired that the beam reaching the treatment rooms be of a particular configuration . . . , beam configuration request signals may also be generated by the operators in a similar manner to indicate, for example, a desired beam intensity, duration and energy." (Id. at 6:8-15.) The specification continues: "such treatment room beam request and beam configuration request signals are received and compared with the . . . beam path . . . configuration signals." (Id. at 6:15-18.) In other words, monitors and detectors in the switchyard detect the "make up," "configuration," or "arrangement of components" of the beam as it passes through the switchyard, possibly sending messages regarding the intensity, energy and duration of the beam. (See id. at 5:25-6:18.) The messages include information about the beam path. (See id.) The messages are received and compared with the beam request signals. (Id. at 6:15-20.) In sum, the general character of the beam - its intensity, duration and path - is measured by monitors in the switchyard, and those measurements are then compared to the requests coming from the control room. (See

- 847 -
5. "Before completing the subsequent launch, processing the final log file to move the memory blocks specified in the final log file into a RAM cache" (Seventh step of Claim 1 and seventh means element of Claim 2).

The parties have agreed to the court's construction of "subsequent launch" as "a launch of a computer program after the final log file for that computer program has been generated and stored in RAM, RAM cache, secondary storage, or some other storage." The "final log file" is "the log file processed so that log entries or log entry portions that would cause duplicate accesses to the same physical address block have been eliminated." The parties have also agreed that "memory blocks" means the smallest number of physical addresses that can be read from or written to the secondary storage device. The only dispute is: what does "processing . . . to move" mean in the context of these other agreed terms?

CAC proposed "prior to completing the subsequent launch, using a portion of the final log file to move memory blocks into all or a portion of the random access memory." The court pointed out that a log file doesn't "move" memory blocks or data. The processor acts on the log file to manipulate data. CAC then proposed "prior to completing the subsequent launch using the final log file to move memory blocks specified in the final log file into the RAM cache."

This formulation is still somewhat confusing. CAC, of course, admits that the log file doesn't move or manipulate data. One skilled in the art would probably intuit that the definition was inelegantly phrased and had to imply that the processor acted on the log file. But the court is defining terms to help a jury understand what the terms would mean to one of ordinary skill. The jurors are not likely going to be skilled artisans in the relevant art. So the definitions should not depend upon the jurors being able to imply meaning from some pre-existing knowledge of the way in which computer processing units manipulate data.

Microsoft states that the term means, "during the subsequent launch, reading, in order, each log entry in the final log file and copying, in the same order, the memory blocks specified in each log entry in the final log file from the secondary storage device to the RAM cache." The action described in this claim term is "processing the final log file to move the memory blocks . . . ." Nothing in the claim term requires movement in a particular order from secondary storage to RAM cache.

The alleged increased speed of the patented method comes from the fact that the program launch is interrupted and the memory blocks specified in the log file are moved into RAM cache. Then, as the launch of the program recommences, requests for information go to the RAM cache, where the information is now stored in optimal order (in method step 5), and from which redundant accesses have been eliminated (in method step 4). See '630 patent, col. 8, ll. 19-26.

It is perhaps true that the preferred embodiment, i.e. the method with the most speed, might read and copy the log entries from the secondary storage device to RAM cache in order. But that is not required by the claim language. For one thing, the agreed definition of "subsequent launch" includes a launch after the final log is stored in RAM cache. There is nothing in the claims or specification that requires, or even hints, that some of the memory blocks required for program launch may not also be, at that time, still in RAM cache. In that situation, there would be no need to copy anything in order from a secondary storage device to RAM cache. One example would be the relaunch of a program before the computer has emptied the cache from the previous launch. The court defines this term as follows:

"Before completing the subsequent launch, processing the final log file to move the memory blocks specified in the final log file into a RAM cache" means: during the subsequent launch, reading each log entry in the final log file and copying those memory blocks specified in log entries that are not already in the RAM cache, from the secondary storage device to the RAM cache.
i. "causes said lower layer to vaporize before said upper layer vaporizes"

Cypress asserts that the term "causes said lower layer to vaporize before said upper layer vaporizes" should be construed to require that the lower layer of the fuse "is converted to vapor" before the upper layer or cap is converted to vapor. Rephrased, Cypress contends that the claim requires the lower layer "to vaporize, not just begin to vaporize."

As discussed above, the original claim language (claim 22 in the application) recites that the energy of the laser light, when transferred to the metal interconnect "causes said metal layer to melt." When that claim was rejected, the applicants amended it to read "causes said lower layer to boil before said upper layer melts." The examiner rejected the amended claim for indefiniteness and for lack of support in the specification. After a telephone interview, the examiner allowed the claim to read "causes said metal layer to vaporize before said upper layer vaporizes."

Cypress argues that this prosecution history precludes EMI from asserting that "vaporizes" means "begin to vaporize." According to Cypress, since "boil" refers to the heating of a substance to the vaporizing point "with consequent bubbling up of gases," the disallowed term "boil" covers the phenomena "to begin to vaporize." Thus, Cypress contends, "vaporize," as was finally allowed by the examiner, must be distinct from "boil," and cannot mean "to begin to vaporize."

The examiner disallowed the term "boil" for indefiniteness and for lack of support in the specification. Indeed, the patent specification nowhere states that the lower metal layer boils. The patent, however, does disclose the vaporization process, and states that the explosion takes place after the surface temperature rises and "the fuse begins to evaporate." When the examiner disallowed the term "boil," he did not preclude the term "vaporize" from meaning "begin to vaporize." To so find would be to interpret the claims in such a way as to exclude the preferred embodiment from the claims.

The court, nonetheless, does not construe "vaporize" to mean "to begin to vaporize," as is urged by EMI. Rather, the court rules that "vaporize" simply means "to convert into vapor." As such, the term "causes said lower layer to vaporize before said upper layer vaporizes" means "causes said lower layer to convert into vapor before said upper layer converts into vapor."

1. "before storage"

Plaintiffs' construction: prior to entering data into a network storage device

Defendant's construction: prior to entering data into a non-volatile memory to be held and from which to be retrieved at a later time

At the claim construction hearing, the parties agreed that this term may be construed properly as "before data is entered in memory from which it may be retrieved at a later time." Transcript, dkt. # 80 at 90, Ins. 24-25; 91, Ins. 1-5, 8-10; 94, Ins. 8-10, 14-15. Plaintiffs indicated that they were concerned that defendant was trying to put a "gloss" on its construction that was overly limiting; defendant stated that this was not its intent. Id. In any event, defendant's "intent" is irrelevant in determining an appropriate construction. Therefore, I will adopt the compromise construction discussed at the claim construction hearing.

Court's construction: before data is entered in memory from which it may be retrieved at a later time

384

1. "beginning a first analyze sequence"

Claims 5, 10, and 15 of the '969 Patent describe a function of the AED as "beginning a first analyze sequence." Cardiac Science contends that this phrase should be construed as "starting a sequence of analysis." Philips, on the other hand, asserts
that this phrase should be construed as "starting to perform analysis for the first time only after a pre-selected impedance is detected."

The specification describes this function as follows:

After detecting an impedance indicating the proper placement of electrodes 50, and without further action by the operator (i.e., automatically), processor 74 begins a first analyze sequence by initiating the generation of a "Do not touch patient. Analyzing rhythm." voice prompt, and analyzing the patient's cardiac rhythm.

('969 Patent at c. 5, ll: 53-58.) The specification proceeds to describe, in sequential order, the manner in which the invention performs all of the functions listed in the claim language. (Id. at c. 6, ll: 23-64.) The specification states that the "second series of analyze/charge/shock sequences is identical to the first series described above, except the energy content of the defibrillation pulse can be about two hundred joules or three hundred joules." (Id. at c. 6, ll: 26-29.)

Philips places significant emphasis on the word "first," and asserts that because there is no need to differentiate the first from the second analyze sequences, the term "first" must mean first in time. Cardiac Science, on the other hand, contends that Philips is attempting to import limitations into the claim term. Cardiac Science asserts that the numerical designators in the claims are merely terms used as placeholders to designate the separate analyze sequences that are claimed. Thus, Cardiac Science maintains that the term "first" does not mean the first in time, but rather the first of two or more analyze sequences.

The Court finds that, consistent with the claim language, the function of "beginning a first analyze sequence" does not occur until a preselected impedance is detected. (Id. at c. 9, ll: 6-7; c. 9, ll: 45-46.) The specification offers no other explanation of this function other than that the first analyze sequence begins after detecting whether the impedance indicates the proper placement of electrodes. (Id. at c. 5, ll: 53-58.) In addition, the sequence of analysis/charge/shock may be relevant. Although the specification states that each sequence is identical, the specification also describes sequential increases to the energy content of the defibrillation pulses. (Id. at c. 6, ll: 19-21, 29-30, 35-39.)

Consistent with the claim language and the specification, the Court construes the term "beginning a first analyze sequence" as "starting to perform analysis for the first time after a pre-selected impedance is detected."

385

30. Beginning execution of said branch instruction

This term appears in claims 7, 8, 9, and 12 of the '037 patent. The plaintiff argues that the execution of the branch instruction begins at the time it is sent to the branch execution unit. ADI argues that the execution of the instruction begins when it is loaded into the instruction register in the branch execution unit. The court agrees with this view. The claim language is drafted in terms of the "execution" of the branch instruction. Based on this language, the court concludes that execution of the instruction cannot begin until the branch instruction arrives at the branch execution unit. The execution of the branch instruction therefore begins when the instruction is loaded into the register in the BEU. The court construes the term to mean "loading the branch instruction into an instruction register in the branch execution unit."

386

30. Being capable of being represented by a defined bit width which is equal to said defined bit width of said operands

The plaintiff proposes that this phrase means "able to be represented by a data field of the same size as the floating point operands." The defendants contend that the disputed phrase means "the bit width of the product of the permissible floating point operands must be no greater than the bit width of each of the operands." The plaintiff objects to the defendants' construction because of the limitation "no greater than the bit width of each of the operands." The claim language, the plaintiff argues, requires the capability of being represented by a bit width equal to the bit width of the operands. The
defendants insist, however, that their "no greater than" limitation is entirely consistent with the claim language and is found in the specification of the 482 patent. After considering the submissions of counsel, the court adopts the plaintiff's construction and construes "being capable of being represented by a defined bit width which is equal to said defined bit width of said operands" accordingly.

Claim 1 contains the term "being delivered." Accolade contends that "being delivered" means "having been transmitted." Citrix contends that "being delivered" means "transmitted from the host computer." The parties dispute whether "being delivered" indicates that the client program must originate from the host computer.

"Being delivered" does not require construction. The intrinsic record does not give any specialized meaning to "being delivered," and the plain meaning of "being delivered" is clear from the words of the term. "Being delivered" in the context of the claimed invention simply means changing the location of the client program from one place to another. Lay jurors would not need this explanation of what "being delivered" means, and offering a construction could only complicate the already clear and well understood language used in the term.

Both Accolade's and Citrix's constructions would work more to confuse rather than to clarify the meaning of "being delivered." The parties propose "having been transmitted" and "transmitted from the host computer." These constructions are taken from the specification that states, "Since the script [client program] is transmitted over the TCP/IP network." Col. 7:60-61. However, "transmitted" does not establish any special meaning for "being delivered." "Transmitted" is simply a synonymous way to say that the client program is "being delivered." Also, "transmitted" is not preferable language to use in construing "being delivered" because "transmitted" will likely be harder for lay jurors to understand than the simple language of the term "being delivered." "Being delivered" has a plain meaning that is already readily understood by lay jurors; thus, the Court does not construe "being delivered."

The parties disagree on whether the client program must originate from the host computer. The intrinsic evidence does not support limiting the claimed invention to require that the client program originate from the host computer. Claim 1 does not use any language requiring the client program to originate from the host computer, and the specification expressly states that the client program can be transmitted "alternatively, by another server on the Internet 12." Col. 7:61-62.

The prosecution history does not show that the host computer must deliver the client program. Citrix cites to the prosecution history, which states, "Independent claim 1 claims an apparatus for remotely controlling a host computer via a web browser on a client computer. An applet or equivalent is downloaded from the host computer to the client computer to permit this functionality." Defs.' Br. 30. However, the language cited by Citrix does not create a limitation where only the host computer delivers the client program. Stating that the client program "is downloaded form the host computer" does not require the host computer to exclusively deliver the client program. When read in context of the applicant's office action response, it becomes apparent that the applicant did not require the host computer to deliver the client program. The sentence following Citrix's excerpt states, "As such, no software is required at the client computer other than the browser software, which comes standard with virtually every personal computer that is sold." Defs.' Br., Ex. 13 (6-18-02 Amendment D), 4 (emphasis added). The applicant then distinguished Doyle, stating, "Doyle requires software to be installed upon the client machine in order for the browser to control remote applications." Id. at 5 (emphasis added). The applicant sought to distinguish Doyle based on whether the client computer requires software, not whether the host computer exclusively delivers the client program. Thus, the applicant did not rely on the host computer exclusively delivering the client program to distinguish the claimed invention from the prior art. As such, Citrix's excerpt from the prosecution history does not demonstrate a limitation on the claimed invention.
The "electrodes being electrically connected" term appears in one step of the method disclosed in Claim 1 of the 879 Patent. That method comprises these steps:

   placing two electrodes on a patient, the electrodes being electrically connected in a first polarity to an energy source external to the patient;

   charging the energy source to an energy level corresponding to a first start amplitude;

   discharging the energy source across the electrodes;

   adjusting the discharge parameter based on the measured patient impedance;

   reversing the polarity of the connection of the energy source to the electrodes to a second polarity;

   discharging the energy source across the electrodes.

'879 Patent Claim 1. The parties agree that the disputed term requires an electrical connection such that current flows in only one direction. Their dispute is over the term "being." Defibtech contends that the term "being electrically connected" is in present tense, and that when read in context of the claim, it means that the circuit between the defibrillator energy source and the patient must be complete at the moment the two electrodes are placed on the patient. Philips would have the court interpret the term to mean that the electrodes are placed such that they "will be" electrically connected during discharge. n5

The court rejects Defibtech's limitation. It is apparent, even to one not of skill in the art, that the electrical connection between the energy source and the patient need not exist from the moment the electrodes are placed on the patient. The patent envisions that discharge is initiated not by placing the electrodes on a patient's chest, but rather by the user manually initiating discharge or the defibrillator automatically initiating discharge in response to heart activity measured through the electrodes. 879 Patent at 5:8-9. There is no suggestion in the patent (beyond a literal reading of the tense of the verb "being") that having the electrical connection exist at the instant the electrodes are placed on the patient is important, necessary, or in any way relevant to the claimed defibrillator method. Claim construction is not a "gotcha" game in which an imprecisely used word invariably dooms the inventor, but rather a process where a court must interpret terms "in the context in which they were used by the inventor, considered by the examiner, and understood in the field of the invention." Toro Co. v. White Consol. Indus., 199 F.3d 1295, 1299 (Fed. Cir. 1999). In this case, a review of the patent shows that "being electrically connected in a first polarity" means "connected such that, during discharge, current will flow from the energy source through the patient in only one direction."

n5 Philips cites Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1369-71 (Fed. Cir. 2003), for the proposition that the steps of a method claim need not be performed in the order in which they are written, but the concept is irrelevant here. Regardless of the order in which one performs the steps of Claim 1, Defibtech's interpretation of "being" would require that the electrical connection between the energy source and the patient exist when the electrodes are placed on the patient. Altering the order of the steps does not alter the meaning of the language describing a single step.

--- Footnotes ---

E. "Said information being reproduced by projecting a light beam via an objective lens"

Plaintiff's construction: the information on the disc is capable of being reproduced by projecting a light beam via an objective lens

Defendants' construction: [not seeking construction]
Plaintiff requests that this term be construed to clarify that this apparatus claim requires no action by a player or additional apparatus for infringement to occur. In other words, plaintiff contends that claim 1 does not require the act of actively reproducing information from the optical disc, but only requires that the information on the disc be capable of being reproduced. In their brief, defendants take the position that construction of this phrase is not necessary. Nonetheless, defendants provide a construction, suggesting that "being reproduced" means "that the information is actually being reproduced (read) from the disc." Defs.' Br., dkt. 71, at 34.

Room for dispute exists because the inventors used an awkward verb construction to explain a concept in their patent: their use of "being," with the past participle "reproduced" puts the concept in the passive voice, so that the action described could be interpreted either as currently occurring or to occur in the future. Plaintiff contends that "being" means "capable of" and defendants contend that it means "actually." This dispute can be resolved by considering the context of the phrase in claim 1. ACTV, Inc., 346 F.3d at 1088 ("[T]he context of the surrounding words of the claim also must be considered in determining the ordinary and customary meaning of those terms"). The patent explains that additional advantages and modifications "will readily occur" to those skilled in the art; therefore, the invention is not limited to the specific details and representative devices and examples actually described in the patent. ’651 patent, claim 1, 10:45-48. Obviously, the patent envisions future action. Thus, it seems clear enough that the inventors used "being reproduced" to explain how or in what matter information will be reproduced on the optical disc. There is no indication that in the second paragraph the inventors are describing an action or method of the disc or a disc player. 4 Plaintiff's construction captures the correct meaning of the phrase because it clarifies that the information is not actually being reproduced (within this phrase), but that the manner in which information is reproduced is by projecting a light beam via an objective lens.

Court's construction: the information on the disc is capable of being reproduced by projecting a light beam via an objective lens.

--- Footnotes ---

3 For instance, to say "Kurosawa's Rashomon is being shown on HBO" could mean either that the movie is being shown right now or that it will be shown in the future.

4 As noted above, however, it remains an open question whether the third paragraph of claim 1 requires that a disc player actually be projecting a light beam.

K. "the adequacy of the funds in the first party's account being verified after the instrument is issued"

<table>
<thead>
<tr>
<th>Term</th>
<th>Plaintiff's Definition</th>
<th>Defendants' Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;a first party creating an instrument for transferring funds to a second party,&quot; the adequacy of the funds in the first party's party account being verified after the instrument is issued;&quot; instrument</td>
<td>The instrument being created before verifying whether an account of the first party has adequate funds or credit to cover or pay the instrument</td>
<td>after the instrument is released, determining whether or not the first party has sufficient funds in his/her account to pay the amount listed on the instrument</td>
</tr>
</tbody>
</table>

This phrase appears in claim 34 of the '148 patent. The parties dispute whether this phrase is a separate step of claim 34. Claim 34 is reproduced below:

34. A funds transfer method comprising:
a first party creating an instrument for transferring funds to a second party, the adequacy of the funds in the first party's account being verified after the instrument is issued;

using a computer to create a variable authentication number (VAN), the VAN being created using at least a secret key of the first party; and

including the VAN with the instrument for subsequent use in attesting to the authenticity of the instrument.

Plaintiff argues that the disputed phrase merely limits the "creating" step of claim 34. Plaintiff again explains that the steps of claim 34 are all recited in present participles and offset by semicolons.

Defendants argue that the phrase is a separate step. First, Defendants say that "[t]here is nothing to indicate that the disputed phrase modifies the 'creating an instrument' step." Def. Brief at 27. Second, Defendants argue that the phrase "after the instrument is issued" indicates that verifying the adequacy of the funds is a separate step that occurs, of course, after the instrument is created.

The limitation does not tell a person of ordinary skill in the art to verify the adequacy of the funds. Rather, it tells the person skilled in the art that an instrument is created without knowing whether there are adequate funds in the account. Thus, the phrase limits the step of creating the instrument by imposing a time sequence restriction. Furthermore, Defendants' argument that nothing indicates that the disputed phrase limits the creating step is incorrect. The words "after the instrument is issued" refers back to the "creating step" and the choice of the gerund "being" as opposed to the verb "is" suggests that the verification of the adequacy of funds is not a separate method step. The Court adopts Plaintiff's construction.

15. biaxial medium (‘412 patent)

CEA's proposed construction is "an existing type of birefringent, manufactured, plastic material wherein two of the principal optical indices are not too close to one another and the third principal optical index is significantly below or above the other two indices, e.g., N1o = 1.660, N2o = 1.6425, N3e = 1.5000."

Samsung's proposed construction is "a type of birefringent material having three unequal principal optical indices."

The specification supports Samsung's proposed construction 43 and is adopted by the court: "a type of birefringent material having three unequal principal optical indices."

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

43 ‘412 patent, 3:9-14 ("According to another special embodiment, the two polarizing means are crossed rectilinear polarizers and the compensating medium a biaxial medium, whereof the smallest index axis is parallel to the homeotropy direction."); '412 patent, 5:47-51 ("Each plate 20 or 22 is a biaxial medium having two principal indices N1o and N2o with values close to one another and a third index N3e below N1o and N2o, the weak index axis N3e being parallel to the homeotropic direction." (emphasis added)). The second quotation in this footnote was included as support for CEA's proposed construction, which CEA changed from "close to one another" to "not too close to one another." CEA concludes its proposed construction with exemplary figures for the three indices, but does not provide convincing explanation as to how those indices are not too close to one another, or how its definition for uniaxial medium ("a birefringent medium wherein the extraordinary index exceeds an ordinary index or vice versa") would not also read on its definition for biaxial medium.

- 854 -
B. "bid/offer system state" or "system bid/offer state"

1. The Parties' Proposed Constructions

The plaintiffs' proposed construction of the term "bid/offer system state" or "system bid/offer state" is "a state during which participants may enter into the system bids and offers for an item at select prices and volumes." (D.I. 463 at 4; D.I. 464 at 17.) The defendants' proposed construction is "a 'state' (as defined above) in which a computer system allows entry of bid, offer, hit, or lift commands and allows select actions by participants with active offerings that other participants are denied, substantially as described in the '580 patent." (D.I. 463 at 4; D.I. 482 at 9.)

The plaintiffs say that "bid/offer system state" or "system bid/offer state" is clearly and broadly defined in the claims themselves, and, therefore, that definition should control. (D.I. 464 at 18 and n.9 (citing, inter alia, Prima Tek II, L.L.C. v. Polypap, S.A.R.L., 318 F.3d 1143, 1150-51 (Fed. Cir. 2003).) In support of that argument, they point to claim 20, which recites "providing a bid/offer system state wherein the passive participants participate by entering bids or offers at select prices and volumes for the item...." ('580 patent, col. 20, II. 8-10.) They also point to claims 22 and 24, which both recite "providing a bid/offer system state wherein a first participant enters [a] bid or offer for the item at a select price and volume..." (Id., col. 20, II. 37-39, 61-63.) Similarly, claim 29 (the apparatus claim) recites a trading system that "provides a system bid/offer state enabling the passive participants to participate by entering bids or offers with respect to the item...." (Id., col 22, II. 16-18.)

In response, the defendants argue that the "wherein" clauses relied upon by the plaintiffs do not provide a complete definition for "bid/offer system state" or "system bid offer state" because they differ from claim to claim. (D.I. 492 at 12.) The defendants cite unasserted claim 14 in support of this argument, which reads "providing a bid/offer system state wherein passive participants enter[] bids or offers for the item at associated select prices and volumes..." ('580 patent, col. 19, II. 41-43.)

2. The Court's Construction

I agree with the plaintiffs' position that "bid/offer system state" or "system bid/offer state" is clearly and broadly defined in the claims of the '580 patent, and that that definition should control. See Prima Tek II, 318 F.3d at 1150-52 (noting that "the scope of the asserted claims may be ascertained from the plain language of the claims" and that "broad claims supported by the written description should not be limited in their interpretation to a preferred embodiment"). The defendants' argument that "wherein" clauses cited by the plaintiffs differ from claim to claim is a futile one, as the wherein clause of claim 14 is nearly identical to the wherein clauses of claims 20, 22, 24, and 29. Nor have the defendants directed my attention to anything in the patent or the intrinsic record that contradicts the definition of "bid/offer system state" or "system bid/offer state" set forth in the claims. 9 Accordingly, I will construe "bid/offer system state" and "system bid/offer state" as "a state during which participants may enter into the system bids and offers for an item at select prices and volumes."

--- Footnotes ---

9 The defendants' proposed claim language would limit "bid/offer system state" or "system bid/offer state" to a state that "allows select actions to participants with active offerings that other participants are denied". (D.I. 463 at 4.) In support of this limitation, the defendants rely almost entirely on a description of the preferred embodiment of the invention (see id. (citing '580 patent, col. 8, 1.66 to col. 11, 1.50)) that is set forth in the specification of the '580 patent, in conjunction with a discussion of "clearing time" and the "when state" (see '580 patent, col. 9, 1.66 to col. 12, 1.38). Where, as here, the disputed claim terms are clearly defined in the language of the claims themselves, the defendants cannot overcome the presumption that those definitions apply "simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history." Teleflex, Inc. v. Ficosa North Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002) (citation omitted). I therefore decline to read the defendants' proposed limitation into the claim language.

--- End Footnotes ---
TERM # 4: "bidder's computer" - Again, there is no reason to define this term by referring to any of the process steps, as defendants propose. Particularly, we find no requirement in the claim that the "computing" step be performed on the Bidder's computer, and therefore, especially, find no support for defendants' attempt to define this term to include the "computing" step. This phrase means: "A computer used by a bidder to access an electronic auction."

394
2. "Bill Value"

Next, the parties dispute the term "bill value." The term "bill value" appears in claims 19 and 30. The plaintiff contends that the term means "a value related to a credit value that is billed to a merchant's account or to a third party." The defendant proposes "a value equal to one or more credit values that is to be billed to a merchant or third party." The dispute appears to be whether the bill value must equal one or more credit values.

In support of its proposed construction, the defendant cites to the '090 specification and a sentence in the '116 specification which states that the "bill segment is then similarly incremented in relation to the amount of the credit value data received from that merchant." '116 patent, 4:42-45. This passage does not clearly limit the term in the manner the defendant proposes. Accordingly, the court adopts the plaintiff's proposed construction.

395
6. "including [ , providing, or establishing] 10 in said message record" and "billing"

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
10 The claims, although essentially the same, use different wording with regard to this step.
- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

The claims at issue disclose a two-step method comprising the steps of (1) "generating a message record for an interexchange call between an originating subscriber and a terminating subscriber" and of (2) including "in said message record" a PIC indicator. To this end independent claim 1, for example, teaches

    generating a message record for an interexchange call between an originating subscriber and a terminating subscriber, and
    including, in said message record, a primary interexchange carrier (PIC) indicator having a value which is a function of
    whether or not the interexchange carrier associated with said terminating subscriber is a predetermined one of said
    interexchange carriers.

( '184 patent, col. 7, ins. 8-16) Excel contends that these steps occur in the network of a facilities-based IXC 11 prior to the billing process. AT&T seeks a construction that defines the billing process as the last step in the overall process disclosed in the patent, wherein the generation and mailing of "hard-copy" bills to subscribers is performed. Although the parties dispute the scope of the term "billing," their proposed constructions are not mutually exclusive.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
11 Excel argues that the process described in the patent specification for inclusion of a PIC indicator in the message record is performed "entirely within, or adjunct to, the network of a facilities-based carrier." Excel's argument is moot given the court's previous constructions which do not limit the practice of the invention to facilities-based carriers. See supra, Part V.B.1. Moreover, the court notes that the claims teach "generating a message record," generally, and that while the initial message record for any given interexchange call is generated by a switch, all other message records are generated by other pieces of equipment. The preferred embodiment, in fact, discloses a system wherein the PIC indicator is included in an EMI message record that is generated by a formatting system using information from the AMA message record.
As an initial matter, the court notes that the claim language itself indicates that the generation of "said message record" occurs prior to its transmission to a billing system. Claims 5, 14, and 20, which depend from claims 1, 12, and 18 respectively, teach "the further step of transmitting each said message record to a billing system." ( '184 patent, col. 7, lns. 31-33; col. 8, lns. 33-35; col. 9, lns. 8-10) (emphasis added). Likewise, claims 6, 15, and 21, which also depend from claims 1, 12, and 18 respectively, teach the further step of billing at least one of said calls as a function of the value of the PIC indicator in the message record generated for each one of those calls.

( '184 patent, col. 7, lns. 34-37; col. 8, lns. 36-39; col. 9, lns. 11-14) (emphasis added). Claim 41 which depends from claim 40 also teaches the additional steps of rating and billing. ( '184 patent, col. 12, lns. 25-32) Although dependent claims cannot limit the independent claims from which they depend, see Karlin Tech. Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 50 U.S.P.Q.2D (BNA) 1465, 1468 (Fed. Cir. 1999) (stating "that limitations stated in dependent claims are not to be read into the independent claim from which they depend"), they are to be considered in interpreting the scope of the claim from which they depend, see Laitram Corp. v. NEC Corp., 62 F.3d 1388, 1392 (Fed. Cir. 1995) (stating that "although each claim is an independent invention, dependent claims can aid in interpreting the scope of claims from which they depend"); see also Transmatic, Inc. v. Gulton Indus., Inc., 53 F.3d 1270, 1277 (Fed. Cir. 1995) (noting that the scope of an independent claim incorporates the embodiments recited in dependent claims). In the '184 patent, the dependent claims anticipate the transmission of the message record to a billing system after the addition of a PIC indicator.

The '184 patent's specification provides further support for reading the claims to require the generation of the message record and inclusion of the PIC indicator therein prior to "billing." According to the specification, "in a typical system" EMI records bearing an indication of the applicable toll charges "are forwarded to a billing system in which they reside until processed to generate, typically, 'hard copy' bills which are mailed to subscribers." ( '184 patent, col. 1, lns. 26-29) In the preferred embodiment,

at the completion of the call, IXC originating switch 301 generates the . . . AMA record for the call (connection). This switch is periodically polled, along with other like switches, by an associated one of message accumulator systems 311 . . . 312. . . .

On a periodic basis . . . each message accumulator sends its accumulated AMA records to a corresponding one of EMI formatting systems 321 . . . 322 . . . . The latter translates the AMA records into the aforementioned industry-standard EMI message record format. The EMI records are thereupon periodically forwarded . . . to a respective one of rating systems 331 . . . 332 . . . . Among the functions of rating systems 331 . . . 332 is to "rate" each call, 12 by which is meant the computation of the standard toll charges or rated charge, applicable to each call, and to add an indication of same to the EMI record. . . .

* * * *

. . . Additional known functionalities may also be carried out by the rating system. Of interest here, however, is the generation of PIC indicator 3419. . . . After perhaps performing various other functions not relevant here, rating system 331 transfers, or transmits, the now rated and PIC-evaluated EMI message to a billing system for subsequent processing.

( '184 patent, col. 3, lns. 26-48; col. 5, lns. 42-45, 57-61) The specification states that "the PIC indicator is advantageously added to the message record in the same system that performs the call rating--and at a time substantially contemporaneous with the rating itself." ( '184 patent, col. 2, lns. 19-22) The specification goes on to state with respect to the preferred embodiment that "advantageously, the value of PIC indicator 3419 can be used in subsequent billing operations." ( '184 patent, col. 4, lns. 44-45)

12 In order to generate the applicable PIC indicator, the rating system "needs to be able to access a comprehensive database
in which all IXC 30 subscriber telephone numbers are stored." ('184 patent, col. 5, lns. 5-37)

Although the figures and language of the specification support AT&T's assertion that "billing" is the last step in the overall process, they do not support its contention that "billing" encompasses only the generation and mailing of "hard-copy" bills. The specification states that "in a typical system" EMI records are forwarded to a billing system wherein they are"processed to generate, typically 'hard copy' bills which are mailed to subscribers." ('184 patent, col. 1, lns. 14, 27-29) (emphasis added). The typical system is not the only system. This is particularly true in light of other statements in the specification that indicate that the EMI records are transmitted to a billing system for "subsequent processing" ('184 patent, col. 5, lns. 60-61) or "subsequent billing operations." ('184 patent, col. 4, ln. 45; col. 5, lns. 65-67; col.6, lns. 12-13, 16-21, lns. 30-35) Thus, although the specification and the claim language distinguish "billing" from those steps which precede it, i.e., the generation of the message record, the gathering of information from the applicable databases, the generation of the PIC indicator, the rating of the call, and the formation of the rated message record, they do not limit it to the generation and mailing of hard-copy bills.

The court, therefore, shall construe the term "billing" to be the last step in the method disclosed in the '184 patent but shall not limit the operations performed therein to the generation and mailing of hard-copy bills, Consistent with this construction, the court shall construe the asserted independent claims as requiring the generation of the message record and inclusion of the PIC indicator therein to occur prior to the transmission of the message record to a billing system.

Billing Authorities

Fenner argues that "billing authorities" should retain its plain and ordinary meaning, but if the Court elects to construe this term it should mean, "authorities which track billing costs associated with a personal identification number." Defendants argue that "billing authorities" are "the different entities responsible for billing individuals for use of allowed calling services." For the following reasons, the Court construes "billing authorities" to mean "the different entities which track billing costs associated with a personal identification number (as construed herein)."

Defendants argue that Fenner's construction ignores the reality that billing includes charging and invoicing as well as tracking, maintaining that "billing authorities" are entities like AT&T or VISA that provide services, track the costs associated with those services, charge the customer for those costs, and then send out bills or invoices to collect on those charges. However, the patent specification and claims consistently discuss "billing authorities" maintaining service profiles and monitoring costs, only inferentially referring to the actual billing of individuals as Defendants' construction suggests. 1:50-59; 5:64-66; 6:5-15.

Presumably, these billing authorities will attempt to collect money for the services provided in the service profile, but stating that the billing authority described in the claims is "responsible for billing individuals for use of allowed calling services" is beyond the scope of the term as used in the patent and is simply not necessary to define "billing authority." Therefore, the Court construes "billing authorities" to mean "the different entities which track billing costs associated with a personal identification number (as construed herein)."

Billing authorities maintaining a service profile for the mobile user

Fenner argues that the terms in this phrase should retain their plain and ordinary meaning, while Defendants argue that the phrase means, "more than one billing authority maintaining a service profile for the mobile user." The Court favors Defendants' construction, which finds support in the surrounding claim language n3 and intrinsic evidence.
n3 The claim language reads, "receiving from the mobile user at the communication switch a billing code identifying one of the plurality of billing authorities maintaining a service profile for the mobile use, wherein different ones of the plurality of billing authorities may maintain the service profile or a second profile for the mobile user."

398

Billing Code

Fenner contends "billing code" should retain its plain and ordinary meaning, alternatively suggesting that if the Court chooses to construe the term, that it should find a "billing code" "identifies a particular billing authority." Defendants argue the "billing code" is "a number code, separate from the personal identification number, that enables selection of a billing authority." As the parties had agreed to include "separate from a billing code" in the construction of PIN there was little argument on that phrase at the hearing. The remaining issues before the Court involve the difference between "enabling selection," and "identifies," and whether a "billing code" is necessarily a number.

Defendants contend that a billing code "enables selection of a billing authority," and offer segments of the prosecution history in support of its construction. Amendment, 12/22/94 at 9-10; Amendment, 11/30/95 at 7. Having disclaimed claim scope during prosecution, Defendants argue, the Court should not allow Fenner to recapture that claim scope by finding that a "billing code" "identifies" billing authorities. The Court disagrees with Defendant, and construes "billing code" to mean, "a code separate from a personal identification number, identifying a particular billing authority."

The specification and claims consistently describe a billing code identifying a billing authority. See 6:5-7 ("a billing code identifying one of the plurality of billing authorities"); 6:12-13 ("requesting a service profile of the mobile user from the billing authority identified by the received billing code"); see also 2:43-4. Further, Defendants' prosecution history evidence does not justify its proposed limitation.

First, the Amendment dated 11/30/95 where Fenner describes, "a billing code which enables selection of multiple billing authorities," does not, taken in context, rule out the possibility that a billing code may identify a billing authority. Amendment 11/30/95 at 7. The sentence following Defendants' quotation reads,

the fact that Lee et al. describes programming a local exchange with personalized calling features in response to providing a code does not suggest, it is submitted, use of a separate billing code to identify a billing authority in a conventional cellular system much less suggest a system in which a billing authority identifier and personal identification number for routing calls to a mobile user are utilized during log on or registration." (emphasis added).

Disclaimers of claim scope must be clearly and unambiguously express to surrender subject matter during prosecution. Middleton, 311 F.3d at 1388. The prosecution excerpt Defendants rely on is not sufficiently clear to show that a billing code does not identify a billing authority.

Second, even if Fenner had unequivocally established that a billing code "enables selection," during prosecution history, that would not necessarily preclude a billing code from "identifying" a billing authority because the phrase "enables selection" is broader than "identifies." "Enables selection" is a permissive phrase suggesting that the billing code somehow allows for, or
participates in, the selection of a billing authority. The term "identifies" suggests a specific role within the selection process, namely, specifying the appropriate billing authority. It is difficult to conceive how claim scope could be disclaimed by representing a broader scope during prosecution than was eventually claimed in the patent. Thus, Defendants have not established that Fenner relinquished claim scope by referring to "enabling selection" of a billing authority during prosecution.

Defendants also argue that a "billing code" is a number, but their support from the prosecution history is not compelling. In a paper broadly describing the proposed networking system, which was later submitted to the patent office during prosecution, the inventor explained that a "Billing Authority' operates like a credit card company, offering on-line credit and service profile verification," further explaining that, "we propose every PCS call should be a 'credit card' call," where "the credit card numbers (or billing codes) used by a PID would contain location information to access the issuing 'billing authority.'" Peter R. Fenner, Mobil Address Management and Billing for Personal Communications (IEEE 1992) at 253, 254. The inventor analogized the then available "credit card" call to his system as a descriptive aid but never went so far as to require that the billing code necessarily be a number. Further, although the specification refers to the billing code as a number, the claims do not require that the billing code be a number, and the Court will not import the limitation.

Accordingly, the Court construes the term "billing code" to mean, "a code, separate from a personal identification number (as construed herein), identifying a particular billing authority (as construed herein)."

399

D. "Billing for Access to the Service"/"Generating a Bill for the Service"

The term "billing for access to the service" appears in claims 3 and 4 of the '945 patent. The term "generating a bill for the service' appears in claims 1 and 2 of the '943 patent. The parties agree that "billing for access to the service," as used in the '945 patent, and "generating a bill for the service," as used in the '943 patent, have the same meaning, but they are unable to agree as to what that single, common meaning is.

ABC asserts that the terms should be defined as "indicating an amount due for access to the service." 137 WebEx asserts that the terms mean "automatically creating an invoice based on past access to a remote computer unit of a split personal computer system." 138

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

137 ABC's Brief, Docket Entry No. 154, at 17.
138 WebEx's Brief, Docket Entry No. 156, at 29.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

1. "Billing"/"Generating a Bill"

The parties' proposed definitions differ in the way that they describe the act of billing or generating a bill. ABC broadly and simply characterizes billing as "indicating an amount due . . . ." WebEx defines billing much more specifically and narrowly. Under WebEx's proposed definition, billing must (1) be conducted automatically, (2) involve an invoice, and (3) be based only on past access to or utilization of the service.

ABC correctly points out that the claim language itself does not require that billing be conducted by any particular entity or person, at any particular time, or with any particular frequency. ABC further argues that the specifications of the '945 and '943 patents give various examples of billing that support ABC's broad definition. The specification of the '943 patent provides a few examples of billing:

The remote system controller can be provided with a billing program which counts the number of minutes that respective local portions . . . are operating at least one of the networked computers of the remote portion . . . . By employing the remote
system controller and the billing program, individuals can 'rent' computer time from the remote portion . . . . 139

The remote system controller can also include a billing program which counts the time period in which an individual utilizes at least one of the remote computer units so that either session billings (in the case of hotel rooms billings, for example) or monthly billings could be made. The time period can be measured in seconds, minutes, or any other suitable unit of time. 140

Similarly, the specification of the '945 patent contemplates a number of ways that billing could be implemented:

In the system described, a service provider such as AOL, could charge $ 20.00 a month . . . for PC service . . . . 141

Public CIU 10 terminals in airports, malls, and hotels will be as common as public phone booths are today, and at about the same cost . . . . 142

The time of connection is noted by a multi shared computer connection unit . . . . 143

ABC also cites definitions from two general purpose dictionaries for the non-technical term "bill." The first dictionary defines the noun "bill" as "a statement of charges for goods or services," and the verb "bill" as "to present a statement of charges to." 144 The other dictionary similarly defines the noun "bill" as "a statement of charges for goods supplied or services rendered" or "the amount owed." 145 The second dictionary defines the verb "bill" as "send a note of charges to." 146

WebEx, in support of its position, cites many of the same excerpts from the specifications of the '943 and '945 patents. 147 It argues that all of these examples involve automation and charging users for past service rendered. WebEx therefore argues that billing must be defined as an automated process only based on service rendered in the past. WebEx also asserts that prior art involved charging users before they used the service. 148 Further, WebEx argues that the USPTO Examiner who conducted the reexamination of the '945 patent manifested his understanding that billing under that patent involved charging only for past services when he stated:

Billing is disclosed in claims 3 and 4 specifically to 'maintain the customer's access to the services' . . . . Thus the instant
invention clearly establishes that payments are for continuing existing services allowing the user access to the remote computer. 149

147 See WebEx's Brief, Docket Entry No. 156, at 29-31.

148 Id. at 30 (citing '943 patent, col.1 ll.33-37; '945 patent, col.1 ll.18-26).

149 Notice of Intent to Issue Ex Parte Reexamination Certificate, at 5, Ex Parte Reexamination of U.S. Patent No. 6,999,945, Control No. 90/008,122 (March 30, 2009) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6J).

Based on the evidence in the record, the court is persuaded that ABC's broader definition of billing is correct. WebEx contends that the court should limit the concept of billing to the examples described in the patent specification that involve automation and charging for past service, but it is a cardinal rule of claim construction that the "claims of a patent are not [generally] limited to the preferred embodiment, or to the examples listed within the patent specification." Dow Chem. Co., 226 F.3d at 1341-42. Although billing may be automated and may only involve charging for service rendered in the past in some embodiments of the invention, the patentee did not indicate that automation of billing or billing only for past service was "important to the invention." Toro Co., 199 F.3d at 1301. Therefore, the claim should not be construed to include those limitations. Moreover, the court does not agree that the examples described in the specification are specifically limited to billing for past service. For example, the '945 patent describes a service provider charging a flat monthly rate for the service. 150 Such a monthly charge could be for future service, i.e., the user could pay for the service in advance.

150 See '945 patent, col.2 ll.33-35 ("[A] service provider such as AOL, could charge $ 20.00 a month . . . for PC service . . . ").

WebEx's argument that the prior art involved up-front payment is inapt. There is no rule of patent law that every element or limitation of a claimed invention must exclude or be different than the prior art. Simply because the claimed invention may encompass one aspect of the prior art does not mean that it is not patentable based on other distinctions. The method of billing employed by the prior art would only be relevant if WebEx could show that ABC clearly and unmistakably disclaimed that type of billing as a way to distinguish the claimed invention from the prior art for patentability purposes. See Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1325-26 (Fed. Cir. 2003) (explaining that a claim term may be interpreted more narrowly than it otherwise would if the patentee "clear[ly] and unmistakabl[y]" disavowed a particular meaning during prosecution in order to obtain his patent). WebEx, however, has presented no such evidence.

Nor is the court persuaded by WebEx's argument that the Examiner understood billing to involve charging only for service rendered in the past. Just because "payments are for continuing an already existing service" 151 does not mean that payments are necessarily for service rendered or received in the past. For example, in the flat monthly rate scenario described above, a user would receive a monthly bill. The amount charged could be for future service. If the user did not pay the bill, the service provider would cease providing the remote control service that the user had, up until that time, received. If the user paid his bill, however, his payment would be "for continuing an already existing service." 152

151 Notice of Intent to Issue Ex Parte Reexamination Certificate, at 5, Ex Parte Reexamination of U.S. Patent No. 6,999,945, Control No. 90/008,122 (March 30, 2009) (included in WebEx's Brief, Docket Entry No. 156, at Exhibit 6J).

152 Id.
Finally, WebEx presents no evidence and makes no argument in support of its position that billing must involve an invoice. Accordingly, consistent with the intrinsic and extrinsic evidence, the court concludes that "billing" or "generating a bill" means "indicating an amount due . . . ."

2. "Access to the Service"/"The Service"

The parties' proposed definitions also differ in that ABC's definition does not attempt to describe the service for which a bill is generated while WebEx's definition identifies the billed-for service as "access to a remote computer unit of a split personal computer system." ABC does not explain why it chose not to define "the service" or "access to the service," nor does it raise any specific objection to this aspect of WebEx's definition. Furthermore, the court agrees with WebEx that a definition explaining what "the service" is will be helpful. The court is therefore inclined to adopt this aspect of WebEx's proposed definition, with one modification.

WebEx has described the service as "access to a remote computer." The asserted claims themselves, however, describe the service provided as "controlling a remote computer" 153 and "connecting a local computer unit to a remote computer unit to permit the local computer unit to operate the remote computer unit." 154 The words "controlling" and "operate" carry a significantly different connotation than the word "access."

Moreover, WebEx criticized ABC for suggesting that the term "logon command" enabled "access to" a remote computer unit, and argued that the claim language made clear that the logon command actually enabled "operation of" a remote computer unit. 155 The court was persuaded by WebEx's argument and adopted a definition for "logon command" including the term "operation." Therefore, consistent with the claim language and the court's definition of "logon command," the court concludes that the service provided by the invention and for which a bill is generated is "operation of a remote computer unit of a split personal computer system."

3. Conclusion

The terms "billing for access to the service" and "generating a bill for the service" mean "indicating an amount due for operation of a remote computer unit of a split personal computer system."

400

The language in claim 1(c) reads: "means for telecommunicating the read billing information to a user." Because it is undisputed that this claim is a means-plus-function construction, the court will construe it pursuant to 35 U.S.C. § 112, P 6. The parties' dispute over claim 1(c) turns on the meaning of the phrase "billing information" as it is used in that claim. The question of whether "billing information" refers to all users, or only one user, is determinative because the alleged infringement by CheckFree concerns a bill payment system in which a supplier telecommunicates a single user's bill information. CheckFree argues that "billing information" is synonymous with "billing data" and, therefore, its product
cannot infringe the '084 patent. Databurst, on the other hand, argues that "billing information" refers to information for only one particular user.

Checkfree argues that in claim 1(c) "billing information" is synonymous with the term "billing data," and, thus, it should be construed to mean "information regarding bills for all users." (Checkfree Mot. at 21.) Specifically, Checkfree contends that the term "billing information" represents the bills for all users, including (1) information about the transactions that are to be billed to each user; and (2) identification information for each user. Recognizing that the pertinent specification does not define the phrase "billing information" but does define "billing data," Checkfree states that "billing data for the customers" includes "customer identification information and information about the transactions that are to be billed to the customer." Checkfree asserts without explanation that the wording of the specification supports the notion that "billing information" is synonymous with "billing data" and therefore includes the billing data for all users. In addition, Checkfree argues that the prosecution history supports its argument that "billing information" is the same as "billing data" as used in the specification. Checkfree claims that the patentee used the two terms interchangeably, as evidenced by the patentee's amendment to claim 1 where "billing data" was replaced with "billing information." Finally, Checkfree relies on inventor testimony to support the correlation between "billing information" and "billing data." In light of this construction, Checkfree maintains that the limitation in claim 1(c) cannot be met by a device that telecommunicates only an individual user's bills.

Databurst argues that claim 1(c) should be construed as a "means-plus-function limitation covering modems 26 and 30, phone lines 32, modem 46 and equivalents thereof, which communicate billing information at a distance as by telephone, radio, optical beams and the like." (Databurst Mot. at 17.) Databurst argues that based on the language of the specification, "billing data" is plural, while "billing information" is the specific unit of information for one customer. Specifically, Databurst alleges that "billing information" is defined in the specification as "customer identification information and information about transactions that are to be billed to the customer." (Databurst Mot. at 18.)

The court must now determine the meaning of the phrase "billing information," as used in claim 1(c) to describe what is telecommunicated from the supplier (such as a credit card company) to the individual user. First of all, contrary to Databurst's contention, the term "billing information" is not defined in the specification or anywhere in the patent. The specification states that a "block 10 contains billing data for the customers." ('084 patent, col. 2, ll. 38-39.) It is undisputed that the term "billing data" refers to the billing data for all customers. The next sentences reads: "This includes customer identification information and information about the transactions that are to be billed to the customer." (Id. at ll. 39-40) (emphasis added). The pronoun "this" refers to the antecedent "block 10" in the preceding sentence. Reading the two sentences together, block 10 (containing "billing data") includes customer identification information and information about the transactions that are to be billed to the customer. 1 Therefore, that section of the specification relied upon by Databurst refers to "billing data" and cannot be read as a definition for "billing information." Further, the ordinary and accustomed meaning of "information" does not provide this court with any guidance as "information" may be either singular or plural. See Webster's Ninth New College Dictionary 620 (9th ed. 1985) (defining "information" as "the communication or reception of knowledge or intelligence").

--- Footnotes ---

1 Although not necessary to the court's construction, the court notes that the testimony of the inventor of the '084 patent acknowledged that "billing information" was the same as "billing data" at the "block 10" stage. (Checkfree Mot., Ex. D, Linse Dep. at 177-78.)

--- End Footnotes ---

The court next turns to the specification more generally for guidance. "Billing data" is used to describe what is broadcast from the supplier to the user. By tracing "billing data" as it travels through different blocks in the specification, "billing data" is consistently referenced until the term "billing information" appears in lines 14 and 20 in column 3. In a nutshell, "billing data" (which both parties agree refers to the data for all customers) is first supplied to block 10, read by a tape reader in block 12, temporarily stored at block 14 or 16, scrambled, encoded or faxed by block 20, 22, or 24, output to a modem at block 26, received by another modem at block 30, transmitted by block 32, 34, or 38, received by block 44 or 46, digitally decoded by block 50 and decoded according to a user's address at block 52. Up to this point, nothing has occurred in the process to change the content or substance of the "billing data," and, therefore, the court reads "billing information" in lines 14 and 20 in column 3 to refer to the billing data for all customers. Therefore, "billing information" in both lines 14

- 864 -
and 20 refers to what was broadcast by the supplier to the user, i.e. billing data. This supports a construction that "billing information" includes the billing data for all customers.

There is, however, some further ambiguity and inconsistency in the use of the phrase "billing information" that occurs later in the specification's description. After the address decoder at block 52 determines if a bill is coming in for a particular user, the "billing information is stored in memory in the message storage unit." (‘084 patent, col. 3, ll. 44-45.) Now, at this point in the process, the billing data has been filtered and "billing information" refers to the individual user's bill. Use of "billing information" after the filtering process, (id.), must have a different meaning from "billing information" before the sorting process, (id. at ll. 14, 20). "Billing information," therefore, as used in the specification, has two distinct meanings.

In order to determine whether "billing information" as used in claim 1(c) means the billing data for all users or for only one user, the court now looks to the prosecution history. The inventors submitted their patent application on August 29, 1988. (Checkfree Mot., Ex. C, Tab 1 at 1.) As originally drafted, claim 1(c) used the term "billing data," not "billing information." (Id. at Tab 1 at 11.) It appears that an examiner marked corrections and comments on their application. (Id. at Tab 1 at 2-14.) On pages 11 and 12, certain corrections to claim 1 are made; the word "data" was replaced by "information." (Id. at Tab 1 at 11-12.) Significantly, in the claim as originally drafted, the term "billing data" was consistently used prior to the filtering at the address decoder, while "billing information" was consistently used after the address decoder. (Id. at Tab 1 at 11.) In the examiner's action dated June 20, 1989, the examiner did not explain his reason for replacing "data" with "information." (Id. at Tab 2 at 1.) In response, the inventors amended claim 1 by changing the word "data" to "information." (Id. at Tab 4 at 2.) Both the claim as originally drafted and the amendment from "data" to "information" supports a construction that "billing information" as used in claim 1(c) means the billing data for all customers.

However, use of the phrase "billing data" in the specification was not changed to "billing information" as it was in the recitation of claim 1. During a lengthy prosecution history, patentees sometimes fail to update the specification language as they amend the claims. Eolas Technologies, Inc. v. Microsoft Corp., 2000 U.S. Dist. LEXIS 18886, 2000 WL 1898853, *15 (N.D. Ill. 2000). It seems likely that inadvertence on the part of the patentees explains the inconsistent use of the phrase "billing information." Further, the court notes that a construction in which the supplier sends to the user only the individual user's billing information does not withstand scrutiny in light of the filtering process included within the patent. The patent contemplates that data would be received by the user, run through an address decoder, and then an individual user's bill would be delivered into the PAID. If the supplier sends the user's receiver only the individual user's bill, there would be no need to have any filtering mechanism.

Conclusion

Based on the above, the court finds that the term "billing information" in claim 1(c) includes the billing data for all customers, and includes for each user: (1) information about the transactions that are to be billed to that user, and (2) identification information for that user. This limitation would not cover any equipment that telecommunicates only an individual user's bill(s) from the supplier to the user.

GO BACK

401

After studying the parties' arguments, we find that the intrinsic and extrinsic evidence leads to agreement with plaintiff Chamberlain on the major claim terms in dispute. We will discuss each in turn. As noted above, Chamberlain argues that "binary code" should not be limited to representation of a base 2 number. We agree. Based on the patent, we find that the patentee intended to distinguish "binary code" from "binary number" or "base 2 number." Although both are computer-readable commands displayed in a string of 0s and 1s, patentee's "binary code" can represent a "binary number" (number consisting of only two digits), a "trinary number" (number consisting of only three digits), or any other numeric or symbolic language designations. First, we look at the claims. Nowhere does the claim language use the term "binary number" or "base 2 number," instead, the claim language consistently uses "binary code" and "binary signal." The only place in the patent where "binary code" is even suggested as synonymous with "binary number," is in the patent's preferred embodiment: "Both of the bit values being set in steps 742 and 746 relate to a translation from the three-level trinary bits 0, 1, and 2 to a binary number" (8:45-48). The Federal Circuit has repeatedly held, however, that "particular embodiments appearing in the written description will not be used to limit claim language that has broader effect." Innova/Pure Water, Inc. v. Safari Water Filtration System, Inc., 381 F.3d 1111, 1117 (Fed.Cir.2004). See also Phillips, 415 F.3d at 1323; SanDisk Corp. v. Memorex Products, Inc., 415 F.3d 1278, 1286 (Fed.Cir.2005). Additionally, the summary of the invention in the specification does not
limit "binary code" to "binary number." In fact, in the entire summary of the invention, the term "binary" is only used to show how the 32-bit encrypted code in the receiver is "compared via a binary subtraction with the stored rolling code" to determine authorization (3:62-63). Without a limitation to "binary number," or clear source code that limits "binary code" to base 2 or binary numbers, we will not read the limited reference in the preferred embodiment into the claim language. Rather, we assume that the patentee intended to revert to the term's customary and ordinary meaning.

We turn, then, to a technical dictionary to aid us in understanding what the ordinary and customary meaning of "binary code" was to a person of ordinary skill in the art. See Phillips, 415 F.3d at 1318. ("Because dictionaries, and especially technical dictionaries, endeavor to collect the accepted meanings of terms used in various fields of science and technology, those resources have been properly recognized as among the many tools that can assist the court in determining the meaning of particular terminology to those of skill in the art of the invention.") The IEEE Standard Dictionary of Electrical and Electronics Terms, Sixth Edition, has three definitions for "binary code," including "A code in which each code element may be either of two distinct kinds or values, for example, the presence or absence of a pulse," "A code that makes use of members of an alphabet containing exactly two characters, usually 0 and 1," and "A code that uses exactly two distinct characters, usually 0 and 1, to represent data or instructions." The definitions vary only slightly and encompass our understanding of patentee's use of the term "binary code" in the patent. Specifically, the IEEE notes, in definition number two: "The binary number system is one of many binary codes." This further supports our understanding that the ordinary and customary meaning of "binary code," to one of ordinary skill in the art, is a code consisting of two values, which may represent a binary number, trinary number, ASCII character, decimal number, or any other numerical or character language designation. Therefore, we construe the term "binary code" to be "a code in which each code element may be either of two distinct kinds of values, which code may represent various kinds of letters and numbers including, but not limited to, a representation of a base 2 number." n4

n4 Lear's argument that plaintiffs' definition of "binary code" and "trinary code generator" is "driven by their need to use memory to find infringement" (Lear's Markman Position slides, pp. 9-10) is an infringement argument, rather than a claim construction argument We will not decide at this point if Lear's product exists in "binary code," as defined by this opinion, only in the computer memory, or if such a use of "binary code" is infringing.

Originally, we construed "binary code" as "a code in which each code element may be either of two distinct kinds of values, which code may represent various kinds of letters and numbers including, but not limited to, a representation of a base 2 number"(Chamberlain I, 2006 U.S. Dist. LEXIS 68899, 2006 WL 2632074, at *4). Lear takes issue with a sentence in Chamberlain I, wherein we stated: ["a]s we noted above, the claims never limit the initial binary code to a 'binary number,' instead leaving the term open to encompass other numerical and character languages, including trinary code." Id. Lear argues that, based on the intrinsic evidence of the patents' claims, "binary code" cannot encompass a trinary code. Therefore, Lear implores us to modify our construction of "binary code," to "a code in which each code element may be either of two distinct kinds of values, which code may represent various kinds of letters and numbers including, but not limited to, a representation of a base two number, but not including a trinary code" (def's brief, at 6).

Not surprisingly, plaintiffs disagree. First, plaintiffs suggest that Lear's arguments are inappropriate for a motion to reconsider. Second, they assert that Lear is simply attempting to rehash its argument that "binary code" should be limited to a binary number -- a construction we rejected in Chamberlain I. Plaintiffs request that we deny Lear's motion to reconsider, and in the alternative, simply modify the sentence at the heart of Lear's concerns. Specifically, they suggest the following modification: "As noted above, the claims never limit the initial binary code to a 'binary number,' instead leaving the term open to encompass other numerical and character languages, including other numerical and character languages that may also be represented in trinary code" (plfs' response, at 7).

Generally, motions to reconsider are only appropriate to correct manifest errors of law or to present newly discovered evidence. Oto v. Metropolitan Life Ins. Co., 224 F.3d 601, 606 (7th Cir.2000); United Mun. Leasing Corp. v. Lexington
Lear's central argument is that we erred in relying on dictionary definitions in construing "binary code," in contravention of Phillips. We disagree. Although Phillips clearly preferred intrinsic evidence to extrinsic evidence in construing patent claims, the Federal Circuit held that a place remains for dictionaries, particularly technical dictionaries, in claim construction. A patent's claims and specification must be "understood and interpreted by the court as they would be understood and interpreted by a person in that field of technology." Phillips, 415 F.3d at 1313. Such person "is deemed to read the words used in the patent documents with an understanding of their meaning in the field, and to have knowledge of any special meaning and usage in the field." Id. Considering that this court does not have such expertise, the Phillips court recognized that we may find guidance in "'those sources available to the public that show what a person of skill in the art would have understood disputed claim language to mean.'" Id., at 1314 (quoting Innova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 381 F.3d 1111, 1116 (Fed.Cir.2004)). The Federal Circuit continued: "Those sources include 'the words of the claims themselves, the remainder of the specification, the prosecution history, and extrinsic evidence concerning relevant scientific principles, the meaning of technical terms, and the state of the art.'" Id. (quoting Innova, 381 F.3d at 1116). As guided by Phillips, we began with the intrinsic evidence -- the claim language itself, the specification, and the prosecution history -- and then turned to the IEEE Standard Dictionary of Electrical and Electronics Terms to aid us in determining what was the ordinary meaning of the terms of art in dispute. We do not believe any such analysis was done in contravention of the principles set forth in Phillips.

We do, however, believe that the sentence with which Lear takes issue in Chamberlain I includes an incorrect term. We stated, "As we noted above, the claims never limit the initial binary code to a 'binary number,' instead leaving the term open to encompass other numerical and character languages, including trinary code." Chamberlain I, , 2006 U.S. Dist. LEXIS 68899, 2006 WL 2632074, at *4. We should have said, "As we noted above, the claims never limit the initial binary code to a 'binary number,' instead leaving the term open to encompass other numerical and character languages, including trinary numbers."

We agree with Lear that "binary code" cannot encompass trinary code. The Phillips court indicated that the context of a term can be highly instructive in claim construction (415 F.3d at 1314). There, the Federal Circuit indicated that the term "steel baffles," "strongly implies that the term 'baffles' does not inherently mean objects made of steel." Id. Likewise, because the '544 patent specification states that the rolling code (binary code) is converted or changed to a trinary code ("544, 3:17-28, 7:8-14), a binary code cannot be a trinary code.

Although we recognize our mistake, and hopefully, have clarified our meaning, we see no reason to alter our construction of "binary code" as "a code in which each code element may be either of two distinct kinds of values, which code may represent various kinds of letters and numbers including, but not limited to, a representation of a base 2 number." For both parties, however, we offer the following clarifying summations. First, a binary code is not limited to a binary number. Second, a trinary code cannot be defined as a binary code with respect to the patents-in-suit.

403

We turn first to defendant's likelihood of success on the merits. Our Markman decision and subsequent reconsideration dealt an enormous blow to defendant's case. Therein we construed the term "binary" to mean "a code in which each code element may be either of two distinct kinds of values, which code may represent various kinds of letters and numbers including, but not limited to, a representation of a base 2 number." Chamberlain Markman, 2006 WL 2632074, at *4. Our construction was based on our understanding of the meaning of "binary code" to a person of ordinary skill in the art and the intrinsic evidence of plaintiff's patent. The construction followed a three-day hearing and briefs from both parties.

Now Lear, under the guise of arguing that we misapplied our construction of "binary code" to its product, essentially argues that we erred in our construction of the term. Through use of examples and analogies, defendant's current briefs give the most specific and clear explanation of its argument. Using "1001" as an example, Lear argues that the appearance of the number is meaningless -- the important consideration is "how it was determined and put together mathematically" (def's
brief at 2). Lear notes that the presentation "1001" could be a binary number that represents the decimal 9, a trinary number that represents the decimal 29, or a decimal number that represents the decimal number 1001. Thus, Lear suggests, though its code is composed of 0s and 1s, which "may appear to a layperson to be binary," it is in fact always a trinary code. (Id.). In its reply brief, Lear explains further. It argues that each of its trinary code digits (trinary being composed of three digits, usually 0, 1 and 2) is represented by a two-bit sequence: 0 = 00, 1 = 01, and 2 = 10 (def's reply, at 5). Then, by example, the trinary number "1102" is represented as 01-01-00-10. When strung together, the code reads "01010010." (Id.). Defendant argues that looks can be deceiving -- that just because Lear's code is composed of 0s and 1s does not mean that it is a binary code.

While Lear's presentation is significantly clearer than its previous presentations, we still decline to alter our claim construction. Through a thorough study of intrinsic and extrinsic evidence, we previously determined that the term "binary code" in plaintiff's patent covers any code composed of two distinct kinds of values -- in Lear's example, 0s and 1s. Thus, defendant's code, while it may represent a trinary number, remains a binary code under our definition. The IEEE Standard Dictionary of Electrical and Electronics Terms, Sixth Edition, to which we cited in our Markman ruling, gives support to such an understanding. It defines "binary code," in one instance, as "A code that makes use of members of an alphabet containing exactly two characters, usually 0 and 1." See Chamberlain Markman, 2006 WL 2632074, at *4. The IEEE, in explanation, notes: "The binary number system is one of many binary codes." See id. It is our understanding, bolstered by plaintiff's patents and extrinsic evidence, that a trinary number system, as stored in a computer, is another one of many binary codes. As computers, "by their very nature, work on alternating electrical charges (i.e., charged or uncharged)" (def's reply, at 4), a processor only operates on binary data - data that is composed of ones and zeros. Lear's code, composed of 0s and 1s (see 010110010 example above), makes use of members of an alphabet containing exactly two characters. Therefore, we also decline to alter our finding that plaintiffs are likely to succeed in showing that Lear's product infringes with respect to the binary code.

404

Once we define binary code to encompass more than just a binary number, we must also adopt Chamberlain's construction of "binary code generator" to mean "a processor programmed to respond to the enabling device to generate a binary code that is different for each activation of the enabling device." Lear's proposed construction - "a processor programmed with a binary arithmetic algorithm operating on an initial binary number to generate a different binary number for each activation of the transmitter" - turns on its understanding of "binary code," as limited to a "binary number." Once we foreclose that argument, Lear's construction must fail.

GO BACK

405

1. binary tree

The first term in dispute is "binary tree," which appears in every claim in the '201 Patent, including the four here relevant: Claims 1, 4, 7, and 8. (Claim 1 is an independent claim, and 4, 7, and 8 are dependent.) Claim 1 reads in relevant part: "A parallel processor array comprising . . . means for interconnecting said processing elements in a binary tree in which each processing element except those at the extremities of the binary tree is connected to one parent processing element and at least first and second child processing elements." '201 Patent at 69:60, 67-69; 70:59-60.

Plaintiff's proposed construction is "a tree where a node has a parent node (except for the root node) and zero, one or two children." Fifth Generation's Rebuttal Markman Brief ("Pl. Reply") at 3. In contrast, defendant reads the term as "an arrangement of nodes where each node has a single parent and two children nodes, except the root node, which has no parent, and the leaf nodes, which have no children." IBM's Opening Markman Brief ("Def. Br.") at 9.

In Phillips v. AWH Corp., 415 F.3d 1303 (Fed Cir. 2005) (en banc), the Federal Circuit explained that "the words of a claim are generally given their ordinary and customary meaning" and that "the ordinary and customary meaning of a claim term is the meaning that the term would have to a person of ordinary skill in the art at question at the time of the invention, i.e., as of the effective filing date of the patent application." Id. at 1312-13. Here, plaintiff asserts that its construction reflects the
"ordinary meaning" of the term "binary tree," Pl. Reply at 3; see also tr. 08/20/09 at 48, and cites both to the dictionary of the National Institute of Standards and Technology ("NIST"), in which "binary tree" is defined as "a tree with at most two children for each node," and to IBM's own website, on which appears a similar definition. See E-Pass Technologies, Inc. v. 3Com Corp., 343 F.3d 1364, 1367 (Fed. Cir. 2003) ("We resort initially to the relevant dictionary definitions to determine the ordinary meaning of the [disputed] term . . . "). However, since the '201 patent was filed in 1986, see '201 Patent at 1, the relevant meaning is the meaning at the time of the invention, see Phillips, 415 F.3d at 1313; PC Connector Solutions LLC v. SmartDisk Corp., 406 F.3d 1359, 1363 (Fed. Cir. 2005) ("A claim cannot have different meanings at different times; its meaning must be interpreted as of its effective filing date.")., and there is no evidence before the Court that establishes what the dictionary definition of "binary tree" was in 1986. Indeed, it appears on this record that there was no entry for "binary tree" in either the 1986 version of the NIST dictionary nor in the contemporaneous version of IBM's Dictionary of Computing published in March 1987. See Def. Letter, 09/27/09. Given the huge changes in computer data processing, and accompanying jargon, between 1986 and the present, resort to NIST and IBM dictionaries from the present does not resolve the issue of the term's ordinary meaning.

The Court must therefore look to the usage of the claim term in the context of the particular claim and in the context of the entire patent as submitted in 1986. See Phillips, 415 F.3d at 1313 ("[T]he person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears but in the context of the entire patent, including the specification."). The parties agree that the structure of Claim 1, the means-plus function language of "means for interconnecting," requires that the binary tree contemplated by Claim 1 have two children for each processing element except for those at the extremities. See tr., 08/20/09, at 44. Yet, plaintiff's proposed construction contradicts the language of Claim 1 and flies in the face of this structure. Taking plaintiff's construction on its face, a node with a single parent could have a single child, and that child could, in turn, have another single child, thus creating a straight line from one node to another, and this structure would still be a "binary tree" even though there is nothing binary about it. See tr., 08/20/09, at 46. Indeed, plaintiff's construction would eliminate what plaintiff itself takes to be the preferred embodiment and therefore cannot be the proper construction. See Primos Inc. v. Hunter's Specialties, Inc., 451 F.3d 841, 848 (Fed. Cir. 2006) ("While we are mindful that we cannot import limitations from the preferred embodiments into the claim, we also should not normally interpret a claim term to exclude a preferred embodiment."). Moreover, plaintiff can point to only one sentence in the patent specification that remotely provides support for its construction: "Since the subtree that is computing the resolve need not be a complete binary tree, the value bits from the children may not arrive in the same clock cycle." '201 Patent at 21:46-49. Plaintiff asserts that this phrase from the patent specification indicates that the term "binary tree" permits a tree with zero, one or two children. Pl. Reply at 4. Yet this phrase does not define the binary tree qua structure -- it only indicates that some tasks may rely on longer legs of a subtree, and thus the report and resolve functions would not be completed simultaneously. See tr., 08/20/09, at 55. IBM's construction does not suffer from these difficulties; but plaintiff contends that IBM's construction improperly imports limitations from the preferred embodiment, see Phillips, 415 F.3d at 1323, because the preferred embodiment in no way offers a "clear disavowal" of embodiments of the binary tree computing system having less than two child nodes. Pl. Reply at 4. By way of support, plaintiff underscores the fact that the patent identifies Figure 2 as "the general configuration of a preferred embodiment of the invention comprising a binary tree of 1023 processing elements." '201 Patent at 8:11-13. In actuality, however, defendant's proposed construction does not import a limitation from the specification, but, rather, it relies on the fact that "the specification is the single best guide to the meaning of a disputed term," Phillips, 415 F.3d at 1320 (internal quotation marks omitted). Here, in fact, the specification is more properly read as dictating the correct scope of the claim, and in this respect, the "the inventor's intention, as expressed in the specification, is regarded as dispositive." Id. at 1316. In this regard, defendant has pointed not only to the claim language itself but numerous instances throughout the specification that confirm that the binary tree contemplated by the patent requires each processing element, except for the root node and the extremities, to have two children. The patent abstract describes the patent as "a plurality of parallel processing elements [...] connected in a binary tree configuration, with each processing element except those at the highest and lowest levels being in communication with a single parent processing element as well as the first and second (or left and right) child processing elements." '201 Patent Abstract. The same information is repeated in the section of the patent devoted to the background of the invention, as well as the summary of the invention. Id. at 1:62-65; 4:56-62; see also Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1551 (Fed. Cir. 1996) ("[W]hen the preferred embodiment is described in the
specification as the invention itself, the claims are not necessarily entitled to a scope broader than that embodiment.

Nor is the holding of E-Pass, upon which plaintiff relies heavily, see tr. 08/20/09 at 25, 29, to the contrary. There, the Federal Circuit overturned the district court's construction of "electronic multi-function card" as "[a] device having the width and outer dimensions of a standard credit card with an embedded electronic circuit." E-Pass, 343 F.3d at 1366. The Federal Circuit found that the district court had taken the preferred embodiment to impose a particular size on the term "card," ignoring language elsewhere in the patent that suggested that the patent was not based on the standardized size of a credit card. Id. at 1370. Here, in contrast, the binary tree that appears in Figure 2 may be a preferred embodiment, but Figure 2 does not suggest that the requirement of two children except at the extremities is a limitation derived from that preferred embodiment. Indeed, the patent elsewhere states directly: "In a binary tree computer, a large number of processors are connected so that each processor except those at the root and leaves of the tree has a single parent processor and two children processors." '024 Patent at 1:62-65. This statement provides critical support for the idea that the definition given to the term "binary tree" by the patentee differs from plaintiff's proposed construction and conforms more closely with defendant's proposed construction. See Phillips, 415 F.3d at 1316 (emphasizing the role of the inventor as "lexicographer").

Based on the foregoing, the Court construes "binary tree" to mean an arrangement of nodes where each node has a single parent and two children nodes, except the root node, which has no parent, and the leaf nodes, which have no children.

1. binary tree computer system

Plaintiff construes the phrase "binary tree computer system" to mean "a computing system (or partitionable portion of a computing system) with nodes connected in a binary tree configuration." Pl. Br. at 19. Defendant's competing construction is "a computer system of nodes connected in a binary tree configuration." Def. Br. at 18.

The parties therefore principally dispute whether a partitionable portion of a binary tree computer system is itself a binary tree computer system. Because subtrees have the full functionality of a main tree, plaintiff argues that its construction captures the notion that a "binary tree computer system" can be a "partitionable portion of a computing system," asserting that "it is well known that a binary tree computer can be divided into a 'subtree' that functions as the full computer system." Pl. Br. at 20. Defendant, for its part, does not dispute that trees are partitionable into subtrees but rather maintains that a subtree would not itself constitute a "binary tree computer system." Def. Br. at 19; Def. Reply at 16-17. This reflects the plain meaning of the phrase, since the patent specifies that a binary tree computer system includes, inter alia, connection a host processor, see ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1088 (Fed. Cir. 2003) ("[T]he context of the surrounding words of the claim also must be considered in determining the ordinary and customary meaning of those terms."). whereas a subtree alone, as the Court has construed the term, would not require such a connection to the host computer.

Although plaintiff cites to the '024 and '540 Stolfo Patents as intrinsic evidence that subtrees are themselves "binary tree computer systems," the '024 Patent incorporates those earlier patents by reference but also deliberately distinguishes itself from them. '024 Patent at 1:23-28. The '024 patent itself does not reference "subtrees" or "partitionability" and as such the incorporation by reference provides no support for the idea that the patent applicant intended for "binary tree computer system" to include a partitionable portion thereof. Cf. Modine Mfg. Co., 75 F.3d at 1553 (arguing that incorporation by reference "does not convert the invention of the incorporated patent into the invention of the host patent" and finding that the single reference to the incorporated patent did not otherwise alter the "presentation of the invention" in the specification). Plaintiff's extrapolation from the fact that a subtree is itself a binary tree to asserting that a subtree of a binary tree computer system is itself a binary tree computer system exceeds the bounds of claim construction, as it reads into the claim language a phrase that is altogether absent from the specification. In SunRace Roots Enterprise Co., Ltd. v. Sun Victory Trading Co., Inc., 336 F.3d 1298 (Fed. Cir. 2003), for example, the Federal Circuit overturned the district court's construction of "shift actuator," which held that the term required the use of a cam, even though no explicit definition of the term appeared in the specification. Rather, the district court imposed the limitation from the preferred embodiment, despite the fact that the invention could conceivably be embodied in a structure that lacked a cam. Id. at 1302. Here, the terms "subtree" or "partitionability" are not even present in the specification, and thus cannot even be plausibly read back into the claim language, which clearly does not include those terms. Cf. Interactive Gift Express, Inc. v. Compuserve Inc., 256 F.3d 1323, 1331 (Fed. Cir. 2001) ("If the claim language is clear on its face, then our consideration of the rest of the intrinsic
evidence is restricted to determining if a deviation from the clear language of the claims is specified.

Nor is plaintiff's assertion that "individual processor circuit cards" are themselves "binary tree computer systems" (thus justifying plaintiff's argument for partitionability) particularly persuasive. See Pl. Br. at 20-21. The specification itself indicates that "the binary tree computer system can . . . be constructed from a plurality of sub-units," '024 Patent at 5:53-55, and refers to specific processor cards -- a three processing element unit ("3-PEU") or a four processing element expansion unit ("4-PEXU"), id. at 5:57-58 -- from which a binary tree may be built, which plaintiff marshals as evidence that subtrees are computer systems. But nowhere in the patent are these cards referred to as "subtrees," and thus plaintiff's reliance on the 3-PEU or 4-PEXU cards as "subtrees" is misplaced: the patent's language clearly indicates that the system is constructed from the cards, not that each card is itself a binary tree computer system.

Accordingly, the Court hereby reaffirms its construction that "binary tree computer system" means a computer system of nodes connected in a binary tree configuration.

2. binary tree configuration

The disputed term appears in Claim 1, which indicates that "N bus controllers [are] connected in a binary tree configuration in which each bus controller, except those at the extremes of the tree, are connected to left and right child bus controllers . . . ." '024 Patent at 7:11-16.

The parties essentially argue for constructions that track their respective constructions of "binary tree" from the '201 Patent. Plaintiff's construction is "a tree arrangement where a node has a parent (except for a root node) and zero, one or two children nodes," Pl. Reply at 15, and defendant puts forward "an arrangement of nodes where each node has a single parent and two children nodes, except the root node, which has no parent, and the leaf nodes, which have no children," Def. Br. at 19. Here, the claim language clearly indicates that the binary tree configuration, as contemplated by the patent, has bus controllers with two children bus controllers except at the extremities. See Phillips, 415 F.3d at 1314 ("[T]he claims themselves provide substantial guidance as to the meaning of particular claim terms."); Catalina Mktg. Int'l v. Coolsavings.com, Inc., 289 F.3d 801, 807 (Fed. Cir. 2002) ("Claim language defines claim scope."). This construction is confirmed by the specification. See Interactive Gift Express, 256 F.3d at 1331 (noting that if claim language is clear, specification is read only to determine if deviation from claim language is specified); see also Phillips, 415 F.3d at 1316 ("[T]he specification necessarily informs the proper construction of the claims."). The specification outlines the "basic structure of the binary tree parallel computer system of the invention" and specifies that "each node . . . is also connected downstream to its own [processing element] and either to two child nodes . . . , or in the case of the nodes at the extremes of the tree, to right and left leaf [processing elements]. '024 Patent at 2:50-56.

Considering as well the Court's construction of "binary tree" from the '201 Patent, which patent is here incorporated by reference, see '024 Patent at 1:24-26, the evidence overwhelmingly supports the Court's construction of "binary tree configuration" to mean "an arrangement of nodes where each node has a single parent and two children nodes, except the root node, which has no parent, and the leaf nodes, which have no children."

b. Claim 5

Claim 5 of the '892 patent reads (bracketed text and letters provided for ease of reference):

[Preamble] 5. A method of providing a bingo game comprising the steps of:

[A] providing a bingo operator for determining at least one winning bingo pattern;
注册至少一张包含多个宾果号码的宾果卡给定操作者；

C 给定一个预定数量的随机宾果号码；和，

D 确定所有注册的宾果卡，其上产生的随机宾果号码形成一个预先至少的一个宾果模式；

E 将中奖的宾果卡持有人的中奖金额授予，其金额与中奖的宾果卡的数量无关。

c. 被告的拟建构

被告认为法院应将以下几个术语的含义建设为普通具有艺术技能的人在轻重记录中的意思。在这一方面，被告声称以下几个术语应进行以下建设

术语“宾果游戏”从序言：一个由元素和限制 [A]-[E] 形成的宾果游戏。

术语“宾果操作者”从段落 [A]：操作一个宾果游戏的人或实体，或其机器或软件。

术语“注册至少一张宾果卡”从段落 [B]：将每张卡分配一个身份，以区分其与其他卡的不同。

术语“一个预定数量的随机宾果号码”从段落 [C]：在一个完整的宾果游戏中将被玩的特定和预指定的随机宾果号码的数量。

E 中奖的宾果卡持有人的中奖金额授予，其金额与中奖的宾果卡的数量无关。

c. 原告的拟建构

原告认为，根据普通接受的某些术语的公众接受并使用字典定义，以下术语应进行以下建设：

“宾果游戏”- 一种“传统”宾果游戏，该术语被公众理解。在这种情况下，原告建议将术语“宾果游戏”在第 5 项中构建为：

预设数量的宾果号码：原告认为术语“预设数量”应根据字典定义“预设”来解释。在这种情况下，原告认为建设应为：“由事先确定、决定或建立的数字或数字范围。”

“注册”：原告认为术语应建设为：

识别一个由玩家选择的独立的宾果卡，将该卡的图案传达给游戏操作者，并让游戏运营商记录该卡的图案，然后开始一个独立的宾果游戏。

III. CONCLUSION
Having carefully reviewed the text of Claim 5, the specification, and the prosecution history of the '892 patent, and having considered the parties' arguments presented at the Markman Hearing, the Court finds that the construction proposed by Defendant is, in all respects, proper. The '892 patent was proposed and amended in order to distinguish the patent from prior art. Plaintiff's proposed construction would have the opposite effect. Therefore, the Court finds as a matter of the law that the following terms from Claim 5 shall have the following constructions:

The term "bingo game" from the preamble: A game of bingo limited by the elements and limitations [A]-[E] from the body of Claim 5.

b. Claim 5

Claim 5 of the ‘892 patent reads (bracketed text and letters provided for ease of reference):

[Preamble] 5. A method of providing a bingo game comprising the steps of:

[A] providing a bingo operator for determining at least one winning bingo pattern;

[B] registering at least one bingo card bearing a plurality of bingo numbers with said operator;

[C] generating a predetermined number of random bingo numbers; and,

[D] identifying all registered bingo cards on which the generated random bingo numbers form one of said at least one [sic] winning bingo pattern and,

[E] awarding the holder of the winning bingo card an award wherein the amount of said award is independent of the number of registered bingo cards on which a winning bingo pattern is formed.

c. Defendant's Proposed Constructions

Defendant contends the Court should give the following terms the meaning they would have had to a person of ordinary skill in the art in light of the intrinsic record. In this regard, Defendant asserts that the following terms should have the following constructions:

The term "bingo game" from the preamble: A game of bingo limited by the elements and limitations [A]-[E] from the body of Claim 5.

The term "bingo operator" from paragraph [A]: A person or entity, or a machine or the software in it, that operates a bingo game.

The term "registering at least one bingo card" from paragraph [B]: Assigning each card an identify that will differentiate that card from all the others in play.

The term "a predetermined number of random bingo numbers" from paragraph [C]: The specific and predesignated quantity of random bingo numbers that will be played during a complete bingo game after which the game will end.

The term "an award wherein the amount of said award is independent of the number of registered bingo cards on which a winning bingo pattern is formed" from paragraph [E]: An award of any type in which the value of the award is not based upon how many cards have a winning pattern.

c. Plaintiff's Proposed Constructions
Plaintiff contends that, based upon the general acceptance of certain terms by the public and by using dictionary definitions, the following terms should be constructed as follows:

"Bingo game" - a "traditional" bingo game as that term is understood by the general public. In this regard, Plaintiff suggests that the Court construct the term "bingo game" within Claim 5 as:

a game simultaneously played by multiple players that contains the following elements: (1) displayed cards that bear numbers, (2) which must be daubed on each card when numbers are determined by random means during the game, and (3) which game is won by at least the first person to hold a card on which a previously designated arrangement of numbers has been covered.

"Predetermined number" of random bingo numbers: Plaintiff argues that the term "predetermined number" should be construed in accordance with the dictionary definition of "predetermined." In this regard, Plaintiff argues that the construction should be: "A number or range of numbers that is determined, decided, or established in advance."

"Registered": Plaintiff argues that the term should be constructed as follows:

identifying a discrete bingo card chosen by a player, communicating the pattern of that card to the game operator, and having the game operator record the pattern of the card prior to play of a discrete bingo game.

III. CONCLUSION

Having carefully reviewed the text of Claim 5, the specification, and the prosecution history of the '892 patent, and having considered the parties' arguments presented at the Markman Hearing, the Court finds that the construction proposed by Defendant is, in all respects, proper. The '892 patent was proposed and amended in order to distinguish the patent from prior art. Plaintiff's proposed construction would have the opposite effect. Therefore, the Court finds as a matter of the law that the following terms from Claim 5 shall have the following constructions:

The term "bingo game" from the preamble: A game of bingo limited by the elements and limitations [A]-[E] from the body of Claim 5.

The term "bingo operator" from paragraph [A]: A person or entity, or a machine or the software in it, that operates a bingo game.
would be improper for the court to read in this limitation simply based on the preferred embodiments. See Teleflex, 299 F3d at 1326.

Finally, Hynix resorts to the prosecution history of two related patents, United States Patent Nos 6,493,267 ("the '267 patent") and 5,726,882 ("the '882 patent"), that share virtually the same specification as the '994 patent. Hynix argues Toshiba made two statements to the patent office disavowing "any definition of bit line that includes a line interrupted by a transistor." Hynix Br at 13. In a letter requesting reconsideration of the '267 patent, the patentees distinguished the "bit line" from another wire on the other side of the switching circuit transistor. Doc # 14, Ex E at 2. But this letter adds nothing to Hynix's case because the patent claims already show that the bit line does not extend past the switching circuit. Hynix also relies on a letter from the patentees requesting an extension of time pertaining to the '882 patent but this letter does not speak to the definition of "bit line" and merely references an embodiment present in the '994 patent. Id, Ex L at 7.

Because Hynix's construction is problematic and Hynix has not provided any reason why the ordinary meaning of "bit line" does not suffice, the court declines to construe this term.

GO BACK

411

(2) first/second plurality of groups of bits

The issue regarding these phrases is whether they should be limited to "4 bit sequences." N-Data and National both urge that the court should give these phrases their plain and ordinary meaning. N-Data further asserts that, at the most, the court should define "bits." Dell argues that the patent "only discusses groups of bits in the context of transmitting 4-bit 'nibbles' during time slots." Dell's Responsive Claim Construction Brief at 19; see also '261 Patent, col. 7, ll. 42-61, col. 8, ll.64-col. 9, l. 5, Table I (discussing the preferred embodiment). It is improper, however, to limit the phrases to their preferred embodiment absent a clear intention of the patentee to do so. The court agrees with N-Data's proposed construction.

The court defines "bits" as "basic units of information storage."

"First/second plurality of groups of" needs no construction.

412

1. "Blend Information"

The first element of independent claim 1 recites "using a pen-tablet unit and a circuit coupled to said unit and responsive to a user's actions on at least the pen to generate progressively varying position and blend information." Adobe contends that the term "blend information" means "pressure information, i.e., data representing the amount of pressure applied by the user to the pen at a particular point during the stroke." Quantel contends that "blend information" is "information which comes from a circuit that responds to a user's actions and so on at least the pen, and (as the claim later recites) is used for calculating new pixel data."

The Federal Circuit has held that "the specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." Vitronics. Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Adobe points out that although the term "blend information" does not appear in either the '566 specification, the specification describes only two types of "progressively varying" information: position and pressure. Accordingly, the court concludes that the specification impliedly defines "blend information" as "pressure information."

GO BACK

413

A. "Blending"
Claim 1 of the 550 patent claims:

A method for blending images, comprising the steps of selecting a first portion of a first image, said first portion of said first image includes different color values . . .

Sportvision contends the term "blending" should be construed as: "Combining at least a first image or video with at least a second image or video such that the result includes all or part of the first image or video and all or part of the second image or video." (Sportvision's Memo at 13.)

SportsMEDIA proposes that the term be construed as: "Combining at least a first image or video with at least a second image or video such that the result includes all or part of the first image or video and all or part of the second image or video, for example, using a keyer to key one video over another video." (SportsMEDIA's Memo at 16.)

Both parties essentially agree on the definition, except that SportsMEDIA's definition includes "... using a keyer to key one video over another video." The Court finds it inappropriate to add SportsMEDIA's proffered additional language. The specification discloses other ways of accomplishing the effect of blending. SportsMEDIA's proffered construction would single out one particular embodiment. The 550 patent describes the use of computers in the "blending" process, rather than keyers. 550 patent, 4:34, 37-40.

Accordingly, the Court construes the meaning of the term "blending" to be: "Combining at least a first image or video frame with a second image or second video frame such that the result includes all or part of both."

V. "GENERATING THE TOOL PATH BY BLENDING BETWEEN THE ISOLOOPS"

The limitation at issue here, which is found in claims 14 and 35, is "generating the tool path by blending between the isoloops." The parties' proposed constructions are as follows:

<table>
<thead>
<tr>
<th>Plaintiff's Proposal</th>
<th>Defendants' Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;producing a tool path with connections between the isoloops by interpolation, i.e., a process that produces intermediate values from the isoloops being connected&quot;</td>
<td>Producing a smooth, continuously spiraling tool path based on weighted averages or other mathematical combinations of successive isoloops as wholes. The tool path so generated must not include sharp turns and must not allow the cutting tool engagement to exceed a predetermined maximum value.&quot;</td>
</tr>
</tbody>
</table>

For the reasons stated below, the Court adopts the construction it circulated at the Markman hearing:

"generating the tool path by blending between the isoloops -- Producing a smooth tool path based on a process that produces intermediate values from the isoloops being connected."

Unlike the question of a "smoothing" requirement in the previous limitation, a requirement of a "smooth tool path" is supported for this step of the claim by the prosecution history and the specification's definition of "tangent continuous."

A. The Toolpath Must Be "Smooth"

The limitation at issue here is "generating the tool path by blending between the isoloops." Although the patent does not define the term "blending," the patentee explained to the examiner that,

Limitation (c) of claim 28 recites generating the tool path by blending between the isoloops. The blending is defined at paragraphs [0170] and [0171] and Fig. 23 as a method for constructing a tangent continuous tool path based on the
parameters of the isoloops.

Bagatell Decl., Exh. J at 23 (emphasis added). As discussed above, the patent defines "tangent continuous" as "forming a smooth curve." (013 patent at 5:30). This prosecution history, combined with the patent's definition of "tangent continuous," compels the conclusion that the construction of "blending" must include a requirement of a smooth tool path.

--- Footnotes ---
6 Attorney Bagatell represented at the Markman hearing that "claim 28" became issued claim 14, and Plaintiff did not disagree.

--- End Footnotes ---

At the Markman hearing, Plaintiff argued that the statement in the prosecution history was insignificant because it did not expressly disavow a broader definition of "blending" by distinguishing prior art. See generally Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1325 ("[W]e have required the alleged disavowing statements to be both so clear as to show reasonable clarity and deliberateness . . . and so unmistakable as to be unambiguous evidence of disclaimer.") But Plaintiff failed to cite or even acknowledge the rule that a "claim term will not receive its ordinary meaning if the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in either the specification or prosecution history." Altiris, Inc. v. Symantec Corp., 318 F.3d 1363, 1370 (Fed. Cir. 2003) (citations omitted) (emphasis added). See also Phillips, 415 F.3d at 1317 ("[T]he prosecution history can often inform the meaning of the claim language by demonstrating how the inventor understood the invention and whether the inventor limited the invention in the course of prosecution, making the claim scope narrower than it would otherwise be.") Here, the prosecution history makes clear that the patentee defined blending "as a method for constructing a tangent continuous tool path." The patentee's statement in the prosecution history could hardly be any clearer. In fact, Plaintiff's attorney conceded during the Markman hearing that during prosecution of the patent his client defined blending as "a method for constructing a tangent continuous tool path." Transcript at 28:20-29:2.

The Court also notes that the Sixth Preferred Embodiment is consistent with the prosecution history, because it states that "[t]he blends are generated using the same exact blending function" as was used for creating isoloops in the embodiment, which was a function creating a tangent continuous tool path. (013 patent at 20:54-55).

In light of the prosecution history, the definition of "tangent continuous" in the "Detailed Description of the Invention," and the language in the Sixth Preferred Embodiment, the Court finds that the tool path created by blending must be "smooth." 7

--- Footnotes ---
7 At the Markman hearing, Defendants argued for the first time that the construction should also state that the tool path must be "based on the parameters of the isoloops." See Transcript at 33:20. Unlike the requirement of a smooth tool path, however, Defendants did not show that such a limitation is supported by language in the patent itself. The Court therefore declines to adopt it.

--- End Footnotes ---

B. It is Not Necessary to State that the Tool Path Must Be "Continuously Spiraling"

Defendants note that the Sixth Preferred Embodiment explains that "[a] spiral-like tool path . . . is then created by blending between successive isoloops." (013 patent at 20:53-54 (emphasis added)). But, as Plaintiff notes, Defendant's proposal that the path be "continuously spiraling" is more limiting than even the preferred embodiment's "spiral-like." The Court therefore omitted the requirement of a continuous spiral from its tentative construction. Defendants did not object at the Markman hearing to its omission, and the Court will not include it.

C. It is Not Necessary to State that the Tool Path May Not Include Sharp Turns

Defendants' argument for requiring that the path not include sharp turns is not entirely clear, but it seems to be that the
purpose of "blending between the isoloops" is to limit variations in the engagement angle of the cutting tool so that the tool engagement can be maintained as close as possible to a predetermined maximum engagement. Sharp turns would undermine this purpose because they increase a tool's engagement angle. Neither the claim nor the specification mentions sharp turns, and for this reason the Court did not include this requirement in its tentative construction. Defendants did not object at the Markman hearing to the omission of this language, and the Court does not include it in its construction.

D. It is Not Necessary to State that the Tool Path Must "Not Allow the Cutting Tool Engagement to Exceed a Predetermined Maximum Value"

"The tool path so generated must not include sharp turns and must not allow the cutting tool engagement to exceed a predetermined maximum value."

Defendants contend that "the patent makes clear from beginning to end that the invention is a method of generating a tool path by controlling the tool engagement." They cite several passages in the specification -- including the abstract, "summary of the invention," "detailed description of the invention," and others -- that describe the patent's method as one that stores a maximum engagement of the milling cutter and defines passes such that a value of the engagement does not exceed the maximum. See '013 patent, front page, 2:24-64, 8:1-3, 8:16-18, 22:36-44, Fig. 3. These passages often refer to this feature as part of the "present invention," and Defendants rely primarily on three Federal Circuit cases in which a specification's reference to the "present invention" was used to limit particular claim language. But in all of those cases the specification's text was tied to particular language in the claim. See Verizon Servs. Corp. v. Vonage Holdings Corp., 503 F.3d 1295, 1308 n.8 (Fed. Cir. 2007) (applying description of "present invention" to limit claim term where the specification referred to "the very claim term that is at issue here."); Honeywell Int'l, Inc. v. ITT Indus., Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006) (construing the claim term "fuel injection system component" to mean "a fuel filter," because the only component described in the specification that otherwise met the claim's requirements was a fuel filter); Watts v. XL Sys, Inc., 232 F.3d 877, 882-83 (Fed. Cir. 2000) (construing the term "dimensioned such that" based in part on the specification because the specification only described one method in which "tapered external threads [are] dimensioned" and referred to that method in the context of "the present invention"). Here, by contrast, there is no reference to engagement anywhere in claims 14 or 35, let alone the particular text at issue here, and no other language in the limitation suggests that it would be appropriate to read the engagement feature into this claim. To do so would therefore be overreaching of the kind disallowed by the Federal Circuit. See Phillips, 415 F.3d at 1323.

415

A. "block"

The parties seek construction of the term "block," which appears in all four claims of the '124 patent (col. 31:1-32:18) (emphasis added):

1. A method for generating sound from data following an MPEG encoding standard comprising:

   transferring a block consisting of independent components of time-domain vectors to a first memory, wherein transferring the block comprises transferring a total of 17 components from a first time-domain vector and 16 components from a second time-domain vector;

   determining products of the independent components in the block with corresponding windowing coefficients;

   accumulating the products in a plurality of sums, each sum corresponding to a different sound amplitude value; and

   generating a sound from the sound amplitude values.

2. The method of claim 1, wherein:

   the step of determining products comprises performing 64 multiplications, each multiplication involving one of the components from the block and a windowing coefficient; and
the step of accumulating comprises adding a pair of the products to each of 32 sums.

3. The method of claim 2, further comprising:

   multiplying each of a series of matrixing coefficients by a corresponding combination of components of a frequency-domain vector;

   accumulating the products to generate four components of a time-domain vector; and

   writing the four components of the time-domain vector to a second memory, wherein transferring the block is from the second memory to the first memory.

4. The method if claim 3, further comprising repeating the steps of claims 1, 2, and 3 eight times wherein no two steps of transferring a block transfers components from the same pair of time-domain vectors.

Proposed constructions are shown below.

<table>
<thead>
<tr>

<td>&quot;The largest possible collection of data to be used in one or more transfer operations that is stored in contiguous storage locations before the one or more transfer operations&quot;</td>
</tr>
<tr>
<td>SANDISK'S PROPOSED CONSTRUCTION</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The claims themselves give meaning to the term "block." In particular, method claim 1 stated that "a block [consists] of independent components of time-domain vectors to a first memory, wherein transferring the block comprises transferring a total of 17 components from a first time-domain vector and 16 components from a second-time domain vector" (col. 31:4-8). 3 Despite this defining claim language, SanDisk argues that numerous additional limitations that do not appear in the claims should apply to the term "block." LSI argues that they should not.

3 While this order cannot possibly explain in a footnote the full details of what these vectors represent, it may be helpful to state that the analog-to-digital conversion of audio information in the present invention involves the conversion of time-domain data to frequency-domain data. Similarly, the digital-to-analog conversion of audio information involves the conversion of frequency-domain data to time-domain data. These vectors are important to the latter conversion.

The first limitation proposed by SanDisk -- that the block be the "largest possible collection of data to be used in one or more transfer operations" -- fails in two respects: (1) it is confusing, and (2) it is wholly unsupported by the intrinsic evidence. As stated, the claim language already included an express limitation on what the block must contain: "a total of 17 components from a first time-domain vector and 16 components from a second-time domain vector." Nothing in the specification supported the additional limitation that the block must contain the "largest possible collection of data." By contrast, the specification touted the efficiency gained by transferring smaller blocks -- specifically, blocks consisting of 33 vector components as opposed to 64 vector components seen in the prior art. This reduction in block size supposedly cut the number of bytes required to be transferred using the present invention "nearly in half" (see col. 11:10-37). In other words, one of the express benefits of the present invention was to minimize both the number and size of blocks transferred out of memory for processing. Given this intrinsic evidence, this limitation fails.

SanDisk also proposes that the vector components in a block be "stored in contiguous storage locations before the one or more transfer operations." In other words, SanDisk would not allow the 33 vector components of a block to be scattered across memory, but would require vector components to be lumped together, back to back, without any intervening data.
While the claims do not expressly contain this limitation, the specification did lend some support to SanDisk's argument. Specifically, the specification noted that "[s]toring the 33 values at consecutive addresses in [memory] increases the speed of reading the values for windowing because consecutive addresses can be accessed with a minimum of page changes" (col. 11:5-9) (emphasis added). In other words, contiguous storage would allow more efficient reading of data values, and minimize page changes. Even so, SanDisk's proposed limitation fails because it excludes the exemplary embodiment. In the exemplary embodiment, "at least one block of 33 vector components is not at consecutive addresses because the current vector V[degree] can be in any of sixteen positions in memory and is not always at the lowest address" (col. 11:37-41) (emphasis added). Stated simply, at least one "block" of vector components will not be contiguously stored in memory prior to transfer. In light of this evidence, this limitation proposed by SanDisk must also fail. See Vitronics, 90 F.3d at 1583. 

Given that the term "block" is given ample meaning by the surrounding claim language, this order construes "block" as simply "a set of data elements."

i. "block" in the '638 patent

Lexar's proposed construction: erasable storage for one or more sectors

Toshiba's proposed construction: a portion of memory that is separately programmable and erasable; those portions of memory containing data cannot be programmed.

Pretec's proposed construction: a set of like items handled as a unit.

6 In its brief, Toshiba did not explicitly propose a construction for "block" in the '638 patent but offered a construction of the term within its proposed construction for the '638 patent term "non-volatile storage blocks." The Court treats this as Toshiba's proposed construction for the '638 claim term "block." Toshiba's presentation at oral argument was consistent with this conclusion.

All three parties have proposed completely different constructions for "block" in the '638 patent. Lexar contends, as it does for the term in all patents in which it appears, that the claim term should be construed as "erasable storage for one or more sectors." Lexar suggests that the dispute (between Lexar and Toshiba) over the term "block" boils down to Toshiba's "insistence that the term 'block' cannot be anything that stores less than two sectors of data." While the Court notes that the debate here is about more than just the number of sectors contained in a block, the Court begins its analysis there.

Lexar proposes that a "block" in the '638 must contain one or more sectors and Toshiba maintains that because the '638 patent is the earliest of the patents-in-suit, a block in the '638 could not be understood by a person skilled in the art as containing more than a single sector. The parties agree, then, that a "block" in the '638 can contain a single sector. The dispute lies in whether a "block" can contain more than one sector in this patent. The lone reference to "sectors" in the '638 patent explains that in one preferred embodiment, a "multi-sector erase is necessary . . . ." ('638 patent, 4:62-65.) This strongly suggests that a block can be made up of more than one sector. The Court therefore finds that Lexar is right, that a "block" in the '638 contains one or more sector.

The Court now turns to evaluate the rest of the parties' respective constructions. Pretec accurately argues that Lexar's proposed cross-patent construction does not fit for "block" in the '638 patent. However, rather than suggest a construction of "block" specific to the '638 patent, Pretec, like Lexar, proposes a cross-patent construction. Pretec proposes a construction based on the non-technical American Heritage dictionary definition of "block:" "a set of like items handled as a unit." But this construction is overly broad. Because a disputed claim term is to be given its ordinary meaning as understood by those skilled in the relevant art, "a general dictionary definition is secondary to the specific meaning of a technical term as it is used and understood in a particular technical field." Hoczest Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1580 (Fed.
Cir. 1996). Here, "block" is a technological computer-related term having to do with data and memory storage. Pretec's general definition is out of place in this context.

The remaining dispute as to the proper construction of the term "block" is between Toshiba and Lexar. The Court first disposes of Toshiba's "those portions of memory containing data cannot be programmed" language. This portion of Toshiba's proffered construction is simply redundant. The language appears in the claims themselves and the Court need not load up a claim term with surrounding language. To do so would render the surrounding claim language superfluous. The Court therefore rejects this portion of Toshiba's proffered construction.

Toshiba and Lexar also disagree about the functions a block performs and whether such functions should be described in the construction of the claim term. Toshiba urges the Court to construe "block" as both "erasable" and "programmable." Toshiba contends that claim I, which recites that "each block is selectively programmable and erasable" supports its construction. Lexar proposes that "block" be construed as erasable but not programmable. Lexar contends that a person of ordinary skill in the art would not construe "block" to be programmable as only sectors can be programmed. Toshiba agrees that sectors are what is programmable but contends that here, in the '638 patent, the earliest of the patents-in-suit, block and sector are functionally equivalent. This ties in with Toshiba's argument that a block in the '638 contains only a single sector. Because the Court has found that a block in the '638 can contain multiple sectors and because the parties agree that a block itself is not programmable, the Court finds that Toshiba's proposed "programmable" language is not properly part of the construction of the term "block." Therefore, the Court construes "block" in the '638 patent as: erasable storage for one or more sectors.

ii. "block" in the '918 patent

Lexar's proposed construction: erasable storage for one or more sectors
Toshiba's proposed construction: the smallest uniquely addressable physical group of nonvolatile memory cells that can be erased within a single nonvolatile memory device

7 Pretec offers no proposed construction here. Pretec only proposes constructions for disputed terms in the '638 and '051 patents.

881

The technology in the '918 patent concerns "super-blocks," larger groupings of single blocks to increase the speed with which blocks can be erased and freed up for programming new data. Lexar's briefs on "block" in the '918 patent are decidedly unhelpful. Lexar again proposes its one-size-fits-all construction for "block" and offers no citations from the '918 patent to support its construction. Instead, Lexar relies on the claim language of other unrelated patents to support its construction. The Court declines to examine those patents to construe a disputed claim term in the '918 patent.

As an initial matter, the Court notes that unlike the parties' dispute over "block" in the '314/'138 and the '638 patents, whether a block in the '918 contains one or more sectors does not appear to be in dispute. At oral argument, Lexar conceded that its proposed "one or more" language was intended to account for the older '638 patent, which expressly allows a block to contain only a single sector. The Court finds, then, that in the '918 patent, a block contains a plurality of sectors.

Toshiba's proposed construction is much narrower than Lexar's. Toshiba believes it important to acknowledge in the construction that a block (one part of a super block) is the smallest physical group of uniquely addressable nonvolatile memory cells that can be erased within a single nonvolatile memory device. As Lexar points out in its opening brief, Toshiba proposes to add limitations to the construction of "block" that speak to how a block might be used, not to what a block actually is. Moreover, the portion of the patent upon which Toshiba relies to support the "uniquely addressable" language, column 2, lines 32-40, refers to past inventions and does not support such a limitation in the construction of "block" in the '918. The additional limitations proposed by Toshiba are not warranted and the Court declines to incorporate them into the construction of "block."
For the foregoing reasons, the Court construes "block" in the '918 as erasable storage for a plurality of sectors.

iii. "block" in the '314/'138 patent

Lexar's proposed construction: Toshiba's proposed construction: 8
erasable storage for one or a plurality of sectors identified by
more sectors a virtual physical block address
and expanding between two memory devices

--- Footnotes ---

8 Pretec offers no proposed construction here. Pretec only proposes constructions for disputed terms in the '638 and '051 patents.

--- End Footnotes ---

Lexar again proposes its one-size-fits-all construction for "block." And again, the dispute between the parties on "block" in the '314/'138 patent turns, in large part, on the number of sectors a block contains. In its briefs, Lexar contends that a block can contain a single sector or more than one sector while Toshiba proposes that "block" must, by definition, contain more than one sector. However, the independent claims in the '314/'138 recite that each block includes "a plurality of sectors" or "two or more sectors." (314 patent, claims 1 & 7.) This language suggests that a block must contain more than one sector and that Lexar's proposed construction ignores the plain language of the claims. Nothing in the specification suggests that the inventor intended to act as his own lexicographer and define "block" differently. Indeed, Lexar admitted at oral argument that "we are not disputing or claiming that it can be one [sector] in the context of the '314 patent." The Court therefore agrees with Toshiba that "block" in the '3141/'138 must contain a "plurality of sectors."

Toshiba suggests that the construction of "block" should account for the distinction made in the specification between a "sub-block" as that which is contained in a single nonvolatile memory device and a "block," which expands between two nonvolatile memory devices. The Court disagrees. To construe "block" as expanding between two nonvolatile memory devices would exclude a preferred embodiment. At column 4, lines 48-53, an embodiment of the invention is disclosed in which a block is contained within "a single nonvolatile memory device" rather than expanding across two such devices. The Court therefore declines to include that portion of Toshiba's proposed language in the construction.

The Court must now determine whether the proper construction of "block" in this patent is "identified by a virtual physical block address" as proposed by Toshiba. The Court finds that this portion of Toshiba's proposed construction is unnecessary. That a block is identified by a virtual physical block address need not be incorporated into the construction of the claim term. The additional verbiage is unnecessary and would improperly import a limitation from the preferred embodiment into the construction of the claim term.

For these reasons, the Court construes "block" in the '314/'138 as erasable storage for a plurality of sectors.

GO BACK

417

10. Modify block ('505 patent, claims 15 and 19)

Plaintiffs define "modify block" as "a text block to be modified, e.g., a contiguous portion of text that can be selected by word processor commands to be deleted, moved or copied." Defendant disputes plaintiffs' proposed definition insofar as plaintiffs have articulated only an example of the definition (by plaintiffs' use of "e.g.") rather than the definition. I agree. Accordingly, "modify block" in claims 15 and 19 of the '505 patent means a contiguous portion of text that can be selected by word processor commands to be deleted, moved or copied.

GO BACK
(ii) . . . an error correction code generation circuit which generates for each block of data to be stored in said memory system an error correction code, . . .

(iii) . . . each block of data comprising a first plurality of digits and each error correcting code comprising a second plurality of digits from which at least one digit of error may be detected and corrected in the block of data . . .

This is the first claim that is affected by collateral estoppel from Judge Young's decision. In the EMC case, Judge Young construed this claim language as follows: "[Error correction code generation circuit] means a single integrated circuit which generates the claimed error correction code . . . Data, as I have already said, is information. Here, the data is in the form of digits. A block of data, as used in this phrase, means a group of data bits which may be corrected by another group of bits called error correction bits. The data is information to be stored in the computer." (A 17.)

This construction, relying as it does on the plain meaning of the words used in the claims limitation, is plainly correct. The only arguably unclear term used by Judge Young is his definition for the phrase "error correction code circuit," which he defined as a "single integrated circuit which generated the claimed error correction code." (A 17.) The words "single integrated circuit" do not appear in the claim, and TM urges that Judge Young erred in so limiting its claim.

Putting to one side the fact that TM is collaterally estopped to challenge Judge Young's ruling, TM is simply incorrect. The limitation refers to "an" -- i.e., one -- error correction code circuit. In other words, the literal language of the claim calls for one circuit that generates an error correction code. The patent specification discloses that this circuit was a single integrated circuit -- that is, "... an interconnected array of active and passive elements integrated with a single semiconductor substrate or deposited on the substrate by a continuous series of compatible processes, and capable of performing at least one complete electronic circuit function." McGraw Hill Dictionary of Scientific and Technical Terms (3d.ed. 1984). Judge Young did not err when he restricted the claim in limitation (ii) to error correction code circuits that generated the correcting digit via a single integrated circuit.

That said, I can think of ways to phrase parts of the interpretation that might be easier for a jury to understand, and I do not understand the doctrine of collateral estoppel to require me to quote Judge Young verbatim. I will, therefore, rephrase it as follows:

The multi-unit memory system I have just described contains a single integrated circuit that is called the error correction code circuit. What does this circuit do? It generates -- that is, it creates -- something called an error correction code, which is a group of mathematically interrelated bits. It creates one of these error correction codes for each block of data that is to be stored in the memory system.

Now, let's take a look at what some of those words mean -- the words that might be unfamiliar to you. Data is simply information. In a computer, data is stored as digits -- specifically, as the digits 0 and 1, as will be explained to you during the course of the trial. Each individual digit is known as a bit, which is a contraction of the phrase "binary digit." For those of you who remember the binary number system from your high school math class -- that's also known as the Base 2 system -- 0 and 1 are the two digits in the binary system. So a block of data is two or more data bits that are used to code information in a computer. That's what the phrase "plurality of digits" means -- it's just a fancy way of saying more than one digit.

An error correction code is also a plurality of digits -- remember, that means more than one of those binary digits, 0 and 1 -- and the error correction code has a particular purpose, which is to detect and correct an error in a block of data. So for every block of data in our multi-unit memory system, there is an associated error correction code, which is capable of doing two things: determining that at least one of the bits in the associated data block is correct, and correcting the error that it has detected, by generating a new, corrected bit of data.

IBM, relying on the specification, has urged me to insert a further limitation: namely, that any block of data can contain no more than 32 bits. However, there is no reason to read any such requirement into the claim, since there is nothing about the phrase "block of data" that necessarily suggests the size of the block -- as opposed to the phrase "an error code generation circuit" -- which does suggest a single circuit rather than multiple circuits. Of course, it is possible that a jury would not find
infringement of the Plaintiff's claims by a system that can detect and correct errors in larger blocks of data, but that does not bear on the construction of the claim.

(iv) . . . a plurality of read/write memory units, which store the digits of said blocks of data and associated error correction codes generated by said error correction code generation circuit and read said digits . . .

(v) . . . at least some of the different digits of each code and its associated data block being stored in different memory units.

Again, these words are not difficult to interpret in light of their plain meaning. These limitations require that there be more than one memory unit to store the blocks of data and their associated error correction codes. These units must be what are known as read/write units -- that is, they must be able to store the data bits and to read them. Moreover, at least some of the different digits of each code and its associated data block must be stored in different memory units. That is, if we have a data block reading 100101001, and an error correction code that corresponds to that particular data block, at least some of the digits of the data block must be stored in a different memory unit from the error correction code.

IBM argues strenuously that no portion of the error correction code can reside in the same memory unit where the underlying block of data is found, relying on the specifications and the preferred embodiment, which clearly show 32 memory units storing only data and 7 associated memory units storing only error correction codes. The claim limitation as written, however, encompasses more than the configuration urged by IBM. This conclusion is reinforced by looking at unasserted Claim 5, which depends on Claim 1 and which clearly states that the all the error correction code bits must be stored on separate memory units from the block data blocks. Under the rule of claims differentiation, when some claims are broad and other, dependent claims are explicitly narrower, the limitation of the narrower claim cannot be read into the broader claim, even to avoid invalidity or to escape infringement. See Karlin Technology Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed. Cir. 1999); Uniroyal, Inc. v. Rudkin-Wiley Corp., 837 F.2d 1044, 1054-55 (Fed. Cir. 1988); D.M.I., Inc. v. Deere & Co., 755 F.2d 1570, 1574 (Fed. Cir. 1985). IBM is free to argue at trial that the patent as construed is invalid, but I am not free to overlook the doctrine of claim differentiation in order to construe the claim limitations more narrowly than they are written.

Similarly, I reject IBM's effort to have me rule that claim limitation (iv) requires that the block of data and its associated error correction code be stored across all of the memory units in the array. Again, IBM is trying to convince me that the claim should be construed so as to limit the invention to its preferred embodiment as described in the specifications. I decline to do so.

419

B. "Block Size Information"

In Rambus' invention, the user can specify the amount of data to be transferred over the bus during a bus transaction. This value is represented by the term "block size." The parties differ as to exactly how this value is to be measured. Rambus argues that "block size" is "the number of sequential data bits to be read from or written to the memory." In essence, Rambus reads block size to be a function of the number of sequential transactions on a bus necessary to respond to the transaction request. Infineon posits that "block size" "specifies the total amount of data that is to be transferred on the bus in response to a transaction request." In other words, Infineon measures block size as a function of size or the amount of data to be transferred over the bus.

1. The Claim Language

The term "block size" occurs numerous times throughout the claims of the '918 patent and the '214 patent. 25 Most of the claims indicate that block size information defines the amount of data to be output or input by the memory device. 26 Indeed, there is nothing in the text of any claim which employs the term "block size" to indicate that "block size" means anything other than the amount of data to be transferred on the bus in response to some sort of transaction request. Thus, from reading the language of the claims, one skilled in the art would conclude that block size information is an instruction indicating the amount of data to be output (or input) by the memory device.
Rambus nonetheless urges that block size means "the number of sequential data bits to be read from or written to the memory" (presumably in response to a transaction request). Rambus does not identify any aspect of the claim language that would support its preferred definition. Additionally, it is worth noting that nothing in the claim language has been cited, or for that matter argued, as supporting the temporal or order requirements which would inhere in a sequential-based definition.

2. The Specification

In general terms, the specification explains that "one object of the present invention is to use a new bus interface built into semiconductor devices to support high-speed access to large blocks of data from a single memory device by an external user of the data, such as a microprocessor, in an efficient and cost-effective manner." '918 patent, col. 3, lines 21-25 (emphasis added). See also '918 patent, col. 4, lines 15-16 ("The bus supports large data block transfers . . .").

In discussing the preferred method of Device Address Mapping and the address registers therein employed, the specification explains that:

   The address registers can include a single pointer, usually pointing to a block of known size, a pointer and a fixed or variable block size value or two pointers, one pointing to the beginning and one to the end (or to the "top" and "bottom" of each memory block.

'918 Patent, col. 7, ll. 36-41. This text and that which follows it clearly bespeaks volume or amount as the measure of a block, not sequence or time.

The several other references to block size in the specification also teach that the term relates to amount of data not the order and timing of bits of data in a particular sequence. 27

--- Footnotes ---

27 '918 Patent, col. 11, ll. 1-5, ll. 41-48; col. 16, ll. 26-35, ll. 44-47; col. 17, ll. 1-2; col. 20, ll. 18-22.

--- End Footnotes ---

3. The Extrinsic Evidence

The construction offered by Rambus purports to be grounded in a table in column 11 of the specification. The table is in a section which refers to the preferred embodiment detailed in Figure 4 of the patent. 28 The specification states:

   BlockSize[0:3] specifies the size of the data block transfer. If BlockSize[0] is 0, the remaining bits are the binary representation of the block size (0-7). If BlockSize[0] is 1, then the remaining bits give the block size as a binary power of 2, from 8 to 1024. A zero-length block can be interpreted as a special command, for example, to refresh a DRAM without returning any data, or to change the DRAM from page mode to normal access mode or vice-versa.
Rambus uses Table 11, as interpreted by its expert, Dr. Huber, as the basis for its construction that block size information is the number of sequential transfers necessary to carry the desired information over the bus line. The table is but one of many encoding schemes and does not purport to define or explain the meaning of block size generally. According to Dr. Huber, the block size indicated in the chart corresponds to the number of sequential transfers necessary to output the data onto the preferred embodiment 8-line bus. That is certainly not apparent from the patent document. Furthermore, during the Markman hearing, Dr. Huber connected almost all of his opinions, not to the patent specification, but rather to a prepared animation demonstrating how block size should be measured as sequential transfers of data. The reason for such reliance seems quite clear -- there simply is no support in the patent document. Also, that view is flatly contradicted by Infineon's expert who explained that block size contains information specifying the total amount of data that is to be transferred. See Markman Hearing, Tr. pg. 442, ll. 11-19. Mr. McAlexander has testified that "the person of ordinary skill in the art would come to [the conclusion] that block size . . . means amount, and in just a plain, simple ordinary meaning of size is an amount, it's not when or how." Markman Hearing, Tr. pg. 439, ll. 11-16 (testimony of Mr. McAlexander).

4. Construction

Infineon's construction is grounded in the specification and the claim language because both sources of information rather clearly reflect that block size is an amount of data, not the order in which it is delivered. There is nothing in the specification to support Rambus' somewhat contorted definition of block size. It simply defies reason (and the specification) to conceive of size as a measure of time.

Moreover, the construction urged by Rambus utterly ignores the clear language of the claim that block size is associated with a transaction request. (See, e.g., '918 Patent, Claim 1-7 and all other claims (8 through 38) dependent upon Claim 1-7). Infineon's definition encompasses this connection and, for that additional reason, it is the definition that is necessitated by the claim language and by the specification. Thus, "block size" is construed to mean "information that specifies the total amount of data that is to be transferred on the bus in response to a transaction request."

420

5. Block Size Information
a. Proposed constructions

The disputed term "block size information" is used in U.S. Patent Nos. 6,032,214 ("the '214 patent") and 6,034,918 ("the '918 patent") and the '120 and '863 patents. Rambus proposes the term be construed as "[a] value representative of a quantity of data to be transferred during a memory read or write operation." JCCS, App. A at 11. Hynix proposes, "information that specifies the total amount of data that is to be transferred on the bus in response to a [transaction] request." Id. The dispute focuses on the amount of data to which the term refers.

b. Claim language

"In Rambus's invention, the user can specify the amount of data to be transferred over the bus during a bus transaction. This value is represented by the term block size [information]." Infineon I, 2001 U.S. Dist. LEXIS 10990, 2001 WL 34138091 at *16. The claims state that "first block size information defines a first amount of data to be output by the memory device onto a bus in response to a read request." '918 patent, cl. 18. The memory device receives the first block size information and responds by "outputting the first amount of data corresponding to the first block size information." Id. Similarly, second block size information typically corresponds to the amount of data to be input in response to a second transaction request. '918 patent, cl. 3.

c. Interpretation

Rambus's first objection to Hynix's proposed construction is that it can be interpreted as requiring the value of "block size information" to be equal to the amount of data to be transferred. If this were the case, for example, then when a request called for 1024 bits of data, the value that conveyed block size information would also have to be 1024. Hynix has allayed these fears by pointing out that "the term specify [in its proposed construction] only indicates that the block size information' is a code that represents the total size of the block of data to be transferred." Hynix at 20; see also Reply at 8 n.2. Hynix also notes that "Rambus's construction is ambiguous in failing to specify that the "block size information' defines a single block of data to be transferred in a single device access. Hynix's proposed construction does not contain this ambiguity and is consistent with the specification." Opp. at 19.

The court finds that block size information must be a value that corresponds to the total number of bits to be transferred. Such a construction comports with the construction of the term by the Eastern District of Virginia and is supported by the claims and the specification. Infineon I, 2001 U.S. Dist. LEXIS 10990, 2001 WL 34138091 at *17 (construing "block size" as "information that specifies the total amount of data that is to be transferred on the bus in response to a transaction request").

Rambus also seeks to clarify in its reply brief that the "total amount" referred to in "block size information" is the data to be transferred from a single device, not from every memory device in a system. Despite Rambus's fear, nothing in the claims, the specification, or Hynix's arguments suggests that "block size information" relates to the amount of data to be transferred from every memory device in a system. Thus, although the court agrees that the intrinsic evidence supports the position that "block size information" relates only to the amount of data to be transferred from a single device, the court does not agree that Hynix's proposed construction is susceptible to the interpretation that "block size information" refers to the amount of data to be transferred from every memory device in a system. "Block size information" is construed as "information that specifies the total amount of data that is to be transferred on the bus in response to a transaction request."

421

1. "operating individual blocks of memory cells with non-overlapping portions thereof storing at least user data and overhead information" ('842 pat., cls. 1, 10)

For this claim term, the parties have two disputes: (1) whether the claimed "operation" can be on "one or more" erase blocks or must be on "multiple erase blocks"; and (2) whether there can be only one user data and one overhead portion in an "individual block."
The first issue comes down to a simple question of interpreting the meaning of "operating individual blocks." Does it allow a reading that only one block may be operated upon, or does it require at least two? As defendants point out, the term says "individual," but that word modifies "blocks," which is plural. Defendants argue that in ordinary speech a person might say she is meeting "individual people" and mean only one person, but I find this unpersuasive. "Individual people" is still plural; at most "individual" suggests the "people" may be met one-by-one. At most, "individual" suggests that the multiple "blocks" may be "operated" upon one-by-one. The claim language resolves this dispute: "individual blocks" must be multiple erase blocks.

The second dispute relates to whether each of the claimed "blocks" may contain only one user data and only one overhead portion. Defendants contend that they must, pointing to the claim language itself. Hrg. trans., dkt. #584, at 62. Both claims 1 and 10 describe "nonoverlapping portions . . . storing at least user data and overhead information" and later claim "writing data to, or reading data from" both "the user data portion of the . . . block" and "said overhead portion." The claim's reference to "the user data portion" and "said overhead portion" supports the proposed limitation.

Against this, plaintiff points to claim 16, a claim depending from claim 10. Claim 16 claims "[t]he method of claim 10, wherein the individual blocks include only one user data portion and only one overhead data portion." According to plaintiff, because claim 16 does nothing more than add a limitation to claim 10 that defendants contend is already present in claim 10, claim 16 would be superfluous under defendants' proposed construction. Under the doctrine of "claim differentiation," superfluous claims are to be avoided. ICU Medical, Inc. v. Alaris Medical Systems, Inc., 558 F.3d 1368, 1376 (Fed. Cir. 2009). However, the doctrine of claim differentiation "is not a rigid rule but rather one of several claim construction tools." Id. The doctrine of claim differentiation "cannot alter a definition that is otherwise clear from the claim language, description and prosecution history." O.I. Corp. v. Tekmar, 115 F.3d 1576, 1582 (Fed. Cir. 1997).

In this case, the meaning of the term is "otherwise clear." What the term "nonoverlapping portions . . . storing at least user data and overhead information" leaves unclear is made clear by the surrounding language ("the data portion" and "said overhead portion"). ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1088 (Fed. Cir. 2003) (court must consider context of surrounding words of claim when construing term). By using the words "the" to refer to a single user data "portion" and "said" to refer to a single overhead "portion," the claim leaves no doubt that it covers a method involving only one user data portion and one overhead portion.

Although plaintiff contends that language in the specification supports a broader construction, the language it cites does not speak to the number of portions but states only that the "partitioning" between user and overhead portions "need not be rigid" and "the relative size of the various partitioned areas may be logically reassigned. Also the grouping of the various areas is largely for the purpose of discussion and not necessarily physically so." '842 pat., col. 8, lns. 52-57. Although the specification "is always highly relevant to the claim construction analysis," Phillips v. AWH Corp., 415 F.3d 1303, 1323 (Fed. Cir. 2005), in this instance it does not suggest that more than one user data or overhead portion is being claimed, and the claim language itself says otherwise.

In summary, the parties' disputes related to this term are resolved as follows: "operating individual blocks of memory cells with non-overlapping portions thereof storing at least user data and overhead information" must include multiple erase blocks and is limited to a single user data and a single overhead portion.

422

9. "[A] device layer having . . . a bonded surface . . . being bonded generally in its entirety to the oxide layer" ('812 patent) means that the surface is joined to the oxide layer by bonds created by heat, not by the growth of or formation of a layer. 7

7 The court discusses this limitation at pages 76-78 of its memorandum opinion of the same date.
1. "Bonus." A bonus is a reward or payment in addition to any payout specified by the normal gaming device pay table. A bonus may be awarded to a player whether the outcome on the gaming device is a win, loss, or no outcome at all. See col. 36, II. 37-46 of the '885 patent. Given the patents' explanation of the mystery jackpot, the court disagrees that a player must win a jackpot in order to win a bonus.

2. "Bonus play period" shall be construed as the period during which the bonus promotion is active. See col. 37, II. 5-48 of the '885 patent. The issue is whether there has to be a "specified portion of time" during which the promotion is active. The specification indicates that a bonus can play until the "bonus payout exceeds the bonus pool," which explanation does not indicate a specified period of time.

A. Claim Construction

Fantasy argues that the "bonus points" limitation should be broadly construed to cover any points awarded in addition to those given in an actual football game. Fantasy contends that the plain meaning of the term "bonus" is "anything given in addition to the customary or required amount," and that nothing in claim 1 limits that term to any specific type of additional points. Fantasy also argues that it did not disclaim coverage of all the bonus points discussed in the 1987 article because it distinguished that reference during prosecution on the grounds that it did not utilize a computer and did not disclose the combination of awarding bonus points and using two separate groups of players for scoring purposes. Fantasy further contends that the specification makes clear that the term "bonus points" includes non-scoring plays, such as total yardage, because it states that "bonus points are . . . awarded based upon the difficulty of the play," not the scoring play. Finally, Fantasy argues that the doctrine of claim differentiation dictates that a broader construction must be given to claim 1 because claim 2 limits the definition of the term "bonus points" to "complex or difficult plays," and claim 3 defines that limitation in terms of specific examples, e.g., "extra points for a quarterback who receives or runs for [a] touchdown."

The defendants respond that the term "bonus points" means additional points awarded beyond those given in an actual football game for scoring plays in which a player scores out of position. The defendants argue that the prosecution history clearly shows that the examiner interpreted the "bonus points" limitation to exclude the scoring methods disclosed in the 1987 article, and that Fantasy acquiesced in that interpretation, thus surrendering a broader meaning for that term. The defendants also contend that, reading the specification as a whole, it is apparent that the "plays" that qualify for bonus points are scoring plays, and that therefore the "bonus points" limitation does not include points awarded for total yardage or any other non-scoring statistic. Finally, the defendants argue that the doctrine of claim differentiation must yield where, as here, the specification and prosecution history clearly define the scope of the invention.

We conclude that the term "bonus points" is limited to additional points awarded beyond those given in an actual football game for unusual scoring plays, such as when a player scores in a manner not typically associated with his position. "The words of a claim are generally given their ordinary and accustomed meaning, unless it appears from the specification or the file history that they were used differently by the inventor." Carroll Touch, Inc. v. Electro Mech. Sys., Inc., 15 F.3d 1573, 1577, 27 USPQ2d 1836, 1840 (Fed. Cir. 1993). The specification states that "computerized football points are awarded for touchdowns, field goals, and points after touchdowns. Bonus points are also awarded based upon the difficulty of the play." '603 patent, col. 13, II. 20-23 (emphases added). The term "bonus points" therefore must be construed to mean points that are awarded for a scoring play in addition to the points given for that scoring play in an actual football game.

Furthermore, the prosecution history in this case clearly demonstrates that Fantasy surrendered any interpretation of the term "bonus points" that encompasses the methodologies taught in the 1987 article for awarding additional points beyond those given in an actual football game. In the application that eventually led to the '603 patent, Fantasy set forth a number of
claims that did not include the "bonus points" limitation and cited the 1987 article as prior art in an Information Disclosure Statement. The 1987 article discloses the concept of "fantasy football" and teaches how to organize a fantasy football game played on paper. That article also details a number of scoring methods that may be utilized in tabulating the total points for each fantasy franchise, including but not limited to assigning points for distance scoring and total yardage. The examiner rejected all but three of the claims in Fantasy's application over, inter alia, the 1987 article, and in doing so made a number of comments relevant to this appeal. First, the examiner noted that the "use of a computer to store data previously maintained on paper files is well known," Paper No. 7 at 6. The examiner also stated that "grouping players . . . is obvious since running backs and pass receivers form the offensive line, special teams line backers and defensive backs form the defensive line; and kickers perform kickoffs and field goals, functions which differ from that of both offensive and defensive teams." Id. at 8-9. Finally, and most significant to the present appeal, the examiner rejected application claim 10, which incorporated the "computer" and "grouping" limitations by reference and added the further limitation that additional points are awarded "based upon the number of yards that were involved in the play that received a touchdown," because the 1987 article "discusses [the] use of a distance scoring method in which player scores are a function of the length of the play." Id. at 9. The examiner, however, also stated that claims 13-15, the only claims that contained the "bonus points" limitation at issue, "are found allowable over [the 1987 article] since the examiner fails to find reference to [the] award of bonus points for players of first and second groups in the prior art." Id. at 11. Fantasy, without comment, rewrote application claims 13-15 in independent form as suggested by the examiner, and those claims subsequently issued as claims 1-3 of the '603 patent.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

2 Although the examiner may have misdescribed certain positions in determining that the grouping of players was known in the art, we are satisfied that the examiner adequately understood the concept of grouping players according to position.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

Contrary to Fantasy's argument on appeal, the examiner found that the use of a computer to play fantasy football games and the organization of players in a first and second group were either known in the art or obvious therefrom. The examiner's rejection of claim 10 also demonstrates that he found the combination of one or more of those limitations with Fantasy's broad interpretation of the term "bonus points" to be unpatentable. Fantasy acquiesced in those rejections by canceling all claims that did not contain the "bonus points" limitation at issue on appeal, and thus cannot now be heard to argue post hoc that it was the combination of the aforementioned limitations that rendered its invention patentable over the prior art. Fantasy therefore disclaimed any interpretation of the term "bonus points" that encompasses scoring methods described in the 1987 article, including distance scoring and total yardage. See Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 USPQ2d 1673, 1676 (Fed. Cir. 1995) ("The prosecution history limits the interpretation of claim terms so as to exclude any interpretation that was disclaimed during prosecution.") (citations omitted).

Fantasy's argument that the specification broadly defines the term "bonus points" to include non-scoring plays, such as total yardage, is not persuasive. Aside from the fact that the prosecution history defines the contours of the "bonus points" limitation, the portion of the specification cited by Fantasy must be read in context. The sentence "bonus points also are awarded based upon the difficulty of the play," id. at ll. 22-23 (emphasis added), uses the word "play" in the context of the preceding sentence. That sentence states that "points are awarded for touchdowns, field goals, and points after touchdowns," id. at ll. 20-22, all of which are scoring plays. Moreover, the specification makes clear elsewhere that only certain types of unusual plays are encompassed within the "bonus points" limitation, including, e.g.,: (1) when a quarterback "receives a pass or runs for [a] touchdown," '603 patent, col. 13, ll. 44-45; (2) when a running back "throws or receives a touchdown pass," id. at ll. 45-46; (3) when a wide receiver "passes the ball or runs for [a] touchdown," id. at ll. 47-49; (4) when a "fumble . . . results in [a] touchdown[.]," id. at ll. 44-45; or (5) when a "lateral recovery is made in the end zone," id. Accordingly, in light of the specification and the prosecution history, we interpret the "bonus points" limitation to mean additional points awarded beyond those given in an actual football game for unusual scoring plays, such as when a player scores in a manner not typically associated with his position.

Finally, Fantasy's claim differentiation argument is without merit. The doctrine of claim differentiation creates only a presumption that each claim in a patent has a different scope that "can not broaden claims beyond their correct scope." Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1368, 53 USPQ2d 1814, 1818 (Fed. Cir. 2000) (citation omitted). Although claims 2 and 3 attempt to further define the term "bonus points," that presumption is overcome by Fantasy's disclaimer of
subject matter in the prosecution history. See 203 F.3d at 1368-69, 53 USPQ2d at 1818-19 (determining that any presumption arising from the doctrine of claim differentiation was overcome by the written description and prosecution history). Consequently, the "bonus points" limitation must be given the same scope in all of the claims of the '603 patent.

We therefore conclude that the "bonus points" limitation must be construed to mean additional points awarded beyond those given in an actual football game for unusual scoring plays, such as when a player scores in a manner not typically associated with his position.

33. Boolean . . . mathematical operation

The court construes "Boolean . . . mathematical operation" as follows: "A Boolean operation is an operation that applies formal logic (for example, AND, OR, NOR, etc.)."

(2) Boot Portion/Program Portion/Data Portion

Both sides seem to agree that "boot portion," "program portion" and "data portion" all relate to the parts or components of the non-volatile memory. And rightfully so. The language of the claims makes clear that these three "portions" all relate to the non-volatile memory (claim 2 discloses "[t]he method of claim 1, wherein said non-volatile memory further comprises a boot portion, a program portion and a data portion," id., col. 29, lines 31-33; claim 26 discloses "[t]he IED of claim 19, wherein said non-volatile memory further comprises a boot portion, a program portion and a data portion," id., col. 31, lines 7-9). The dispute about these terms centers on whether they necessarily involve an integrated flash memory.

Square D argues that "boot portion" means that "part of the non-volatile memory containing the boot or startup code"; "program portion" means "a part of the non-volatile memory containing program code"; and "data portion" means "a part of the non-volatile memory containing stored data." On the other hand, EI argues that "boot portion" should be construed to mean "flash memory integrated with the processor that provides storage for code executed by the processor during processor startup"; "program portion" means "flash memory integrated with the processor that provides storage for program code"; and "data portion" means "flash memory integrated with the processor that provides storage for data."

To be sure, the specification does speak in terms of a processor containing "integrated flash memory divided into three different types . . . Program flash memory 1915 provides storage for the main program code. Boot flash memory 1925 provides storage for the program code that executes during processor startup. Data flash memory 1960 provides storage for data." U.S. Patent No. 6,745,138 B2, col. 11, lines 57-64. But nothing in the specification requires that the non-volatile memory be flash memory. Indeed, the specification specifically instructs that "in the foregoing discussion, flash memory could be replaced with other types of non-volatile memory such as battery backed SRAM, ferro-electric RAM ("FRAM"), etc." Id., col. 28, lines 40-43. Thus the Court will not limit these claims as EI urges. Rather, the Court construes "boot portion" to mean "the part of the non-volatile memory containing the boot or startup code"; "program portion" to mean "the part of the non-volatile memory containing program code"; and "data portion" to mean "the part of the non-volatile memory containing stored data."

Claim 1 of the '440 patent provides:

A method for controlling access to a computer having a central processing unit (CPU), the CPU executing a boot program to initialize the computer, the method comprising the steps of: following power-up clear or reset of the CPU,
interrupting execution of the boot program; and loading a verification program from a nonvolatile dedicated memory; upon attempted access by a user,

executing the verification program to determine whether the user is authorized to access the computer: if the user is authorized, completing execution of the boot program and providing access to the computer; and if the user is not authorized, denying the user access to the computer.

('440 patent, 7:46-63.) (Emphasis added.)

Claim 1 of the '981 patent provides:

A method of operating a computer having a central processing unit, the central processing unit executing a boot program to initialize the computer, the method comprising the steps of:

a) prior to completion of the boot program, acquiring control of the central processing unit;

b) loading a verification program;

c) upon attempted access by a user, verifying that the user is authorized using the verification program; and

d) controlling access to the computer by monitoring system calls.

('981 Patent, 17:62-18:5.) (Emphasis added.) The language critical to this dispute has been emphasized. Because the same disputed term "boot program" is used in claim 1 of the '440 patent and claim 1 of the '981 patent, the court will discuss the term as it is used in both patents. Given that the '440 and '981 patents are related, share the same priority date, and are both a continuation of the '497 patent, the disputed term must have a consistent meaning across both patents. See Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 979-80 (Fed. Cir. 1999).

C. Construction of "Boot Program" in the '440 and '981 Patents

Claim 1 of the '440 patent indicates that the security method of controlling access to the computer must "interrupt[] execution of the boot program," and only if the user is authorized does the computer complete execution of the boot program. Similarly, claim 1 of the '981 patent indicates that the security authorization must occur "prior to completion of the boot program." The patents give no special meaning to the term "boot program," and the term does not appear anywhere else in the specification of either patent.

Digital Privacy submits that "boot program" simply equates to "boot process," or the series of programs involved in the process of booting a computer from a power off or reset state to a state at which the user interface is presented. Digital Privacy contends a verification program interrupts the boot program if it occurs at any point from power off until the user has complete access to the computer after the operating system is fully loaded and executed. (Digital Privacy's Markman Br., at 6.)

RSA argues the term "boot program" is a term of art that ordinarily has the specific, narrow meaning of "a short computer program that is permanently resident or easily loaded into a computer and whose execution brings a larger program, such as 1) an operating system or 2) its loader, into memory." (RSA's Markman Br., at 15-16.) RSA contends that outside the context of the patents at issue, the term of art "boot program" can refer to either the BIOS 3 boot program, whose execution loads the boot loader program into memory, or the boot loader program, which is loaded from the boot record and loads the operating system. In the context of the technology description in the patents, however, RSA submits "boot program" can only refer to the BIOS boot program.

------------------- Footnotes -------------------

3 BIOS is an acronym for Basic Input/Output System.
After careful review of the intrinsic evidence presented in the claims, specifications, and prosecution histories of the '440 and '981 patents, the court construes the disputed term "boot program" to mean the BIOS boot program. The patented invention is a means of providing the maximum level of computer security against unauthorized users, which is accomplished by prohibiting access, and even power, to any peripheral or internal device of the computer system until after a user has been authorized to have access to that peripheral or internal device by a verification program.

As further discussed below, the intrinsic evidence clearly indicates that the central processing unit (CPU) does not turn on power to any peripheral or internal device until after the verification program has verified the authenticity of a user. Given that the verification program must interrupt the boot program ( '440 patent), or occur prior to completion of the boot program ( '981 patent), and given that the computer peripherals do not have power until after the verification program is complete, the "boot program" in the patents must be complete prior to any step in the boot process that requires power to a computer peripheral. Because the hard drive is one of the peripheral devices that lacks power before the successful completion of the verification program, and because the operating system is loaded and executed from the hard drive, the "boot program" in the patents must be completed before the operating system is loaded and executed from the hard drive.

4 The operating system can also be loaded from other peripherals, such as a floppy disk drive or a CD-ROM drive. However, the CPU does not turn on power to any of the peripherals before the verification program authorizes the user.

Under Digital Privacy's construction of "boot program," the verification program can occur at any point during the "boot process." However, the "boot process" includes loading and executing the operating system from the hard drive, or another peripheral device such as a floppy drive. The patents indicate there is no power to any peripheral or internal devices until after the verification program has been successfully run. Therefore, "boot program" as it is used in the patents cannot include any action by, or access to, a peripheral or internal device, including the loading of the operating system from the hard drive.

5 Furthermore, the court notes that claim 5 of the '981 patent specifies:

The method of claim 1, wherein the step of controlling access to the computer comprises the steps of: monitoring and storing system calls made by the central processing unit while loading the verification program; and if the user is verified as an authorized user, booting the computer system;…

Reading claims 1 and 5 together indicates that the computer system is booted after the boot program is interrupted to run the verification program. Boot program and booting the system are not used as equivalent concepts.
port, parallel port, and internal modem depending on the configuration of the secure computer system."

( '440 patent, 6:4-11; see also '440 patent, 4:23-30.)

Likewise, in the '981 patent, the "Summary of the Invention" explains that the verification program determines whether the user is authorized to use the computer. Then, once the user is authorized, the CPU specifies which peripherals the user is authorized to access. ( '981 patent, 2:44-46). In other words, only after a user is verified, "the CPU is allowed to access all peripherals the user has been authorized to use." ( '981 patent, 2:55-59.) These statements clearly indicate that a user does not have access to any peripherals until after authorization by the verification program. The detailed specifications confirm this understanding of boot program. (E.g., '981 patent, 4:55-63, 6:35-49).

The '981 patent explains the initialization of the secure computer system as follows. First, when the computer is initialized, such as by a power up, clear, or warm boot reset, the standard computer BIOS determines the system configuration. ( '981 patent, 12:44-53.) Second, when the BIOS boot program attempts to load the boot loader program from the hard drive, the invention in the patent intercepts the attempted read of the boot loader program from the hard drive and directs it to a ROM 6 that simulates the hard drive. This ROM contains boot loader program code and the verification program. ( '981 patent, 12:65-13:13.) In a computer not equipped with this security invention, the BIOS boot program is complete after the boot loader program has been loaded from the hard drive. The computer then begins the operating system load. However, in a computer equipped with this security invention, prior to completion of the boot program, i.e., before any loader program has been read from the hard drive, the verification program is loaded and run.

--- Footnotes ---

6 ROM is an acronym for Read Only Memory.

--- End Footnotes ---

Third, and most important for the construction of "boot program" as it is used in claim 1, the '981 patent specifies that if all required steps of the verification program are successfully completed, "the CPU will then boot from hard drive 113 in order to execute the disk operating system for secure computer 110." ( '981 patent, 14:62-66). The patent unequivocally states that the operating system is loaded from the hard drive after the verification program is complete. This description confirms that the only boot program that can be interrupted in claim 1 of the invention is the BIOS boot program.

The prosecution histories of the patents also demonstrate that the "boot program" in the claims is less than the entire chain of programs required to bring the computer to a state where it can accept input from a user. In the initial application for the '497 patent, filed June 4, 1992, the applicants stated the computer peripherals were powered off until the user was authorized to use the secure computer. (Def. Ex. 4A, at P019423, P019431.) In an amendment to the '497 patent application, filed October 28, 1993, the applicants distinguished their invention from a prior art reference, the Dykes invention (United States Patent Number 4,797,928), by telling the Patent and Trademark Office Examiner that their invention differed from the Dykes invention because they use a CPU system boot ROM that "controls BIOS routines." (Def. Ex. 4G, at P019628.) In the '440 patent prosecution, the applicants again stated that the CPU does not turn power on to any computer peripheral, including the hard drive, until after the verification program has run. (Def. Ex. 5A, at P019963, P019971.) In the '981 patent prosecution, the applicants indicated that a user cannot access any peripherals until after the user is authorized by the verification program. (Def. Ex. 7A, at P020281, P020282.) The applicants repeatedly refer to a "secure hard drive," which implies the invention keeps the hard drive secure until after the verification program authorizes a user. (E.g., Def. Ex. 7A, at P020287.) The applicants discuss how their invention simulates a hard drive during the BIOS boot program, and actually intercepts and redirects the BIOS boot program's attempted read of the boot loader program from the hard drive. (Def. Ex. 7A, at P020291, P020299.)

In the October 2, 1995, Preliminary Amendment to the '981 patent, the applicants clarified claim 1, which had previously read "A method of operating a computer comprising the steps of: a) prior to boot, acquiring control of the CPU..." to read instead "A method of operating a computer having a central processing unit, the central processing unit executing a boot program to initialize the computer, the method comprising the steps of: a) prior to completion of the boot program, acquiring control of the central processing unit [CPU]...." (Def. Ex. 7B, at P020374.) (Emphasis in original.)

- 894 -
clarification indicates the inventors originally described their invention as a security measure occurring "prior to boot" of the computer. Such a description stands in stark contrast to Digital Privacy's current proposed construction that the verification program can run at any point in the boot process.

The titles of both patents use the description "Preboot Protection," which is a further indication that the invention was for a computer security system that prevented access before the computer was booted.

For the reasons stated above, the intrinsic evidence makes clear the term "boot program" in claim 1 of the '440 patent and claim 1 of the '981 patent means the BIOS boot program. Even though the intrinsic evidence is unambiguous, the court notes that extrinsic evidence presented during the Markman hearing and in the Markman briefs is consistent with the court's construction of boot program. The court admitted extrinsic evidence to understand the language in which the patent is written and to give the court a familiarity with the terminology of the art to which the patent is addressed. See Markman, 52 F.3d at 986. Although such extrinsic evidence supports the court's construction of the disputed term "boot program," it is not necessary to determine the meaning or scope of the term. See Pall Corp. v. Micron Separations, Inc., 66 F.3d 1211, 1216 (Fed. Cir. 1995).

RSA's expert stated at the hearing that both patents describe an interruption of the BIOS boot program's access to the hard drive. Deposition testimony of two of the named inventors supports the conclusion of RSA's expert. Mr. Joseph Kimlinger stated that the patented invention was to "inhibit" or "block" access to the hard drive. (Def. Ex. 53, at 121; see also id. at 80-84, 123-24.) Mr. David Mooney explained that "the way our patent worked was to - basically at power-on, we took control of the entire system prior to any operating system being loaded." (Def. Ex. 54, at 61.) Although both of Digital Privacy's experts stated at the Markman hearing that figure 7A of the '981 patent did not show an interruption of the BIOS boot program, that testimony contradicted the testimony each of the two experts had given in their depositions. Furthermore, at the Markman hearing, both Digital Privacy experts confirmed that there is no embodiment, example, or description in either patent that shows any access to the hard drive before the verification program is run.

The court found RSA's expert, Dr. Paul Clark, to be quite credible, particularly as an expert on computer hardware and the computer security industry, and more credible than either of Digital Privacy's experts, Mr. Peter Bartoli and Mr. Thomas Beretvas. Mr. Bartoli described his expertise as more oriented to software than hardware, and more oriented to network security than physical security, even though he stated the patents are directed to hardware designers of physical security systems. Mr. Beretvas stated he is not an expert in personal computer operating systems or computer security issues and had never heard the term "boot program" or "preboot" prior to the case.

For example, in the November 1, 1996, Business Summary of Integrated Technologies of America, Inc., the company touts itself as having the "only patented PRE-BOOT security system" that uses smart cards. This security product "controls BIOS; it is not controlled by BIOS!" (Def. Ex. 27, at P013787-88, P013790). The company also makes this claim in a December 1996 White Paper and a January 1997 White Paper ((Def. Ex. 28, at P001.771-72; Def. Ex. 30, at P013958-60). The 1996 Business Summary claims an advantage over other computer security products because with Integrated Technologies's products "control of the system cannot be booted from the floppy drive or the hard drive" without the smart card verification. (Def. Ex. 27, at P013800.) As a final example, the Windows 95 user's guide to one of Digital Privacy's products claims "we have the patent on pre-boot protection, meaning only [this product] can stop intruders before DOS or Windows is even loaded! They can't even get the system booted!!" (Def. Éx. 29, at P016084.)

The court can look at extrinsic evidence to demonstrate the state of the prior art at the time of the invention. Markman, 52 F.3d at 980. RSA's expert witness, Dr. Paul C. Clark, explained some of the security concerns for personal computer owners in the early 1990s when plaintiff first applied for the patents. At that time, computers would always attempt to boot first from the floppy drive, and second from the hard drive. Therefore, unauthorized users could bypass security systems stored...
on the hard drive by booting from the floppy drive. In both the '440 patent and the '981 patent, Digital Privacy specifically stated that one of the problems in the computer security field that its invention addressed was the vulnerability to bypass. ( '440 patent, 1:48-51; '981 patent, 2:9-11.) Digital Privacy's invention avoids the bypass problem because only authorized users can ever access the hard drive.

A. Boot Selection Flag

The parties dispute as to the meaning of the phrase "boot selection flag" centers around whether the phrase "boot selection flag" encompasses several different values in the partition table or is limited to the system ID byte of the first partition. The method step provides for the test to determine an automation or normal boot sequence to read a boot selection flag and comparing it with a known flag setting. "Boot selection flag" is not a phrase commonly used in the computer industry. However, in the embodiment of the invention in the specification the system ID byte is used as the boot selection flag.

Symantec relies on the claim language's use of the singular form of flag to assert that the boot selection flag must be one value. On the other hand, Altiris claims that a flag is commonly known as one or more bits of data used as a signal. Therefore the claim language's use of the singular form for "boot selection flag" could still be consistent with an interpretation that the "boot selection flag" is several values in the partition table. Because both interpretations are possible from the language used in the claim, this court must refer to the specification for guidance.

Symantec relies on the fact that the system ID byte of the first partition is used in the embodiment to assert that such a limitation would be consistent with the claim's use of the singular form for "boot selection flag" and should be imposed on the claim. Symantec also claims that nothing in the specification indicates that the "boot selection flag" was intended to encompass anything else. Altiris argues that the patent specification explicitly discloses that other entries in the partition table can be used as a boot selection flag. Altiris relies upon language from two places in the specification stating: "The customized MBR code examines the partition table flags (a small database contained within the MBR which specifies the location and type of partitions on the disk) to determine which of the four partitions to load and execute;" and "The custom MBR code examines the flags in the partition table to determine which partition is to be loaded and executed. This step of the process of the invention is a test of whether an automation boot or normal boot should be implemented." '593 Patent at col. 4, lines 7-10; col. 6, lines 1-5. Altiris claims that this language supports its position that the boot selection flag can be the collection of the bootable/non-bootable entries in the partition table that indicate what boot sequence will occur (referred to as bootable flags).

However, the specification also refers several times to a "special flag" in the singular. The specification states that "when the MBR code again gains control, it recognizes the special flag and causes the 'normal' operating system to boot. Before booting the 'normal' operating system, the MBR code resets the special flag, so that next time the computer boots, it will be directed to again boot from the automation partition." Id. at col. 4, lines 39-43.

Although it appears that the specification refers to both flags and a flag, this court concludes that because the singular form of flag is used in both the claim and the specification and the embodiment in the specification uses single value of the system ID byte of the first partition as the boot selection flag, the claim should be limited to the singular boot selection flag identified in the embodiment. See Wang Labs., Inc. v. America Online, Inc., 197 F.3d 1377, 1381-83 (Fed. Cir. 1999) (limiting term to system used in the specification because it was the "only system that is described and enabled in the specification and drawings"); Toro Co. v. White Consol. Indus., Inc., 199 F.3d 1295, 1301-02 (Fed. Cir. 1999) (limiting term to its consistent description in the sole embodiment). The patent does not give a clear indication that anything other than the system ID byte could be used as the boot selection flag. The portions of the specification relied on by Altiris do not constitute additional embodiments of the invention and the patent does not teach one of ordinary skill in the art to use anything other than the system ID byte. Therefore, defining the boot selection flag as a collection of the bootable/non-bootable entries in the partition table is too broad. Reviewing this phrase in the full context of the patent, this court concludes that the phrase "boot selection flag" should be construed to mean the system ID byte of the first partition.
In its initial decision, the administrative law judge adopted P&S's proposed claim construction for the disputed term, "mounting means for said conducting member to permit movement thereof between a first position, wherein said pair of contacts are in respective, circuit making engagement with said pair of terminals, and a second position, wherein both of said pair of contacts are in spaced, circuit-breaking relation to said pair of terminals." The administrative law judge found that the claim was satisfied if either of the two contacts was moved into a spaced, circuit-breaking second position, because collectively, "both" contacts would be in a position that resulted in the circuit breaking.

The administrative law judge also adopted P&S's proposed construction of the disputed term, "a unitary, electrically conducting member carrying a pair of spaced electrical contacts." The term was construed to mean "a member that provides an electrical current carrying path between two or more spaced contacts." The administrative law judge found that this construction was consistent with the specification and rejected defendants' argument that the structure be limited to a "buss bar." A buss bar is an I-shaped component known in the electrical engineering field and depicted in the patent as an embodiment of the claimed member.

On review, the Commission found that the administrative law judge's constructions did not give meaning to the claim limitations that "both" contacts be in a spaced, circuit-breaking second position and that the electrically conducting member be "unitary" and "carry" the pair of spaced contacts. The Commission found that the plain language of the claim required a construction of "both" that was not satisfied by the movement of only one contact. See Commission Op. 2009 ITC LEXIS 525 at *13. It also found that the specification required construing "unitary" to mean that the member was a single, continuous piece and that both contacts are disposed on the same member. See 2009 ITC LEXIS 525 at *9-*10.

Based on its modifications to the administrative law judge's claim constructions, the Commission reversed the administrative law judge's initial decision and held that the products did not infringe the '398 patent. The Commission noted that only one of the contacts in the accused devices moves into a spaced, circuit breaking second position, and that the electrical contacts for some of the accused products are carried on separate metal plates connected by a braided wire.

We agree with the Commission that the proper construction of the term "mounting means for said conducting member to permit movement thereof between a first position, wherein said pair of contacts are in respective, circuit making engagement with said pair of terminals, and a second position, wherein both of said pair of contacts are in spaced, circuit-breaking relation to said pair of terminals" requires that each of the contacts moves from its first position into a spaced, circuit breaking relation with respect to each of its respective terminals.

P&S argues that the claim should be interpreted to simply require that the contacts in the second position be spaced such that the circuit is broken. According to P&S, this limitation would be satisfied as long as either one of the contacts was moved into spaced, circuit-breaking position, since "both" contacts collectively would be in a "second position" that results in the circuit breaking.

We reject this argument. The plain language of the claim requires that both of the pair of contacts move into spaced, circuit-breaking relation to the terminals. If P&S wanted its claim to read on devices where only one contact moved into spaced, circuit-breaking relation to the terminals, then it could have written its claim to read, "wherein at least one of said pair of contacts is in spaced, circuit-breaking relation to said pair of terminals."
Plaintiff's Proposed Construction:

Function - Comparing a set of stored unique identification characteristics codes with the codes derived from the live digitized impressions of the live body part to establish identity of both the inputs.

Structure - One or more components (such as a computer) adapted to comparing a set of stored unique identification characteristic codes with the codes derived from the live digitized impressions of the live body part to establish a match or no match situation.

Defendants' Proposed Construction

The phrase is indefinite for at least the following reasons: (1) the term "both the inputs" lacks antecedent basis, and (2) there is no corresponding structure in the specification for "comparing . . . to establish identity of both the inputs" because the specification describes, at most, using one set of codes to establish the identity of another set of codes.

The plain language of the claim establishes that the function of this clause is to compare the identification code derived from a live impression to that of the stored identification code to determine whether the two codes match. Defendants argue that this clause fails for indefiniteness because: (1) there is no antecedent basis for the phrase "both the inputs," and (2) there is no corresponding structure to carry out this function.

1. "Both the Inputs"

A claim term should be given the ordinary and customary meaning "that the term would have to a person of ordinary skill in the art in question at the time of the invention." Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) (en banc). "[T]he person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Id. The language of the Fifth Clause itself provides antecedent basis for the phrase "both the inputs." It explains that the program will compare a set of stored identification characteristic codes (e.g., codes stored on the magnetic strip of a credit card), with codes derived from a live impression. Therefore, from simply reading the claim, one skilled in the art would understand that "both the inputs" refers to the stored code and the code derived from the live impression. Furthermore, when the claim is read in the context of the entire patent, including the specification, it is clear that "both the inputs" refers to the stored code and the code derived from the live impression. See '474 Patent at 12:10-20. The phrase "both the inputs" therefore has antecedent basis in both the claim and the specification, and is not indefinite.

2. Structure

Plaintiff argues that both the claim and the specification teach one skilled in the art how to compare the inputs and describes the structure for doing so. For example:

In comparing a live biological characteristic to that of the stored unique biological characteristic identification code, the program finds on the live scanned image the same type of biological characteristics. If the biological characteristics are found, the program then checks to see if they are in the same relative location. If the predetermined number of biological characteristic identification codes match, then the computer program indicates a match condition. If the predetermined number of biological characteristics do not match, then the computer program indicates a no match condition.

From the language cited above, it is clear that the stored code is used to identify the live code. In other words, one input is used to establish the identity of the other input. Defendants argue, however, that there is nothing in the specification which discloses a structure for identifying both the inputs separate and apart from each other, which Defendants allege is what Clause Five requires. This technical argument misconstrues the plain language of the claim.

Clause Five provides a means for comparing the stored code with the live code to "establish identity of both the inputs," or stated differently, to find a match among both the inputs. 2 From a plain reading of the claim, the function recited by Clause Five is not, as Defendants allege, to establish the identity of each input separate and apart from the other. Rather, the
function is to compare two inputs, the input from the stored information and the input from the live impression, to establish a match. With this understanding, the language of the specification recited above, clearly discloses the structure for performing this function. See id. Therefore, Clause Five of Claim Two does not fail for indefiniteness.

2 At oral argument both parties agreed that the words "establish identity" in Clause Five means "finding a match."

432

9. "the telephone wiring network includes a branch network which couples one of the plurality of telephone devices to the telephone network telephone network [sic], and the branch network includes circuitry for preventing transmission of signals in the high frequency band to one of the telephone devices on the branch network": the branch network is part of the telephone wiring network.

Defendants propose "branch network" be defined as "[a] path of electrical wiring and/or circuitry that includes a slit off a main conductive path and is defined by wiring topology independent of physical enclosures." n40 Defendants assert that "[t]he plain meaning of 'branch network' in the context of the asserted claims is a network of wiring that includes a split off of a main conductive path." n41 Defendants provide no support to this purported "plain meaning" other than extrinsic evidence in the form of the deposition testimony of Inline's expert, Dr. Beckmann. Inline proposes that "branch network" be defined as "the local network of telephone wires internal to a residence or other structure where telephone devices are located." n42 Inline supports its proposed definition by citation to the language of claim 61 of the '596 patent; language from claim 1 of the later-issued '585 patent (directed at a "branch conductive path"); and language from the common specification defining "local networks." n43

n40 D.I. 439 at 32.
n41 Id.
n42 D.I. 480 at 5.
n43 Id. at 38-39.

The parties have not cited, and the court has not found, specification discussion of "branch network." The intrinsic and extrinsic "evidence" cited to the court does not clearly support the parties' competing constructions. Therefore, consistent with the language of claim 61 of the '596 patent, the court determines the "branch network" is part of the telephone wiring system.

433

I. BRIDGE

This term "bridge" appears throughout the claims and specification of the '788 patent. The parties propose the following constructions:

<table>
<thead>
<tr>
<th>Term</th>
<th>DisplayLink's proposed construction</th>
</tr>
</thead>
</table>

- 899 -
Bridge: Component(s) for communicating between two or more buses each using different interface standards.

Term: MCT's proposed construction
Bridge: Device that converts electrical signals between different domains in the form understood by the receiving domains, through which each signal travels over a fixed path.

MCT asserts that there is no support in the patent for DisplayLink's proposed construction that a bridge is a device used to communicate between two buses. DisplayLink asserts that MCT's proposed construction is not necessarily wrong but that it lacks clarity.

Claim 1 of the '788 patent claims

a bridge disposed external to the computer and connecting the USB controller and the VGA controller one to the other for the passage of the data therebetween, the bridge receiving the bus control command and issuing a first-in-first-out control signal to the USB controller to receive the USB based display signals from the USB controller in a first-in-first-out manner, the bridge circuit converting the USB based display signals into corresponding VGA signals and forwarding the VGA signals to the VGA controller which in turn applies the VGA signals to the display device.

Id. at 5:1-11; see id. at 6:45-56. Thus, the function of the bridge is to convert USB based display signals into corresponding VGA signals. Figure 1 of the specification shows the bridge being between the VGA controller and the USB controller. The specification states that "[t]he bridge that is connected between the USB controller and the VGA controller receives the USB based display signals from the USB controller in a first-in-first-out (FIFO) manner and converts the USB based display signals into corresponding standard VGA signals . . . ." Id. at 2:33-36. Thus, as the claim states and the specification supports, the bridge receives a "bus control command." Id. at 5:1-11.

Further, while the claims do not specifically state that the bridge connects to a second bus that exists between the bridge and the VGA controller, Figure 2 of the patent shows the bridge connecting to the VGA controller via a PCI or AGP bus. Additionally, the patent specification states that "Fig. 2 is a block diagram of a bridge circuit of the USB-to-VGA converter of the present invention." Id. at 2:4-5. Thus, the specification confirms that the bridge also connects to a second bus.

Accordingly, the court adopts DisplayLink's proposed definition and construes the term "bridge" as follows:

Component(s) for communicating between two or more buses each using different interface standards.

1. "Bridging node" (‘366, Claims 5, 19, 21; ’311, Claim 16) 25

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

25 It is undisputed that the ’366 and ’311 patents should be construed together because they are, for all relevant purposes, identical. (R. at 40 (May 6, 2004).)

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

The parties agree that a bridging node is a non-terminal or intermediate node in a network but disagree as to whether the term also serves a customary function within the network that should be included in its construction. Broadcom argues that bridging nodes had a customary meaning at the time of patenting and offers as support a "word search conducted on the USPTO website," which discloses twenty-two patents using that term. (Acampora Rep. at 5-6.) This evidence, however, provides little support to Broadcom, as it indicates nothing about how these patents define the term at issue, much less
whether they each use it in the manner that Broadcom proposes. 26 In contrast, Agere notes that no dictionary or treatise extant at the time of patenting contained a definition of "bridging node" and that a Special Master in a prior federal lawsuit has found, through exhaustive analysis, that the term at issue had no customary meaning. (Goodman Rep. PP 119-20; Agere Resp. Ex. 18 at 44 (ST Microelectronics, Inc. v. Broadcom Corp., Civ. No. 02-362, Special Master's Report and Recommendation on Claim Construction (E.D. Tex. Dec. 31, 2003)).) This Court finds the Special Master's reasoning, in combination with the lack of meaningful evidence supporting Broadcom's argument, persuasive and holds that "bridging node" did not have a customary meaning to persons of skill in the art at the time the patents were issued.

26 Broadcom cites language from four of these patents that allegedly supports its definition, but such support is tenuous at best. For example, patent 4,644,468 uses bridging nodes to, inter alia, "reformat" data. See U.S. Patent No. 4,644,468, col. 3, l. 66-col. 4, l. 3. This is substantially different from the mere "repeating" function that Broadcom proposes.

In the absence of a customary meaning, Agere urges the Court to adopt in full the construction given by the Special Master in the Texas litigation. 27 There are three aspects, however, in which this definition appears deficient. First, the Special Master defined "bridging node" as a node "that is used to bridge." This is, of course, circular. Instead, the Court finds that "bridging" means to relay messages, a definition that, although Agere contends it is incomplete, neither party claims is incorrect. (Cf. Goodman Rep. P 133 (arguing that bridging node is not limited to relaying function; see also infra note 29).) Second, the Special Master found that a bridging node is a node "in a tree." As Broadcom notes, this appears to refer to an embodiment of the invention that uses the spanning tree topology. 28 This embodiment is set out in dependent claim 8, which describes the "bridging devices" of the "communication network" of claims 7 and 5 (wherein the bridging nodes are claimed) as "participating in spanning tree routing." Therefore, if the bridging nodes of claim 5 were limited to spanning tree embodiments, claim 8 would be rendered superfluous. Such a construction would violate the doctrine of claim differentiation, which generally requires courts to avoid construing a claim in a manner that would render another claim superfluous. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004) ("Where the limitation that is sought to be 'read into' an independent claim already appears in a dependent claim, the doctrine of claim differentiation is at its strongest."). Thus, the Court rejects the "tree" requirement in Agere's proposed construction. Finally, the Special Master's definition contains a second and distinct sentence that sets out two additional functions of the bridging node: "a network interface function" and "a routing function." These functions are mentioned solely in the "spanning tree" embodiment discussed above ('366 patent, col. 8, l. 54-col. 9, l. 3), and therefore cannot properly be used to limit the broader claim term.

27 Agere also raises a collateral estoppel argument. This argument fails because, inter alia, the parties to the first suit apparently settled their claims before the district court could approve the Special Master's report. (Agere Supplemental Br. at 5.)

28 Agere argues that its construction refers only to a "tree," while the preferred embodiment discusses a "spanning tree." This argument, however, is belied by the fact that the second sentence of Agere's construction is taken verbatim from the "spanning tree" preferred embodiment, as discussed below.

In sum, the Court will modify Agere's proposed construction by striking the references to "tree," "network interface," and "routing," and by replacing "bridges" with "relays." The resulting construction is: "A non-terminal node that relays messages in an interconnected network." 29

29 Dr. Goodman opines that this definition is inappropriate because it describes a "repeater," and that the patentee distinguished between repeaters and bridging nodes in the prosecution history. What the prosecution history demonstrates, however, is that the patentee amended his application to replace the term "repeater" with the term "base station," while also
adding the "spanning tree" preferred embodiment, including the bridging node language at issue. (Compare Agere Resp. Ex. 23 at 18, with Agere Resp. Ex. 57 at 17-18.) Not only does this set of amendments fail to imply any particular relationship between "repeater" and "base station"--the latter could have been substituted because it was a synonym or, alternatively, because it had a different and more accurate meaning to the patent than the former--it also fails to support any conclusion regarding the relationship between the deleted "repeater" and the added "bridging node" language.

--- End Footnotes ---

435

a. a storage for storing the previous brightness level

The parties agree that the term "storage" refers to a "memory." D.I. 1388 at P 390; D.I. 1387 at 23. The parties dispute the meaning of "brightness level." LGD contends that "brightness level" means a "gray scale value or luminance value" and proposes that the phrase "a storage for storing the previous brightness level" be defined as "memory that temporarily holds the brightness level of the video signal received from the host through input logic for the previous time increment." Id. at P 394. AUO contends that the term "brightness level means "a level of intensity of light," and therefore, the term "a storage for storing the previous brightness level" should be defined as "memory for storing a previous level of light intensity of a video signal input through input logic." D.I. 376 at Exh. M-2.

After reviewing the claim language in light of the specification, the Court concludes that "brightness level" means a "level of intensity of light." This construction is consistent with the specification which explains that brightness "should be considered in terms of the quantity of light." AUO-5 (160 patent) at col. 8, ll. 32-35. While it is true that the specification suggests that a "brightness level can be represented as a target brightness by a gray scale," the Court does not read the specification to limit the representation of a video signal's brightness level to "gray scale values." Id. at col. 3, l. 67.

436

1. Broad Band Information

Broad band information is information that requires high bandwidth for transmission relative to the available bandwidth of the transmission channel or medium considering temporal requirements. In the context of the '484 patent, the term "broad band information" may refer to any image.

437

A. "broadcast"

Claim 56 of the 553 patent provides:

A method of adding a graphic indication of a first down to a video of a football game during a broadcast of said football game, comprising the steps of . . .

Sportvision contends that the term "broadcast" does not need to be construed.

SportsMEDIA contends that the Court should define "broadcast" as "distribution of video content." (Defendant and Counterclaimant's Memorandum of Points and Authorities in Opposition to Plaintiff's Markman Memorandum on Claim Construction, hereafter, "SportsMEDIA's Memo," Docket Item No. 178, at 11.).

In response to SportsMEDIA's proposed construction, Sportvision contends that if the Court is going to construe the term, it should be construed to mean, "transmission for public use." (Sportvision's Markman Memorandum on Claim Construction,
The noun "broadcast" appears in many places in the specification of the 553 patent. Generally the term is used in the context of (a) "... broadcast of a live event ..." or (b) "... broadcast of a target at a live event ..." 553 patent, 2:15-17. The common definition of the term is, "a wide-spread distribution." SportMEDIA's proposed construction is more limiting than the common definition of the term.

The Court gives the noun "broadcast" its commonly understood meaning: "A wide-spread distribution."

Lucent contends that this phrase means "a message sent to a group of devices." (D.I. 396 at 32.) In support of its contention, Lucent cites several telecommunications dictionaries published between 1984 and 2001. (D.I. 396 at 34-35.)

Extreme contends that this phrase means "a connectionless message addressed to all of the other nodes in the network." (D.I. 395 at 32.) Extreme cites the IEEE Standard Dictionary of Electrical and Electronics Terms published in 1988 in support of its construction. (D.I. 399 at 33.)

Foundry contends that this term means "a message that is sent to all nodes in the network." In support of its contention, Foundry cites the Abstract section of the patent specification and the prosecution history. (D.I. 385 at 31.)

The Court is not persuaded that the dictionaries cited by Lucent are the appropriate sources for defining "broadcast message" as it was used in data networking at the time the '607 patent application was filed in 1990. Further, the definitions proposed by Lucent and Extreme are conflicting. Thus, the Court will look to statements made in the specification and prosecution history to choose between these competing dictionary definitions.

In the Abstract section of the specification, the patent indicates that "[a] facility is provided in a data network to prevent a so-called connectionless broadcast message from flooding the network as a result of each network node retransmitting such messages to its neighboring nodes even though a neighboring node may have received them from another neighbor." In the Background of the Invention section of the specification, the problem that the patent purportedly addresses is the "failure in the provision of connectionless service in a network of communications nodes arranged in an arbitrary topology [to] route, in an efficient manner, a broadcast message from a source node to each of the other nodes." ('607 patent at 1:14-16.) In the Detailed Description of the specification, the patent uses the term "broadcast" and "connectionless" interchangeably, and seeks to "ensure that all of the nodes receive the message." (Id. at 2:14-20.)

After reviewing the prosecution history, the Court finds that, in overcoming the prior art, Lucent distinguished the invention disclosed by the '607 patent from patents directed to routing "multicast" and "limited broadcast" messages. (D.I. 383, App. 10 at LFE067679.) Further, the Court finds that Lucent amended the claim at issue specifically to include the term "broadcast" to qualify the term "message" in order to overcome prior art cited by the Examiner in a rejection notice. (Id. at LFE067657.)

For these reasons, the Court concludes that the term "broadcast message" is construed to mean "a message that is sent to all nodes in the network," and accordingly chooses the dictionary definition proposed by Extreme.

C. "browser"/"browser based subscribers"

Plaintiff, citing to the Dictionary of Computer and Internet Words at page 35, argues that the term "browser" should be construed as "a program that allows you to find and access documents from anywhere on the Internet." (Dkt. 86 at Ex. 1, p.
3). Plaintiff also relies on the Shames Declaration. n3 Defendants argue that the term "browser-based subscribers" should be
construed as "subscribers, as mutually defined by the parties (i.e. "a person who pays for access to a service that allows the
user to access, view, and enter remotely-stored data").", who use a computer on which only web browser software is required to
be installed to access, view, and enter data on HTML forms and documents stored on the database server." (Dkt. 86 at Ex.
2, p. 1).

Defendants cite to the patent specification, the Microsoft Computer Dictionary at pages 62 and 479 and Resonate, 338 F.3d
at 1362 (providing that "consumers typically access the web using client software applications known as web browsers that
run on their personal computers"). As the term "browser" is only used in the context of "browser-based subscribers" in
Claim 1, the Court will construe the entire phrase "browser-based subscriber" while utilizing the parties' agreed construction
of the term "subscriber." A person skilled in the art would understand the phrase "browser-based subscriber" to mean "a
person who pays for access to a service that allows the user to access, view, and enter remotely-stored data utilizing a
software application that locates and displays web pages."4

The plain language of Claim 1 provides that browser-based subscribers are individuals who have secure electronic access
via a modem and an ISP to a home page which provides access to subscriber areas. (229 patent, col. 5, ll. 55-62). The
specification confirms that browser-based subscribers enter the system via a home page and access subscriber areas via a
subscriber log-in and password. (Id., col. 3, ll. 51-57). A home page, as defined, is an "entry page" of a website.

In contrast, the plain language of Claim 4, which addresses the direct access system, provides that direct access subscribers
can access a direct access server (Citrix (R)), rather than a home page and subscriber areas, via a modem and ISP. (Id., col.
6, ll. 33-36); see Phillips, 415 F.3d at 1314 (other claims of patent in question, even if unasserted, can be valuable sources
when determining meaning of a claim term"). The plain language of the claims make clear that the difference between the
browser-based subscriber and the direct access subscriber is what is utilized in order to gain access to the desired data and
forms. The browser-based subscriber utilizes an internet service provider and a web site while the direct access subscribers
utilize an internet service provider and Citrix (R).

The specification describes the type of computer used by browser-based subscribers. Defendants correctly note that the
browser-based system is depicted in Figure 1 of the specification. (See Dkt. 68 at p. 4). "Browser-based subscriber 12
utilizes a single PC-type computer which operates on Windows software. This browser-based subscriber 12 gains access to
the system 11 via modem 14 and an internet service provider (ISP) 16. A local network of browser-based subscribers 20
connected to a hub 22 may also gain access to this system 11 via a modem 24 and ISP 26." (Id., col. 3, ll. 45-50).

In contrast to browser-based subscribers who utilize a PC-type computer operating on Windows software, direct access
subscribers who do not necessarily have "state-of-the-art" computer terminals operating on Windows access the same high
speed database and query system by connecting via an ISP to a Citrix (R) type server. (Id., col. 4, ll. 27-37). As noted by
Defendants, the specification provides with respect to browser-based subscribers that "no new software is required to be
installed, no new hardware is required to be purchased and connection is made at normal modem speed." (Id., col. 2, ll.
38-41). Defendants therefore argue for a construction that includes reference to a "computer on which only web browser
software is required to be installed."

While Defendants' proposed construction attempts to encompass the type of computer utilized by browser-based subscribers
described in the specification, the Court finds that, based on the plain language of the claims, the construction should focus
on what browser-based subscribers utilize in order to gain access to the information sought rather than on the type of
computer used. While Plaintiff's definition focuses on the program utilized, Plaintiff's dictionary definition of browser as a
program "that allows you to find and access documents from anywhere on the Internet" is inconsistent with the claim.

The browser-based subscribers access documents through secured subscriber areas rather than from "anywhere on the
internet”. Webopedia defines "browser" as "a software application used to locate and display web pages." n4 This definition is consistent with the plain language of the claim which provides that browser-based subscribers utilize the web. Accordingly, the Court declines to adopt either parties' construction of the term "browser" and construes the phrase "browser-based subscriber" to mean "a person who pays for access to a service that allows the user to access, view, and enter remotely-stored data utilizing a software application that locates and displays web pages."

440

1. "Brush Data"

The second element of claim 64 recites the step of "providing brush data comprising pixel values for pixels in a patch in which the pixel values rise at least over a selected distance inwardly from the periphery of the patch."

Adobe contends 1) that "brush data" consists of data describing the size and shape of the brush, as well as a weight and a color, or its gray-scale equivalent, intensity, for every pixel contained in the brush, and 2) that such data is "pre-defined" in the sense that it is defined before the user begins a brush stroke and cannot be modified during the stroke.

Although there does not appear to be any dispute as to whether "brush data" consists of data describing the size and shape of the brush, as well as a weight for each pixel in the brush, the issue of whether "brush data" includes data describing a color or an intensity for each pixel in the brush is hotly contested. Adobe argues that if brush data were not to include color or intensity then claim 64 would not recite a painting process at all. At trial, Mr. Taylor, Quantel's expert witness, purported to describe how the claimed invention can paint without color. Referring to Figure 8, reproduced below, Mr. Taylor testified that if the wire transmitting pen intensity data to the processor (20) were severed "so there is no pen intensity fed in, in other words, that goes to zero," then a user will draw a "perfectly anti-aliased" black line with the stylus. See Tr. at 225.

[SEE Fig.8. IN ORIGINAL]

As Adobe points out, however, cutting that wire is the equivalent of choosing "black" as a color or intensity because pen intensity will effectively be set at zero, as Mr. Taylor testified. Thus, it would appear that the image creation process recited in claim 64 may be carried out only if color or intensity data is provided to the processor. Accordingly, the court concludes that "brush data" necessarily includes data describing a color or intensity for every pixel in the brush.

In support of its contention that "brush data" is pre-defined, Adobe relies on a disclosure in the specification showing the use of read-only memories for storing color values and weights for each pixel in the selected brush. See col. 4, lines 41-50; col. 5, lines 19-21. According to Adobe, if such data is stored in read-only memories, by definition it cannot be modified during a stroke because data cannot be written into the memories. Adobe also points out that the specification explicitly provides that if random-access memories are substituted for the read-only memories, they are used just like the read-only memories until a new color or shape is selected. See col. 9, lines 36-43.

The disclosures upon which Adobe relies, however, appear in the specification's description of the preferred embodiment of the invention of the '755 patent. The use of read-only memories to store color values and weights for each pixel in a selected brush is represented in Figure 5. The specification expressly notes that Figure 5 is only "one embodiment of the system of the present invention." See col.2, lines 63-64. The use of random-access memories in place of the read-only memories is represented in Figure 11. The specification states that Figure 11 "shows an expanded arrangement capable of providing full colour processing." See col.3, lines 7-8. Adobe thus impermissibly attempts to limit claim 64 to specific examples in the specification. Because Adobe does not identify any other evidence in support of reading the limitation it proposes into claim 64, the court concludes that "brush data" is not necessarily "pre-defined."
S. buffer terms -- "memory means comprising a buffer to buffer data to be transferred between the data transmit/receive
device and the host device" and "a data buffer for permitting independence in terms of time of the data transmit/receive
device attachable to the second connecting device from the host device attachable to the first connecting device"

Dependent Claim Three of the '399 Patent provides, "[a]n interface device according to claim 1, wherein the memory means
comprises a buffer to buffer data 19 to be transferred between the data transmit/receive device and the host device." '399
accordance with claim 1 wherein the memory has a data buffer for permitting independence in terms of time of the data
transmit/receive device attachable to the second connecting device from the host device attachable to the first connecting

Footnotes

19 The parties agree that "a buffer to buffer data" means a buffer to accomplish the task of buffering. Tr. 3:64 (Papst &
CMs)

The Camera Manufacturers define "a buffer to buffer data" and "a data buffer" as volatile memory used to temporarily store
data to compensate for differences between the rate in the flow of data between the data transmit/receive device and the host
device. Papst proposes that "memory means comprising a buffer" is memory adapted to store the data gathered by the
transmit/receive device until it is transferred to the computer, thus allowing time independence in terms of when the data is
acquired and when the data is later transferred to a host computer.

Under Papst's construction, the data could be stored indefinitely. In essence, Papst asserts that a buffer can be temporary or
semi-permanent memory; it could be non-volatile EEPROM 20 memory. Tr. 3:70. This definition would make the term
"buffer" indistinguishable from the term "memory" in Claim One of the Patents, giving Claim Three of the '399 Patent and
Claim Sixteen of the '449 Patent the same scope as Claim One -- a violation of the doctrine of claim differentiation. As
explained previously, a dependent claim references a prior claim and specifies a further limitation. See 35 U.S.C. § 112. The
presence of a dependent claim creates a presumption that the limitation set forth in the dependent claim is not present in the
independent claim. See Phillips, 415 F.3d at 1315. 21

20 EEPROM is electrically erasable programable 20 read only memory.

21 Papst asserts vaguely that the claim differentiation doctrine is not violated because Claim Three "further defines
memory." Papst's Reply at 33. Because Papst does not explain how it further defines memory, the Court does not credit this
vague assertion.

The ordinary meaning of the term "buffer" is a "temporary memory for data, normally used to accommodate the difference
(attached to CMs' Markman Br. as Ex. O). Thus, a buffer is temporary. See id. (a buffer is "temporary memory" used
"during transfer."). A buffer is used to synchronize the transfer of data between two devices to accommodate the difference
in the rate at which one device can transfer data and the other can receive the data.

[Buffering is a] programming technique used to compensate for the slow and possibly erratic rate at which a peripheral
device produces or consumes data. If the device communicates directly with the program, the program is constrained to run
in synchronism with the device; buffering allows program and device to operate independently. Consider a program sending
output to a slow device. A memory area (the buffer) is set aside for communication: the program places data in the buffer at
its own rate, while the device takes data from the buffer at its own rate. Although the device may be slow, the program does not have to stop unless the buffer fills up; at the same time the device runs at full speed unless the buffer empties.

Id.; see also The IEEE Standard Dictionary of Electrical and Electronic Terms 113 (6th ed. 1996) (attached to Papst's Reply as Ex. F, corrected copy filed at Dkt. # 270) (a buffer is "[a] device in which data are stored temporarily, in the course of transmission from one point to another; used to compensate for a difference in the flow of data, or time of occurrence of events, when transmitting data from one device to another").

The buffer is described in the specification: "the memory means can have an additional buffer for purposes of synchronizing data transfer from the data transmit/receive device to the interface device and data transfer from the interface device to the host device. Preferably, the buffer is implemented as a fast random access memory or RAM buffer." '399 Patent, col. 7:26-31; '449 Patent, col. 6:26-31; see also '399 Patent, col. 10:17-20 (under the preferred embodiment a "random access memory . . . serves as a data buffer to achieve independence in terms of time of the output line 16 from the output lines 11a, 11b, and 11c to the data transmit receive device and to the host device respectively"); '449 Patent, col. 9:17-20 (same). The buffer in the interface device is used in the way ordinary buffers are -- for "synchronizing data transfer from the data transmit/receive device to the interface device 10 and data transfer form the interface device 10 to the host device." '399 Patent, col. 7:26-29; '449 Patent, col. 6:27-29.

Papst points out that the specification explains that a "buffer can be implemented in the memory means 14 to permit independence in terms of time." '399 Patent, col. 9:8-12; '449 Patent, col. 8:8-12. But this statement must be read in context. It comes from a description of a preferred embodiment of the invention, specifically a buffer implemented by a random access memory. The specification describes an ongoing process of data transfer, not the storage of data separated by days, weeks, or months from the time of its transfer as Papst suggests.

The court construes "a buffer" (for buffering data) and "a data buffer" as "memory used to store data temporarily to compensate for differences between the rate in the flow of data between the data transmit/receive device and the host device."

442

(5) buffer, first-in-first-out buffer

The dispute with regards to these terms is whether "buffer" is a device or circuitry. In light of the intrinsic evidence, the court defines "buffer" as "temporary storage circuitry."

The court gives "first-in-first-out buffer" its plain and ordinary meaning in light of the above definition.

443

1. "buffer"

<table>
<thead>
<tr>
<th>NICE's Construction</th>
<th>Witness's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Memory used for temporary storage of data.</td>
<td>Device in communication with the digital audio tape and the random access storage device that temporarily stores data.</td>
</tr>
</tbody>
</table>

The parties dispute the meaning of the term "buffer," as used in claim 1 of the '371 patent. Their respective proposed constructions are listed above. NICE contends that Witness's construction unnecessarily reads a limitation into the claim as to how the buffer relates to other components of the claimed method and that this relationship can be determined from the plain meaning of the claim language. Witness contends that the specification confirms that the buffer is in communication with the random access storage ("RAS") and digital audio tape ("DAT"), citing:

Apparatus and method have been devised wherein information can be retrieved from a digital audio logger as the logger continues to receive audio. The audio logger is provided with a buffer that receives audio in real time and temporarily stores
the same in the buffer. A digital audio tape (DAT) and a random access storage (RAS) device are in communication with the buffer to simultaneously receive data when the buffer down loads data.

(‘371 Pat., col. 1:45-53 (emphasis added).)

After reviewing the claim language and the specification, the Court concludes that, in this context, a buffer is, as Witness's contends, a "device in communication with the digital audio tape and the random access storage device that temporarily stores data." The language of both the claim and the specification support a construction of buffer as a device in communication with the RAS and DAT.

444

(b) Claim No. 2 (Dependent Claim) -- Disputed Limitations

Claim 2, which is a dependent claim, recites the computer system as defined in Claim 1 and then adds a new element: a "message buffer," which is connected to the switch. The buffer works as follows: if the switch has already established a path for a message to run from Input Circuit A to Output Circuit B, and Input Circuit C receives a message that is also addressed to Output Circuit B, then the switch will establish a path from Input Circuit C to the message buffer. The second message in line will proceed to the buffer, which the parties agree is a place where messages wait until their path is clear. It is my understanding that the head of the message will proceed out of the buffer toward the designated output circuit as soon as that circuit is free to receive it; the head need not wait until the entire message has been received at the buffer.

This language presents no interpretive problems. IBM argues that the "message buffer" must have sufficient capacity to store an entire message, claiming that it would be a misnomer to call anything smaller a "message buffer." This is hardly a persuasive argument. While it might be desirable to have an amply-sized buffer, there is absolutely nothing in the claim language that requires it.

445

1. "buffer" or "buffer memory"

These terms are located in several claims in both the '872 patent and the '094 patent. Doc # 81 at 13-14. The parties dispute whether these terms should be ascribed their ordinary meaning. 3Com proposes the dictionary-derived construction "a memory for temporary storage of data." Id at 13, 19. Realtek proposes the construction "a memory that (1) stores frame data such that the frame data can be retrieved independently of the order in which the frame data were stored and the frame data can always be retained and reused; and (2) is not a first-in-first-out (FIFO) system." Id at 13-14, 19. The primary issue before the court is whether the specification rebuts the presumption that the terms should be ascribed their ordinary meaning.

Realtek contends that the patentee disclaimed FIFO-based systems in the specification. Specifically, Realtek argues that the specification "explains the shortcomings and problems of prior FIFO-based systems." Doc # 333 at 12. An inventor "may use the specification [intentionally] to [] disclaim or disavow the broad scope of a claim. However, this intention must be clear." Conoco, Inc v Energy & Environmental Intern, L C, 460 F.3d 1349, 1357 (Fed Cir 2006)(internal citations omitted). While the specification does highlight the shortcomings of FIFO-based systems, the specification also lauds the "communications throughput available from the simpler FIFO-based systems." '872 patent at 2:8-10. The specification's mix of praise and criticism is not a "clear disavowal" of FIFO technology.

Realtek further argues that prosecution history supports its proposed construction. Doc # 333 (03-2177) at 15-16. Realtek relies on a statement differentiating the Firoozmand reference from the claimed invention. 3Com stated that the claimed application described a "much more sophisticated control environment than that required by the FDDI system of Firoozmand." Doc # 339 (Gutman decl) (03-2177) Ex F at 5. Realtek argues that this statement distinguishes the claimed invention from a "FIFO-based scheme." Doc # 333 (03-2177) at 16. 3Com argues that this statement, read in context,
describes a "CSMA/CD network (such as Ethernet) as more sophisticated than a token ring network" and does not address "the relative sophistication of a FIFO buffer." Doc # 340 (03-2177) at 8. The paragraph in question discusses details related to CSMA/CD networks such as frame transmission, collisions and backoff. Doc # 339 (Gutman decl) (03-2177) Ex F at 5. Viewed in context, the court finds that this statement is unrelated to buffer or buffer memory and has no bearing on construction of the terms "buffer" or "buffer memory."

In addition, Realtek points to the "Vulcan" document the patentee used to "swear behind" the Firoozmand reference. Doc # 333 (03-2177) at 16-17. Realtek concedes that the Vulcan document "shows that the inventors once contemplated using the prior FIFO-based technique of transmitting early a packet once the amount of data in [FIFO] reached a threshold." Doc # 333 (03-2177) at 17. According to Realtek, "understanding that the FIFO disclosed in the Firoozmand and Vulcan prior art could not retain and reuse data frames, the inventors replaced the FIFO with a transmit buffer in order to avoid the major disadvantage of a FIFO." Id. As 3Com points out, however, the purpose of "swearing behind" was to show an earlier invention date. Doc # 340 (03-2177) at 8. If the Vulcan document showed a different invention than the claimed invention, the Vulcan document could not be used to prove an earlier date of invention. Rather than disclaiming FIFO-based devices, the prosecution history confirms that use of FIFO buffers in the claimed invention was specifically contemplated by the patentee.

Realtek argues that construing the claims as 3Com suggests would render the claims invalid as reading on prior art or being unsupported by written description. Doc # 333 (03-2177) at 14. Realtek further argues that "[o]ne of the well-established maxims of claim construction is that the claims should not be so broadly interpreted as to read on prior art." Id. But the court only applies this claim construction maxim if the disputed claim term is ambiguous.

While we have acknowledged the maxim that claims should be construed to preserve their validity, we have not applied that principle broadly, and we have certainly not endorsed a regime in which validity analysis is a regular component of claim construction. Instead, we have limited the maxim to cases in which "the court concludes, after applying all the available tools of claim construction, that the claim is still ambiguous."

Phillips, 415 F.3d at 1327, quoting Liebel-Flarsheim, 358 F.3d at 911. The claim terms at issue are not ambiguous. Both the plain meaning and the prosecution history support the construction that 3Com proposes.

For the reasons stated above, the court adopts 3Com's proposed construction "a memory for temporary storage of data."

446

1. "a buffer, coupled to the first port, storing received packets"

The parties dispute whether the '884 patent is limited to embodiments with a buffer large enough to store more than one packet at a time. 3Com offers the construction "a temporary storage device connected to the first port for received packets." Doc # 81 (05-0098) at 37. D-Link propounds the construction "a temporary storage device connected to the first port that is of sufficient size to store a plurality of received packets." Id at 37-38. Realtek does not propose a specific construction. Id.

D-Link advances several considerations to support its construction. First, D-Link makes much of the fact that the '884 specification usually refers to packets in the plural. See, for example, '884 patent, 1:66-2:5 ("In particular, the present invention provides an interface that comprises the first port on which incoming data is received at the data transfer rate of the network, a buffer coupled to the port that stores received packets, and a second port coupled with the buffer through which transfer of packets to the host is executed." (emphasis added)). The specification's repeated references to "packets" in the plural are simply too tenuous a basis for limiting the scope of claim one. Whether this usage reflects the patentee's intent to claim only embodiments with buffers large enough to store multiple packets at once is, at the very best, ambiguous. For, as 3Com posits, it could be that "packets' refers to the obvious fact that multiple packets will go through the claimed device, not to the capacity of a particular component therein to hold more than one packet at once." Doc # 88 at 6.

Accordingly, the court adopts "a temporary storage device connected to the first port for received packets."

GO BACK
3. "buffer overflow/buffer overload"

The second limitation of claim 1 of the '499 patent requires "detecting whether buffer overflow is threatened by the storage of further cells arriving for transmission on said virtual path." The term "buffer overflow" is used in claim 1, and the term "buffer overload" is used in various dependent claims. The parties agree that the terms mean the same thing. The plaintiff argues that these terms are common and therefore there is no need to construe them. The defendants propose that the term means "exceeding the maximum capacity of the buffer for that VPC." The court has previously rejected the defendants' argument that the buffer be assigned to a particular VPC. The court agrees with the plaintiff that the terms "buffer overflow" and "buffer overload" need no additional construction, in light of the agreed construction of "buffer."

VII. '379 patent

Like the '641 patent, the '379 patent claims a system and method for ensuring that the most current data, as opposed to "stale" data, is retrieved from memory. The claimed invention relates to how a memory controller coordinates requests to read data from the memory and requests to write data to the memory. Generally, when a read request is asserted that corresponds to a buffered write request, the write request must go first to ensure that what is read from memory is the most current data. The invention disclosed in the '379 patent does this by comparing the address of each read request to the buffered write requests, noting any matches, halting read execution when there is a match, and executing the buffered write requests.

LGE contends that the trial court erred in construing system claims 1 and 23 as requiring all write requests to be executed after a match is detected, as opposed to executing any number of write requests until the write request corresponding to the matching read request is executed. We agree. The claim language does not require all write requests to be executed after a match is detected. Moreover, claim 2, which depends from claim 1, expressly requires the execution of all write requests, as does independent method claim 7. See Phillips, 415 F.3d at 1314 (recognizing the utility of claim differentiation). In addition, the claim limitation at issue is written in means-plus function-claim language ("means for . . . causing an execution of buffered write requests"). Because the recited function is clear on its face, it was improper to incorporate the additional functional limitation of executing "all" buffered write requests. Smiths Indus. Med. Sys., Inc. v. Vital Signs, Inc., 183 F.3d 1347, 1357 (Fed. Cir. 1999); see also Wenger Mfg., Inc. v. Coating Mach. Sys., Inc., 239 F.3d 1225, 1233 (Fed. Cir. 2001) ("[A] court may not import functional limitations that are not recited in the claim . . . .").

13. "Building at least one long-term and at least one short-term statistical profile from at least one measure of the network packets": n13 Generating at least two separate data structures, one a statistical description representative of historical network activity, and one a statistical description of recent network activity, where the statistical descriptions are based on at least one measure of the network packets and are generated through the use of statistical analysis; i.e., something more than simply collecting and retrieving data.

n13 338 patent, multiple claims.

End Footnotes
The specification incorporates by reference a specific statistical analysis technique disclosed in "A. Valdes and D. Anderson, 'Statistical Methods for Computer Usage Anomaly Detection Using NIDES', Proceedings of the Third International Workshop on Rough Sets and Soft Computing, January 1995." ('338 patent, col. 5, 11. 41-49) Although the court acknowledges that the specification also indicates that the "profile engine can use a wide range of multivariate statistical measures to profile network activity indicated by an event stream" ('338 patent, col. 5, 11. 37-39), nevertheless, the court concludes that the specification and referenced article require that some manipulation of the data take place; i.e., generating a "statistical" profile means more than collecting and retrieving data.

B. Where is the "charge sink means" located?

Claim 1 describes a charge sink means "buried within said semi-conductor material." It also states that the charge sink means must extend laterally from the contact toward the light sensing element "while beneath the surface of said semiconductor material." The parties interpret the term "buried within" differently.

Before addressing the meaning of "buried within," this court must first determine the meaning of "said semiconductor material." "Said" refers to element a of claim 1. Element a specifies a light sensing element comprising "a first region of semiconductor material overlaid by a first electrode . . . ." The expert witnesses testified that this first region would extend only a few microns below the top surface of the element. The term "said semiconductor material," however, is not limited to a few microns near the surface of the semiconductor substrate. 2

2 Loral did not suggest limiting "said semiconductor material" to a top portion of the substrate such as that depicted by 12 on Figure 1 until this court began to ask questions which suggested that interpretation. When this court recalled Dr. Wen to inquire further about this interpretation, Dr. Wen accepted this interpretation with great reticence and equivocation. After all, the number 12 on Figure 1 is nowhere identified as the region near the surface of the semiconductor material sensitive to light. Moreover, the number 12 region would be much thicker than the "first region of semiconductor material overlaid by a first electrode . . . ." The expert witnesses testified that this first region would extend only a few microns below the top surface of the element. The term "said semiconductor material," however, is not limited to a few microns near the surface of the semiconductor substrate.

The specification shows that the semiconductor material referred to in element d comprises the entire substrate. Column 3, lines 17, read:

The N type impurity forming region 14 will diffuse into layer 12 during and following the deposit of layer 12 over substrate 11. Therefore, region 14 is located near the surface between substrate 11 and layer 12, and not necessarily located solely within substrate 11; that is, region 14 [the charge sink region] is buried within the semiconductor material.

(emphasis added). While describing only one embodiment of the invention, this passage clarifies that "buried within" uses the entire substrate as its reference and not simply a top layer. "Said semiconductor material," as clarified by the specification, refers to the "semiconductor material" serving as the substrate for the light sensing element and the rest of the invention. Consequently, the words "said semiconductor material" define the entire semiconductor substrate below the top surface of the device.

With that understanding of semiconductor material, the claim language clearly defines a charge sink means completely surrounded by semiconductor material. The claim describes a charge sink means "buried," "within," and "beneath the surface of said semiconductor material." Standing alone, the single term "buried" or the single term "within" might describe something only partially submerged and still in contact with the surface of the substrate. The use of "within" in conjunction with "buried," however, leaves no question that this claim describes structure completely surrounded by semiconductor material. The addition of "beneath the surface" further clarifies that the charge sink means is completely submerged and does not contact any surface of the device.
The specification further underscores the meaning of the words of the claim. The passage in column 3, quoted above, describes the charge sink means, 14, as sandwiched between two layers of semiconductor material, 11 and 12 in the Figure. Thus, "buried within" means what it says: semiconductor material completely surrounds the charge sink means. In other words, the significance of "buried within" together with "beneath the surface" requires a charge sink means surrounded by and submerged within the semiconductor material. Indeed, figure 1 of the '485 patent depicts the charge sink means in precisely this location.

The prosecution history also supports this meaning. The original claim read: "charge sink means buried within said semiconductor material and disposed in proximity to said light sensing element for receiving excess charge accumulated in said light sensing element." The examiner rejected this claim as obvious over references showing charge drains in contact with the surface of the semiconductor material. Evidently the examiner overlooked the full significance of the terms "buried within" by noting that the claims did not recite the location of the charge region "other [than] that it be 'within the semiconductor material.'" The examiner anticipated, however, the problem of identifying the location of the charge sink means.

In response to the examiner's concern, the applicant amended the claim to read: "charge sink means buried within said semiconductor material and disposed for receiving excess charge accumulated in said light sensing element, said charge sink means being located beneath and not in contact with the surface of said semiconductor material." The examiner made no further rejections on this point. In other words, the inventor amended the claim to add "beneath and not in contact with the surface" to clarify the location of the charge sink means.

The examiner's remarks in the initial rejection suggest he did not focus on the term "buried." Instead, the examiner read original claim 1 to cover surface drains. To address this rejection, the inventor narrowed and clarified the meaning of the claim. The inventor's use of the words "buried within" together with "beneath the surface" show an intent to depict the charge sink region, as shown in Figure 1, surrounded completely by semiconductor material and not in contact with any surface of the device.

Finally, the testimony of Dr. Bower instructs further on this point. He explained that one skilled in the art would read the words "buried within" to describe a structure completely surrounded by material. In fact, while recognizing "buried within" is not a term of art, an artisan in 1973 would read those words and think of a "buried layer." A buried layer, Dr. Bower explained, is a structure associated with bipolar technology that is completely surrounded by material. Transcript at 138-40.

The disputed portion of claim 1 of the '485 patent reads:

d. charge sink means having a contact for applying a bias thereto buried within said semiconductor material and disposed for receiving excess charge accumulated in said light sensing element, said charge sink means extending laterally from said contact toward said light sensing element while beneath the surface of said semiconductor material.

(Emphasis added). The doctrine of equivalents requires that the accused device have an identical or equivalent element for each limitation contained in the claim - sometimes known as the "all elements" rule. See Warner-Jenkinson 520 U.S. at 18, 29 ("Each element contained in a patent claim is deemed material to defining the scope of the patented invention, and thus the doctrine of equivalents must be applied to individual elements of the claim, not to the invention as a whole. It is important to ensure that the application of the doctrine, even as to an individual element, is not allowed such broad play as to effectively eliminate that element in its entirety."). See also Dolly, Inc. v. Spalding & Evenflo Cos., 16 F.3d 394, 399, 29 U.S.P.Q.2D (BNA) 1767, 1769 (Fed. Cir. 1994); Perkin-Elmer Corp. v. Westinghouse Elec. Corp., 822 F.2d 1528, 1532-33, 3 U.S.P.Q.2D (BNA) 1321, 1324-25 (Fed. Cir. 1987); Pennwalt Corp. v. Durand-Wayland, Inc., 833 F.2d 931, 935, 4 U.S.P.Q.2D (BNA) 1737, 1739-40 (Fed. Cir. 1987) (in banc).

Claim 1 of the '485 patent and the specification define the charge sink means both as to structure and location. The specification calls for a distinct region of semiconductor material doped opposite to the surrounding semiconductor.
material. The claim language locates this structure as "buried within the semiconductor material" and provides that it "extends laterally [i.e., parallel to the surface] from said contact toward said light sensing element while beneath the surface of the semiconductor material." The district court properly construed the claim to mean:

"Claim 1 of the '485 patent defines the charge sink means as a distinct structure of semiconductor material doped opposite from its surrounding semiconductor material. The claim also locates that structure within the semiconductor material. According to the claim, the charge sink means must extend parallel to the top surface of the semiconductor and perpendicular to a contact toward a light sensing element."

Loral, 931 F. Supp. at 1023.

The court also noted that Fig. 1 of the '485 patent reproduced above, "provides excellent depiction of the location of the charge sink structure." Id. at 1019. The prosecution of the '485 patent fully supports the district court's claim interpretation and indicates that only a narrow range of equivalents can be afforded the charge sink location and structure.

B. "Burst mode," "burst mode operation," "burst mode read operation" (claims 1-14, 20, 22-23)

"Burst mode" memory processing was prior art to the '990 patent. 1:8-10. Burst mode processing improved on serial processing, in which data from several memory locations had to be transmitted one location at a time. Decl. of Andrew Wolfe in Supp. of AMD Br. ("Wolfe Decl.") P 31. In contrast, burst mode made memory processing faster by allowing data from several memory locations to be transferred at the same time. Id. P 30.

Footnotes:

4 "Memory locations" are cells that store data.
5 AMD construes "burst mode operation and "burst mode read operation" as "a serial transfer in which the contents of a plurality of locations are provided in response to the address of one location." Samsung argues that these terms should receive the same construction as "burst mode."

6 An "address" is an identifier for a memory location.

The Court agrees with Samsung that in the context of the '990 patent, "burst mode" provides consecutive memory locations with consecutive addresses. First, this limitation is provided by the specification. In the "background of invention" section, the specification states, "When a memory is read sequentially (that is, consecutive reads access memory locations at consecutive addresses), the memory access can be made faster by reading from the array several consecutive locations simultaneously. Such a 'burst mode' access is provided by memory 202 of Fig. 2." 1:36-41 (emphasis added). The
specification explains why burst mode allows for faster memory performance: "Since only one address decoding operation and only one memory array access are performed to read four consecutive memory locations, the memory reads are sped up." 1:47-51 (emphasis added). The specification also explains that in some embodiments, the invention improves burst mode processing by allowing the "burst mode read" to "start at any location and [to] . . . continue for any number of locations." 1:58-61. This "boundaryless burst mode access" allows "any number of locations, not only groups of four locations, [to be] . . . read consecutively in burst mode. Sequential memory access is consequently quite fast." 1:61-64.

Second, Samsung's proposed definition is taken from a brief filed by AMD when it appealed the Patent Trademark Office's ("PTO") initial rejection of the '990 patent. See Decl. of Aaron R. Fahrenkrog in Supp. of AMD Br. ("Fahrenkrog Decl."), ex. G (Jan. 26, 1995 Office Action). In the "summary of the invention" section of its appellate brief, AMD wrote, "Burst mode access is a sequential access in which the memory receives the address of one memory location and provides the contents of a plurality of consecutive memory locations." See Fahrenkrog Decl., ex. I (Sept. 27, 2005 Br.) at 2.

AMD points out that its construction of "burst mode" is taken from AMD's request for reconsideration, filed on April 27, 1995. In this filing, AMD responded to the PTO's conclusion that claim 2 merely recited a serial transfer. AMD attempted to distinguish the "burst mode" in claim 2 from the prior art as follows: "A burst mode transfer as claimed in claim 2 is not any serial transfer but a serial transfer in which the contents of a plurality of locations are provided in response to the address of one location." Fahrenkrog Decl., ex. H (Apr. 27, 1995 Amendment after Final Office Action) at 4. AMD is correct that in this document, it did not specify that the "plurality of locations" were consecutive. This omission is not dispositive, however, because there is no evidence that AMD was attempting to distinguish the invention on this basis. Instead, AMD focused on the innovation of transferring data in different rows having different row addresses. See id. (The prior art "does not teach or suggest transferring data in different rows having different row addresses in response to the same address . . . as recited in Claim 2").

Accordingly, the Court adopts Samsung's construction of "burst mode."
array drivers and output as signal 51. The corresponding portion of the specification explains that the phased burst signals are signals 50, not 51. See '234 patent, col. 8, ll. 62-66. ("In an exemplary system, each phase array driver 100 receives two phased burst signals 50 which are 180 [degree] out of phase and generates two power regulating signals 51 which are 180 [degree] out of phase.")(emphasis added). Consequently, after considering the parties' arguments and the relevant portions of the specification, the court defines "burst mode signals" to mean "low-frequency PWM signals which regulate the power to a load based on the pulse width of the PWM signals."

GO BACK

454

Burst state

The Court modifies Plaintiffs' proposed construction and construes "burst state" as "the camera takes a pre-determined number of pictures in rapid succession in response to one or more signals from a motion detector." The claim itself teaches that when the camera is in the burst state, a signal is sent to the camera "to cause the camera mechanism to take a predetermined number of pictures in rapid succession." Claim 17, col. 8:62-64. The specification similarly teaches that when the camera is placed in the burst state, "when the controller 301 receives a signal from motion detector 106, the controller causes a series of exposures to be taken one after another in rapid succession." Col. 4:29-32.

Defendants' proposed construction, "a user-selected mode of operation of the motion detector camera in which two or more photographs are taken in three seconds or less in response to a single signal from the motion detector," interjects limitations that are not supported in the claims or specification. First, Defendants would require the user to select the burst state mode. Defendants contend that user selection is the only manner the specification discloses for placing the motion detector camera into the burst state. Defendants argue that use of the word "selectively" within the claim indicates user input or selection is required for entry into a burst state. Defendants' limitation strains the claim language and imports limitations from the preferred embodiment. The claimed method includes the step "selectively placing the motion detector camera into one or more of a burst state, a pause state, and a test state," which the Court will also construe. The claim language uses the passive tense and does not limit who or what can selectively place the camera into the particular states. The specification also teaches that the camera can be programmed to automatically go into a pause state. Col. 4:35-44. During the hearing, Defendants argued, "The second step is an active step of selectively placing the camera into one of those programmed steps [sic], either by leaving it alone in the default it came in or by changing the parameters. That is the selective part of it." Transcript (Docket No. 94) 28:10-14. Thus, Defendants concede that someone other than the user may make the initial selection of camera state.

Second, Defendants would require that two or more photographs are taken in three seconds or less. Defendants argue "in rapid succession" requires a more precise definition. Defendants base their three-second limitation on other prior art and the speed at which they approximate an animal "at game trail speed [could] traverse the detection zone of the motion detector camera." See Defendants' Response to Plaintiffs' Claim Construction Brief (Docket No. 74) at 17. The patent does not limit "in rapid succession" any more precisely. Defendants do not argue that "in rapid succession" is a term of art requiring explanation for the jury. It is a phrase potential jurors will be familiar with, and the Court will not place additional limitations on the claim language based on such weak support.

GO BACK

455

B. "burst time period"

The term "burst time period" and the related phrase, "having an associated time period," appear in various forms in the '995 Patent, the '932 Patent, and the '839 Patent claims. Claim 1 of the '839 Patent contains representative usages:

1. A method for handling audio/video source information, the method comprising:
   receiving audio/video source information;
compressing the received audio/video source information into a time compressed representation thereof having an associated burst time period that is shorter than a time period associated with a real time representation of the received audio/video source information;

storing said time compressed representation of the received audio/video source information; and

transmitting, in said burst time period, the stored time compressed representation of the received audio/video source information to a selected destination

The parties have agreed to construe all of the variant phrases together. The construction of "burst time period" involves the parties' dispute of whether the "burst time period" is limited to a transmission time period that is of definite duration and known at the time of compression.

Burst points to the language of approximation used in the patent specification to describe transmission rates, on which the duration of the transmission period is based. See '839 Patent at 8:15-18 (referring to fiber optic bandwidth as "about 200 Megabytes/second"). However, this language does not preclude a construction that would require a fixed time period. TCM would permit a known transmission time period even with fiber optic cable. Apple reads "burst time period" in the context of the phrases "having an associated burst time period" and "said burst [transmission] time period" to require a known transmission time. See, e.g., '995 Patent, claim 1 (having formulation); '705 Patent, claim 1 (said formulation). According to Apple, the claim language further shows that the "associated burst time period" is created and associated with the time compressed representation during compression and before transmission. If the time period is approximate or not known, then the representation cannot "have" an associated time period during compression nor can one be "associated" with the representation during compression.

The words "associated" and "said" time period do not necessarily suggest a fixed period of known duration. Rather, these words are used in a way to permit comparison between the transmission time and the playback time. See, e.g., '995 Patent, claim 1 (referring to the time compressed representation "having an associated time period that is shorter than a time period associated with a real time representation of said audio/video source information."). Indeed, the specification indicates that transmission times will be approximate. '839 Patent at 12:4-11 ("Thus, the invention can be used to receive and transmit programs via microwaves at an accelerated rate similar to and at least as fast as, the transmission and reception of programs over optical fibers.")

TCM permits a transmission period to be known and associated with the representation during compression; data compression does not. This is consistent with the court's construction of "time compressed representation" as not requiring TCM. Therefore, the "burst time period" does not require a definite time period known at the time of compression.

Burst's construction of burst time period as a "transmission time period shorter than the time period associated with a real time representation" is consistent with the court's construction of "time compressed representation." The court accordingly adopts Burst's construction.

456

C. Bus

The district court construed "bus" to mean "a multiplexed set of signal lines used to transmit address, data and control information." In its Markman opinion, the district court noted Rambus's proposed ordinary meaning of "bus," but held that the patentees acted as their own lexicographer by redefining "bus" to be a multiplexed bus. Multiplexing refers to the sharing of a single set of lines to send multiple types of information. Under the district court's construction, the "bus" carries three types of information: address, data, and control information.

The term "bus" is very common in the electrical arts and has a well-recognized meaning in such arts, namely, a set of signal lines (e.g., copper traces on a circuit board) to which a number of devices are connected, and over which information is
transferred between devices. The New IEEE Standard Dictionary of Electrical and Electronic Terms 141 (5th ed. 1993). The claims generally recite outputting data over a "bus." The claims do not specify that the bus multiplexes address, data, and control information. See '918 patent, col. 26, ll. 19-27. Nothing in the claims compels a definition different from the ordinary meaning of "bus." Before according "bus" this meaning, however, this court must consider the usage and meaning of the term as used in the relevant context of the specification.

In general, most references to "bus" in the specification do not limit the ordinary meaning of this term. Only two references potentially limit the meaning of "bus" in the context of the specification. In the Summary of the Invention, the patentee stated that the "present invention" includes a bus for carrying substantially all address, data, and control information. '918 patent, col. 3, ll. 50-60. The patentee further stated that "the bus carries device-select information without the need for separate device-select lines connected directly to individual devices." n6 Id. In the Detailed Description, the patentee stated:

"The present invention is designed to provide a high speed, multiplexed bus for communication between processing devices and memory devices . . . . The bus carries substantially all address, data and control information needed by devices for communication with other devices on the bus. In many systems using the present invention, the bus carries almost every signal between every device in the entire system. There is no need for separate device-select lines since device-select information for each device on the bus is carried over the bus. There is no need for separate address and data lines because address and data information can be sent over the same lines."

'918 patent, col. 5, ll. 36-46. See also '918 patent, col. 5, ll. 52-53. While clear language characterizing "the present invention" may limit the ordinary meaning of claim terms, see Scimed, 242 F.3d at 1343; Bell Atlantic, 262 F.3d at 1268, such language must be read in context of the entire specification and the prosecution history. Although the above references, taken alone, may suggest some limitation of "bus" to a multiplexing bus, the remainder of the specification and prosecution history shows that Rambus did not clearly disclaim or disavow such claim scope in this case. See Inverness Med. Switz. Gmbh v. Princeton Biomeditech Corp., 309 F.3d 1365, 1372, 64 USPQ2d 1926, 1932 (Fed. Cir. 2002) (statements made during prosecution were not a clear and unambiguous disclaimer of a claim scope). Thus, Rambus did not limit the ordinary meaning of "bus" in the patents-in-suit.

n6 The multiplexed bus eliminates device-select (point-to-point) connections by multiplexing control information with address and data information. This elimination of point-to-point connections is one focus of the multiplexed bus. See '918 patent, col. 2, ll. 12-15 (While some prior art buses multiplexed address and data information, they retained point-to-point connections for control information.); col. 2, ll. 16-19, 26-34, 36-42, and 44-49.

In this case, the prosecution history shows that a multiplexing bus is only one of many inventions disclosed in the '898 application. Although some of Rambus's claimed inventions require a multiplexing bus, multiplexing is not a requirement in all of Rambus's claims. A careful review of the prosecution histories of the patents-in-suit shows that Rambus expressly recited multiplexing in the claim language for claims limiting the bus to the inventive multiplexing bus. For example, original claim 1 of the '898 application recites a "bus including a plurality of bus lines for carrying substantially all address, data and control information needed by said memory device." Other original claims further require that the "bus carry[] device-select information without the need for separate device-select lines connected directly to individual semiconductor devices." This claim language indicates that Rambus did not redefine "bus" in the specification to be a multiplexing bus. Indeed, it is because Rambus viewed "bus" under its ordinary meaning that Rambus specified -- in the claim language -- that the inventive multiplexing bus carries substantially all address, data, and control information and that the bus operates without the need for device-select lines.

Several restriction requirements issued by the PTO also clarify that some of the inventions described in the '898 application did not require the multiplexing bus. The PTO issued an eleven-way restriction requirement during prosecution of the '898 application. Later, during prosecution of U.S. Patent No. 5,841,580 (the grandparent of the '918 patent and the parent of the '263 patent), the PTO issued a two-way restriction, dividing the claims into two distinct groups: a multiplexing bus group (Group I) and a latency invention group (Group II). That two-way restriction stated:
The memory device in Group I does not require the access-time register of Group II, and the semiconductor device in Group II does not require the plurality of conductor [sic] being multiplexed to receive an address as claimed in Group I.

Rambus elected to prosecute the latency claims from Group II in the '580 patent. Therefore, the claims of the '580 patent do not require a multiplexing bus. The claims of the '580 patent, however, do recite a "bus." See '580 patent, col. 24., l. 46. By stating that the latency claims, which recited a "bus," do not require multiplexing, the PTO demonstrated an understanding of "bus" that is not limited to a multiplexing bus.

The specification and prosecution histories, taken in their entirety, convince this court that Rambus did not redefine "bus" to be a multiplexing bus in the patents-in-suit. None of Rambus's statements constitute a clear disclaimer or disavowal of claim scope. In these patents, the term "bus" carries its ordinary meaning as a set of signal lines to which a number of devices are connected, and over which information is transferred between devices.

A. "Bus"

The parties dispute the meaning of "bus" as that term is used throughout the claims of the patents in suit. Rambus argues that "bus" means any "set of signal lines (for example, wires) to which a number of devices are connected, and over which information is transferred between devices." According to Rambus, "the term "bus" is old and very common in the electrical arts" and, in the patents in suit, the term is used in its ordinary and customary sense "as a set of signal lines over which information is transferred." To support the contention that this is the ordinary and customary construction of the term "bus," as used in its patents, Rambus relies not upon intrinsic evidence but upon the extrinsic evidence of the IEEE (Institute of Electrical and Electronics Engineers) Standard Dictionary of Electrical and Electronics Terms, Fourth Ed., IEEE Inc., New York (1988), p. 116, to explain how one skilled in the art would understand the term. The IEEE Dictionary defines a bus as "a set of signal lines used by an interface system, to which a number of devices are connected, over which information is transferred between the devices." Id. 8

Of course, a court cannot use an inconsistent dictionary definition to contradict the meaning derived from the intrinsic evidence, but such definition may be of some assistance to the court in interpreting technical terms. See Vanguard Prods. Corp. v. Parker Hannifin Corp., 234 F.3d 1370, 1372 (Fed. Cir. 2001) ("Although a dictionary definition may not enlarge the scope of a term when the specification and the prosecution history show that the inventor, or recognized usage in the field of the invention, have given the term a limited or specialized meaning, a dictionary is often useful to aid the court in determining the correct meaning to be ascribed to a term as it was used.")

Infineon, on the other hand, contends that "bus" actually has a specialized meaning conferred by the specification of the patents in suit, which describes and explains the bus and its use with the other inventions as the Rambus "multiplexed bus." Before the '898 application was filed in 1990, most buses generally had point-to-point interfaces wherein the CPU would communicate with different memory devices by different and separate lines. Furthermore, within each bus in the prior art, the lines would be dedicated to carrying either data, address, control or device-select information. In the new inventive Rambus bus, a single bus is multiplexed so that the bus lines carry all the address, control, data and device-select information over a single bus. In Infineon's view, the use of the term "bus" throughout the claims is limited to the new inventive bus described in the specification.

1. The Claim Language

The analysis begins by first considering the claim language. Most of the 57 claims at issue use the term "a bus" or "the bus" or "an external bus." None of the claims, however, expressly define the term "bus," nor do they dispositively support
either proposed definition. Rather, the claims generally speak of outputting or inputting data over a bus.

9 The term "bus" is used in claims 1, 2, 6, 8, 16, 18, 19, 20, 24, 33, and 14 of the '918 patent, claims 1, 2, 4, 10, 15, 16, 18, and 25 of the '214 patent, claims 2, 14, 27, and 30 of the '263 patent and claim 26 of the '804 patent. 

Infineon urges the court to consider the language of claim 26 of the '918 patent as illustrative of its view of the term:

26. An integrated circuit device having at least one memory section which includes a plurality of memory cells, wherein
the integrated circuit device outputs data on an external bus synchronously with respect to first and second external clock
signals, the integrated circuit device comprises:

interface circuitry, coupled to the external bus to receive a read request, the interface circuitry includes a plurality of
output drivers, coupled to the external bus, to output data on the external bus in response to the internal clock signal,
synchronously with respect to the first and second external clock signals and in accordance with the value stored in the first
internal register.

'918 patent, Claim 26 (emphasis added). Infineon posits that this claim calls for data to be output onto the bus, and a read
request to be received on the same bus, thus supporting its conclusion that "bus" means a multiplexed bus. 10 While the
language of this single claim somewhat supports Infineon's construction, the specification must reviewed to determine how
the inventors used the term "bus" and whether they intended the term to have a special meaning. See Watts v. XL Sys., Inc.,
232 F.3d 877, 882 (Fed. Cir. 2000) ("One purpose for examining the specification is to determine if the patentee has limited
the scope of the claims"). "Even if [the claims] were clear on their face, [the court] must consult the specification to
determine if the patentee redefined any of those terms." Id. at 883.

10 The testimony of Infineon's expert, Mr. Joseph McAlexander also supports this conclusion. See Markman Hearing, Tr.
pg. 370 l. 13 to pg. 371, l. 19 (explaining that claim 1 of the '918 patent clearly indicates that a read request and output data
are to travel across a single bus).
requested data over the same bus. Each memory device contains only a single bus interface with no other signal pins." '918 patent, col. 4, lines 9-13 (emphasis added). See also '918 patent col. 3, l. 61 through col. 4 l. 1. (the DRAM "is modified to use a wholly bus-based interface rather than the prior art combination of point-of-point and bus-based wiring used with conventional versions of these devices. The new bus includes clock signals, power and multiplexed address, data and control signals").

Throughout the "Detailed Description," the specification repeatedly explains the use of the new multiplexed bus:

The present invention is designed to provide a high speed, multiplexed bus for communication between processing devices and memory devices and to provide devices adapted for use in the bus system.

***

The bus consists of a relatively small number of lines connected in parallel to each device on the bus. The bus carries substantially all address, data and control information needed by devices for communication with other devices on the bus. In many systems using the present invention, the bus carries almost every signal between every device in the entire system. There is no need for separate device-select lines since device-select information for each device on the bus is carried over the bus. There is no need for separate address and data lines because address and data information can be sent over the same lines.

***

Virtually all the signals needed by the computer system can be sent over the bus.

'918 patent, col. 5, ll. 29-45 (emphasis added). The inescapable lesson that emerges from comparing the claims of the patents with the inventors' fulsome textual description of the invention is that the inventions include a new bus and new devices that work with the inventive bus, all to the inventor's stated purpose, which is "to provide a high speed multiplexed bus for communication between processing devices and memory devices and to provide devices adapted for use in the bus system." '918 Patent, col. 5, ll. 29-33 (emphasis added).

Additionally, not only does the specification define "bus" to be a multiplexed bus, but it also sets a background for explaining how the inventive multiplexed bus works with various other features of Rambus' inventions. Thus, the explanation of the inventions also supports the conclusion that the term "bus" means the multiplexed bus. For example, every embodiment described in the specification involves the use of a multiplexed bus. 11 Not once do the patents indicate that any of the inventions can, or should be, used with the prior art dedicated bus architecture.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

11 See e.g. '918 patent, col. 4, ll. 1-4 ("In a preferred implementation, 8 bus data lines and an AddressValid bus line carry address, data and control information for memory addresses up to 40 bits wide.") (emphasis added); '918 patent, col. 5, ll. 59-64 ("In the preferred implementation, memory devices are provided that have no connections other than the bus connections described herein and CPUs are provided that use the bus of this invention as the principal, if not exclusive, connection to memory and to other devices on the bus.") (emphasis added); '918 patent, col. 8 ll. 17-25 ("The preferred bus architecture of this invention comprises 11 signals: BusData[0:7]; AddrValid; Clk1 and Clk2; plus an input reference level and power and ground lines connected in parallel to each device. . . . The bus lines for BusData[0:7] signals form a byte-wide, multiplexed data/address/control bus").

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -

This understanding is confirmed by the testimony of Mr. Joseph McAlexander, Infineon's expert, who explains that the patents "describe several bus architectures. But in every instance when they describe the bus of the invention it is always a multiplexed address, data and control bus." Markman Hearing, Tr. p. 360, l. 25 to p. 361, l. 4. Rambus' expert did not refute this conclusion.

In Toro Co. v. White Consolidated Indus., Inc., 199 F.3d 1295 (Fed. Cir. 1999), the Federal Circuit found it significant that
the disputed patent contained only one embodiment of the invention. On the issue of whether a "ring" described in the patent must be attached to the "cover," the court noted that:

The specification and drawings show the restriction ring as 'part of' and permanently attached to the cover. No other structure is illustrated or described. . . .

. . . This is not simply the preferred embodiment; it is the only embodiment. . . .

. . . Nowhere in the specification, including its twenty-one drawings, is the cover shown without the restriction ring attached to it.

Id. at 1301. See also O.I. Corp. v. Tekmar Co. Inc., 115 F.3d 1576, 1581 (Fed. Cir. 1997) (rejecting patentee's argument that the invention could have smooth or cylindrical walls when 'all of the 'passage' structures contemplated by the written description are thus either non-smooth or conical."); General Amer. Transp. Corp. v. Cryo-Trans, Inc., 93 F.3d 766, 770 (Fed. Cir. 1996), cert. denied 520 U.S. 1155, 117 L. Ed. 2d 493, 117 S. Ct. 1334 (1997) (the disputed claim construction was "not just the preferred embodiment of the invention; it is the only one described. Nothing in the claim language, specification, or drawings suggests that any of the [limitations] may be eliminated . . .") (emphasis in original). Likewise, it is significant here that Rambus does not list a single example of how any of the new inventions would work with any type of bus other than a multiplexed bus. 12

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

12 The failure of the specification to describe any other kind of bus in connection with the invention distinguishes the principal decision upon which Rambus relies, Johnson Worldwide Assoc., Inc. v. Zebco Corp., 175 F.3d 985 (Fed. Cir. 1999). In Johnson Worldwide, the Federal Circuit placed great emphasis upon the fact that the disputed claims did not require the narrower construction. 175 F.3d at 991. The Johnson Worldwide opinion distinguished Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456 (Fed. Cir. 1998) (which adopted the narrower claim construction) because the written description in Laitram made clear that the asserted claims will bear only one interpretation. In Johnson Worldwide, there was no such unambiguous language in the claim; "nothing suggests that 'heading' is required to be the heading of a trolling motor." Johnson Worldwide, 175 F.3d at 991.

The facts of Johnson Worldwide are distinguishable from the Rambus patents here. The Johnson Worldwide court noted that the "many uses of the term throughout the . . . patent are consistent with a broader definition" and that the "varied use of the term in the written description demonstrates the breadth of the term rather than providing a limited definition." Id. at 991. Thus, the dual usage of the term did not create "a special and particular definition" Id. Here, there are not varied uses of the term "bus," only a single multiplexed bus.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

The Federal Circuit's holding in Wang Labs., Inc. v. America Online, Inc., 197 F.3d 1377 (Fed. Cir. 1999) is instructive as well. In Wang, the court considered whether the ordinary and accustomed meaning of the term "frame" could be overridden by the inventor's explanation in the specification:

The parties agreed before the district court that the term "frame" can in general usage be applied to bit-mapped display systems as well as to character-based systems . . . . The disagreement was as to whether the term "frame" in the '669 claims embraced this general usage, or whether the term would be understood by persons of skill in this field as limited to the character-based systems described in the '669 patent.

Wang, 197 F.3d at 1381. As is true here, the only system described and enabled in the specification and drawings in Wang used the narrower, specific arrangement of the character-based system. Id. at 1382. The only time that the patent mentioned non-character-based systems was in the "Background of Invention" section. Id. The Federal Circuit agreed with the district court's conclusion that those references were merely acknowledgments of the state of the prior art, not an enlargement of the patent's invention; and that a person skilled in the field of art would not have understood that those references were included in the applicant's invention. Id. Similarly, Rambus is limited to the description set forth in the specification, which is only a description of the multiplexed bus.
In an effort to distance the claims from the specification, Rambus argues that one skilled in the art would recognize that any kind of bus could be used with the many inventions of the specification, not just the new multiplexed bus. The Federal Circuit has rejected this exact argument, which attempts to escape the language of the specification. See Watts, 232 F.3d at 883 (inventor's arguments that "one of ordinary skill would be aware of a myriad ways to effect a sealing connection . . . may be true, [but] it does not overcome the fact that the specification specifies that the invention uses misaligned taper angles"). The fact that the inventions might conceivably be used with any kind of bus does not overcome the oft-repeated assertions in the specification which describe, and even tout, the new Rambus inventive bus while demonstrating that the inventions are to be used with the multiplexed bus.

Rambus next argues that Infineon is trying to improperly limit the scope of the claim to the limitations described in the preferred embodiment. See Karlin Tech., Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 973 (Fed. Cir. 1999) ("The general rule, of course, is that the claims of a patent are not limited to the preferred embodiment, unless by their own language."); CVI/Beta Ventures, 112 F.3d at 1158 ("as a general matter, the claims of a patent are not limited by preferred embodiments"). The specification, however, clearly distinguishes between the "invention" of the multiplexed bus and "the preferred embodiment" of the bus. The patent often describes the broader invention of a bus multiplexed for address, data and control information. This description is then followed by a narrower description of the 'preferred embodiment' that is an implementation of the multiplexed bus.

For example, the patent states:

The new bus includes clock signals, power and multiplexed address, data and control signals. In a preferred implementation, 8 bus data lines and an AddressValid bus line carry address, data and control information for memory addresses up to 40 bits wide. Persons skilled in the art will recognize that 16 bus data lines or other numbers of bus data lines can be used to implement the teaching of the invention.

'918 patent, col. 3, l. 67 through col. 4, l. 7. (emphasis added). The new multiplexed bus is the broadly defined invention and the preferred embodiment has certain characteristics such as 8 or 16 multiplexed lines, an AddressValid line, and addresses of up to 40 bits. Numerous references in the specification highlight these differences. 13 Usually, the preferred embodiments described in the specification give a technical example of how the overall invention works, thus helping to explain the claim language. "Although claims are not necessarily restricted in scope to what is shown in a preferred embodiment, neither are the specifics of the preferred embodiment irrelevant to the correct meaning of claim limitations." Phonometrics, Inc. v. Northern Telecom, Inc., 133 F.3d 1459, 1466 (Fed. Cir. 1998). Where, as here, the several embodiments described in the specification each involves only a multiplexed bus, that weighs heavily in construing the term bus to mean a multiplexed bus. See Wang, 197 F.3d at 1383.

Footnotes
13 See e.g. 918 patent, col. 5, ll. 37-50 ("The bus carries substantially all address, data, and control information needed by devices for communication with other devices on the bus. . . Using the organization described herein, very large addresses (40 bits in the preferred implementation) and large data blocks (1024 bytes can be sent over a small number of bus lines 8 plus one control line in the preferred implementation."); 918 patent col. 14, ll. 49-67 ("In the bus-based system of this invention" a master can use the device ID to access a specific device "including the address and control registers. In the preferred embodiment, one master is assigned to carry out the entire system configuration process." (emphasis added); 918 patent, col. 16., ll. 12-21 ("The bus architecture of this invention can include more than one master device. The reset or initialization sequence should also include a determination of whether there are multiple masters on the bus, and if so to assign unique master ID numbers to each. Persons skilled in the art will recognize that there are many ways of doing this. For instance, the master could poll each device to determine what kind of device it is . . .") (emphasis added).

Finally, it is significant that the specification only mentions the generic (or "dedicated") bus architecture in the "Comparison of Prior Art" section. 14 In these references to "bus," however, the inventors are distinguishing their new inventive bus from the prior art. The inventors explain that "none of the buses described in patents or other literature use only bused connections. All contain some point-to-point connections on the backplane." 918 Patent, col. 2, l. 67 to col. 3, l. 3. Thus, it
does not help Rambus to point out, as it does, that this text of the comparison uses the same term ("bus") to describe a completely different architecture from the "new" bus which, according to Rambus, means that the term "bus" must necessarily encompass any set of information transfer lines, including those cited as prior art. The "Comparison With Prior Art" section states only what the invention does not cover; and, in so doing, the specification expressly distinguishes the prior art buses from the disclosed bus of the invention. Of course, it is settled that "claims are not correctly construed to cover what was expressly disclaimed." Cultor Corp. v. A.E. Staley Mfg. Co., 224 F.3d 1328, 1331 (Fed. Cir. 2000) (description in specification that distinguished other types of catalysts "effected a disclaimer of the other prior art acids"). See also Wang, 197 F.3d at 1382 (references to "bit-mapped" protocols in "Background of Invention" were acknowledgments of the state of the art and not an enlargement of the invention described in the patent). The argument which Rambus makes based on the term "bus" as used in the discussion of prior art runs afoul of this basic precept of claim construction.

Footnotes:

14 For example, the specification explains that the bus of an earlier patent (U.S. Patent No. 3,821,715) "multiplexes addresses and data over a 4-bit wide bus and uses point-to-point control signals to select particular RAMs or ROMs." 918 patent, col. 2 ll. 13-15. The specification also explains that in the DRAM of a previous patent (U.S. Patent 4,449,207) "the external interface to this DRAM is convention, with separate control, address and data connections." 919 patent, col. 2, ll. 32-33.

In a further effort to use the discussions of prior art to support its proposed definition of "bus," Rambus relies on Clearstream Wastewater Sys. v. Hydro-Action, Inc., 206 F.3d 1440 (Fed. Cir. 2000), to argue that its inventions involve "combination claims," therefore it is entirely permissible to include both the new and the generic buses in its inventions:

> Clearly, the written description does point out the disadvantages of the [prior art] rigid conduit system and the advantages of the [new] flexible-hose system. However, the written description does not require that only the new flexible-hose system, but not the old, rigid conduit system, could be used in the claimed wastewater treatment plant. It is well established in patent law that a claim may consist of all old elements . . . for it may be that the combination of old elements is novel and patentable. Similarly, it is well established that a claim may consist of all old elements and one new element, thereby being patentable.

Id. (emphasis added).

Infineon properly agrees that combination claims can include some, or even all, prior art elements. However, Infineon also is correct in asserting that the proper framework for the current analysis is whether one of ordinary skill in the art would understand the Rambus disclosure to assert the combination theory recently embraced by Rambus.

The patent specification here does not support that theory because, unlike Clearstream, the specification in Rambus' patents do not describe the generic prior art bus in combination with any of the claims. Indeed, the "Comparison With Prior Art" discussion is at considerable pain to dissociate the inventive bus, and its uses, from the prior art, and to establish a similar disconnect of the other inventions from the prior art. '918 Patent, col. 2, l. 7 to col. 3, l. 47.

Thus, the specification clearly demonstrates that when the inventors used the term "bus" in the claims, they were referring to the new multiplexed bus described in the specification. 15 Upon reading the patent, one skilled in the art would conclude that the patentee explicitly defined bus: "the present invention includes a memory subsystem comprising at least two semiconductor devices . . . connected in parallel to a bus where the bus includes a plurality of bus lines for carrying substantially all address, data and control information needed by said memory devices." 918 patent, col. 3, ll. 50-55.

- 923 -
Nothing in the specification - no drawing and no embodiment - indicates that the bus in the claims has the dictionary definition that Rambus now asserts.

Footnotes

15 Other than the "Comparison with Prior Art" section, the patent specification only once indicates that a bus can be anything but the multiplexed bus: "Persons skilled in the art recognize that certain devices, such as CPUs, may be connected to other signals lines and possibly to independent buses, for example a bus to an independent cache memory, in addition to the bus of this invention." '918 patent, col. 5, ll. 54-57. In this reference, the inventors clearly distinguish between the multiplexed bus of the invention and any other kind of bus to be used in the system.

Footnotes

3. The File History

Despite the obvious descriptions in, and implications of, the patent itself, Rambus argues that the patent history teaches that the term "bus" includes more than just the multiplexed bus. While it is doubtful that a court should look to the patent history to contradict the unambiguous meaning described in the specification, see Multiform Desiccants, 133 F.3d at 1478 ("when the specification explains and defines a term used in the claims, without ambiguity or incompleteness, there is no need to search further for the meaning of the term"), the patent history here does not in any fashion clarify the scope of the disputed term. Rambus relies upon two statements made, and actions taken, in the prosecution of the patents stemming from the 1990 '898 application.

In June 1997, during the prosecution of the parent application 16 to the '263 patent (which is also the grandparent to the '918 patent), 17 the Patent Examiner issued a requirement for restriction under 35 U.S.C. § 121, 18 finding that this patent claimed two distinct inventions. The examiner divided the claims into two groups, one group describing a plurality of conductors to be used with the multiplexed bus and the second group describing an access-time register within the memory device (the latency invention). 19 Asserting that the groups were not "connected in design, operation, or effect," the Patent Examiner required the inventors to elect to pursue only one group of claims. Rambus prosecuted the claims in Group II (the latency invention), resulting in the '580 patent.

Footnotes

16 This application eventually issued as U.S. Patent No. 5,841,580.

17 When considering a patent's prosecution history, it is proper to look to statements made in the prosecution of related patents stemming from the same application, as is the case here. See Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 980 (Fed. Cir. 1999) ("When multiple patents derive from the same initial application, the prosecution history regarding a claim limitation in any patent that has issued applies with equal force to subsequently issued patents that contain the same claim limitation."); Mark I Marketing Corp. v. R.R. Donnelley & Sons Co., 66 F.3d 285, 291 (Fed. Cir. 1995) ("Thus, the relevant prosecution history here includes not only the '659 application but also the parent '815 and grandparent '668 applications."); Jonsson v. Stanley Works, 903 F.2d 812, 818 (Fed. Cir. 1990) (prosecution history of parent application is relevant to understanding scope of claims issuing in a continuation-in-part application).

18 A requirement for restriction is issued by the PTO when a patent application contains more than one distinctly claimed invention. 35 U.S.C. § 121.19 The June 9, 1997 Office Action explains:

4. Restriction to one of the following inventions is required under 35 U.S.C. 121:

   Group I. Claims 151-55, drawn to a memory device having a plurality of conductors being multiplexed for sequentially receiving an address, classified in Class 365, subclass 230.02.

   Group II. Claims 156-158, drawn to a semiconductor device having at least one access-time register, classified in Class 395, subclass 290.
The inventions are distinct, each from the other because of the following reasons:

5. Inventions I and II are disclosed as different combinations which are not connected in design, operation or effect. These combinations are independent if it can be shown that (1) they are not disclosed as capable of use together, (2) they have different modes of operation, (3) they have different functions, or (4) they have different effects. (MPEP 806.04, MPEP 808.01). In the instant case the combinations [sic] the memory device in Group I does not require the access-time register of Group II, and the semiconductor device in Group II does not require the plurality of conductor being multiplexed to receive an address as claimed in Group I.

6. Because these inventions are distinct for the reasons given above and have acquired a separate status in the art as shown by their different classification, and the search required for invention I is not required for invention II, restriction for examination purposes as indicated is proper.

(emphasis added).

From this action by the PTO and from the fact that the same Patent Examiner reviewed the '263 and '918 patents in suit, Rambus asks the Court to make the leap in logic that the PTO must have understood that the multiplexed bus was not necessary for every other invention arising from the specification. This kind of speculation into the motivations of the patent examiner is not useful to a reviewing court or a competitor reading the patent history. "It is the applicant's representations during the prosecution that potentially shed light on the construction of the claims." Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456, 1462-63 (Fed. Cir. 1998) (emphasis in original) (rejecting argument that meaning could be derived from the representation of the reexamination requester). The snippet of patent history upon which Rambus relies only shows that: (a) a single Patent Examiner at one time indicated that some claims should not be lumped together, and (b) that, rather than making an affirmative response to this restriction, Rambus chose to drop the claims for the multiplexed bus and pursue the latency invention. No more can be inferred from this exchange.

Rambus also relies on a second piece of evidence contained in the file history. Specifically, in November 1995, a different Patent Examiner rejected claims pending in the grandparent to the '804 patent as being obvious in view of prior art reference, U.S. Patent No. 5,129,069 to Helm, et al. Under Rambus' view of the file history, the Patent Examiner must have equated the generic term "bus" (recited in claims 176-181 of the grandparent application) with the non-multiplexed bus contained in the Helm patent when he initially rejected the claims. Nevertheless, this same Patent Examiner allowed claim 26 of the '804 patent (which contains a reference to an external bus) to issue without requiring that the term "bus" be limited to a multiplexed bus. Again, this kind of guessing as to what a Patent Examiner may have been thinking is not generally helpful to construing the claim terms because it requires both the court and the public to pour over oftentimes complex and voluminous patent histories, speculate as to the motivation behind an office action, and then follow the patents in an effort to divine whether that same Patent Examiner may have had reason to construe another claim in the same manner. This invitation to haphazard guesswork certainly cannot be considered sufficiently reliable to trump the clear language of the specification. See Vitronics, 90 F.3d at 1582 ("Usually, [the specification] is dispositive; it is the single best guide to the meaning of a disputed term").

Moreover, the standard for construing claims in the patent application process is far different than the standard for construing claims in a litigation context. Patent examiners construe claims under a broader standard than that used by a court in undertaking claim construction. The Federal Circuit has held that "it would be inconsistent with the role assigned to the PTO in issuing a patent to require it to interpret claims in the same manner as judges who, post-issuance, operate under the assumption that the patent is valid." In re Morris, 127 F.3d 1048, 1054 (Fed. Cir. 1997). In the posture of a claim construction during litigation, if the intrinsic evidence is ambiguous, "another claim construction canon comes into play. Because the applicant has the burden to 'particularly point[] out and distinctly claim[] the subject matter which the applicant regards as his invention' 35 U.S.C. § 112, P 2 (1994), if the claim is susceptible to a broader and a narrower meaning, and the narrower one is clearly supported by the intrinsic evidence while the broader one raises questions of enablement under § 112, P 1, we will adopt the narrower of the two." Digital Biometrics, 149 F.3d at 1344. See also Athletic Alternatives, Inc. v. Prince Mfg. Inc., 73 F.3d 1573, 1581 (Fed. Cir. 1996) ("Were we to allow AAI successfully to assert the broader of the two senses of 'between' against Prince, we would undermine the fair notice function of the requirement that the patentee distinctly claim the subject matter disclosed in the patent from which he can exclude others temporarily.") Therefore, even if
one were to conclude that the patent history casts doubt on the clear meaning of the specification (which it does not), Rambus should be limited to the embodiment and description of a multiplexed bus set forth in the specification because it is the narrower of the two constructions.

The simple fact here is that reference to the file history does not contradict the clarity given by the specification. What Rambus has done is fixate upon two isolated events in the file history and, without connecting them to the issued patents, urges the Court to ascribe significance to the events by divining what an examiner must have meant by directing a certain action. That kind of sophistry is not among the tools available for claim construction under the carefully defined protocol established for that task by the Federal Circuit.

4. Claim Differentiation

Rambus relies on the doctrine of claim differentiation to support its contention that "bus" means only a "generic" bus. The doctrine presumes "a difference in meaning and scope when different words or phrases are used in separate claims. To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Toro Co., 199 F.3d at 1302 (Fed. Cir. 1999) (quoting Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987)). Rambus highlights the claims contained in Rambus U.S. Patent No. 5,983,320 (the '320 patent), 20 in which the independent claims of the '320 patent cover the concept of the "new" multiplexed bus. Each claim contains qualifying language to limit the bus to one that carries multiplexed address, data and control information over the same bus. For example, claim 7 of that patent claims a method for programming memory having a bus, where the bus "comprises a group of general purpose signal lines carrying substantially all of the time-division multiplexed address, data and control information for a memory transaction, wherein the address information is indicative of a range of addresses for a corresponding one of the individually addressable discrete memory sections of the memory device . . . " 21 Therefore, Rambus argues that, when it wanted to limit the term "bus" to a bus that carries multiplexed information, it knew how to do so.

--- Footnotes ---

20 The '320 patent is a "sister" or "brother" patent to the '804 patent. Rambus bases the notion of cross-patent claim differentiation on footnote 2 of Laitram Corp. v. Morehouse Indus., Inc., 143 F.3d 1456, 1460 n.2 (1998). Because the argument of claim differentiation fails for other reasons, it is assumed, without deciding, that this is a proper use of related patents and their prosecutions.

--- End Footnotes ---

21 According to Rambus, other Rambus patents include similar limiting language: U.S. Patent No. 5,995,443, Claim 33 ("the bus further includes a plurality of conductors terminated by an impedance to a power source") and U.S. Patent No. 6,032,215, Claims 33 and 37 (same) and Claim 38 ("the bus further includes a plurality of conductors wherein each conductor is terminated at an end by a resistor to a power terminal.")

--- End Footnotes ---

This argument is unavailing because it too contradicts the clear meaning of the specification. "The doctrine of claim differentiation cannot broaden claims beyond the scope that is supported by the specification." ATD Corp. v. Lydall, Inc., 159 F.3d 534, 541 (Fed. Cir. 1998). See also Multiform Desiccants, 133 F.3d at 1480 (same). "Although the doctrine of claim differentiation may at times be controlling, construction of claims is not based solely upon the language of other claims; the doctrine cannot alter a definition that is otherwise clear from the claim language, description, and prosecution history." O.I. Corp. v. Tekmar Co., Inc., 115 F.3d 1576, 1582 (Fed. Cir. 1997) (concluding "that the description provides a clear meaning for the language of the claim in this case and that it trumps the doctrine of claim differentiation"). See Toro Co., 199 F.3d at 1302 (claim differentiation "does not override clear statements of scope in the specification and the prosecution history"). "The presumption that separate claims have different scope is a guide, not a rigid rule." ATD Corp., 159 F.3d at 541 (quoting Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 404 (1967)). Having determined that the written specification limits the term "bus" to a multiplexed bus, it would be impermissible to allow
Rambus to rely upon claim differentiation (citing to other patents) to broaden the meaning of the term. 22

22 Along these same lines, Rambus argues that the claims of the original '898 application specifically claim a multiplexed bus, therefore the reasoning behind claim differentiation would apply to give "bus" a generic meaning within the specification because the original claims are part of the specification. See In re Dossel, 115 F.3d 942, 945 (Fed. Cir. 1997) ("The statute thus makes clear that under current law the specification of a patent consists of, and contains, both a written description of the invention and the claims."); Northern Telecom, Inc. v. Datapoint Corp., 908 F.2d 931, 938 (Fed. Cir. 1990) ("The original claims as filed are part of the patent specification.") However, Dossel explains that "modern usage . . . does not always conform to that statutory structure. For example, when discussing the process of claim construction, it is not uncommon for the process to be described as requiring an examination of the claims, the specification, and the prosecution history, treating them as distinct entities." 115 F.3d at 945. To the extent that the claims of the original application (which never issued), indicates that the inventors distinguished between the new multiplexed bus and a generic bus, this difference does not trump the clear descriptions in and implications of the written description.

5. The Extrinsic Evidence

A review of the intrinsic evidence clearly demonstrates that when the term "bus" is used in the claims, it means the new inventive Rambus multiplexed bus. "Because the intrinsic record is clear, [the court] does not give weight to an inconsistent dictionary definition," Digital Biometrics, 149 F.3d at 1346, as offered by Rambus.

A reading of the entire specification, without parsing it into individual quotes, unmistakably conveys that one of the primary benefits of every invention claimed in the patents in suit, and described in the specification, is to increase the speed of operation of the memory device. High speed access is the crown jewel of the specification and to that end, the multiplexed bus, in combination with the other inventions, increases the transfer speeds and decreases the amount of space occupied by the transfer lines. One skilled in the art reading the specification would certainly conclude that the "bus" meant to be used with the inventions is the new, inventive, high-speed, multiplexed bus. This conclusion is supported by the testimony of Joseph McAlexander, an expert who is experienced in the art and whose explanation for reaching that conclusion is highly credible because it is fully consonant with the specification and the claim language as explicated by the specification. 23 Mr. McAlexander's testimony is consistent with, and complimentary of, the intrinsic evidence. 24 On the other hand, the testimony of Rambus' expert, Dr. William Huber, is at odds with the intrinsic evidence and depends on a dictionary definition (other extrinsic evidence) that is not consistent with the many descriptions given by the inventors in the specification.

23 See Markman Hearing, Tr. p. 379, l. 20 to p. 380, l. 3 (Mr. McAlexander states, "Because the patent very strongly distinguishes numerous times the multiplex bus of the invention from the prior art, and states specifically in numbers of places, that the bus architecture of this new bus design is essential for the type of high speed activity that is required across the bus, and it distinguishes from the prior art because the prior art is stated not to be able to give that high speed type of transaction.")

24 Other portions of Mr. McAlexander's testimony generally support this construction. See Markman Hearing, Tr., pg. 361, ll. 14-24; pg. 364, l. 22 to pg. 365, l.22; pg. 367, l. 17 to pg. 368, l. 13; pg. 371, ll. 3-19.

6. Construction

For the foregoing reasons, the term "bus" means a multiplexed set of signal lines used to transmit address, data and control information.
"Bus" is the next term disputed by the parties. The term "parallel bus" occurs in claim 19 of the 366 Patent. 366 Patent, 54:41. In addition, the term "communications bus" occurs in claims 1, 7, and 11 of the 037 Patent. 037 Patent, 55:53, 56:32, 57:24. The parties agree that the term "bus" is used consistently in the two patents, although they differ as to what this meaning should be. Plaintiff argues that "bus" should be construed to mean "a channel or path for transferring a signal, data, or power from one or more sources to one or more destinations." Defendant proposes the construction "a path for transferring information from any of several sources to any of several destinations." The dispute between the parties boils down to two issues: namely, (1) whether a bus may connect as few as two endpoints, rather than requiring that it have the capability of connecting at least three devices; and (2) whether a bus transfers only information or data, or whether it may transfer a signal or power as well as information.

The parties again cite numerous technical dictionaries and treatises in support of their positions. For example, both parties point to the AP Dictionary, which defines bus as, inter alia, "a channel or path for transferring data or power from one of many sources to one or more of many destinations." Id. at 329. Plaintiff also cites two of the nine definitions of bus that appear in the IEEE Dictionary: (1) "a signal line or set of lines used by an interface to connect a number of devices and to transfer data"; and (2) "one or more conductors used for transmitting signals or power from one or more sources to one or more destinations." Id. at 128. As noted above, the Federal Circuit's decision in Texas Digital announced a general rule for determining if one or more of several possible dictionary definitions should be adopted as the legal meaning of a disputed term: namely, that a claim term may be construed to encompass all such definitions that are consistent with the intrinsic record. 308 F.3d at 1203. At the same time, the court noted that the "intrinsic record must always be consulted to identify which of the different possible dictionary meanings of the claim term in issue is most consistent with the use of the words by the inventor." Id.

In the instant case, the court looks to the specification to provide the "best guide" for selecting among the competing definitions of "bus" found in the cited technical references. Accord Vitronics, 90 F.3d at 1582. Taking the 037 Patent as an example, the specification discloses multiple network controllers, mass storage processors, memory cards, and a host processor coupled to a "backplane bus." 037 Patent, 5:50-54. Similarly, the specification of 366 Patent describes the various elements of the file server as being connected over a "VME bus" -- i.e., an IEEE Standard 1014-1987 backplane bus. 366 Patent, 8:6-10; IEEE Dictionary at 1259. A "backplane bus" is in turn defined as "[a] set of signal lines to which a number of devices are connected and over which information is transferred between them." Id. at 129 (defining "simple 32-bit backplane bus"). In other words, the embodiment of the invention disclosed in the specification includes a bus that (1) connects "a number" (i.e., at least two, but usually more) devices and (2) transfers information between those devices.

Although mindful of its obligation to avoid reading limitations from the specification into the claim, the court believes that this definition of "bus" bests fits the language of the claims themselves as well as the description of the preferred embodiment. Accord Irdeto, 383 F.3d at 1300 (reaffirming doctrine that specification may define claim terms by implication). As to the number of devices, it is noteworthy that claim 7 of the 037 Patent reveals only that a "plurality" of processors -- i.e., more than one processor -- are connected to the communications bus. 037 Patent, 56:26-47. In contrast, other claims recite at least three devices connected -- for example, the plurality of processors and data memory coupled to the communications bus in claim 11 of the 037 Patent. Id. at 57:24-27. Furthermore, the function of the "bus" described in the claim language is to provide for the transfer of "message[s]," id. at 56:46, or "NFS requests," 366 Patent, 54:45. Both of these functions are best characterized as transferring data or information between the devices connected to the bus. Accordingly, the court construes the term "bus" as used in the patents in suit to mean "a set of signal lines to which two or more devices may be connected and over which information is transferred between those devices."

----- Footnotes -----
v. Advanced Power Tech., Inc, 301 F. Supp. 2d 1065 (N.D. Cal. 2004) (Patel, J.), is similarly misplaced. That case involved a patent claiming a lithographic machine for use in semiconductor manufacturing rather than a patent for a network file server architecture, and is thus at best only marginally relevant to construing the claims at issue here.

459

4. bus

In a case of role reversal the Court cannot help but notice, the parties have taken atypical approaches to the construction of "bus." OPTi, the plaintiff, has minted a narrow construction of "bus" to mean "a communications interface connecting two or more devices, in which information is conveyed on a set of bi-directional signal lines. A bus is distinct from a point-to-point unidirectional interconnect." nVidia contends that a "bus" is simply "a set of signal lines."

OPTi bases its construction on citations from the preferred embodiment in the specification. In addition, OPTi contends that other claim language requires its "bi-directional" limitation. The Court has previously rejected these arguments when offered by nVidia and rejects them again. OPTi does not deny that nVidia's construction is the well-known construction of one of ordinary skill in the art. Further, OPTi's arguments do not overcome the presumption that a patentee is not limited to the preferred embodiment absent a clear disavowal of claim scope. Accordingly, "bus" means "a set of signal lines."

460

1. "Bus"

Term

VIA & Intel's Proposal

"A set of parallel conductors that is capable of transmitting signals between two or more modules (such as computer processors and local memories) connected to these conductors."

CCCC's Proposal

"One or more conductors used for transmitting signals or power from one or more sources to one or more destinations."

i. Serial or Parallel

The parties' primary disagreement about the term "bus" is whether, as used in the patent, "bus" refers to any sort of bus, or only a parallel bus. 1 One definition of bus circa 1998, as provided by IEEE, is as CCCC proposes: "one or more conductors used for transmitting signals or power from one or more sources to one or more destinations." Buses may be classified as either "serial" or "parallel." Levy Decl. (dkt. # 130 2) PP 3-4. A parallel bus is one containing more than one conductor used simultaneously to transmit data, while a serial bus has only one conductor for data. Id. PP 5-6.

Footnotes

1 Because from the parties' original filings and arguments it was unclear the precise definition of "parallel bus" that one skilled in the art would have used in the context of the '369 patent at the time its application was filed, the court ordered the parties to file supplemental declarations on the definitions of "parallel bus" and the related term "serial bus," as well as certain other bus-related terms the parties believed would be helpful to the court to understand. From the supplemental declarations the parties filed, it appears that they generally agree on the applicable definitions of "parallel bus" and "serial bus." In its filing in response to the court's order, Salik Decl. (dkt. # 198), CCCC included in its declaration information beyond that requested by the court. Defendants also object on several grounds--such as relevance, and lack of factual support--to CCCC's supplemental declaration. Defendants' objections are all well-taken and sustained. 2 This declaration was docketed only in case C-05-01766. All other references to docket numbers in this order are those used for case C-05-01668.

- 929 -
The dispute over whether the construction of bus is limited to parallel buses is informed by reviewing the use of "bus" and "parallel bus" in the specification. CCCC argues that since the term "parallel bus" appears in certain places in the patent, the drafter clearly intended "bus" alone to not be limited to a parallel bus. Defendants, on the other hand, contend that all uses of "bus" refer to "parallel buses."

The defendants are correct that at least some uses of "bus" necessarily refer to a parallel bus. For example, the background section of the patent states:

When various computer processors employ differing parallel buses, it is not possible to directly connect the computer processors to the same bus. In such case, the processors must operate within separate computer systems utilizing separate buses and accessing separate local memories.

'369 patent at 1:53-58. The first sentence contemplates a situation involving "differing parallel buses," and the second sentence, in explaining the limitations of such a situation, refers merely to "buses," even though these "buses" are those discussed in the first sentence and as a result, necessarily parallel. However, the background section specifies parallel buses twice, but mentions buses without further specification eleven other times.

It is not clear that each mention of "bus" should be taken to be a reference to a parallel bus. For example, the background section begins with the sentence: 

"[t]he present invention relates in general to interface circuits providing communication between computer systems and in particular to an interface circuit permitting a bus master connected to one computer bus to directly access data stored in a memory connected to another bus." '369 patent at 1:10-15. This sentence does not clearly refer only to parallel buses.

 Defendants nevertheless argue that the patent's references to "bus" refers to parallel buses. First, they argue that the specification sets forth the problem to be solved in the prior art only in terms of parallel buses. However, the problem to be solved need not necessarily limit the patent claims. See, e.g., Brookhill-Wilk I, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1301 (Fed. Cir. 2003). Further, it does not appear that the patentee has acted as his own lexicographer, providing a clear definition of "bus" as a parallel bus. See Rambus Inc. v. Infineon Technologies AG, 318 F.3d 1081, 1094-95 (Fed. Cir. 2003) (references to "multiplexed bus" in specification does not limit "bus" as used in claims to a "multiplexed bus"); Multiform Desiccants Inc. v. Medzam Ltd., 133 F.3d 1473, 1477 (Fed. Cir. 1998) (any special meaning assigned to a term "must be sufficiently clear in the specification that any departure from common usage would be so understood by a person of experience in the field of the invention."). Nor does it appear that the defendants' narrower construction of "bus" is necessary to preserve the validity of the claim. As CCCC points out, the problem of cache coherency is not necessarily limited to the parallel buses, even if the problem to be solved and preferred embodiment are stated in the context of parallel buses. Thus, because the patent specification refers to both "buses" and "parallel buses" and because there is no special definition of "bus" clearly defined in the specification, the court concludes that "bus" is not limited solely to a parallel bus.

ii. Signal or Power

The parties also disagree as to whether "bus" should be defined as transmitting signals only or "signals or power." The patent clearly contemplates information passing through the bus, so it is undisputed that a bus transmits signal. The patent does not disclose power passing through the bus.

CCCC's proposed construction, using "signals or power," is too broad because it would allow a bus that is only used for transmitting power and not signal. While it is true that a signal, which is an electrical current, carries power, albeit a very small amount (P = I^2*R or power = current squared multiplied by resistance), defining the term as transmitting either "signal or power" implies that the bus can solely transmit power, which is not disclosed. Therefore, although it is implicitly understood that a signal carries power, it should not be defined to be "signal or power."

iii. Transmission

CCCC proposes the use of one of many available IEEE dictionary definitions to construe "bus." Defendants argue that in light of the Federal Circuit in Phillips, it is inappropriate to just select the broadest possible dictionary definition. The focus
is on how the particular claim term is used in the patent claims and specification. Upon review of the available IEEE
definitions circa 1998, IEEE definition number 2, which relates to a "microcomputer system bus," defines "bus" to be "a
signal line or set of lines used by an interface system to connect a number of devices and to transfer information." See Salik
Decl. (dkt. # 46), Ex. 10. This definition of bus, which describes a shared bus, is more appropriate in light of the claim
language. The preamble specifies "the first bus providing a first plurality of bus masters connected thereto", '369 patent at
12:43-4, and "the second bus providing a second plurality of bus masters connected thereto", '369 patent at 12:58-9. It is
thus clear from the claim language that the patent contemplates shared buses--buses that are connected to a plurality of bus
masters such that the buses connect multiple devices--and not buses that connect a single source to a single destination.
Indeed, all uses of "bus" in the claims and the specification of the '369 patent describe a shared structure to which multiple
bus masters are connected.

iv. Construction

Based on the foregoing, the court construes "bus" as "a signal line or set of signal lines used by an interface system to
connect a number of devices and to transfer information between the devices." The parties have agreed that the construction
of "first bus" and "second bus" follows the construction of "bus."

16. Communication bus

With respect to the term "communication bus," Foundry argues that the term should be given its ordinary meaning. Foundry
submits that the ordinary meaning of "communication bus" is "a communication medium to which two or more devices are
connected and over which information is transferred between them." Lucent contends, however, that "communication bus"
should be construed to mean "a signal line or a set of lines used by an interface system to connect a number of devices and
to transfer data." The court construes "communication bus" consistent with the ordinary meanings of the term "bus" - "a
signal line or set of lines that may be used by an interface system to connect a number of devices and to transfer
information." See Newton's Telecom Dictionary (1996); see also Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193,
1203 (Fed. Cir. 2002).

3 "If more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may
be construed to encompass all such consistent meanings."

2. "Source bus" and "Gate bus"

Although Ixys urges this court not to expound upon the meaning of the terms "source bus" and "gate bus" and their relation
to one another, the claim term at issue (as well as Ixys' own proposed construction) includes both phrases. This court is
loathe to leave significant disputed words within a claim element undefined, and so it will undertake to interpret the
language of those terms fully.

At the outset, APT argues that the source bus and gate bus must be electrically isolated. This seems a self-evident limitation:
it is common knowledge within the industry that a "bus" is an electrical conduit through which a signal or current may flow,
and so an electrical interconnection between the two buses would render them effectively one entity. In addition, any
individual skilled in the art would understand that a power MOSFET would not function correctly if the gate were shorted to
the source; it stands to reason that any device intending to function as a MOSFET must have a gate and source that are
electrically isolated.
With reference to the precise meaning of the "gate bus" itself, the specification discloses that it is in "common" with the first metallization layer (presumably meaning in electrical contact), '715 patent, 8:12-14, and that "with the improved structure, the turn-on or turn-off signal propagates from the gate pad through the gate bus portion of the second metallization through the first metallization layer..." '715 patent, 6:25-28. Ixys urges that this court apply a more generalized interpretation, based on the common understanding of the word "bus" as "one or more conductors used for transmitting signals or power," a definition taken from the IBM Dictionary of Computing, which therefore does not speak directly to the issue of semiconductor construction at hand here.

Reliance on extrinsic evidence is improper where intrinsic evidence exists to define the term. Vitronics, 90 F.3d at 1583. Although the specification to which APT points appears less a definition of the gate bus and more a description of one embodiment of its functioning, it is well known to those skilled in the art that the function of a transistor "gate" is to switch the transistor on or off depending on the signal that it receives. The court will thus construe "gate bus" to mean generally "the conductor used to transmit an electrical signal or power to the gate." If indeed the only current that travels to the gate is the on-off signal, this definition will end up subsuming APT's proposal.

In light of this, and in the absence of any intrinsic evidence altering the meaning, the court construes "source bus" congruently as "the conductor used to transmit an electrical signal or power to the source regions."

4. bus controllers

This disputed term appears in all the claims except dependent Claims 6 and 10. Claims 1 and 7 establish that the bus controllers are connected in a binary tree configuration, and each bus controller includes "a buffered interface connecting said processing element to said bus controller for transmitting instructions and data between the bus controller and the connected processing element" (Claim 1), '024 Patent 7:29-32, and "means for interpreting instructions received from the host computer and for executing such instructions addressed to it and for passing instructions to bus controllers down the tree. . . ." (Claim 7), id. at 8:29-33.

Plaintiff asserts that the term is not generally known in the art of computing but that "buffers" are, and that, when such meaning is combined with the "means of writing information," the construction of "bus controller" is "clear." Pl. Reply at 23. Despite that assertion of clarity, however, the construction plaintiff then offers is, on its face, circular and confusing, as it uses the term "bus controller" in the definition of the same: "A buffered interface connecting the processing element to the bus controller that enables writing information into the memory of the processing element without involving the microprocessor of said connected processing element." Pl. Br. at 21. 5 Even though it borrows phraseology directly from the claims, plaintiff's construction conflates the buffered interface, which is part of the bus controller, with the bus controller itself.

5 Prior to submitting its opening brief, plaintiff had indicated to defendant that its construction was "a buffer interface connecting the processing element to the bus controller and the means for writing information into the memory of the connected processing element without control of the main processor of the connected processing element." See Def. Reply at 20 n.13.

At the Markman hearing, plaintiff offered the unpersuasive argument that "is" and "includes" were synonymous, and therefore its construction meant that a bus controller "includes" a buffered interface. See tr., 08/20/09, at 143-45. The Federal Circuit has held that "including" is a broad term that refers to essential elements but permits additional elements to be added, Lucent Techs., Inc. v. Gateway, Inc., 525 F.3d 1200, 1214 (Fed. Cir. 2008); but plaintiff can provide no case that supports the premise that "is" can be read more broadly to mean "includes." Moreover, even assuming arguendo plaintiff's tortured linguistic alchemy permitted "is" to mean "includes," plaintiff's construction would still suffer from circularity by
relying for its definition on the very term it seeks to define.

In contrast, defendant defines the plural "bus controllers" as "controllers that transfer instructions and data from the host computer to the connected processing elements, and data from the connected processing elements to the host computer over a bus." Defendant's construction also fairly tracks Claim 1's language, as well as Claim 7's language which says that the bus controllers "include[] means for interpreting instructions received from the host computer . . . and for passing instructions to bus controllers down the tree." Def. Br. at 22. The patent specification provides support for this construction, which reads: "The BCxs [bus controllers] act as buffered repeaters that transfer Function Calls and data from the Host Computer to the selected PE(s), and data with its Fault Message from the selected PE to the Host Computer." '024 Patent at 2:64-3:1. In short, the specification tells us that the bus controllers, by acting collectively as a "bucket brigade," transfer data and instructions from the host computer to the processing elements and from processing elements to other processing elements. Id. at 2:38-40. So too does the abstract provide that the bus controllers "include[] a buffered interface . . . for transmitting instructions and data between the bus controller and the processing element . . . ." '024 Patent Abstract.

Accordingly, the Court construes "bus controllers" to be controllers that transfer instructions and data from the host computer to the connected processing elements and data from the connected processing elements to the host computer over a bus.

1. bus master

OPTI's construction of "bus master" is "the device which initiates a data transfer on a bus." nVidia contends the "bus master" is "a device connected to a bus which arbitrates for control of the bus and can receive data transferred on the bus."

Both parties rely on PCI Local Bus Specification Revision 2.0 that was specifically incorporated by reference into the patent specification. In the PCI Local Bus Specification, there are references to the bus master arbitrating for each access it performs. nVidia asserts therefore that its construction must be correct. The Court is not persuaded by nVidia's argument.

The most relevant section of the PCI Local Bus Specification 2.0 to determine a proper construction for "bus master" would be the glossary. A review of the glossary section of the PCI Local Bus Specification 2.0 reveals that the "master" is defined as the "agent that initiates a bus transaction." Further, the specification is consistent with this definition. See 906 patent, Col. 10:34-35 ("These data transfers may be either read or write data transfers; the master is the initiator, and the target is the responding device . . ."). Accordingly, the Court adopts OPTI's construction of "bus master."

4. "business office device"

The next disputed term "business office device" appears in various claims of the '289, '120 and '618 Patents. n6 Ricoh proposes the following construction:

A business office device is an intelligent module of an office machine system that includes a device engine for carrying out the mechanical operations of the office machine system, and its own communication capability that enables it to communicate intelligently with other modules of the office machine system, or with other devices. The intelligent business office device makes use of an intelligent communication protocol.

(Chart at 13). Pitney asserts that "business office device" is "a copier, printer or facsimile or other business office equipment." (Id.).
The parties agree that "business device engine" should be construed in the same way as "business office device." (Chart at 13).

The Court finds that the intrinsic evidence, particularly the claims in this instance, provides a straightforward definition for this term which is consistent with Pitney's proposed construction. As the Federal Circuit noted in Phillips, the claim in which the term appears and other claims of a patent, including both asserted and unasserted claims, can serve as "valuable sources of enlightenment as to the meaning of the claim term." Phillips, 415 F.3d at 1314. Claim 1 of the '289 Patent reads:

A method, comprising the steps of:

- storing semi-static state data in a business office device, the semi-static state data including data which may change infrequently over a life of the business office device;
- initiating communication between the business office device and a computer, by the business office;
- transmitting the semi-static state data from the business office device to the computer; and
- receiving the semi-static state data by the computer.

'289 Patent, Claim 1. Notably, dependent claims 4 through 6 further recite:

4. A method according to claim 1, wherein: the business office device is a copier . . .

5. A method according to claim 1, wherein: the business office device is a facsimile machine . . .

6. A method according to claim 1, wherein: the business office device is a printer . . .

Id., Claims 4-6. Thus, the plain language of the claims appearing in the '289 Patent clearly defines copiers, facsimiles and printers as examples of a "business office device." This language is consistent with Pitney's construction.

Additionally, Pitney's construction is further supported by the specification. In the Background of the Invention, the patentee states:

The present invention relates to a method and apparatus for communicating and controlling various types of business office equipment or devices transparently and uniformly. The types of business equipment could be copiers, facsimiles and/or printers.

The creation of business office devices such as a copier, facsimile or printer requires activities assigned to various groups which must be integrated into at a certain time.

Id., col. 1, ll. 15-23 (emphases added). Support for this construction is further found in the Abstract which describes the claimed invention as "[a] method and apparatus for controlling and communicating with business office devices, such as copiers, facsimiles and/or printers." Id., Abstract. In light of the intrinsic evidence, the Court finds that the patentee acted as his own lexicographer with respect to the term "business office device" by setting forth a clear definition in the specification.

Ricoh argues that Pitney's proposition is incorrect because: 1) the prosecution history supports its construction which includes language regarding intelligent modules and communication, (Chart at 13-14); and 2) by adopting Pitney's construction, the Court would not maintain integrity between the Court's definitions. (Tr. of Markman Hr'g at 44-45). With respect to Ricoh's first argument, the Federal Circuit clearly indicated that the specification is usually dispositive and "the single best guide to the meaning of a disputed term." Phillips, 415 F.3d at 1315. The Court remains mindful that "because the prosecution history represents an ongoing negotiation between the PTO and the applicant, rather than the final product of that negotiation, it often lacks the clarity of the specification and thus is less useful for claim construction purposes." Id.
at 1317. In this case, the Court relies heavily upon the specification as opposed to the prosecution history in defining this term since it provides a clear definition for "business office device" -- one that is consistent with Pitney's construction.

The Court further rejects Ricoh's second argument as a basis for adopting its proposed construction. Ricoh argues that integrity between the Court's constructions is not maintained because the "business office device" must be "just the engine" of a device, rather than the device as a whole. (Tr. of Markman Hr'g at 44:14-45:1). Ricoh, however, fails to provide any basis for limiting the construction to "just the engine" when the claims and specification clearly indicates otherwise. Consequently, the Court concludes that a "business office device" means "a copier, printer or facsimile or other business office equipment."

5. "business relationships of the client"

<table>
<thead>
<tr>
<th>Disputed Claim Term or Phrase</th>
<th>Versata's Proposed Construction</th>
<th>SAP's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>business relationships of the client</td>
<td>Business relationships that may affect the fulfillment of the client's order request, including client information, used to identify fulfillment partner(s). business relationships between the client and the order servicing organization, between the client and the fulfillment partner, or between the order servicing organization and the fulfillment partner.</td>
<td></td>
</tr>
</tbody>
</table>

This phrase is used in claim 4 of the '235 patent. The pertinent language of claim 4 reads as follows:

using electronically stored routing rules to select a fulfillment partner from business relationships of the client to provide each item ordered.

SAP's suggested construction attempts to capture the portion of the specification which describes various relationships which a client, an order servicing organization, and a fulfillment partner may have. See '235 Patent, col. 6, ll. 12-30. SAP's construction, however, allows for a relationship between an order servicing organization and a fulfillment partner, a relationship not contemplated by the cited examples. In fact, each of the additional examples cited by Versata includes relationships between, at a minimum, the client and either the order servicing organization or the fulfillment partner. See, e.g., '235 Patent, col. 3, ll. 10-18; col. 7, ll. 6-14; col. 8, ll. 13-21; col. 10, ll. 34-40; col. 10, ll. 41-47; col. 11, ll. 1-9; and col. 12; ll. 1-15. Absent any example of a relationship that excludes a client, the court is unwilling to expand the scope of this term to include such an example in its construction.

Accordingly, the court construes "business relationships of the client" as "business relationships that may affect the fulfillment of the client's order request, including business relationships between the client and the order servicing organization, or between the client and the fulfillment partner."

A. "Automatic" and "Without Manual Intervention"
Liquidnet requests that I construe several terms within claim one of Patent '834 to include the words "automatically" and "without manual intervention." For example, it proposes that the term "by at least one computer" be construed throughout the patent claim as "by one or more computers, without manual intervention." Because claim one does not use the words "automatically" and "without manual intervention," or any analog, Liquidnet relies for support on the patent's specification - which, unlike the claim itself, frequently uses both terms. Of particular relevance, the specification outlines in detail "that there is a need in the art for an electronic marketplace that does not require any manual intervention or traders," and asserts that "[t]he present invention addresses [that] need by providing for the automated transmission of orders (i.e., without manual trader intervention) from various order management systems . . . to an electronic trading marketplace[.]

48 In total, Liquidnet proposes that this construction be read into five different terms that appear one or more times in the claim: (1) that "by at least one computer" be construed as "by one or more computers, without manual intervention"; (2) that "subsequently generating" be construed as "subsequently producing in a format understood by the electronic marketplace automatically, without manual intervention"; (3) that "sending" be construed as "automatically transmitting, without manual intervention"; (4) that "subsequently sending" be construed as "subsequently transmitting automatically, without manual intervention"; (5) that "periodically determining" be construed as "automatically determining, from time to time, without manual intervention."

49 Patent '834 col. 2 ll. 30-33. 50 Id. col. 2 ll. 38-43 (emphasis added).

This language, along with the fact that the specification discusses multiple preferred embodiments wherein the patented method occurs automatically, provides evidence that the inventor envisioned the patented method occurring without manual intervention. However, this pervasive use of the words "automatically" and "without manual intervention" does not settle the issue. It is the claim itself, and not the specification, that defines an invention, and courts are well-advised not to add limiting modifiers (e.g., an adjective like "automatically") to broad claim language (e.g., a verb like "sending") without sufficient justification.

51 See Lemelson v. United States, 752 F.2d 1538, 1552 (Fed. Cir. 1985) (holding that a district court erred in construing the term "prepositioning" to mean "automatic prepositioning" even though the specification only discussed automatic prepositioning and did not discuss manual prepositioning at all). As Patent '834 itself states of the specification: "The above description is included to illustrate the operation of the preferred embodiments and is not meant to limit the scope of the invention. The scope of the invention is to be limited only by the following claims." Patent '834 col. 12 ll. 42-45. This may be boilerplate language found in almost any patent, but it must still be taken seriously. A patent applicant should not be allowed to use a patent's described embodiments to broaden that patent's scope when doing so is desirable (e.g., to sue for alleged infringement by later inventions) and to narrow it when doing so is desirable (e.g., to avoid invalidation by prior art).

52 See Renishaw PLC, 158 F.3d at 1249-50 ("Nor may we in the broader situation, add a narrowing modifier before an otherwise general term that stands unmodified in a claim. For example, if an apparatus claim recites a general structure (e.g., a noun) without limiting that structure to a specific subset of structure (e.g., with an adjective), we will generally construe the claim to cover all known types of that structure that are supported by the patent disclosure." (citations omitted)).

As stated, the Federal Circuit has discussed two ways in which the specification can be used to narrow the construction of a patent's claims. While these are not necessarily the only ways that such narrowing can occur, they do provide a good starting point for analysis.
First, the claim may contain ambiguous language that is susceptible to being construed as requiring the requested limitation. The closest such term in claim one is "by at least one computer." During the Markman hearing, Liquidnet contrasted computerized operations with manual operations, and stressed that the patented method was computerized. However, while the computerization of a process does suggest a degree of automation, this term does not rule out manual intervention. As a matter of common sense, it is apparent that some computer functions require manual intervention (e.g., a user must often click a key to save a document to a computer's hard drive). In addition, and perhaps more importantly, the specification states that even though computers are used in the prior art, these processes are not fully automated. If, as the specification states, the use of computers in the prior art does not mean that those processes occur automatically, the use of computers in the patented method cannot require such automation.

See 12/16/09 Markman Hearing Transcript ("Tr.") at 64-65.

Although computers are heavily used to facilitate trading of securities, manual intervention is still required at certain steps in the trading process. For example, most traders at institutional investment management firms record their orders to purchase or sell securities in computerized order management systems (OMS's). However, one or more traders at each firm must manually review the orders in the OMS and attempt to fill the orders by contacting one or more market intermediaries. Typically, the traders transmit the orders in the OMS by telephone or separate data entry links to registered broker-dealers for the securities, to electronic marketplaces that trade the securities, or to other market intermediaries. Accordingly, manual effort is required to actually execute the orders in the OMS.

See Patent '834 col. 1 ll. 20-33 ("Although computers are heavily used to facilitate trading of securities, manual intervention is still required at certain steps in the trading process. For example, most traders at institutional investment management firms record their orders to purchase or sell securities in computerized order management systems (OMS's). However, one or more traders at each firm must manually review the orders in the OMS and attempt to fill the orders by contacting one or more market intermediaries. Typically, the traders transmit the orders in the OMS by telephone or separate data entry links to registered broker-dealers for the securities, to electronic marketplaces that trade the securities, or to other market intermediaries. Accordingly, manual effort is required to actually execute the orders in the OMS.").

Nevertheless, Liquidnet asks me to read the claim terms to include the words "automatically" and "without manual intervention" on the grounds that the purpose of the invention will be frustrated unless the patented method includes such limitations. As Liquidnet argues, the specification explicitly describes the importance of the invention's automatic nature to solving issues not addressed in the prior art. I am also convinced that the invention, as it is actually practiced, involves a large degree of automation, and that its success in the marketplace is at least partly due to this automation. However, while an invention's purpose can be useful for interpreting "ambiguous" claim language, the Federal Circuit has made clear that "the court's task is not to limit claim language to exclude particular devices because they do not serve a perceived 'purpose' of the invention." In our patent system, it is the claims, and not the invention to which they relate, that define a patent's scope.

See Tr. at 48-49.

Liquidnet differs from all its counterparts in that traders do not have to enter orders themselves. Its software searches participants' order management systems (OMSs) and automatically alerts traders to natural matches.

See, e.g., 5/31/02 Dow Jones News Story, Ex. 8 to Declaration of Gaston Kroub ("Kroub Deck"), counsel for Liquidnet, at 2 ("Liquidnet differs from all its counterparts in that traders do not have to enter orders themselves. Its software searches participants' order management systems (OMSs) and automatically alerts traders to natural matches.").

E-Pass Techs., Inc. v. 3Com Corp., 343 F.3d 1364, 1370 n.3 (Fed. Cir. 2003).

Id. at 1370.

Moreover, it is apparent from the specification that the claimed invention is not exclusively aimed at addressing the lack of automation in the prior art. The patented method is also designed to address the need for an electronic trading system that offers anonymity, 60 creates a high amount of liquidity, 61 and prevents over-execution of trades. 62
prosecution, the patent applicants removed the term "automatically" from the claim language in response to the PTO's assertions that the automatic nature of the method would not distinguish the patent from the prior art. In doing so, the applicants made clear that "although Applicants still do not agree with the Examiner's previous discussion [regarding automatic execution], . . ., this limitation is not relied upon as a distinguishing element in the current claims." 63 While this statement is not definitive in determining the scope of the claim at issue, it further supports the view that the patented method need not proceed automatically.

59 See id. ("An invention may possess a number of advantages or purposes, and there is no requirement that every claim directed to that invention be limited to encompass all of them.").

60 See Patent '834 col. 21. 32.

61 See id. col. 21. 33.

62 See id. col. 2 ll. 18-22. At the Markman hearing, Liquidnet argued that it is the automatic nature of the patented method that creates liquidity and prevents over-execution. See Tr. at 48. And the specification corroborates that the use of manual effort contributed, in part, to the existence of these problems in the prior art. See, e.g., Patent '834 col. 1 ll. 34-37 ("One problem arising from this manual effort is that institutional traders cannot execute trades involving large quantities of securities without adversely affecting the market price of the securities."). However, the specification also discloses other ways that the invention addresses gaps in the prior art. For example, the patented method is designed to allow "[t]raders [to] communicate with the ETM to anonymously negotiate trades of securities." Patent '834 col. 2 ll. 52-53 (emphasis added). This is a proposed benefit of the patented method that is entirely independent of the invention's automatic nature.

63 7/12/06 Amendment to Patent '834, Ex. 4R to Brenner-Leifer Decl., at 7.

Liquidnet and ITG have both made persuasive arguments regarding whether the patented method should be construed to occur automatically. Because one skilled in the art could reasonably have adopted either interpretation, this is one of those unfortunate situations where the patent has failed to perform adequately its public notice function, and my decision may consequently undermine the reasonable expectations of persons who are engaged in practicing or designing around the claimed invention. Nevertheless, this case cannot proceed with two interpretations of the same term, and I must therefore choose the definition that most closely accords with the claim language and the intrinsic evidence. While I do not doubt that the applicants believed their invention would work best when the method is automated, the intrinsic evidence is insufficient to read such a limitation into the claim. If automation was absolutely necessary to the invention, the words "automatically" and "without manual intervention" should have appeared in the claim itself.

Accordingly, I do not construe any of the disputed terms to include the words "automatically" or "without manual intervention."

GO BACK

N) the claimed one or more communication session being created by the location facility, "by determining the then current location of the personal computer"

01 Communique suggest that the appropriate construction should be "The one or more communication sessions are created by the location facility by determining a current address or communication session for communicating with the personal computer." Citrix, however, suggests that the proper construction should be

In response to the claimed request from the remote computer, the location facility searches the dynamic directory to obtain the current IP address of the claimed personal computer and uses that current IP address to create the requested communication channel between the remote computer and the personal computer by forwarding to the data communication

- 938 -
facility the remote computer's request for communication with the personal computer.

The court agrees with 01 Communiques that Citrix improperly tries to read "dynamic directory" into the claim. This would violate the principle of patent law that claims should be read in light of the specification, but that features should not be imported from the specification into the claims. SciMed Life Sys v. Advanced Cardiovascular Sys. Inc., 242 F.3d 1337, 1340-1341 (Fed. Cir. 2001). Therefore, the court rejects Citrix's proposed construction and instead adopts that of 01 Communiqué.

GO BACK

469

With regard to the claim 1's limitation that the information be encoded "in said bit areas by the presence or absence of printing," Datastrip argues that this phrase, properly construed, only requires that the bit areas that are used to encode information be printed or not. Datastrip contends that claim 1 is not limited to matrix codes 2 as Symbol contends, but also covers variable width codes because variable width codes, like bar codes and the PDF417, still encode information by "the presence or absence of printing" at the bit area (module) level, which is all that is required by claim 1 of the '221 patent. Datastrip also argues that someone skilled in the art at the time claim 1 was filed considered presence/absence encoding to simply mean printing was used to define a bit area, not that a matrix code was being used. Datastrip therefore concludes that any testimony indicating that the PDF417 does not use presence/absence encoding is premised on a faulty claim construction.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
2 A code that uses presence/absence encoding can also be called a "matrix code." A matrix code is a two-dimensional code that uses the position of printed and blank areas within the matrix to encode information, with each printed or blank area being the same size. In a matrix code, the data is coded by the position of a printed or blank bit area.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Symbol responds by arguing that claim 1 is directed to a specific type of encoding, presence/absence encoding, which is distinct from variable width encoding used by bar codes and the PDF417. Symbol notes that claim 1 specifically recites that information is "encoded by the presence or absence of printing," not by the variable width of the printing. Symbol also notes that the '221 patent expressly distinguishes the claimed invention from bar codes, which use variable width encoding. Symbol then argues that substantial evidence was presented to the jury that indicated there were fundamental differences between presence/absence encoding, which is used in matrix codes, and variable width encoding, which is used in bar codes and the PDF417.

Claim 1 of the '221 patent requires that the "information be[] encoded in said bit areas by the presence or absence of printing." '221 patent, col. 7, ll. 24-25. Contrary to Datastrip's arguments, this phrase limits claim 1 to presence/absence encoding, such as matrix coding, as opposed to variable width encoding, such as bar coding. When construing a patent claim, we first look to the intrinsic evidence of record: the claim, the specification, and the prosecution history. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582-83, 39 U.S.P.Q.2D (BNA) 1573, 1576-77 (Fed. Cir. 1996). Claim 1 requires that the information be "encoded in said bit areas by the presence or absence of printing." '221 patent, col. 7, ll. 24-25 (emphasis added). The claim language requires the information in the data strip be encoded by using the presence or absence of printing in the bit areas. The plain language of the claim requires the usage of presence/absence encoding.

The specification supports the claim's plain language. First, the specification's only discussion of variable width encoding is in the BACKGROUND OF THE INVENTION section, where it is discussing the prior art. The patent explains that "prior printed systems include bar codes which are a series of parallel printed lines so spaced and dimensioned as to convey information when scanned . . . ." '221 patent, col. 1, ll. 17-20. The specification contrasts the bar code prior art with the claimed invention, indicating that the invention provides bits of information by the "presence or absence of printing." Id. at col. 1, ll. 24-46. Second, the encoding method used in the preferred embodiment, dibit encoding, is presence/absence encoding. As the patent explains, a dibit conveys information by the presence or absence of printing in two adjacent bit areas. Id. at col. 3, ll. 54-63. Like any other presence/absence encoding, such as a matrix coding, dibit encoding uses the location of printed and blank areas within the data strip to encode information, i.e., whether the printed or blank bit area is
Datastrip correctly asserts that the phrase "presence or absence of printing" must be construed to mean what the phrase meant to someone skilled in the art at the time the '221 patent was filed. See Cybor, 138 F.3d at 1456, 46 U.S.P.Q.2d (BNA) at 1174. Based on the evidence of record, we conclude, as a matter of claim construction, that to those skilled in the art at the time of the patent's filing, the phrase "presence or absence of printing" did not include variable width encoding.

After holding a Markman hearing, the Court issued its Memorandum Opinion and Order on Claim Construction in which it construed six terms integral to the determination of this case and the instant motions. (doc. 270) The claims were construed as follows:

1. "connected and connectable" -- These terms mean "directly joined to one another within the same unitary piece of equipment without any intervening equipment."

2. "unified structure" -- Although not a claim term, the Court defines the term "unified structure" to mean "a consolidated structure with all components directly connected to one another."

3. "bypass" -- "Bypass" means "a structure and path by which data channels completely go around and in no respect go through the TST switch."

4. "control store" -- "A 'control store' is included within a single unified DRTST switching unit that includes a memory, processor, and operating software that determines (1) which data circulating on the network loop is to be selected and diverted to the TST switch of a given switching node; (2) how that data passes through the TST switch; (3) which data is output from the TST switch back onto the network loop; and (4) which data is to bypass the TST switch of that node."

5. "means for measuring" -- The Court finds that this term is not capable of construction.

6. "direction of the timing adjustment interval" -- This term means "[t]he timing adjustment control command signal is fed in a reverse direction from the data signal; that is, from a downstream digital switching unit to an upstream digital switching unit, in a direction opposite the data flow."

Lucent contends that this term should be given its ordinary meaning. (D.I. 396 at 6.) Defendants contend that the term "bytes" means "the number of bytes in a packet being received from a customer's terminal, by an access node." (D.I. 395 at 13; D.I. 385 at 13.) In support of this construction, Defendants cite a description of the variable named BYTES used in an algorithm of the preferred embodiment. (‘810 patent at 7:35-36.)

The Court finds that Lucent has not clearly defined the term "bytes" by way of describing this parameter. Thus, the Court
concludes that the ordinary meaning of the term has not been rebutted. In the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

GO BACK

473

1. "Current-controlled complementary metal oxide semiconductor (C3MOS) logic"

This dispute concerns whether C3MOS logic is fabricated "using CMOS processes" only, as Broadcom asserts, or "using MOSFETs" (encompassing both CMOS and BiCMOS processes), as Agere claims. Importantly, both Broadcom's expert, Dr. Fair, and Agere's expert, Dr. Blalock, testified that C3MOS logic is made using CMOS processes. (Fair '194 Rep. P 37; Blalock Rep. P 57.) Agere provides no expert evidence in support of its position, relying instead on a vague citation to a technical paper stating that BiCMOS, which combines bipolar and CMOS technologies on the same chip, is "probably" "the technology of the future." KENNETH R. LAKER & WILLY M.C. SANSEN, DESIGN OF ANALOG INTEGRATED CIRCUITS AND SYSTEMS 156 (1994). Broadcom responds, correctly, that this citation has little to do with the instant dispute, in that it does not refute the testimony of the two expert witnesses. Thus, the Court finds that Broadcom's proposed construction accurately reflects the understanding of persons of ordinary skill in the art, and that construction is therefore adopted.

GO BACK

474

The Court construes "CPE" (or customer premises equipment) as "customer side equipment in a wireless communication system that transmits data to and/or receives data from a base station." This construction is similar to the construction of base station, as the base station and the CPE are related.

A. Parties' Construction Arguments

Plaintiff's original proposed construction reads "equipment in a wireless communication system that transmits data to a base station." Plaintiff's rationale for its original construction of "CPE" is essentially the same as its rationale for its construction of "base station." Plaintiff's revised proposed construction reads "equipment in a wireless communication system that facilitates communication between a base station and at least one end user." Plaintiff's revised construction is similar to Plaintiff's revised construction of "base station" as well, and Plaintiff provides essentially the same support for the construction of "CPE" as Plaintiff did for "base station."

Defendants seek a construction that reads "equipment installed at a customer premises that relays data between a base station and end users." Defendants first argue that "CPE" (or customer premises equipment) must be installed at a customer premises. For support, Defendants first provide technical dictionary definitions that show one of ordinary skill in the art at the time of filing would have known the CPE must be installed at a customer premises. As with Defendants' argument for "base station," Defendants also argue the '311 patent (incorporated by reference in the patent-in-suit) explicitly shows the CPE being installed at the customer premises. See '311 patent, Figure 7. Defendants also ask the Court to construe CPE as requiring the CPE to "relay[] data between a base station and end users." Defendants' argument here cites to the specification where it states that the CPE is coupled to end users in addition to the base station. See, e.g., '759 patent, 4:13-14 ("Each CPE is further coupled to a plurality of end users . . . ").

B. Analysis

The Court construes "CPE" as "customer side equipment in a wireless communication system that transmits data to and/or receives data from a base station." As with "base station," the Court primarily agrees with Plaintiff's original construction, but the Court has made changes. For the same reasons as the Court's construction of "base station," the Court adds the "receives" language. Furthermore, the Court adds the language "customer side" to the beginning of Plaintiff's original construction. The Court concludes that merely stating "equipment" is not sufficient because it would fail to give effect to the "customer premises" language in the actual claim term.
However, the Court disagrees with Defendants that the equipment must be installed at a customer premises. While the term does plainly read customer "premises" equipment, the specification shows that the equipment need not be installed at the customer premises. The specification never limits the CPEs to being installed at the customer's premises. Indeed, the specification mentions "fixed and portable" subscriber units and the specification also discusses "mobile cellular telephone systems," which would clearly not be installed at the customer premises. See '759 patent, 1:15-20. While the '311 patent (incorporated by reference) may show the CPEs installed at the customer premises, the '311 patent is merely "[o]ne exemplary broadband wireless communication system" and thus only a preferred embodiment. See '759 patent, 3:28-34. See also Phillips, 415 F.3d at 1323("although the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments"). The Court additionally disagrees with the Defendants' proposed construction language that requires the "CPE" to "relay[] data between a base station and end users." As with the Court's construction of "base station," the Court believes that while there is a relationship with the CPE and end users that is briefly mentioned in the specification, the invention here refers to the relationship with the base station and the CPE. Hence, the relationship with end users is not necessary to include in the construction of "CPE."

Finally, the Court disagrees again with Plaintiff's revised construction for the same reasons the Court disagreed with Plaintiff's revised construction of "base station." The "facilitates" language is not grounded in the specification as the "transmits and receives" language. Further, the Court concludes it is not necessary to include the relationship between the end users and the CPE. Therefore, the Court construes "CPE" as "customer side equipment in a wireless communication system that transmits datato and/or receives data from a base station."

1. "CPU"

Claim 1 describes, inter alia, "a control circuit including a central processing unit located within the housing for detecting a plurality of electrical parameters of the appliance during operation." (Emphasis supplied). P3's proposed construction of the term "central processing unit" ("CPU") in its opening brief is "an electronic circuit that executes software programs" (emphasis supplied), and in its reply brief its preferred construction is "an electronic circuit that executes computer programs." (Emphasis supplied). UPM claims that this construction is inconsistent with the specification because the specification does not mention that the CPU executes software programs. UPM argues that the construction of CPU should be what the specification describes: that "the CPU receives signals generated by a zero-crossing detecting circuit [], an analog-to-digital converter [], and a time base signal generator []. The CPU processes the data and provides an output to the display unit . . . ."

Considering the intrinsic evidence of record, namely the claims and the specification, UPM has failed to demonstrate how P3's construction of a "CPU" as an electronic circuit that executes computer or software programs is inconsistent with the claim language or specification or is a deviation from how the term is understood by a person of ordinary skill in the art. Simply because the word "software" is not used in the specification does not make the specification inconsistent with P3's proposed construction. UPM's proposed construction is an attempt to import improperly the limitations from the specification into the claims, without any showing that the specification in this case was intended to be coextensive with the claim. Phillips, 415 F.3d at 1323.

Any ambiguity in the usage of the term is clarified by looking at the extrinsic evidence proffered, which also supports P3's construction, as the Modern Dictionary of Electronics provides that a CPU is a "primary unit of the computer system that controls interpretation and execution of instructions." Modern Dictionary of Electronics, 158 (7th ed. 1999) (emphasis supplied). The intrinsic evidence shows that the claimed CPU is that is to execute various programs and instructions. There is nothing in the specification inconsistent with this understanding of the term's ordinary meaning, and thus the term CPU is construed as "an electronic circuit that executes computer programs."

1. Cache
OutlookSoft asserts that the proposed definition of cache is "a mechanism for data storage and transfer." Hyperion asserts that the proper construction is a "computer memory having a first part that stores data and a second part that stores data requests." Both parties cite to functions the cache performs in claim 1 and both parties cite to statements made by the Examiner during prosecution. However, the parties' citations do not define "cache." Instead, these citations relate to additional claim limitations. To incorporate these limitations into the term cache would render the limitations within claim 1 moot. Bedrock principles of claim construction counsel against a construction that renders additional limitations superfluous. See Merck & Co., Inc. v. Teva Pharmaceuticals USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005).

An example of how the parties incorrectly support their respective positions may prove beneficial. In support its two-part cache argument, Hyperion places great emphasis on the Notice of Allowability of the 292 File History. The reason for allowance in the file history was:

Applicant's invention in claim 1 claims features of the two part cache function described in the preferred embodiment in pages 18-20. Claim 1 claims a spreadsheet with a cache wherein said cache stores data for use by said spreadsheet program in rendering said at least one spreadsheet.' This claim limitation is the first part -- the data cache -- of Applicant's inventive two part cache. The second part of Applicant's inventive spreadsheet cache -- the key cache -- is claimed in the language said cache formulates a single query for transmission from said client across said network to said server requesting all required data.'

In other words, the data cache and key cache functionality that Hyperion seeks to have incorporated into the term "cache" is actually specifically claimed in claim 1. To include the functionality of the data cache and key cache in the construction of the term cache would therefore render a large part of claim 1 superfluous. OutlookSoft's proposed construction suffers from the same deficiencies. Thus, the Court adopts neither party's proposed construction.

The Court will instead develop its own construction using the common and well understood meaning of the term cache while at the same time allowing for the multi-functionality that the elements in claim 1 require. Generally, a cache is nothing more than temporary memory storage. However, in this case, the cache also performs other functions. Thus, there must be an associated set of computer instructions that allow for the functionality described in the claims of the OutlookSoft patents. Accordingly, within the context of this patent, "cache" is "temporary memory storage operating in conjunction with computing instructions to perform various functions."

The parties do not dispute the meaning of the term "cache." A "cache" is a memory. More specifically, according to its plain meaning, a cache is a portion of memory that can be accessed quickly. See Novell's Encyclopedia of Networking 116 (1997).
Toshiba further argues that the invention disclosed in the '846 Patent specifically stated that it was superior to the prior art because it implements "all three caching strategies, cacheable non-cacheable, write-through, and copyback, to be utilized in the same machine, and which allows for selection of any one of the three strategies under software control using software control bits." 846 Patent at 1:62-67, 3:1-4. Toshiba claims that no cacheable modes are described or suggested in the patent other than write-through and copyback.

The parties also raise substantial arguments regarding two pieces of prior art cited by the PTO during the prosecution of the '846 Patent. In rejecting the claims, the PTO relied on the fact that U.S. Patent No. 4,433,374 ("the Hanson reference") disclosed "three modes of written data into the cache memory": "non-write through mode [normal write command]," "write through mode [Store-Thru command]" and "non-cacheable mode [Dispersed Write]." Pl's Exh. O at 4 (brackets in original). Intergraph claims that the PTO's rejection was based on the number of modes disclosed in the Hanson reference rather than the types of modes disclosed, because the Hanson reference did not disclose a copyback mode. Intergraph attempted to overcome this rejection by amending its claims to include limitations related to data consistency rather than asserting the failure of the Hanson reference to disclose a copyback mode. Pl's Exh. P at 11-12.

In response, Toshiba cites statements from Dr. Wolfe claiming that, in the "normal write" mode disclosed in the Hanson reference and cited by the PTO, "data was held in a disk-drive cache until the disk drive was not busy, and was then written to the disk." Wolfe Dec., Exh. A P 45. Despite the fact that Dr. Wolfe's very next sentence is "Hanson does not disclose a copyback mode," Toshiba claims that Dr. Wolfe's explanation of the "normal write" is consistent with the copyback mode recited in Claim 4 of the '846 Patent. Aside from drawing an obtuse parallel between Dr. Wolfe's explanation and Claim 4's recitation of immediately storing data only in the cache memory, Toshiba provides no explanation as to why Dr. Wolfe allegedly contradicted himself in his report. Accordingly, Toshiba's argument in this regard is unconvincing.

Toshiba additionally relies on a second piece of prior art asserted by the PTO. In attempting to distinguish from U.S. Patent No. 4,669,043 ("the Kaplinsky reference"), Intergraph stated that its claimed invention accomplished combining write-through and copyback caching strategies whereas the prior art disclosed only systems using one strategy or the other. Defs' Exh. Z at 11, 13-14. Intergraph distinguished the Kaplinsky reference based on the inability to add additional modes to the reference disclosed therein, not the absence of a particular mode. Id. at 13. As with the Hanson reference, the salient point regarding the Kaplinsky reference was numerosity rather than type. A system's ability to select a caching strategy as new requirements arise, rather than committing to a particular strategy in advance and therefore being unable to adapt, increases the flexibility and functionality of the system. Id. at 11.

Intergraph further claims that the PTO's citation of Hanson, which did disclose a plurality of modes, was in response to Intergraph's distinction of Kaplinsky. The Examiner stated that "when Hanson et al's teachings of different cache data storage modes is incorporated into Kaplinsky's system, it would have been obvious to one of ordinary skilled [sic] in the art that the different cache data storage modes can be controlled by the system attributes stored in the descriptor table." Pl's Exh. O at 4. This further supports the contention that the ability to select from among different available strategies was the salient issue in this exchange.

While the specification cites specific examples known at the time to demonstrate the invention's multiple cache storage modes, the claims themselves do not limit the invention to the delineated modes. The intrinsic record supports Intergraph's contention that the PTO was chiefly concerned with the number, rather than type, of modes. Furthermore, the claim language itself refers to "a plurality of cache data storage modes." '846 Patent at Claims 1 & 9. The term "cache data storage modes" is broad, and to limit the modes to those specifically identified in the specification would be to improperly import claim limitations where none exist. Accordingly, the court adopts Intergraph's construction of "cache data storage modes": "strategies for writing data to cache and to primary memory."
creates a cache in the memory of the computer in which it resides; (iii) includes executable remote messaging code; (iv) at least one of the cache drivers includes executable interception code; and (v) at least one of the cache drivers includes executable invalidate code. ('244 Patent, at 26:60-27:31). Claim 22 of the '244 Patent adds that the cache driver (vi) allocates to the cache, space in the memory of the computer. (Id. at 27:42-46).

Superspeed contends that the definition of "cache driver" means "a program that implements a cache." (Instrument No. 69, at 24-26). The parties have already agreed that the definition of cache means "a portion of system main memory (e.g., RAM) used for temporary storage of data." (Instrument No. 69, at 9-10). Thus, it is not necessary to re-define cache within the definition of "cache driver." However, it is necessary to determine how the term "driver" in "cache driver" is used within the context of the claims and specifications of the patents-in-suit.

The specifications of the '244 Patent refer to the "cache driver" as "cache driver software." ('244 Patent, at 4:8-10; 5:14-16) ("When the OpenVMS system (14) performs a read data I/O access to a disk (12) the cache driver (10) software intercepts the I/O.") (emphasis added). The specifications also describe the "cache driver" as something that is loaded on to a computer or operating system, rather than a separate physical device that is inserted or attached to the computer. (See id. at 3:18 ("When the cache driver is first loaded on the operating system all the disks (12) present on the computer system are located. . . ."); Id. at 3:36-38 ("The cache driver (10) maintains remote message communication channels (18) with other cache drivers loaded on other computers "). Thus, the "cache driver" is accurately described as software or a program that is loaded on a computer.

The specifications describe the function of the "cache driver" software as follows:

The cache driver (10) maintains remote message communication channels (18) with other cache drivers loaded on other computers that can access a common set of disks (12). Whenever the OpenVMS system (14) changes the data on the disk (12) for example by doing a write data access to the disk (12), the cache driver (10) uses its remote message communications channels (18) to send a message to each of the remote cache drivers in the list contained in the TCB [the control block] (16) disk control structure.

... . . .

When the OpenVMS system (14) performs a read data I/O access to a disk (12) the cache driver (10) software intercepts the I/O. Using the size of the read data access the cache driver (10) selects which of the three caches, small, medium, or large, the data transfer fits. Having selected the appropriate sized cache the TCH [the cache hack] (26) cache control structure is selected. Using the read data I/O access disk block as a pointer into the disk block value hash table (30) of the TCH (26), the cache driver (10) attempts to locate a matching TCMB (24) bucket control structure.

... . . .

If a TCMB (24) bucket control structure with its corresponding cache data bucket (22) was obtained from one of the three sources described above, cache data space can be assigned for this disk (12) read data. The disk (12) is accessed normally, however the read data is not only sent to the requesting user on the OpenVMS system (14), but also copied to the cache data bucket.

According to the specifications, the "cache driver" controls the cache by communicating with the cache control structures and disk control structures. The "cache driver" also creates cache by assigning cache data to available cache data buckets and copying the data to the cache data bucket.

In order to assist the Court, both parties refer to the definition of "driver" as set forth in the IEEE DICTIONARY. The IEEE DICTIONARY defines "driver" in many contexts:

(1) (communication practice) An electronic circuit that supplies input to another electronic circuit.

(2) (A) (software) A software module that invokes and, perhaps, controls and monitors the execution of one or more other
software modules (B) (software) A computer program that controls a peripheral device, and, sometimes, reformats data for transfer to and from the device. See also: test drives.

(3) A program, circuit or device used to power or control other programs, circuits or devices. See also: bus driver, device driver

(4) An electrical circuit whose purpose is to signal a binary state for transmitting information. Also referred to as a generator in international standards.

IEEE DICTIONARY, at 318. (Instrument No. 69, Exh F).

Here, the cache driver is software that creates or controls cache in the memory of the computer in which it resides and uses remote message communication to communicate with an I/O device or other cache driver programs and computers. Superspeed argues that the appropriate definition for "driver" in this context is "[a] software module that invokes and, perhaps, controls and monitors the execution of one or more other software modules." IEEE DICTIONARY, at 318. (Instrument No. 69, at 25-26). By linking the IEEE definition of "driver" to the agreed definition of "cache," Superspeed contends that "cache driver" may be defined as "software that invokes or controls the cache." (Id.). Superspeed further contends that this definition can be simplified by removing the terms "invokes or controls" and replacing it with the term "implementing." (Id. at 26). However, the Court finds that the term "implementing" is overly vague in the context of the specifications that state that the cache driver communicates with structures that control the cache. Thus, the Court does not find that Superspeed's additional modification to include the term "implementing" is necessary.

Oracle argues that the appropriate definition of "driver" in this context is "[a] computer program that controls a peripheral device, and, sometimes, reformats data for transfer to and from the device." IEEE DICTIONARY, at 318. (Instrument No. 77, at 33). Oracle ultimately attempts to use this IEEE definition to support its proposed construction that "cache driver" means "device driver that controls a cache." The Court initially notes that Oracle's proposed definition of "cache driver" includes both of the terms that the definition purports to define. Furthermore, including the term "device driver" does nothing to clarify what a "driver" is -- which is the entire basis of dispute.

In addition, Oracle entirely focuses on the cache driver communication with I/O devices, to support the conclusion that the cache driver operates on the device driver level. (Id. at 32). However, it is not necessary to limit the cache driver to communication on the device driver level, because the specifications indicate that the cache driver is not limited to communication with peripheral I/O devices. Rather, the cache driver uses remote message communications to communicate with I/O devices, as well as other operating systems and cache drivers. (244 Patent, at 3:34-42, 4:8-17, 4:52-58) The cache driver also communicates with other internal software programs and disks, such as the TCH cache control structure, TCB disk control structure, and TCMB bucket control structure. (Id.).

Because the "cache driver" controls the cache by communicating with the cache control structures, and creates cache by copying read data to the cache data buckets, the Court finds that the term "cache driver" means "a software program that creates or controls a cache."

480

4. "Cache memory"

The court defines the term "cache memory" to mean "a high speed memory that bridges main memory and the CPU." The court rejects the plaintiff's argument that no definition of this term is required and, at the same time, rejects the defendant's argument that the patentee expressly limited the scope of this term in an exchange with the examiner. In the pertinent correspondence, the patentee remarked that the cache memory was by definition, "a memory having a higher speed than the local memory and which is disposed between the local memory and the processor." This statement must be read in the context in which it was made. The applicant was distinguishing the Kaplinsky reference from the present invention, and the court is not persuaded that this statement has the effect of incorporating a concept of "local memory" into the claims of these patents.
VI. '641 patent

The '641 patent discloses a system for ensuring that the most current data is retrieved from the main memory. Because individual devices can update data in their own local cache memory without immediately writing the new data back to the main memory, data in the main memory can be "stale." Therefore, the system claimed in the '641 patent monitors the data being transferred over the bus, and if data stored in the cache matches the address of the data being transferred, a hold signal is asserted. Then, the data being transferred is compared with the data on the cache. If there is a difference, the data stored on the cache, which is the most recent data, is also transferred.

The trial court concluded the '641 patent claims asserted were not infringed based on its patent exhaustion holding, which we reverse above. However, LGE contends that the trial court also improperly construed claims 1, 5, and 14. In particular, LGE disputes the trial court's construction of "cache memory means" (in claims 1 and 5) and "cache memory" (in claim 14), which were construed as "one of at least two high speed memories located close to the CPU of a computer to give the CPU faster access to blocks of data than could be taken directly from the larger, slower main memory and never using valid/invalid bits." Claim Construction Order at 18-22. LGE contends that the trial court improperly read claims 1 and 14 as requiring at least two caches. It also contends that the trial court improperly read in the limitation that neither cache uses valid/invalid bits.

We agree with LGE that the trial court erred in reading the limitation of at least two high speed memories into claims 1 and 14. Unlike claim 5, which expressly requires at least two cache memories, claims 1 and 14 have no such express limitation. Cf. Phillips, 415 F.3d at 1314 ("Differences among claims can also be a useful guide in understanding the meaning of particular claim terms." (citing Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991))). To the contrary, claims 1 and 14 only require one or more CPUs and a cache memory coupled between the CPU and the bus. Because the claims expressly cover one central processing unit, they logically also cover systems with only one cache coupled between that single central processing unit and the bus. Defendants rely on the fact that the written description describes a system with multiple caches. However, as we explain in more detail below, the patent application initially described two inventions, and these statements relate to the other invention that is not claimed in the '641 patent.

We also agree with LGE that the trial court improperly read the limitation of never using valid/invalid bits into the claims. The patent's background section suggests that valid/invalid bits were used to manage data in systems with more than one cache. In particular, it explains that the purpose of the invalid bit is to redirect a processor attempting to access an address in its cache to another cache with a more updated memory associated with that address. '641 patent col. 1 ll. 44-52. The claims at issue do not themselves expressly include or exclude the use of valid/invalid bits. Defendants, however, contend that the trial court's construction is supported by the specification and prosecution history. The specification states that "a further object of this invention [is] to provide a cache memory system wherein the use of valid/invalid data indicators are avoided." '641 patent col. 1 ll. 65-67. It further states that "[i]t should be kept in mind during the following description, that the invention maintains data integrity by assuring that cache data is always the most up-to-date in the system. Thus, there never is a 'valid' or 'invalid' indication with respect to any cache data as it is always assured that if data is provided by a cache, that it invariably is valid (i.e. most up-to-date)." Id. col. 3 ll. 27-33.

Defendants are correct that reviewing the specification in construing claims is appropriate. Phillips, 415 F.3d at 1315-17, but such review need not be done in the abstract. Here, as noted above, the original patent application disclosed two inventions. As the examiner observed, one invention "was drawn to a cache system for updating each copy of the data stored in a plurality of caches when the data is modified," and the other was drawn to "a cache system for sending the most current data to a requestor by monitoring the address of a data on a data bus for detecting whether the [data] is stored and modified in the cache." The patent examiner concluded that these two inventions were distinct and required the applicant to elect one invention. The applicant ultimately limited the original application to the latter group of claims, which issued as the '641 patent, and the other claim group was separated into a different application, which ultimately issued as U.S. Patent No. 5,097,409.

%Here, the discussion of valid/invalid bits in the specification was relevant to multi-cache systems, because the patent's background provides that "[s]o long as a write back cache is utilized with only one processor, data management is straight
forward. However, when more than one central processor uses the same main memory, data management problems multiply. "'641 patent col. 1 ll. 39-43. The patent explains that the data management problems in multiple CPU systems are a result, at least in part, of their containing more than one cache memory. Managing data in multiple cache systems was the subject of the invention not elected during prosecution and, therefore, the statements in the specification referring to valid/invalid bits are not relevant to the invention ultimately claimed in the '641 patent. Cf. Pitney Bowes, Inc. v. Hewlett-PackardCo., 182 F.3d 1298, 1311 (Fed. Cir. 1999) (observing that a written description describing multiple inventions may not be relevant" in toto" to each of those inventions). Indeed, the unelected claims expressly contained the limitation that the "cache memory means hav[e] no provisions for indicating the invalidity of said data units," whereas the elected claims contained no such limitation.

For the same reasons, we do not find that the patentee disavowed the use of valid/invalid bits under the doctrine of specification disclaimer. "[T]he specification may reveal an intentional disclaimer, or disavowal, of claim scope by an inventor. In that instance, . . . the inventor has dictated the correct claim scope, and the inventor's intention, as expressed in the specification, is regarded as dispositive." Phillips, at 1316; see also SciMed Life Sys. v. Advanced Cardiovascular Sys., 242 F.3d 1337, 1341 (Fed. Cir. 2001). However, because the statements relied upon by defendants relate to the invention not elected during prosecution, there is no clear disavowal with respect to the invention actually claimed in the '641 patent.

3. Claim Construction

The parties dispute the meaning of several of the terms in Claims 1 and 10 of the patent: (1) cache memory; (2) output rendered pixel; (3) coupled; and (4) interpolator.

Regarding the meaning of cache memory, Silicon Graphics contends that the court should use the plain meaning of the terms. nVidia contends that read within the context of the prosecution history of the '481 patent and its parent application, cache memory should be construed to mean a cache memory configured to store a complete texture mapping.

E. The Prosecution History

The court draws the following facts from the '481 patent and its prosecution history. In particular, the court looks to the prosecution history of the '481 patent and the patent which issued from the parent application of the '481 patent, U.S. Patent No. 5,548,709 ("the '709 patent").

1. Prosecution of the '709 Patent

On March 7, 1994, Marc R. Hannah and Michael D. Nagy filed Application No. 8/206,959 ("the '959 application") with the Patent and Trademark Office ("PTO"). As first filed, the application contained 19 pending claims, including Claim 19, which claims a TRAM comprising an interpolator and a cache memory. Claim 19 read:

A single semiconductor chip comprising a cache memory for storing texture information and an interpolator for generating a texel by interpolation from said texture information stored in said cache memory, wherein said cache memory and said interpolator both reside on said single semiconductor chip.

The other claims pertain to a TRAM including an on-chip main memory in addition to the elements recited by Claim 19.

On March 21, 1995, the PTO rejected pending Claims 1, 4, 10, 13 and 19 in the '959 application, as being anticipated or obvious in light of an article by Tom Williams on Intel's 80860 chip, entitled "80860 May Force Rethinking of Graphics System Architectures," Computer Design, 28:42 (July 1, 1989) ("the Williams 80860 reference"). In rejecting the pending claims, the examiner stated:

As per claims 1 and 19, Williams teaches that Intel's 80860 RISC-based 64-bit microprocessor chip contains a memory management unit, data and instruction caches, and pixel-generated circuitry for shaded 3D graphics. Williams further teaches that the 80860 graphics section contains interpolation and adder logic for rendering shaded triangles. And Williams teaches that the 80860 is used for texture mapping. Memory and I/O [in/out] are inherent features of any microprocessor
design therefore the 80860 would have main memory as well as I/O.

(Citations omitted).

On June 29, 1995, the applicants responded to the rejection over the Williams 80860 reference, arguing there were differences between the pending claims in the '959 application and the Williams 80860 reference. Regarding the rejection of pending Claims 1, 10 and 19, the applicants contended in full:

Williams describes the Intel 80860 microprocessor ("80860") as having on-chip graphics processing circuitry. Although the 80860 is capable of texture mapping, it does not have the specialized architecture found in the present invention. In particular, the graphics processor in the 80860 does not have a dedicated memory unit which can store a texture pattern, in contrast to the TRAM in the present invention. Although the Examiner is correct in stating that memory and I/O are inherent features of any microprocessor design, the present invention is clearly not a microprocessor. Indeed, the on-chip TRAM of the present invention is designed to receive and store a complete texture pattern, whereas the 80860 would have to access off chip memory containing the texture pattern. There is no indication that the data cache alone in the 80860 is suitable for holding a texture pattern. As a result, the texture mapping capability of the present invention would be superior to that of the 80860 because of fewer off chip memory accesses. Therefore, since the TRAM of the present invention or an equivalent is not found in the 80860 as described by Williams, Applicants respectfully request reconsideration and withdrawal of the rejection of claims 1, 10 and 19 under 35 U.S.C. § 102.

(Emphasis added).

On October 20, 1995, the PTO issued an examiner action allowing Claims 1-18 of the '959 application and rejecting Claim 19. In allowing Claims 1-18 over the Williams 80860 reference, the examiner stated in full:

In view of the Applicant's remarks [contained in the June 26, 1995 response], the totality of the structural combinations recited is not rendered obvious by the prior art. Specifically, the cited prior art [Williams 80860 reference] does not teach a dedicated memory unit for storing a texture pattern, fault prediction means comprising more than cache miss notification as per the specification on pg. 15, lines 3-12, parallel memory access scheme, generating interpolations for different data widths, using interpolation schemes together on a single ic chip, and that filtering and pattern storage be done on a single chip.

In rejecting Claim 19 as anticipated by the Williams 80860 reference, the examiner stated in full:

As per claim 19, Williams teaches that Intel's 80860 RISC-based 64-bit microprocessor chip contains a memory management unit, data and instruction caches, and pixel-generated circuitry for shaded 3D graphics. Williams further teaches that the 80860 graphics section contains interpolation and adder logic for rendering shaded triangles. And Williams teaches that the 80860 is used for texture mapping.

(Citations omitted).

On January 16, 1996, the applicants canceled Claim 19, and on February 14, 1996, the PTO issued a notice of allowability for Claims 1-18 of the '959 application, which issued as U.S. Patent No. 5,548,709 ("the '709 patent"). The inventors assigned the patent to Silicon Graphics.

Like the '481 patent, the '709 patent discloses a semiconductor chip used to perform texture mapping and a method of performing texture mapping. The invention claims a chip containing a main memory, a cache memory, an interpolator, and a memory controller which controls the data transfers between the main memory and the cache memory. The invention differs from the invention of the '481 patent in that the '709 patent claims a chip containing a memory controller and a main memory on the chip. The '481 patent does not claim a memory controller or a main memory that is on the chip containing the interpolator and the cache memory.

The '709 patent has 18 claims. Claims 1 and 10 are independent claims. Claim 1 is an apparatus claim covering a semiconductor chip (TRAM). It includes six elements: (1) an input; (2) a main memory coupled to the input; (3) a cache memory coupled to the main memory; (4) a memory controller coupled to the main memory and cache memory; (5) an
interpolator coupled to the main memory and cache memory; and (6) an output coupled to the interpolator. Claim 1 reads as follows:

Claim 1

In a computer system, a semiconductor chip for performing texture mapping, said semiconductor chip comprising:

- an input for inputting textures to said semiconductor chip;
- a main memory coupled to said input for storing said textures;
- a cache memory coupled to said main memory, for storing recently used textures;
- a memory controller coupled to said main memory and said cache memory for controlling data transfers between said main memory and said cache memory;
- an interpolator coupled to said main memory and said cache memory for producing an output rendered pixel by interpolating from said recently used textures stored in said cache memory;
- an output coupled to said interpolator for outputting said output rendered pixel, wherein said input, said main memory, said cache memory, said memory controller, and said interpolator reside on a single substrate.

Claim 10 is a method claim covering the texture mapping process performed by a semiconductor chip (TRAM). It includes six elements: (1) inputting textures; (2) storing textures in a main memory; (3) storing recently used textures in a cache memory; (4) controlling data transfer; (5) interpolating from recently used texture to produce an output rendered pixel; and (3) outputting an output rendered pixel. Claim 10 reads as follows:

Claim 10

In a computer system, a method of performing texture mapping, said method comprising the steps of:

- inputting textures to a semiconductor chip;
- storing said textures in a main memory of said semiconductor chip;
- storing a recently used texture in a cache memory of said semiconductor chip;
- controlling data transfers between said main memory and said cache memory;
- producing an output rendered pixel by implementing an interpolator and interpolating from said recently used texture stored in said cache memory, wherein said interpolator resides on said semiconductor chip;
- outputting said output rendered pixel from said semiconductor chip.

2. Prosecution of the '481 Patent

On May 22, 1996, Hannah and Nagy filed Application No. 08/206,117 ("the '117 application), as a continuation of the '959 application. When first filed, the '117 application contained the specification and the original 19 claims of the '959 application. On November 5, 1996, the applicants filed an amendment, canceling pending Claims 1-19, and adding pending Claims 20-37. These claims are related to the '959 application's Claim 19. Both Claim 19 of the '959 application and Claims 20-37 of the '117 application disclose a semiconductor chip comprising a cache memory and an interpolator, but not an on-chip main memory, which is an element of the claims of the '709 patent.

In the remarks section of the preliminary amendment, Silicon Graphics made the following representations concerning the then pending claims:
The present invention is directed at a semiconductor integrated circuit chip which is dedicated to graphics processing, and in particular, texture mapping. For example, Independent Claims 20 and 29 include the unique limitation of a cache memory and an interpolator residing on the semiconductor chip dedicated to texture mapping, wherein the cache memory is configured to store a complete texture mapping.

While prosecuting the parent application, several related claims had been rejected as being anticipated by the article by Williams [the Williams 80860 reference].

Williams describes the Intel 80860 microprocessor ("80860") as having on-chip graphics processing circuitry. Although the 80860 is capable of texture mapping, it does not have the specialized architecture as claimed by applicants. In particular, the graphics processor in the 80860 does not have a cache memory that, alone, is capable of holding a complete texture pattern.

The present invention as claimed, however, includes the structural limitation of having a cache memory that is configured to store a complete texture mapping. As a result, the texture mapping capability of the present invention would be superior to that of the 80860 because fewer off chip memory accesses would be necessary.

(Emphasis added) (Citations omitted).

The applicants stated in conclusion:

Therefore, since the unique combination of a semiconductor chip dedicated to graphics processing having a cache memory that is configured to store a complete texture mapping, so as to require less memory accesses off chip, is not disclosed or suggested by any of the cited prior art references, applicants respectfully submit the claimed invention is in condition for allowance.

In a January 14, 1997 office action, the examiner rejected pending Claims 20-37 for obviousness-type double patenting, and rejected pending Claims 20-28 as indefinite under 35 U.S.C. § 112, second paragraph.

In the remarks accompanying this action regarding the double patenting rejection, the examiner compared Claims 1 and 2 of the '709 patent with pending Claims 20 and 21 of the '117 application. The examiner found that Claims 1 and 2 of the '709 patent differ from pending Claims 20 and 21 "in that [the '709 patent] claims 'an input for inputting textures to said semiconductor chip,' a 'main memory . . . for storing said textures,' and 'a memory controller' in addition to all of the elements of claims 20 and 21 of this application." The examiner found the only differences between the inventions of the '709 patent and the '117 application were as follows:

1) an input to the semiconductor chip is recited in [the '709 patent] and not in this application, 2) the cache memory of this application is recited to store "a complete texture mapping" whereas the cache memory of [the '709 patent] is recited to store "a recently used texture[,]" and 3) the main memory is disposed on the chip in [the '709 patent] and off the chip in this application.

With respect to the second enumerated difference, the examiner observed:

since both caches store texture map data, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have stored in the cache [] "a recently used texture" in place of [] "a complete texture mapping" to facilitate a type of texture processing desired.

The examiner compared pending Claim 29 to the '709 patent's Claims 10 and 11. The examiner found Claims 10 and 11 of the '709 patent differ from pending Claims 29 and 30 "in that [the '709 patent] claims 'inputting textures to a semiconductor chip,' [] 'storing said textures in main memory . . . ' [] and 'controlling data transfers between said main memory and said cache memory' in addition to all of the steps of claims 29 and 30 of this application." The examiner found the only differences between the inventions are as follows:

1) inputting textures to the chip in [the '709 patent]; 2) storing the textures in the main memory on the chip in [the '709 patent]...
With respect to the second enumerated difference, the examiner observed:

since both caches store texture map data, it would have been obvious to one of ordinary skill in the art at the time the invention was made to have stored in the cache a "recently used texture" in place of ["a complete texture mapping"] to facilitate the type of texture processing desired.

On April 29, 1997, the applicants also filed an amendment. The applicants amended pending Claims 20 and 29 by deleting the term "complete texture mapping" and inserting "texture mapping data" in its place. The applicants also amended Claim 20 to require "an input configured to input texture mappings to said semiconductor." The applicants stated that they had submitted a Terminal Disclaimer to overcome the examiner's rejection for obviousness-type double patenting over the '709 patent. The applicants also stated: "Applicants have amended claims 20 and 29 in response to the Examiner's rejection under 35 U.S.C. § 112 second paragraph. Moreover, the claims have been amended to more accurately claim the operations of the present invention."

On April 30, 1997, the applicants filed a Terminal Disclaimer agreeing that any patent issuing from the '117 application would only be enforceable for the statutory term of the '709 patent.

On August 20, 1997, the PTO issued a notice of allowability, allowing the '117 application's pending Claims 20-37, which issued as the '481 patent's Claims 1-18. The inventors assigned the patent to Silicon Graphics.

The parties' claim construction disputes concern terms in the '481 patent's independent claims, Claims 1 and 10, which are the same as the '117 application's pending Claims 20 and 29, respectively. Claim 1 of the '481 patent reads as follows, with disputed phrases italicized:

Claim 1

A computer system having semiconductor chip for performing texture mapping, said semiconductor chip comprising:

  an input configured to input texture mappings to said semiconductor chip;

  a cache memory coupled to said input, said cache memory configured to store texture mapping data;

  an interpolator coupled to said cache memory for producing an output rendered pixel by interpolating from a texture mapping stored in said cache memory; and

  an output coupled to said interpolator for outputting said output rendered pixel, wherein said input, said cache memory, and said interpolator reside on a single substrate device.

Claim 10 of the '481 patent reads as follows, with disputed phrases italicized:

Claim 10

A method for performing texture mapping, said method comprising the steps of:

  storing texture mapping data on a cache memory residing on a semiconductor chip;

  producing an output rendered pixel via an interpolator interpolating from a texture mapping stored in said cache memory, said interpolator residing on said semiconductor chip; and

  outputting said output rendered pixel from said semiconductor chip.

II. DISCUSSION
Based upon the above findings, the court construes the meanings of the disputed terms of the '481 patent.

A. Claim Construction

1. What is the Legal Standard Under Which the Court Construes the Patent Claims?

Claim construction is a matter for the court. Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995) (en banc), aff'd, 517 U.S. 370, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). The court construes claims according to their "ordinary and accustomed meaning." See Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1249 (Fed. Cir. 1998). Claims are construed from the vantage point of a person of ordinary skill in the art at the time of the invention. Markman, 52 F.3d at 986. In construing a claim, a court looks first to the intrinsic evidence of record, namely, the language of the claim, the specification, and the prosecution history. Insituform Tech. Inc. v. Cat Contracting, Inc., 99 F.3d 1098, 1105 (Fed. Cir. 1996), cert. denied, 520 U.S. 1198, 113 L. Ed. 2d 703, 117 S. Ct. 1555 (1997). The claim language itself defines the scope of the claim, and "a construing court does not accord the specification, prosecution history, and other relevant evidence the same weight as the claims themselves, but consults these sources to give the necessary context to the claim language." Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1552 (Fed. Cir. 1997).

Although extrinsic evidence such as expert testimony may be considered if needed to assist the court in understanding the technology at issue or in determining the meaning or scope of technical terms in a claim, Hoechst Celanese Corp. v. BP Chems. Ltd., 78 F.3d 1575, 1579 (Fed. Cir.), cert. denied, 519 U.S. 911, 136 L. Ed. 2d 198, 117 S. Ct. 275 (1996), reliance on any extrinsic evidence is improper where the public record, i.e., the claims, specification, and file history, unambiguously defines the scope of the claims. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996).

2. What is the Proper Construction of the Phrases "Cache Memory Configured to Store Texture Mapping Data" and "Storing Texture Mapping Data on a Cache Memory" in Claims 1 and 10 of the '481 Patent?

The parties dispute whether the phrases "a cache memory configured to store texture mapping data" in Claim 1 and "storing texture mapping data on a cache memory" in Claim 10 require a cache memory that stores a complete texture map. nVidia contends they do. Silicon Graphics contends they do not.

According to Silicon Graphics, the plain language of the claims does not require a cache memory configured to store a complete texture map, but only one configured to store "data" used for "texture mapping."

nVidia makes several arguments in support of its proposed claim construction. Each is based on the statements the applicants made to the examiner in the course of presenting their applications for the '709 and '481 patents. First, nVidia contends with these statements the applicants acted as their own lexicographers in describing and defining the cache memory and adopted a definition that it is a memory configured to store a complete texture mapping. Second, nVidia contends that by these statements the applicants disclaimed any meaning for the cache memory other than one that would store a complete texture pattern. Third, nVidia contends that the court should avoid construing the cache memory as configured to store less than a complete texture map, as that would render the claims obvious in light of the Williams 80860 reference.

a. Did the applicants act as their own lexicographers and define the phrase "cache memory" to mean a cache memory configured to store a complete texture mapping?

As a starting point, the court agrees that the plain meaning of the words in Claims 1 and 10 do not appear to describe a cache memory configured to store a complete texture mapping. Normally, the words "texture mapping data" read to suggest that the cache is configured to store some data, but not necessarily all or a complete texture mapping.

nVidia's position depends, therefore, on whether it can demonstrate that the applicants had used these words to express something other than their ordinary meaning. The Federal Circuit teaches that a term in a claim can be given something other than its ordinary and accustomed meaning when the patentee has chosen to be his own lexicographer "by clearly setting forth an explicit definition for a claim term." Johnson Worldwide Assoc., Inc. v. Zebco Corporation, 175 F.3d 985, 1999 WL 243570, *4 (Fed. Cir. 1999).
In this case, the court has four critical facts before it. First, in prosecuting both the '481 and '709 patents and in distinguishing their invention from the prior art, the applicants described the specialized architecture of their invention as including an on-chip TRAM designed to receive and store a complete texture pattern or complete texture mapping. Second, after offering this description of their invention, the applicants amended the '481 patent's Claims 1 and 10 to delete the words "complete texture mapping" and inserted in their place the words "texture mapping data." Third, in amending Claims 1 and 10, the applicants reported to the examiner that "the claims have been amended to more accurately claim the operations of the present invention." Fourth, Silicon Graphics now contends that the patent claims a cache memory that is not designed to receive and store a complete texture mapping.

While the second and fourth facts may be consistent with the words in Claims 1 and 10 if they are read according to their ordinary meaning, Silicon Graphics's current contention as to the architecture or configuration of the cache memory claimed is not consistent with the first and third facts. The question the court now addresses is what is the significance of the first and third facts? More precisely, can and should the inconsistency between the second and fourth facts and the first and third facts be resolved in the context of claim construction?

The court first notes that the Federal Circuit teaches "common words, unless the context suggests otherwise, should be interpreted according to their ordinary meaning." Desper Products, Inc v. QSound Labs, Inc., 157 F.3d 1325, 1336 (Fed. Cir. 1998). In Desper Products, the Federal Circuit interpreted the term "prior to" according to the "context of the specification." Id.

Silicon Graphics urges the court to approach any inconsistency between their statements concerning the Williams 80860 reference and the claims as an obviousness issue. The court, however, is inclined to find that this is, at least in part, a matter that can be resolved in the context of claim construction.

Prosecution history is an important source of intrinsic evidence in interpreting claims because it is a contemporaneous exchange between the applicant and the examiner. Id. at 1336-37. Starting with the prosecution history of the '709 patent, we see that in distinguishing pending Claims 1, 10 and 19 from the Williams 80860 reference, the applicants represented that a distinctive feature of the invention is that the "on-chip TRAM of the present invention is designed to receive and store a complete texture pattern." Pending Claim 19 claims a TRAM with only a cache memory for storing texture information. In the context of pending Claim 19, the applicants' statement must mean that the cache memory "is designed to receive and store a complete texture pattern."

The applicants subsequently canceled pending Claim 19. When the applicants refiled their application as the '117 application, they based pending Claims 20 and 29 on the '959 application's pending Claim 19; all three claims claimed a TRAM containing a cache memory and an interpolator, and all three claims do not claim an on-chip main memory. When presenting these claims to the examiner, the applicants claimed as a specific structural limitation an equivalent limitation to the one they placed on pending Claim 19 to distinguish it from the prior art: a cache memory that is configured to store a complete texture mapping.

Next, the examiner rejected Claims 1 and 10 for double patenting in light of the '709 patent. In explaining the action, the examiner referred to the phrase "complete texture mapping" in the '117 application as one of three differences in the claims of the two inventions. The examiner then discounted this distinction, finding it would have been obvious to store "a recently used texture" in the cache memory in place of "a complete texture mapping." This latter statement by the examiner is somewhat confusing, because the examiner appears to have inverted the chronology of the patents by stating that storing "a recently used texture" would be obvious in place of storing "a complete texture mapping."

The applicants overcame the double patenting rejection by filing a terminal disclaimer agreeing that any patent that issued from the '117 application would have the same statutory term of protection as the '709 patent. A terminal disclaimer is a technical and procedural device that allows inventors to incorporate later developments into their original patents without violating the double-patenting bar. 35 U.S.C. § 253.

The applicants also amended pending Claims 20 and 29, replacing the phrase "complete texture mapping" with the phrase "texture mapping data." Silicon Graphics now argues the applicants took the opportunity to disclaim the "complete texture mapping" limitation.
The applicant's amendment could have been a significant change in the invention they were claiming, if they did not already define "cache memory" to mean a cache memory configured to store a complete texture mapping, or give the same meaning to the phrase "complete texture mapping" as to "texture mapping data." This change would have been significant in such a case both because it would have deleted what the applicants had previously described as a unique aspect of their invention, and because it would have sought to capture or recapture a structure they had specifically disclaimed.

One would expect that, if the applicants had intended these significant changes, they would have so stated and would have identified their intention to the examiner. They did not. Instead, the applicants explained to the examiner that they had amended their claims "to more accurately claim the operations of the present invention." If that statement is correct, then it must be that the applicants had not intended the amendment to make a significant change in the description of their invention and in the matters claimed. Accordingly, if that statement is correct, and the amendments were nothing more than an attempt to "more accurately" claim the operations of the claimed invention, then we should read them so that they "more accurately" claim the invention.

The applicants have previously described their invention as "having a cache memory that is configured to store a complete texture mapping." It would not be a more accurate description of the invention to withdraw from the invention the structural limitation that the cache memory be configured to store a complete texture mapping, which the applicants have previously stated is one of the unique aspects of their invention. The applicants relied on this distinction in the '117 and '959 applications to distinguish their invention from prior art. Disclaiming it would have required an explanation as to how the invention overcame the prior art Williams 80860 reference.

It must be, then, that by stating that they were providing a more accurate description of their invention, the applicants did not intend to contradict their prior description, but to add precision to it. Accordingly, the applicants must have believed that the phrase "texture mapping data" added precision to their claims, while, at the same time, maintained the structural limitation that the cache memory be configured to store a complete texture mapping.

The applicants' representations throughout the course of the prosecution history demonstrate that the applicants acted as their own lexicographers in defining the phrase "cache memory." While prosecuting the '959 application, the applicants represented that the cache memory claimed in pending Claim 19 was designed to store a complete texture pattern, even though the claim did not contain the phrase "complete texture pattern" or the term "complete." Instead, the applicants acted as their own lexicographers to define cache memory to mean something different than its ordinary meaning. The applicants retained their own definition of the phrase "cache memory" when prosecuting the '481 patent by representing pending Claims 20 and 29 of the '117 application were configured to store complete mapping data. Even when the applicants dropped the words "complete mapping data" out of the claim, this did not remove the structural limitation, because the stated reason for the amendment was to "more accurately claim the operations of the present invention."

In this context, the court finds that the applicants have acted as their own lexicographers. The applicants clearly set forth an explicit definition of the phrase "cache memory" in Claims 1 and 10 of the '481 patent. See Johnson Worldwide Assoc., Inc. v. Zebco Corporation, 1999 WL 243570, *4. It is apparent from the applicants' statements that they intended to use the phrase "texture mapping data" consistently with the phrase "complete texture mapping" so as to define the cache memory as configured to store a complete texture map. The public had a right to rely on the applicant's representations during the prosecution history. See Spectrum Intl, Inc. v. Sterilite Corp., 164 F.3d 1372, 1378 (Fed. Cir. 1998); Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1347 (Fed. Cir. 1998) ("The public has a right to rely on such definitive statements made during prosecution. Notice is an important function of the patent prosecution process . . . .").

Accordingly, the court construes the phrase "cache memory" in Claims 1 and 10 of the '481 patent to mean a cache memory configured to store a complete texture mapping.

b. Did the applicants disclaim a chip that stores less than a complete texture pattern in on-chip memory?

Because the court has found that the applicants acted as their own lexicographers by defining cache memory to mean a cache memory designed to store a "complete texture mapping," the court need not reach the issue of whether the applicants disclaimed a chip that stores less than a complete texture pattern in on-chip memory.

c. Is it proper for the court to interpret "cache memory" as meaning anything other than a cache memory configured to store
a complete texture mapping?

nVidia argues that Silicon Graphics's proposed construction results in Claims 1 and 10 of the '481 patent being as broad as the '959 application's Claim 19, which the examiner rejected based on prior art, and which the applicants canceled. nVidia argues that the court should not adopt a meaning of the phrase "texture mapping data" which would invalidate the '481 patent. Because the court has found that the phrase "texture mapping data" in Claims 1 and 10 of the '481 patent means "complete texture mapping," the court need not reach this issue.

5. "Cache memory means"

Claim 1 of the '835 patent recites a "cache memory means" term. This term is drafted according to § 112 P 6. The claimed function is "storing data from main memory." Again, the parties dispute whether "storing" is used in the passive or active sense and this dispute affects the parties' positions on the appropriate corresponding structure. The court concludes that "storing data" in the context of this claim is used in the passive sense and means "retaining" data. The cache memory 320 is the corresponding structure. '835 Patent, Col. 14, ll. 42-46; col. 19, ll. 34-36, ll. 40-42, ll. 65-66; col. 20, ll. 38-42; Figs. 9 and 10A.

(c) Catching Policy Identification Information

StorageTek's proposed construction of this element is "storing information that identifies and is used to retrieve the particular policy selected." Cisco proposes "storing information that identifies and is used to retrieve a separately cached instance of network policy." The dispute between the parties is whether there is a requirement in the claim that the policy itself be "separately cached."

Cisco argues, in its Response and Supplemental Memorandum on Claim Construction ("Cisco Supp. Brief") that claim 1 requires the policy to be separately cached because the invention itself is entitled "policy caching method" and the preamble of claim 1 makes it clear that a "policy caching method" is being claimed. 16 Cisco also notes that the words "policy cache" or "policy caching method" are found in every independent claim of the 040 patent, indicating that the term, as used in the preamble, limits the scope of the invention claimed. See Karsten Mfg. Corp. v. Cleveland Golf Co., 242 F.3d 1376, 1380 (Fed. Cir. 2001) (where preamble term appeared in every claim, district court properly found that the preamble term described and limited the invention being claimed). Portions of the specification also consistently demonstrate that instances of PDU policy are separately stored in a "cache" or temporary memory. See, e.g. 040 Patent at Col. 2, In. 43-49 ("The present invention provides a network policy caching scheme which addresses the problem of enforcing policy at high data throughput rates by . . . caching the relevant portion of the policy, and applying that cached policy to the other related PDU's without requiring a complete analysis of the other related PDUs."); 040 Patent, Fig. 1, Element 110.

16 The amount of reliance a Court should place on the patent title in claim construction, however, is minimal. See Pitney Bowes, Inc, v. Hewlett-Packard Co., 182 F.3d 1298, 1312 (Fed. Cir. 1999) (describing the patent title as nearly irrelevant to claim construction process).

Additionally, in prosecuting the patent, the patentee characterized the invention as follows:

As recited in independent claims 1, 11, and 18, Applicant's invention provides a method and system wherein the contents of one protocol data unit (PDU) from a group of related PDUs is analyzed to determine a network policy for the PDU from
a plurality of policies. The instance of PDU policy is cached, as is the policy identification information identifying the instance of PDU policy. Lastly the instance of PDU policy is applied to the other related PDUs, without requiring a complete analysis of these PDUs, by utilizing the cached policy identification information to retrieve the cached instance of PDU policy.

See 11/4/97 Amendment and Response at 3 (emphasis added); 5/8/98 Response at 2 (same).

StorageTek responds that the preamble and the description of the invention in the summary of the invention do not limit claim 1 where claim 1 itself is silent on whether the policy itself is separately cached. StorageTek also argues that because the term "policy cache" in the preamble does not give "life and meaning" to the remainder of the claims, it cannot be viewed as limiting. See StorageTek Supp. Brief at 3. Attempting to rebut Cisco's reliance on the prosecution history, StorageTek contends that the description of the invention in the prosecution history does not limit claim 1 as the specification and prosecution history explain that the invention provides several steps to completely process a PDU. StorageTek argues that claim 1 does not require all of the steps, where as claim 11 requires all six steps. The Court, however, fails to see how this fact is important. Claims 11 and 18, which the patentee relied on along with claim 1 in describing the invention, also do not explicitly mention or require the caching of the policy. Yet the patentee described the "invention" recited in claims 1, 11 and 18 as caching the instance of PDU policy as well as the policy identification information. Additionally, while StorageTek argues that the policy cache is separately claimed in claim 19 and, under the doctrine of claim differentiation a separate policy cache cannot be incorporated into claim 1, claim 19 claims an instance policy cache "operatively coupled" to the exception processing means provided in claim 18. Based on the language of the claim, it appears that claim 19 is directed towards the "caching of the instance of PDU policy" in conjunction with the exception processor of claim 18. Due to the difference in scope of claim 19 and claim 1, the doctrine of claim differentiation is not properly raised.

Finally, Cisco relies on extrinsic evidence from its expert and the inventors of the 040 patent to support its construction. Cisco's expert asserts that requiring the instance of policy to be stored separately in a cache is necessary to serve the purpose of the invention to speed up filtering and auditing of packets. See Smith Decl. PP 43-44. Defining claim 1 to require the separate caching of the policy is also consistent with the testimony of the inventors. See Olson Decl. P 16; Hughes Depo. 131:21-24, 133:24-134:5.

Because the patent consistently emphasizes the importance and necessity of caching the policy itself, and the patentee explicitly characterized the invention claimed in claims 1, 11 and 18 as including a separate policy cache, the Court construes "caching policy identification information" as "caching policy identification information" means storing information that identifies and is used to retrieve a separately cached instance of network policy.

485

Claim 1 of the '040 patent includes the step of "caching policy identification information." StorageTek contends that the district court erred when it construed that claim language to require not only caching of policy identification information, but also caching of an instance of network policy. Cisco argues, as it did before the district court, that the written description and prosecution history make it clear that the invention involves utilizing the cached policy identification information to retrieve a cached instance of policy, and therefore the claims must be construed to require the instance of policy to be cached. As discussed below, we agree with StorageTek that the district court's interpretation of claim 1 was overly narrow.

Our analytical focus must begin with and remain centered on the language of the claims themselves. Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1201, 64 USPQ2d 1812, 1817 (Fed. Cir. 2002). Claim 1 is a method claim with two steps--determining an instance of network policy to be applied to related PDUs based on the contents of one PDU, and caching policy identification information identifying that instance of network policy. The claim does not include any step relating to caching the instance of network policy or any limitation indicating that the instance of network policy is stored in or retrieved from a cache. According to its plain language, the limitation construed by the district court, "caching policy identification information," requires only the identification information, not the instance of network policy, to be cached.

The district court based its interpretation in part on the presence of the phrase "policy caching method" or "policy cache" in
the preamble of every independent claim of the '040 patent. Whether to treat a preamble as a claim limitation is determined on the facts of each case in light of the claim as a whole and the invention described in the patent. See Catalina Mktg. Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 808, 62 USPQ2d 1781, 1784 (Fed. Cir. 2002). In the case of the '040 patent, the written description consistently uses the terms "policy caching method" and "policy cache" to refer to the invention as a whole, not to the specific step of storing an instance of network policy or to the cache that stores the instance of network policy, which the written description refers to as the "instance policy cache." Similarly, the term "policy caching method" or "policy cache" in the preamble of each claim serves as a convenient label for the invention as a whole. See IMS Tech., Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1434, 54 USPQ2d 1129, 1137 (Fed. Cir. 2000) (holding that preamble phrase "control apparatus" does not limit claim scope when it merely gives a descriptive name to the claimed invention). In contrast, any claim in the '040 patent that requires the instance of policy to be cached includes an explicit "instance policy cache" limitation in the body of the claim. See '040 patent, col. 17, l. 20 (claim 19 includes "instance policy cache means"). Thus, the preamble terms "policy caching method" or "policy cache" do not limit claim scope and simply refer to the invention set forth in the body of the claim, which, depending on the limitations provided in a particular claim, may include caching policy identification information or caching an instance of policy or both. Claim 1 includes only the step of caching policy identification information, and therefore it was improper for the district court to further limit the scope of claim 1 based on language in the preamble.

The district court also relied on the written description, prosecution history, and a declaration by Cisco's expert witness regarding the purpose of the invention to define claim 1 to require a cache for the instance of network policy. In so doing, the district court disregarded the well-established rule that while proper claim construction requires an examination of the written description and relevant prosecution history to determine the meaning of claim limitations, additional limitations may not be read into the claims. See, e.g., Prima Tek II, L.L.C. v. Poly泪, S.A.R.L., 318 F.3d 1143, 1148, 65 USPQ2d 1818, 1821 (Fed. Cir. 2003); Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186, 48 USPQ2d 1001, 1005 (Fed. Cir. 1998). We have recognized that there is sometimes a fine line between reading a claim in the written description and relevant prosecution history, and reading a new limitation into the claim. Comark, 156 F.3d at 1186, 48 USPQ2d at 1005. However, "interpreting what is meant by a word in a claim 'is not to be confused with adding an extraneous limitation . . ., which is improper.'" Intervet Am., Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 1053, 12 USPQ2d 1474, 1476 (Fed. Cir. 1989) (quoting E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433, 7 USPQ2d 1129, 1131 (Fed. Cir. 1988)).

Cisco relies on the fact that Figure 1 of the '040 patent shows two caches--a "cached instance classification" cache and a "cached instance policy" cache--to support its theory that claim 1 requires the instance of network policy to be cached. This argument, however, ignores Figure 2, which is a flowchart showing the steps of the inventive method. Figure 2 includes a step for caching policy identification information, but notably does not show a step for caching an instance of network policy. Given the lack of explicit language in claim 1 requiring the instance of network policy to be cached and the absence of any such step from Figure 2, the written description is not a basis for construing the claim as requiring the step of caching an instance of network policy.

Cisco's use of the prosecution history to narrow the meaning of claim 1 is also misplaced. During prosecution, the patent applicants stated that in the invention as recited in claims 1, 11, and 18, the instance of network policy and the policy identification information are both cached. While on its face this statement appears to limit claim scope, it cannot do so absent some claim language referring to the caching of the instance of network policy. The prosecution history statement describes generally the features of the claimed invention and erroneously suggests that the independent claims include a cache for the instance of network policy. The applicants' inaccurate statement cannot override the claim language itself, which controls the bounds of the claim. See Rambus Inc. v. Infineon Techs. AG, 318 F.3d 1081, 1089, 65 USPQ2d 1705, 1711 (Fed. Cir. 2003) (holding that general statement introducing new limitations does not limit scope of claims not amended to include the new limitations); Intervet, 887 F.2d at 1054, 12 USPQ2d at 1477 (holding that erroneous statement made during prosecution does not limit claim scope because "the claims themselves control").

Finally, the district court improperly relied on extrinsic evidence in the form of a declaration by Cisco's expert to support its construction of claim 1. Resort to extrinsic evidence is appropriate only when an ambiguity remains after consulting the intrinsic evidence of record. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583, 39 USPQ2d 1573, 1578 (Fed. Cir. 1996). Moreover, the district court did not use the extrinsic evidence to assist in defining a claim limitation, but rather used it to limit claim scope based on the purpose of the invention, which is impermissible. See Comark, 156 F.3d at 1187, 48 USPQ2d at 1005 (rejecting defendant's attempt to limit claim term to its functional purpose as disclosed in the preferred
B. Claim Construction

A review of the intrinsic evidence begins with the claims themselves. See Vitronics, 90 F.3d at 1581, 39 U.S.P.Q.2d (BNA) at 1576. The claims are to be construed in light of the specification and "both are to be read with a view to ascertaining the invention." Bell Communications Research v. Vitalink Communications Corp., 55 F.3d 615, 620, 34 U.S.P.Q.2d (BNA) 1816, 1819 (Fed. Cir. 1995); see also Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2d (BNA) at 1577 (stating that the specification is reviewed to determine whether the patentee used terms inconsistent with their ordinary meaning). Finally, the court should consider the prosecution history for any express representations regarding the scope and meaning of the claims. See Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2d (BNA) at 1577.

The claim terms are generally given their ordinary and customary meaning. See id. Accordingly, a technical term used in a patent is interpreted as having the meaning a person "experienced in the field of the invention" would understand it to mean. Hoechst Celanese Corp. v. BP Chem. Ltd., 78 F.3d 1575, 1578, 38 U.S.P.Q.2d (BNA) 1126, 1129 (Fed. Cir. 1996). See also Johnson Worldwide Assoc., Inc. v. Zebco Corp., 175 F.3d 985, 989, 50 U.S.P.Q.2d (BNA) 1607, 1610 (Fed. Cir. 1999) (noting the "heavy presumption" that courts "give full effect to the ordinary and accustomed meaning of claim terms."). Of course, a patentee is free to act as his or her own lexicographer and may define a claim term differently from its ordinary meaning. See id. However, if the patentee chooses to act as his or her own lexicographer, this special definition must be "clearly stated within the patent specification or file history." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2d (BNA) at 1576.

There is no indication in the written description or in the prosecution history that the patentee intended "CAD system" and "CAD commands" to be defined differently from their ordinary or customary meanings. Therefore, this court's task is to determine the ordinary meaning of "CAD system" and "CAD command" to one experienced in the field of the invention. See Hoechst Celanese Corp., 78 F.3d at 1577, 38 U.S.P.Q.2d (BNA) at 1129.

In the written description, the patentee describes a CAD system as a package "commonly used to create and edit drawings and other graphic displays on a computer screen or other cathode ray tube (CRT) display." '393 Patent, Col. 1, ll. 17-21. The district court relied heavily on this sentence as the proper understanding of CAD system to one of skill in the art. However, in the very next sentence of the written description, the patentee further describes CAD systems as "particularly well-suited for producing engineering design drawings." '393 Patent, Col. 1, ll. 21-22. The district court disregarded how this sentence further refines and narrows the broad description found in the previous sentence. As a result, the district court adopted an unduly broad definition of "CAD system."

The proper understanding of "CAD system" is ascertained by reading these two sentences in conjunction. For something to be a CAD system as understood by one of skill in the art, and as used in this patent, the system must not only be used to create and edit drawings on a computer screen, but must also be well-suited for producing engineering drawings. Thus, a "CAD system" is a species of graphics programs particularly well-suited for producing engineering drawings. "CAD commands," consequently, are those commands that enable a user to produce engineering drawings in a CAD environment.
The remainder of the written description supports this interpretation of "CAD system" and "CAD commands." For example, a user of a CAD system "can construct detailed design drawings and edit the drawings as necessary directly on screen." '393 Patent, Col. 4, ll. 38-40 (emphasis added). Similarly, "CAD commands are used to produce a design drawing or the like on a computer screen display." '393 Patent, Col. 4, ll. 15-17. Also, by using the technical term "CAD system" throughout the written description, the patentee is, of course, referring to the system described earlier in the patent--a system well-suited for producing engineering drawings. See col. 1, ll. 18-22. The fact that the specification does not repeatedly refer to engineering drawings or use particularly elaborate examples to illustrate the functionality of the invention does not suggest that the inventor intended to give "CAD system" a meaning broader than the ordinary and customary meaning of the term. See Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577 (stating that a patentee must clearly indicate that a claim term is used in a manner other than its ordinary meaning). Such statements further defining or describing "CAD system" are unnecessary given the explicit description of the term elsewhere in the patent and would have been redundant. Finally, merely because a CAD system is capable of producing simple drawings such as circles, lines, and the example found in Figure 4 of the '393 patent does not suggest that any graphics editor that can create such simple drawings is a "CAD system." This logical fallacy urged upon us by appellee must be rejected.

The doctrine of claim differentiation also supports this interpretation of "CAD system" and "CAD commands." Under this doctrine, two patent claims are presumptively of a different scope. See Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1366, 53 U.S.P.Q.2D (BNA) 1814, 1823 (Fed. Cir. 2000). This presumption is heightened if the absence of such a difference in meaning and scope would make a term in a claim superfluous. See Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023, 4 U.S.P.Q.2D (BNA) 1283, 1288 (Fed. Cir. 1987). For example, claim 8, depending from claim 1, restricts the "second means for electronically displaying in response to user input commands" of claim 1 to a CAD system. '393 Patent, Col. 10, ll. 60-62. Claim 8 also limits "merging means for merging said first and second images" of claim 1 to "editing means responsive to CAD user input commands of said second image for modifying said first image." '393 Patent, Col. 10, ll. 60-62. To broadly define CAD system as simply a generic graphics editor, as the district court did, would render claim 8, as well as claims 9 through 13, which also incorporate the CAD limitation, superfluous in light of claims 1 through 7. Thus, the doctrine of claim differentiation supports the conclusion that "CAD system" refers to graphic editors particularly well-suited for engineering design drawings, and "CAD commands" are those commands used by such a system.

3. "Calculating"

I construe "calculating" in the '415 patent to mean "determining" because of the patent's interchangeable use of those two terms. The '415 patent claims the laboratory automation system "reading the identification code [on the first carrier] and calculating" three different things:

the priority of the first specimen relative to any other specimens entered into the LAS;
the priority of each test to be conducted on the first specimen relative to one another; and
the most direct route from the receiving station to a first workstation for conducting the highest priority test of the first specimen

(Filing 64-3, Ex. C, at 6:13-21.) The term "recalculating" appears later in claim 1, and the term "calculations" appears in claim 3.

The specification of the '415 patent uses the word "determine" synonymously to describe all of these "calculations." (Id. at 2:40-55, 4:10-16.) Moreover, while the claims of the '415 patent refer to "calculation" of the "most direct route" (id. at 6:19-21), the specification states that the laboratory automation system "will determine the optimal route to workstation 30, while simultaneously determining the priority of the requested test." (Id. at 4:62-67 (emphasis added).) The abstract of the '415 patent likewise states that the laboratory automation system "reads the identification code and thereby determines" priorities. (Id., Abstract.) Hill-Rom Co., Inc. v. Kinetic Concepts, Inc., 209 F.3d 1337, 1341 (Fed. Cir. 2000) (abstract properly used in interpreting meaning of claim terms). "Determines" is also used as a synonym for "calculates" in the
description of the Summary of the Invention. (Filing 64-3, Ex. C, at 2:11-15) ("A further object is to provide a method for automating a laboratory which determines optional routing to a particular workstation . . . .").

Similarly, during prosecution the University used "determine" as a synonym for "calculate" in summarizing the invention by noting that "[a]t processing station 28, the carrier assignment is entered into the LAS to determine which work stations the specimen must utilize, the order in which the stations are to be utilized and any other pertinent information with respect to priority or turn around time." (Filing 64-5, Ex. E, at SHD001480 (emphasis added.).)

Neither the claims nor the specification of the '415 patent require that the "calculation" of priorities be accomplished by mathematical computation. One can readily envision "calculations" that require no computation; for example, the calculation of the "most direct route" could involve a determination of which workstations are busy and which are available —not the kind of mathematical computation the defendant's proposed construction requires. Similarly, in some circumstances, calculation of the priority among tests to be conducted on a specimen might involve a simple determination to follow an order given by a health care practitioner. Therefore, "calculating" in claims 1 and 3 of the '415 patent means "determining."

C. Calculating/Determining

Claim 1 and Claim 9 contain disputed limitations which refer to the calculation of the rate of blood flow. 4 Although the language used in each limitation is slightly different -- the former refers to "calculating" while the latter refers to "determining" -- both parties agree that the meaning of each limitation is the same. However, the parties do not agree what the meaning is. Plaintiff would interpret "calculating/determining" to mean: (1) the actual access blood flow using the measured amount of distinguishable blood characteristic (for example, flow = 600 ml/minute), (2) a number related to the flow rate from which flow rate can be determined, or (3) determining whether the flow rate is above or below a predetermined threshold (for example flow >/= 600 ml/minute)." (Pl's Reply Brief at 13). In contrast, defendant suggests the proper construction would be limited to: "determining a number representing the amount of flow of blood in the line per unit time without using a recirculation calculation, and using the equations set forth in the specification." (Def's Opening Brief at Exh. 1).

Nothing in the record, however, suggests that the terms "calculating" or "determining," as used in patent '989, mean anything other than, "to determine by mathematical equation." See WEBSTER'S NINTH NEW COLLEGIATE DICTIONARY (1991).

--- Footnotes ---

4 The relevant, disputed limitation in Claim 1 reads as follows: "calculating the rate of flow of said shunt blood flow in said arterio-venous shunt from said measured amount of distinguishable blood characteristic." The relevant, disputed limitation in Claim 9 reads as follows: "determining the rate of patient blood flow in said shunt from the measured amount of said changed parameter."

--- End Footnotes ---

While defendant asserts that representations made by plaintiff to the PTO now prevent plaintiff from relying on the plain language of the claim limitations, the Court is unpersuaded by this argument. Defendant relies heavily on a representation made by plaintiff to the PTO in which plaintiff stated:

[Recirculation and blood flow] are unrelated quantities, for shunt recirculation can only occur when the patient is connected to a hemodialysis machine through intake (arterial) and delivery (venous) lines. . . . Line blood flow, however, is a cardiovascular system quantity. It is the flow of blood, in mL/min, inside a patient, and a functioning shunt in a patient will always conduct such flow, whether a patient is connected to the dialyzer or not.

(Wong Decl., Ex. B at FH 989 0143). Specifically, defendant emphasizes plaintiff's statement that recirculation and blood flow "are unrelated quantities" in support of its position that the "calculations/determinations" anticipated by patent '989 do not, and cannot, rely on recirculation measurements in any way.

- 961 -
This emphasis, however, distorts the meaning and context of plaintiff's statement. As plaintiff stated in oral argument, the PTO was concerned that prior art which calculated recirculation in shunts rendered the '989 patent obvious. In response to this concern, plaintiff carefully explained to the PTO that the '989 patent device calculated, as an ultimate computation, blood flow -- a rate distinct from, or "unrelated" to -- recirculation rate. However, in making this distinction clear to the PTO, at no time did plaintiff disavow the device's possible reliance on a recirculation rate in calculating its ultimate blood flow determination.

Defendant also asserts that the equations set forth in the specification are the equations contemplated by the '989 patent. The intrinsic evidence cited by defendant in support of this argument, however, is comprised of nothing more than references taken out of context and puffed up to support defendant's position. While plaintiff did proffer various dilution equations in the specification to illustrate the preferred embodiments of their device calculations, no statements in the prosecution history suggest that plaintiff, or the PTO, intended to limit the blood flow calculation to the preferred embodiment equations. See Rhine, 183 F.3d at 1346.

A. Claims 1 and 9 of the '989 Patent

The parties dispute the meaning of the terms in claims 1, 9, 24, and 32 of the '989 patent. We turn first to the construction of claims 1 and 9. Transonic and NMT dispute the meaning of the term "calculating" in the final limitation of claim 1, which recites "calculating the rate of flow of said shunt blood flow in said arterio-venous shunt from said measured amount of distinguishable blood characteristic." '989 patent, col. 8, ll. 53-55. They also dispute the meaning of the term "determining" in the final limitation of claim 9, which recites "determining the rate of patient blood flow in said shunt from the measured amount of said changed parameter." 1 Id. at col. 9, ll. 34-35. Transonic argues that, based on the language of the claims, these terms should be defined as "calculating shunt blood flow using indicator dilution equations." NMT contends that the terms should be defined to require the use of the exact equations disclosed in the '989 specification. Despite their disagreement about the precise meaning of these two claim terms, Transonic and NMT agree that these terms should be given the same meaning. We therefore discuss claim construction of the term "calculating," but apply our final claim construction to both the terms "calculating" and "determining."

--- Footnotes ---

1 Claim 1 of the '989 patent is quoted above. Claim 9 reads as follows:

9. A process for determining patient blood flow in a patient hemodialysis shunt, comprising:

removing blood from a downstream location in a hemodialysis shunt by way of an inlet connected to an inlet side of a hemodialysis circulating line to provide blood flowing in said circulating line;

delivering the blood flowing in said circulating line by way of an outlet connected to an outlet side of said circulating line to an upstream location of said shunt, the blood from said outlet being delivered to said shunt so as to mix with patient blood flow in said shunt to produce mixed blood, whereby blood removed from said shunt by way of said inlet is a portion of said mixed blood;

changing a selected blood parameter in said circulating line to produce a distinguishable blood characteristic at the outlet side of said circulating line;

measuring in said circulating line the amount of said changed parameter present in said portion of the mixed blood; and

determining the rate of patient blood flow in said shunt from the measured amount of said changed parameter.

'989 patent, col. 9, ll. 13-35.
As noted, the preliminary injunction portion of this case has previously been before our court, so we begin with a discussion of our prior holding. In Transonic III, we concluded that the district court erred when it construed the claim terms "calculating" and "determining" to mean "to determine by mathematical equation." Transonic III, 10 Fed. Appx. at 934. In reaching that conclusion, we considered the intrinsic record, including the claims themselves, the '989 patent specification, and the prosecution history of the '989 patent, to determine whether the patentee limited the scope of the claims. Based on statements made by the patentee in the specification, we observed that "the '989 patent describes the determination of shunt blood flow with reference to specific equations." Id. We further noted that the specification contains "no description of 'calculating' or 'determining' blood flow that does not require the use of at least one of the disclosed equations" and that there is no indication that "the invention encompasses other methods of 'calculating' or 'determining' blood flow." Id.

We also considered the prosecution history in Transonic III, finding that "the disclosed equations are part of the claimed invention, play an important role in achieving the objects of the invention, and help to distinguish the invention from the prior art." Transonic III, 10 Fed. Appx. at 934. We concluded that "Transonic disclaimed any interpretations of the terms 'calculating' and 'determining' that do not reflect the stated significance of the disclosed equations to the invention as a whole." Id. In sum, we construed the claim terms "calculating" and "determining" as "requiring the use of at least one of the equations set forth in the specification of the '989 patent." Id.

As an initial matter, NMT contends that we are bound by this prior construction of claims 1 and 9 because it is the law of the case. Conversely, Transonic contends that the preliminary injunction proceedings were by their very nature provisional and that, as such, we are not bound by the claim construction set forth in Transonic III.

Our initial inquiry is whether, on remand, the district court was bound by our claim construction in Transonic III. Generally, the law of the case doctrine prohibits a court from revisiting an issue once it has been decided in pending litigation. Arizona v. California, 460 U.S. 605, 618, 75 L. Ed. 2d 318, 103 S. Ct. 1382 (1983) ("The [law of the case] doctrine posits that when a court decides upon a rule of law, that decision should continue to govern the same issues in subsequent stages in the same case."); see also Bio-Technology Gen. Corp. v. Genentech, Inc., 267 F.3d 1325, 1331 (Fed. Cir. 2001) ("BTG's position is contrary to the claim construction that is the law of this case."). The Supreme Court, however, has made clear that findings of fact and conclusions of law made by a court during a preliminary injunction proceeding are not binding on the court during trial. See Univ. of Tex. v. Camenisch, 451 U.S. 390, 395, 68 L. Ed. 2d 175, 101 S. Ct. 1830 (1981) (stating that "findings of fact and conclusions of law made by a court granting a preliminary injunction are not binding at trial on the merits"). We have consistently followed the Supreme Court's precedent by holding that a claim construction reached during an appeal from a grant of a preliminary injunction is tentative and is not binding on the district court in subsequent proceedings. Guttman, Inc. v. Kopykake Enters., 302 F.3d 1352, 1361 (Fed. Cir. 2002) ("District courts may engage in a rolling claim construction, in which the court revisits and alters its interpretation of the claim terms as its understanding of the technology evolves."). A district court therefore is at liberty to change the construction of a claim term as the record in a case evolves after a preliminary injunction appeal. Alternatively, a district court may adopt a construction reached by our Court in a preliminary injunction decision. Since the district court was not bound in this case, we also are not bound. We therefore review the court's claim construction under our traditional standard of review for claim construction, de novo. Cybor, 138 F.3d at 1456.

Claim language defines claim scope. SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1121 (Fed. Cir. 1985) (en banc). The terms used in the claims bear a "heavy presumption" that they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art. CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1366 (Fed. Cir. 2002). Nevertheless, an inventor may use the specification and prosecution history to limit the scope of the claim terms. Watts v. XL Sys., Inc., 232 F.3d 877, 882 (Fed. Cir. 2000). Thus to help determine the proper construction of a patent claim, a court consults the claims themselves, the written description, and, if in evidence, the prosecution history. Markman, 52 F.3d at 979-80.

Claim 1 of the '989 patent does not limit the term "calculating," except to require that the rate of flow of shunt blood flow be calculated "from said measured amount of distinguishable blood characteristic." '989 patent, col. 8, ll. 34-55. The claim language does not limit "calculating" to the use of any particular type of scientific principle or mathematical relationship. Turning to the specification, we have often stated that "one purpose for examining the specification is to determine if the patentee has limited the scope of the claims." Watts, 232 F.3d at 882. "The specification is always highly relevant to the
claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.” Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). In this case, the patentee's statements made in the SUMMARY OF THE INVENTION, and reproduced in pertinent part below, are instructive:

Blood flow, Q, measured by the dilution method (A. C. Guyton Textbook of Medical Physiology, Sixth Edition, p. 287, 1981) is given by:

\[ Q = \frac{V}{S} \] (Eq. 1)

where \( V \) is the amount of injected indicator and \( S \) is the area under a dilution curve and is equal to the average concentration of indicator in the blood for the duration of the curve, multiplied by the duration of the curve.

* * *

The change of characteristics is measured by known sensors, such as sound velocity sensors, electrical impedance sensors, optical sensors, thermal sensors, isotope sensors, or the like, and the blood flow relationships are calculated in accordance with the foregoing equations.

'989 patent, col. 1, ll. 56-61 & col. 4, ll. 26-27. As discussed in Transonic III, the specification does not disclose "calculating" or "determining" without the use of one of the disclosed relationships.

During prosecution, an inventor may surrender coverage of material that would otherwise be covered by a claim, but only if the surrender is clear and unmistakable. Bayer AG v. Elan Pharm. Research Corp., 212 F.3d 1241, 1252 (Fed. Cir. 2000) ("In determining whether there has been a clear and unmistakable surrender of subject matter, the prosecution history must be examined as a whole."). During prosecution of the '989 patent, in response to an Office Action rejecting the pending claims, Transonic identified several "primary features of the invention." Included in these features was "the calculation of shunt blood flow (line blood flow) from the sample via dilution principles as is taught in the present application." As discussed above, the only "calculation . . . via dilution principles" taught in the specification of the '989 patent revolves around the disclosed equations. In the same response, Transonic argued that the disclosed equations are critical to achieving the purpose of the invention and are novel over the prior art. It stated in pertinent part as follows:

The purpose of the invention is to measure shunt (blood line) blood flow, and for this purpose the application sets out the flow relationships which permit calculation of the line blood flow from other measurements. These relationships are not taught in the prior art . . . .

Moreover, Transonic distinguished a prior art reference during prosecution by explaining that, "in the present invention[,] shunt flow is calculated from a dialysis flow and a concentration curve measurement." Based upon the claim, the specification, and the prosecution history, we again conclude that Transonic "disclaimed any interpretations of the terms 'calculating' and 'determining' that do not reflect the stated significance of the disclosed equations to the invention as a whole." Transonic III, 10 Fed. Appx. at 934.

On remand from Transonic III, the district court further construed claims 1 and 9 as requiring the use of "the exact equations defined in the specification of the '989 patent." Transonic Sys., Inc. v. Non-Invasive Med. Tech. Corp., No. 1:00CV00046ST and No. 1:99CV00041B (D. Utah Sept. 14, 2001). The court stated: "In light of [the Federal Circuit's] claim interpretation, and because NMT's methods do not use at least one of the '989 patent equations, there is insufficient evidence that would allow a jury to find that NMT's methods infringe the '989 patent." Id.

The district court rejected Transonic's contention that the claims include equations that are variations of the general equations set forth in the specification, i.e., \( Q = \frac{V}{S} \). Transonic Sys., Inc. v. Non-Invasive Med. Tech. Corp., No. 1:00CV00046ST and No. 1:99CV00041B (D. Utah Sept. 14, 2001). Transonic renews this contention on appeal and argues that the district court went beyond our claim construction to require that NMT's methods use the exact equations disclosed in the specification. Transonic contends that the proper scope of the claims includes those equations that express the same mathematical relationships disclosed in the specification but are tailored to a specific indicator, also disclosed in the specification. Although the district court's reasoning is understandable, we do not think that the term "calculating" is limited to the exact equations disclosed in the '989 patent specification.
The specification discloses the use of several indicators to create a dilution curve as follows:

A dilution curve is obtained by measuring changes in a physical parameter of the blood over a period of time, and plotting the resulting variations. For example, if the blood parameter being measured is sound velocity, the injection of an indicator such as a saline solution, having a different sound velocity than blood, will produce a change in the measured parameter as the indicator passes the sensor location. The indicator dilutes the blood, and produces a sound velocity curve which is a measure of that dilution. Although injection of a saline solution is convenient for producing a measurable change in a blood parameter such as sound velocity, other changes of parameters may also be suitable. Thus, changes in temperature, electrical impedance, optical characteristics, and the like may also be used as indicators to produce dilution curves. For purposes of this disclosure, however, reference will primarily be made to the use of saline solution as the indicator, with resulting changes in sound velocity in the blood being measured to provide a dilution curve.

'989 patent, col. 1, ll. 66-67 & col. 2, ll. 1-17. Equations that embody the mathematical relationships disclosed by the specification, but are modified for a specific indicator, are within the scope of the claims. It would be improper to read such embodiments out of the claims. Vitronics, 90 F.3d at 1583 ("Indeed, if 'solder reflow temperature' were defined to mean liquidus temperature, a preferred (and indeed only) embodiment in the specification would not fall within the scope of the patent claim. Such an interpretation is rarely, if ever, correct and would require highly persuasive evidentiary support, which is wholly absent in this case."). Accordingly, we conclude that the terms "calculating" and "determining" must use at least one of the equations set forth in the specification of the '989 patent, i.e., "Q=V/S", but that the claims also cover the use of indicators other than saline. In other words, the elements of the equation, "V" and "S", may be altered to account for the characteristics of different indicators, such as saline, temperature, etc., so long as the relationships set forth in the equations in the specification are still expressed.

490

B.

1.

In Transonic II this court examined the relation between the "dilution principles" discussed in the '989 patent specification, the equations set forth in that specification, and the meaning of "calculating" and "determining" in the asserted claims. Rejecting the notion that infringement lay only in solving for shunt blood flow using the "exact equations" in the '989 patent specification, this court recognized that the specific arguments of the various equations might vary depending on the choice of indicator and the properties inspected to ascertain indicator density at any given time. As the court explained,

The specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term." Vitronics Corp. v. Conceptronic, Inc., 90 F. 3d 1576, 1582 (Fed. Cir. 1996). In this case, the patentee's statements made in the SUMMARY OF THE INVENTION, and reproduced in pertinent part below, are instructive:

Blood flow, Q, measured by the dilution method (A. C. Guyton Textbook of Medical Physiology, Sixth Edition, p. 287, 1981) is given by:

\[ Q = \frac{V}{S} \] (Eq. 1)

where V is the amount of injected indicator and S is the area under a dilution curve and is equal to the average concentration of indicator in the blood for the duration of the curve, multiplied by the duration of the curve.

***

The change of characteristics is measured by known sensors, such as sound velocity sensors, electrical impedance sensors, optical sensors, thermal sensors, isotope sensors, or the like, and the blood flow relationships are calculated in accordance with the foregoing equations.
"989 patent, col. 1, ll. 56-61 & col. 4, ll. 26-27. …The specification [of the '989 patent] does not disclose "calculating" or "determining" without the use of one of the disclosed relationships.

***

During prosecution of the '989 patent, in response to an Office Action rejecting the pending claims, Transonic identified several "primary features of the invention." Included in these features was "the calculation of shunt blood flow (line blood flow) from the sample via dilution principles as is taught in the present application." As discussed above, the only "calculation …via dilution principles" taught in the specification of the '989 patent revolves around the disclosed equations. In the same response, Transonic argued that the disclosed equations are critical to achieving the purpose of the invention and are novel over the prior art. It stated in pertinent part as follows:

The purpose of the invention is to measure shunt (blood line) blood flow, and for this purpose the application sets out the flow relationships which permit calculation of the line blood flow from other measurements. These relationships are not taught in the prior art. …

Moreover, Transonic distinguished a prior art reference during prosecution by explaining that, "in the present invention[,] shunt flow is calculated from a dialysis flow and a concentration curve measurement." Based upon the claim, the specification, and the prosecution history, we again conclude that Transonic "disclaimed any interpretations of the terms 'calculating' and 'determining' that do not reflect the stated significance of the disclosed equations to the invention as a whole."

Transonic II, 75 Fed. Appx. at 775-76.

The court concluded:

The terms "calculating" and "determining" must use at least one of the equations set forth in the specification of the '989 patent, i. e., "Q=V/S", but that the claims also cover the use of indicators other than saline. In other words, the elements of the equation, "V" and "S", may be altered to account for the characteristics of different indicators, such as saline, temperature, etc., so long as the relationships set forth in the equations in the specification are still expressed.

Id. at 776-77.

2.

Although the court explained that "calculating" or "determining" required the "use of at least one equation" set forth in the '989 patent specification, it did not delve into what it meant to "use" an equation or relation. Based on the '989 patent specification's frequent reference to dilution curves, on remand following Transonic II the trial court concluded that "calculating" means that the accused infringer has to "calculate a dilution curve."

Transonic contends that the trial court erred in this claim construction. In particular, Transonic contends that the construction is not required by the plain language of the claims, and, indeed, violates the canon of claim differentiation by making superfluous the specific reference to dilution curves in claim 18. Nor is the trial court's reading compelled by the '989 patent's written description, which discusses dilution curves in the context of explaining various mathematical relations but does not suggest that a curve must actually be drawn, or the area under a curve must be measured from a graph, in order to make use of the relations set forth in the specification. Finally, Transonic maintains that the trial court erred in ignoring the effect of a broadening amendment during prosecution, in which specific reliance on dilution curves was moved to issued claim 18 as a special case of the asserted claims. As set forth below, we agree with Transonic.

3.

For this analysis the court focuses on language, and prosecution history, of issued claims 1, 9, and 18. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996); Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 619-20 (Fed. Cir. 1995).
As originally filed, claim 1 required:

[1] measuring the [a] amount and [b] duration of said changed physical property in said arterial line and [2] producing a dilution curve from said measurement; and

[3] determining from the area of said dilution curve the blood flow in said arterio-venous shunt.

(ll. 21-25).

Responding to a June 19, 1996 Office Action (and examiner interview), the inventors cancelled original claim 1 and added new independent claims (43 and 52) that issued as independent claims 1 and 9. The inventors explained that the new independent claim 43 was "revised to more clearly highlight the features of the invention which distinguish it over the prior art of record." Arguing that new independent claims 43 and 52 (issued as 1 and 9) "define the primary features of the invention," the inventors defined those features as:

- "The sampling of the mixture downstream in the shunt using the intake of the hemodialysis circulating system;" and
- "The calculation of shunt blood flow (line blood flow) from the sample via dilution principles as is taught in the present application."

As issued, claim one requires:

measuring the amount of distinguishable blood characteristic in said removed portion of mixed blood; and

calculating the rate of flow of said shunt blood flow in said arterio-venous shunt from said measured amount of distinguishable blood characteristic.

'989 patent, col. 8, ll. 51-55 (emphases added). For this analysis, claim 9 differs only by reciting "determining" instead of "calculating."

The district court, Transonic argues, limited "calculating" in a manner consistent with the originally filed claim, but inconsistent with the broadened language that actually issued in claims 1 and 9.

By comparison, Transonic points to issued claim 18. It reads:

18. The process of claim 9, further including:

[1] producing from the changed parameter measurement an indicator dilution curve representing said distinguishable blood characteristic; and

[2] determining from said indicator dilution curve said blood flow rate in said shunt.

'989 patent, col. 10, ll. 9-13 (emphases added). As Transonic argues, issued claim 18 basically appends to claim 9 (which, with issued claim 1, replaced original claim 1) the limitations from original claim 1.

In view of this record, two long-standing principles of claim construction support the view that "calculating" is not limited to "producing a dilution curve," nor to "calculating a dilution curve." First, this court's case law precludes a reading that restricts "calculating" to the limitations removed by broadening amendment. See United States v. Telectronics, Inc., 857 F.2d 778, 783 (Fed. Cir. 1988) ("Courts are not permitted to read back into the claims limitations which were originally there and were removed during prosecution of the application through the Patent Office." [cit. omitted]); Kistler Instrumente AG v. United States, 224 Ct. Cl. 370, 628 F.2d 1303, 1308 (Ct. Cl. 1980) ("It is significant that none of the claims in the patent which ultimately issued contain the narrow limitation of original claim .... It must be concluded that the Patent Office did not feel that this was a critical limitation. Thus, defendant's insistence upon this court's reading back into the claims limitations which were originally there and were removed during prosecution of the application through the Patent Office
cannot be permitted."). Thus, "calculating" in issued claim 1 is broader than "calculating" in originally filed claim 1. The district court's construction is consistent with the plain language of the originally filed claim, but not the issued claim.

Second, by the doctrine of claim differentiation the court presumes that "determining" in claim 9 must have a different scope from the narrow limitations set forth in claim 18. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F. 3d 898, 910 (Fed. Cir.), cert. denied, 543 U.S. 925, 160 L. Ed. 2d 223, 125 S. Ct. 316 (2004) ("The presence of a dependent claim that adds a particular limitation raises a presumption that the limitation in question is not found in the independent claim."). "There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims. To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Tandon Corp. v. U.S. International Trade Com., 831 F. 2d 1017, 1023 (Fed. Cir. 1987). Claim 18 plainly requires "producing …an indicator dilution curve" and "determining" the shunt blood flow from it. By straightforward application of this doctrine, "determining" in claim 9 (and "calculating") has broader scope; it does not require "producing an indicator dilution curve." Although claim differentiation is only an interpretative presumption, NMT identifies no substantive reason to foreclose its application here. Cf. Comark Communications, Inc. v. Harris Corp., 156 F. 3d 1182, 1187 (Fed. Cir. 1998).

The '989 patent specification is fully consistent with a reading of "calculating" or "determining" that does not require creating a dilution curve or measuring the area (in part) underneath it. In the Summary of Invention, Transonic introduces its use of dilution methods to ascertain shunt blood flow. Discussing blood flow Q as a function of indicator volume V and defined variable "S", the specification explains:

S is the area under a dilution curve and is equal to the average concentration of indicator in the blood for the duration of the curve, multiplied by the duration of the curve.

'989 patent, col. 1, ll. 62-65. As this passage explains, the area under a dilution curve can be ascertained without actually drawing such a curve and measuring the area under it. Put differently, the parameter relevant to the claims at bar, "S", represents the product of average indicator concentration over a specific interval, and the duration of that interval. In short, although "S" may have meaning as an area in the context of a dilution curve, charting indicator concentration over time, the fact that S may be graphically illustrated does not require that an infringer actually plot the curve. Aside from claim 18, which specifically requires "producing …an indicator dilution curve," the claims at bar do not so require. The '989 patent specification, both at claim 18 and the written description explaining dilution principles, thus does not support the district court's analysis. The trial court erred in reading "calculating" and "determining" to mean "calculation of a dilution curve."

As this court explained in Transonic II, an infringer "calculates" or "determines" shunt blood flow within the meaning of the asserted claims by "using" at least one equation set forth in the '989 patent. A method or device "calculates" shunt blood flow within the meaning of the asserted claims if it solves for the flow as a function of the parameters set forth in the relevant question.

For example, the '989 patent expresses the basic relation between shunt blood flow (Q) and 'dilution' as a ratio of indicator volume (V) and the product of a measuring interval and the average indicator concentration over that interval (S). I. e., Q=V/S. This expression captures an intuitive relationship in which a high blood flow rate suggests a briefer interval over which indicator can be detected, or a lower average concentration as the indicator rapidly dissipates in the presence of a high blood flow rate (and vice versa). A method or device that solves for shunt blood flow by measuring or deriving indicator volume, identifying a measuring interval over which the indicator is detectable, and obtaining the average indicator concentration over that interval, and combining this information according to a relation described in the '989 patent, therefore "uses" that relation. A method that obtains S by plotting a dilution curve and measuring the area beneath it provides one way of "using" this relation or equation, but the asserted claims are not limited to that approach.

The court further reaffirms the analysis in Transonic II, where the court held that such "use" of an equation set forth in the '989 patent includes varying the specific parameters at issue to account for different indicators or different indicator or blood properties that are inspected to ascertain indicator density. That is, "the elements of the equation, 'V' and 'S', may be altered to account for the characteristics of different indicators …so long as the relationships set forth in the equations in the specification are still expressed." 75 Fed. Appx. at 777. The elements of the equation may be altered to account for use of a different indicator, a different way of introducing that indicator to the bloodstream at the upstream location, and a different changed blood characteristic measured at the downstream location, so long as the resulting equation utilizes indicator
5. "Calculating a Price" and "Calculate a Price"

Walker proposes that the claim terms "calculating a price" and "calculate a price" be construed to mean "ascertaining an exchange of value expressed as the composite credit or account parameters that a credit card issuer is willing to offer a customer, together with any fee or credit for modifying or entering into the credit account." Capital One proposes a construction "computing a fee or credit using a mathematical formula." Both Walker and Capital One base their proposed constructions of these claims terms on their proposed constructions of the claim terms "price for a credit account" and "price for a proposed credit account." Significantly, Capital One includes "computing . . . using a mathematical formula" in its proposed construction whereas Walker proposes "ascertaining an exchange of value." Thus, Walker proposes a broader construction of "calculate" that would permit the use of methods other than a computation for determining a price. As an example, Walker argues that if a customer wants to increase its minimum monthly payments by 30%, the issuer could make the change for free because the new terms are more favorable to the issuer. Walker argues that this new price -- a fee of zero -- is "calculate[ed] by simply ascertaining the trade-offs in the modified terms, without performing any 'computation' and without using a mathematical formula."

Since the court did not find Walker's "exchange of value" language to be an appropriate construction of "price" when that term is used with "for a credit account," it also finds that Walker's proposed language should not be adopted where the "price" is used in conjunction with "calculate." Walker cites three examples in the specification where a "price" is "calculated" and argues that these examples support its construction. In the first example, Walker notes that an issuer may be willing to issue a credit card to someone with a poor credit history if the card has a low credit limit and a high annual fee. (478 patent, Col. 2:60-67). In the second example, Walker notes that "[i]f a customer calls to cancel his account, the card issuer may be able to rewrite the terms of the customer's existing account and thereby entice him to stay." (478 patent, Col. 3:1-5). In the third example, Walker notes that "[t]he invention also benefits credit card issuers by providing them with an opportunity to charge a fee for changing the terms of a customer's account." (478 patent, Col. 3:6-8). The examples cited by Walker simply do not support its contention that the "price" is "calculated" by "ascertaining an exchange of value." Rather, the examples simply indicate how the invention may be used: to issue credit to people with poor credit histories; to rewrite accounts; and to the benefit of issuers. Tellingly, the claims consistently use the term "calculate" to mean that the invention uses a computation to determine a fee for the customization of a credit account. Capital One notes that the Walker Patents detail a calculation where "Price = Base x Adjustment = $ 30 x 96% = $ 28.80" and provide that other formulae may be used. (478 patent, Col. 7:64-65).

Keeping in mind that the field of the invention is computer programming in the credit account industry, the court finds that Capital One's proposed use of the word "computing" is consistent with use of the term "calculate" in the Walker Patents. Each example and description of "calculation" contained in the Walker Patents contains some form of "computation." Furthermore, given that the invention involves an apparatus and program, any program used to calculate a price or fee would need to be written using some criteria. This computer program intended to generate a "price" for the customization of the accounts would need to have some pre-established criteria for determining how each modification of the credit parameters would affect the final price. This is precisely the method that is described in detail in the specification. (478 patent, Col. 6:48-8:22). However, the court does not believe that it is appropriate to state in the construction that the "price" is "computed . . . using a mathematical formula." The specification does include examples of mathematical formulae but it does not limit the method of computing the price to mathematical formulae. Instructing the jury that a mathematical formula is required by the claim language may cause confusion.
Walker has proposed that these terms be construed so as to reference the fact that the calculation is undertaken with reference to the account parameters. The court finds ample support for this proposition (e.g. '478 Patent, Col. 6:48-52) even if it does not agree with Walker's phrasing. It is clear from the Walker Patents that every "calculation" conducted to determine the price is done with reference to the account parameters. This is critical, because without this limitation almost any type of computation could be read into the patent, when it is clear that it is the interplay between the various account parameters that is to be calculated when determining the price. For these reasons, the court construes the terms "calculating a price" and "calculate a price" to mean "computing a fee or credit (that may be zero) for modifying or entering into a credit account, based on the credit or account parameters."

4. The Calculating Step

The "calculating step" of Claim 1 states: "calculating at the programmed computer a remaining quantity of unfilled orders to fill using current-status information transmitted to the programmed computer." '877 Patent col.32 ll.38-40. Papyrus argues that in this step "the programmed computer uses some current-status information to mathematically determine the remaining quantity for each order that still needs to be filled, i.e., the leaves quantity." Pl. PCCO 2. According to Papyrus, under its construction, "the calculating step provides information about the progress of each unfilled or pending order by determining the leaves quantity for each order." Pl. MHSP vol. 1 at 52. The focus of Papyrus's construction, therefore, is the unfilled portion within each individual order.

As support, Papyrus relies on the plain meaning of the phrase, the specification, and dictionary definitions. Pl. Br. 15-16. It first asserts that because the term "fill" modifies the phrase "a remaining quantity," the calculating step concerns a remaining quantity to fill for each of the unfilled orders. Pl. MHSP vol. 1 at 54. In addition, Papyrus contends that the phrase "calculating . . . a remaining quantity of unfilled orders to fill" does not refer to the calculation of a single quantity, but rather, the calculation of the number of shares needed to fill each pending order. '877 Patent col.32 ll.38-40 (emphasis added); Pl. MHSP vol. 1 at 57-58; see KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000) (construing the indefinite article "a" to mean "one or more").

With regard to the specification itself, Papyrus notes that the written description teaches that "the invention provides continuous information as to the handling of the transmitted instruction, that is, partial executions against orders, cancellations, and the like" resulting in the "clerk, manager, or investor [having] complete knowledge of the status of an order or quote request through the trading day." '877 Patent col.6 ll.55-61. Further, the preferred embodiment explains that the computer program processes incoming data packets by updating the record to indicate a new stage or status for the corresponding instruction. Id. col.29 ll.37-52. Once the programmed computer receives the data, the base station computer then uses the current-status information to mathematically determine the number of shares needed to fill each pending order. See '877 Patent col.10 ll.17-21, Fig. 1 step 328; Pl. MHSP vol. 1 at 58. Indeed, the specification notes that the leaves quantity is calculated for each execution or partial execution. See '877 Patent col.29 ll.43-44 ("the leaves must be amended to reflect the execution"), col.30 ll.54-57 ("the remaining quantity or leaves that must be traded to fill the order is calculated at step 860."). Fig. 17 at step 860.

Alternately, NYSE construes the calculating step as "mathematically processing the current-status information to expressly determine a number of unfilled orders." Def. PCCO 2. In so proposing, NYSE argues that leaves are the number of shares remaining to be executed in a single order, while Claim 1 specifies calculating the remaining quantity of unfilled orders in the plural. Def. MHSP 113. NYSE contends that the only calculation the patent describes making before selecting a broker is the number of pending instructions. Def. MHSP 108. Specifically, it cites language in the specification stating that
brokers, and finding the floor broker with a comparatively few number of such instructions.

'877 Patent col.9 ll.55-60 (emphasis added). The Abstract and Summary of the Invention recite a similar description. See id. at Abstract ("the method uses a programmed computer to compare a relative number of instructions having a pending status . . . and find the floor broker having comparatively few pending instructions."); id. col.6 ll.64-col.7 l.4 ("[t]he method includes the steps of . . . determining the one of the one or more floor brokers who is best able to handle a further instruction by comparing the relative number of reviewed delegated instructions having a pending status . . . ").

NYSE also relies on the prosecution history, where Papyrus's amendment to Claim 1 allegedly "changed the claim from one directed to calculating leaves to one directed to calculating the number of unfilled orders." Def. MHSP 112. While the calculating step in the original text states "calculating at the programmed computer the remaining quantity that must be traded to fill a particular order using the current-status information transmitted to the programmed computer concerning the particular order," the amended step states "calculating at the programmed computer a remaining quantity of unfilled orders to fill using the current-status information transmitted to the programmed computer." Pl. App. Ex. 11 at 202 (emphasis added). Papyrus's own amendment also describes that the "calculation" of the number of open orders assigned to each broker sets up the "selecting step." The amendment states that

the management method compares a relative number of previously delegated instructions to the floor brokers which have a pending status so that the floor broker having comparatively few pending instructions can be found. The method then selects or suggests that the found floor broker be the one to whom a further instruction is delegated.

Pl. App. Ex. 8 at 176 (emphasis added).

Accordingly, the court finds that neither party's proposed construction fully encompasses the meaning of the calculating step. On one hand, the specification makes clear that the booth clerk frequently receives current-status information, including leaves quantities. See '877 Patent col. 10 ll. 17-21, col.29 ll.40-44, col.30 ll.54-57 & Fig. 1 step 328. Moreover, the specification clearly defines "leaves" as "the unfilled portion (leaves) of an orders [sic]," and as a quantity "which advises the broker of the quantity of stock required to be traded to fill the order." 13 '877 Patent col.15 ll.50-51, col.16 ll.55-57. On the other hand, the specification and prosecution history contain language suggesting that the calculating step involves a comparison of unfilled orders. See '877 Patent Abstract, col.6 ll.64-col.7 l.4, col.9 ll.55-60; Pl. App. Ex. 8 at 176, Ex. 11 at 202. During the Markman Hearing, Papyrus conceded that the clerk can compare the relative number of pending instructions through visual observation. Pl. MHSP vol. 1 at 64. Furthermore, in its discussion of the selecting step, Papyrus again stated that: ". . . the specification explains that a clerk may compare the relative number of pending instructions just by looking at lists of pending instructions for different brokers." Pl. MHSP vol. 1 at 73; see '877 Patent col.9 ll.24-27. The court must therefore settle on a construction of the calculating step that encompasses both leaves and the relative number of unfilled orders. See Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("[a] claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so."). Accordingly, the court construes the calculating step to mean "mathematically processing the current-status information to expressly determine a number of unfilled orders to be completed."

13 Even though the definition of "leaves" appears in reference to the HHD, the court must apply the same definition to the term in its use throughout the patent, as "a claim term should be construed consistently with its appearance in other places in the same claim or in other claims of the same patent." Rexnord Corp., 274 F.3d at 1342.

4. Calculating costs involved in moving such product to said destination based upon said destination and such product n5
DE maintains that the phrase means "determining applicable costs involved in moving such product to said destination based upon said destination and such product." Dell contends that the phrase should be construed as "mathematically determining the costs of moving the selected product including the costs of shipping, insurance, licensing fees, handling fees, documentation fees, and taxes on these costs."

Dell's construction, defining "calculating," as "mathematically determining," improperly imports a limit into the specification, because not all of the calculations of costs involve mathematical computation. For example, when the customer is able to determine the real price of his transaction, the code for the product is obtained by accessing a database "containing lookup tables of the harmonized international tariff tables and classification system, as well as the formats for any necessary import-export data, and administrative requirements for all countries involved in possible transactions." '020 Patent, col. 6, ll. 56-60. The court therefore finds that the word "calculating," shall be construed, in accordance with its plain meaning, as "determining."

In addition, Dell's construction requires certain costs to always be included in the cost calculation, such as transportation, insurance, duties, tariffs, and taxes. The court agrees with Dell's construction to the extent that it requires the determination of all actual underlying costs of shipping the product. See id. at col. 15, ll. 22-23 ("calculating costs involved in moving such product to said destination based upon said destination and such product"). These costs can include the cost of all freight for each leg of the journey, insurance (if desirable), sales taxes, handling charges, document generation and forwarding charges, import/export duties, and 'value added' taxes as well as luxury taxes (if applicable). Id. at col. 7, ll. 7-11. Dell's listing of costs improperly constrains the specification, however. The specification recognizes that the illustrative flowchart in the Appendix "show[s] many of the variables which will ultimately determine the final transaction price but in no way should this chart be construed to mean the only or all encompassing variables. Since each product or service is of itself unique and since the buyer and sellers geographic location can change, the variables are never fixed." Id. at col. 13, ll. 30-35 (emphasis added). Although all costs of a transaction must be determined at this step, the actual costs involved will vary depending upon the type of transaction. As Dell observes, a potential customer must have "the full cost of a foreign transaction displayed in front of him before the transaction is actually carried out." Id. at col. 9, ll. 1-3. The court bases its construction on the fundamental precept that a customer must be presented with all actual costs of moving a product.

Accordingly, the court finds that "calculating costs involved in moving such product to said destination based upon said destination and such product," must be construed as, "determining all applicable costs of moving the selected product to said destination."

Lextron's second argument is that the district court ignored the requirement that the calculation must be made "for the selected drug treatment." According to Lextron, its system does not perform calculations for any selected drug treatments but "merely considers the date an animal received some treatment and the longest withdrawal time of any drug treatment used in the feedlot."

We agree with Lextron that the claims require that the recited calculation be performed with respect to the withdrawal period for a specific drug selected for a particular animal. The claim language makes this clear, requiring that the computer calculation be "in response to entry of a selected drug treatment" and that it determine when the animal may be released "for the selected drug treatment." The specification also makes clear that the calculations are performed with respect to the specific drug treatments selected by an operator. Because the district court interpreted the claims to require merely the calculation of the "days to ship," without including as part of the calculation a drug withdrawal period corresponding to the treatment selected for the particular animal, the court's interpretation is incorrect.
Although we vacate the judgment in Micro Chemical's favor, we decline Lextron's invitation to rule that its modified system does not infringe as a matter of law. That question is one for the district court, not for us on this appeal, which was directed solely to the issue of claim construction. On remand, the district court, applying the correct claim interpretation, can determine whether Lextron's accused system performs in the manner recited in the claims either literally or under the doctrine of equivalents.

2. "CALCULATING . . . FROM THE RELATIVE MAXIMUM . . . AND MINIMUM"

The term "RELATIVE MAXIMUM AMPLITUDE" means the intensity of the composite waveform. See '372 patent, col. 11:39-40. The term "RELATIVE MINIMUM AMPLITUDE" is the background intensity or zero frequency. Id. at col. 11:40-41. The phrase "CALCULATING . . . FROM THE RELATIVE MAXIMUM . . . AND MINIMUM" (Claim 1) is construed to mean that both the relative maximum and relative minimum of the red and infrared waveforms must be "mathematically" used in the oxygen saturation calculation. In addition, the Court finds, as Masimo argues, that the minimum must be part of the composite, meaning that it must be determined after the composite waveform is generated. See Masimo Mot. at 12-14, and Reply at 13.

This Court declines to follow Nellcor's construction, which asserts that the maximum and minimum amplitudes are used "at some point in the calculation" of oxygen saturation - not necessarily after the composite is formed. See Nellcor Opp. at 17. Doing so would be contrary to the language of the claims and the file history, since both clearly indicate that "the maximum and minimum come from the composite waveforms," and thus, cannot be used in a calculation prior to the formation of the composite. '372 patent, col. 59: 41-43; See Masimo Mot. at 13; Reply at 12.

a. Claim Language

The claim language supports Masimo's construction. The language of the '372 claims require that the minimum must be part of the composite waveform, and must be determined after the composite waveform is generated. See 372 col. 59: 40-44 (explaining in Claim 1 that the time measure is processed to collectively determine "a composite waveform having a relative maximum and minimum amplitude . . . thereafter calculating the amount of blood constituent from the relative maximum and minimum amplitude of the composite") (emphasis added).

The strategic placement of the term "thereafter" in the claim demonstrates Nellcor's intent to conduct the calculation after the composite is formed. Further, if the calculation must "use" both the maximum and the minimum, as required by the claim language, then it only makes sense for the calculation to be completed after the formation of the composite, since the composite is composed of the necessary maximum and minimum waveforms.

b. File History

The file history also supports Masimo's construction, in that the Examiner distinguishes the '372 patent from prior art (and specifically the New, Jr. patent), by highlighting that, in the '372 patent, there is a composite waveform "having a relative maximum and minimum", whereas in the New, Jr. patent, there is "no composite signal." See Lateef Decl. Ex.1 at 208. The Examiner further contrasts '372 from New, Jr by explaining that '372 "yields a composite relative maximum and minimum." See also id. at 209.

Thus, the Court agrees with Masimo's construction and rejects Nellcor's contention that the relative minimum can be determined and used in the calculation of saturation before generating any composite waveform. See Masimo Reply at 11.
Nellcor next contends that the trial court erred when it ruled that "calculating ... from the relative maximum and minimum" requires that any calculation using the relative minimum must be made only after formation of the composite signal. We agree with Nellcor that the district court's claim construction is incorrect. The composite signal in the frequency domain embodiment of the '372 patent consists of data for each of 512 frequencies starting at zero frequency. The Fourier transform at zero frequency is equal to the average value of the signal in the time domain and represents the average background intensity of that signal. '372 patent, col. 11, ll. 54-58 & Fig. 10.

In the frequency domain embodiment of the '372 patent, the zero frequency component of the composite signal is computed when the average value of the signal is determined, which is before the transformation for the other frequencies that make up the composite signal. That average value is then subtracted from each of the 512 data points before the Fourier transform is computed for the rest of the 511 frequencies that make up the composite signal.

The district court was correct when it stated that the relative minimum value must be part of the composite signal, but it was incorrect in concluding that the minimum value may be determined only after the composite waveform is generated. Experience with oximeters has shown that infrared light has a different average detected background intensity than does red light. The detected background intensities for the red and infrared light are represented by the average value of the signal for each of those two wavelengths. Calculating the oxygen saturation of blood requires a determination of the ratio of the difference in absorbance level at those two wavelengths, with the detected average background intensities removed from each. Accordingly, in order to make that calculation, the infrared and red signals have to be normalized relative to one another. In the invention of the '372 patent, the relative maximum values of the infrared and red signals are divided by their respective relative minimum, or zero frequency, components to normalize each relative to the other. This division produces the same result regardless of whether it is performed before or after the transformation of the data to the frequency domain.

The district court found that the placement of the word "thereafter" in claim 1 supported its conclusion that the minimum value could be used only after the composite signal was generated. We disagree. "Thereafter" refers to the time when the amount of blood constituent is calculated, not to the time when the relative minimum is used. By requiring that the relative minimum value be used in any calculation of the oxygen saturation only after the composite signal has been formed, the district court added a limitation that is not present in the claim language and is not supported by the specification or prosecution history. We have stated that we "cannot construe the claim to add a limitation not present in the claim itself." Hewlett-Packard Co. v. Mustek Sys., 340 F.3d 1314, 1325 (Fed. Cir. 2003). In light of our analysis, we believe that "calculating the amount of blood constituent from the relative maximum and minimum amplitude of the composite periodic waveforms of the detected wavelengths" means only that both the relative maximum and the relative minimum of the red and infrared waveforms must be mathematically used in the oxygen saturation calculation.

5. "Calculating the reaction parameter"

Claim 50 of the '774 patent covers a method that requires a "computer implemented process," comprising several steps. The method requires determining the fluorescence polarization of the first and second mixtures and then comparing the fluorescence polarization levels of the two mixtures. The fourth step requires "calculating the reaction parameter." Caliper proposes that the term "calculating the reaction parameter" be construed as: "calculating a result that constitutes a measurement of or otherwise reflects the extent of the reaction."

MDC proposes: "calculating a result that constitutes a measurement of the extent of the reaction." The only contention is whether the construction should contain the words proposed by Caliper, "or otherwise reflects." Caliper's inclusion of the words "or otherwise reflects" is vague and ambiguous, although the primary contention appears to be whether the computer can generate more than a mere number when displaying the measurement of the extent of the reaction. The specifications contemplate alternative displays of information.

The specifications indicate that the computer receives the data regarding the interactions and "interprets the data, and ... provides it in one or more user understood or convenient formats, e.g., plots of raw data, calculated dose response curves, enzyme kinetics constants, and the like." ('774 Patent at 20:56-60.) The specifications also indicate that the computer, using the fluorescence polarization comparison, "may then interpolate or extrapolate a quantitative measure of the reaction, its
level of inhibition or enhancement which quantitative measurement may then be displayed to the investigator.” (’774 Patent at 19:46-50.)

Accordingly, the Court adopts MDC’s construction of the term "calculating the reaction parameter" to mean: calculating a result that constitutes a measurement of the extent of the reaction. However, this construction encompasses more than a display of a mere number to indicate the measurement of the extent of the reaction, and can include other user understood or convenient formats as described in the patent.

498

4. "calculating said glucose concentration in said sample from one of said reflectance readings" means calculating the amount of glucose contained per unit volume in the sample from the reflectance reading taken at the expiration of the predetermined time period.

499

The district court also construed "calculating said glucose concentration in said sample from one of said reflectance readings" to mean "calculating the amount of glucose contained per unit volume in the sample from the reflectance reading taken at the expiration of the predetermined time period." Claim Construction Order, 2002 U.S. Dist. LEXIS 27575 at *10 (emphasis added). This construction again improperly limited claim 4 of the ’162 patent to predetermined timing methods. This court construes "calculating said glucose concentration in said sample from one of said reflectance readings" to mean "calculating the amount of glucose contained per unit volume in the sample using a reflectance reading taken when the reaction between glucose in the blood sample and the reagents in the test strip has reached a suitably stable endpoint."

500

8. The phrase "CALIBRATION CODE CIRCUITRY FOR TRANSMITTING A DESIRED CALIBRATION CODE" (claim 10) requires a calibration code that is a value that indicates known wavelength(s) of light. The value must be a single known quantity. Further, the calibration code circuitry must be a part of the sensor probe.

501

1. "Call Authorization amount." Used in ’114 patent, Claims 1, 6, and 7; ’768 patent, Claims 1-3, 5-11.

"Amount of call authorization." Used in ’114 patent, Claims 1 and 6.

"Active Call Authorization Amount." Used in ’768 patent, Claims 1-3, and 5-11.

The parties initially stated that the primary dispute between them involves these three related claim terms. TGIP proposed: "a call amount that is useful for obtaining call service." Defendants suggested "any customer defined variable (i.e. not fixed or pre-set) amount, assigned to a calling card at the time of activation or recharge." A candid discussion between the court and the parties at the Markman hearing revealed that the more important issue is how the term "associating" applies to, and affects, these three terms.

To assist in the analysis, the relevant portion of the first claim of each patent is set out with these terms in bold:

Claim 1 from the ’114 patent:

at least one data terminal located at a predetermined location remote from the host computer and connectable to the input port for associating, at the host computer, an amount of call authorization to a security number of a calling card using data transmitted between the data terminal and the host computer during one or more charging transactions, the means for
associating of the data terminal including:

means for entering the security number;

means, operative during any initial transaction and any recharge transaction, for entering any monetary amount corresponding to the amount of call authorization;

means for connecting to the host computer to transfer the security number and the call authorization amount; and

means responsive to the transfer for receiving a verification message from the host computer authorizing receipt of the monetary amount to thereby associate at the host computer the call authorization amount to the security number, wherein the calling card does not store the call authorization amount; and

wherein the database includes a record for each calling card security number having a call authorization amount associated therewith, the record including a balance; and

Claim 1 from the '68 patent:

activating the particular pre-paid calling card account in the database of prepaid [sic] calling card accounts in response to receipt of the activation information by associating an active call authorization amount with the particular pre-paid calling card account;

for each pre-paid calling card account that is activated, maintaining in the database information sufficient to identify:(i) a date on which the particular pre-paid calling card account is activated, (ii) a particular point-of-sale location at which the particular pre-paid calling card account is activated, and (iii) the active call authorization amount that was associated with the particular pre-paid calling card account when activated on said date and from said point-of-sale location;

At the hearing the parties agreed generally that:

1. The "data terminal" is the terminal at which the calling card is swiped or data is otherwise entered at the point of sale where the customer obtains the card or recharges the card. Tr. p. 13-14; and

2. The "host computer" is the central computer, or a system of networked computers, that keeps track of all the cards or card accounts. Tr. p. 14-16.

The parties also agreed that, at a minimum, the three terms in dispute describe variable amounts selected by the customer. The real question is whether these terms can also be defined as including a pre-set amount, say $5.00 or $10.00. Tr. p. 11-13, p. 34-35. TGIP says they can. Tr. p. 21. The Defendants argue they can not. Tr. p.22.

TGIP points, among other things, to '114 patent col. 2, 11. 52-54, which describes using a keypad at the point of sale or recharge "for entering any monetary amount corresponding to an amount of call authorization associated with a particular calling card . . . ." TGIP also relies upon its request for reexamination of the '768 patent in which it stated that "[a]n active call authorization amount means a call amount that is then useful for obtaining the call service . . . . a call authorization amount (albeit inactive) may be associated with the account prior to the user purchasing the calling card account because the calling card account is not associated with an 'active call authorization amount' until an active, or usable, amount is joined with the account. . . . " Request for Reexamination, 7/6/2000, p. 3, Ex. E to TGIP's Opening Claim Construction Brief [Doc. # 200, Attachment # 5, p. 3 of 24]. Additionally, during the reexamination process, the Board of Patent Appeals stated that claim limitations of an "active call authorization amount" "do not require (but do not exclude) point-of-sale activation of varying call amounts . . . . The active call authorization amounts could be a limited number of predetermined values as in the prior art." See Board of Patent Appeals Decision of 9/26/2003, Ex. H, p. 11 to TGIP's Opening Claim Construction Brief [Doc.# 200, Attachment # 8, pp. 11 of 31].

The court does not discount TGIP's statement in reexamination proceedings out of hand, but recognizes that it was submitted to the PTO after some years of disputes concerning the patents. The court must be careful about allowing statements made during a reexamination to enlarge the patent's scope, or to recapture scope which had been earlier
surrendered when limiting arguments made to obtain the patent have not been retracted and brought to the attention of the new examiner. See Creo Prods. v. Presstek, Inc., 305 F.3d 1337, 1344 (Fed. Cir. 2002); Hakim v. Cannon Avent Group, PLC, -- F.3d --, 2007 U.S. App. LEXIS 3926, 2007 WL 542697, *3 (Fed. Cir. 2007). This would seem especially true when the statement in question was peripheral to the issues being addressed by the examiner and the Board of Appeals.

Of course, TGIP also relies upon the familiar cannons of construction that a patent is defined by its claims, that claims should be given their full scope, and that limitations should not be imported from descriptions of preferred embodiments.

Defendants rely heavily upon statements in the specification such as: "The present invention relates to . . . activation and recharging of calling cards in customer defined amounts." '114 patent, col.1., 11. 6-9. Defendants also argue that TGIP disavowed all cards issued in fixed or pre-set amounts pointing to statements distinguishing prior art such as: "The most significant drawback is the requirement that pre-paid calling cards be issued in fixed or preset amounts." ' 114 patent, col. 1, 11. 46-48, and '768 patent, col. 1, 11. 51-53. See Astrazeneca AB v. Mut. Pharm. Co., 384 F.3d 1333, 1340 (Fed. Cir. 2004).

It appears to the court that nothing in the claim language itself eliminates all cards with a pre-set amount. n3 The first use of the disputed phrase is in Claim 1 of the ‘114 patent: "associating, at the host computer, an amount of call authorization to a security number of a calling card . . . ." '114 patent, col. 6, 11. 14-16. In Claim 1 of the '768 patent Reexamination Certificate ("Reexam Cert") we see: "activating the particular pre-paid calling card account in the database of prepaid [sic] calling card accounts in response to receipt of the activation information by associating an active call authorization amount with the particular pre-paid calling card account." '768 patent Reexam Cert, col. 1, 11. 33-37. The statements in the specification and prosecution history of each patent establish that the intent was to go beyond the previous fixed limit card, but they do not eliminate the possibility that what is claimed is a new system which describes: (1) an "open ended" card (or one with a high upper limit) so the customer picks any amount (or any amount less than the high limit); and (2) a card with an amount preprinted on the card, or alternatively two or more amounts, one of which must be selected by the customer.

--- Footnotes ---

n3 The record contains a much more detailed exposition on this issue, including the responses of the parties to various hypotheticals. See Tr. pp. 10-60.

--- End Footnotes ---

Whether the claim language can be defined as including this second type of card is the real dispute. See Tr. p. 11-13. Both patents use the indefinite article "an" when referring to the call authorization amount or the amount of call authorization. The specification describes an embodiment in which there is "an amount of call authorization associated with a particular calling card . . . ." '114 patent, col. 2, 11. 53-54. The court concludes that the claim language describes at least some types of cards with a pre-printed amount, or perhaps a limited choice of amounts. To this extent,"call authorization amount" and "active call authorization" simply mean a monetary amount assigned to the card or account.

But the analysis does not end there. Two systems or scenarios for use of cards with pre-set dollar amounts are technically feasible. Tr. p. 16-18, 42.

Scenario 1: Cards of say $5.00 or $10.00, etc., where the security number is pre-associated with that amount at the host computer, but the card is not valid until it is "swiped" at the point of sale so the host computer knows it is activated. (In other words the host computer database already "knows" the security number of the card, and the amount of the card, and all that is needed is to validate or activate the card.)

Scenario 2: Cards of say $5.00 or $10.00 etc., where a security number is not associated with a particular card or amount until the card is swiped. This could include a card with a limited number of choices available, say a choice between $5.00, $10.00, or $15.00. (In other words the host computer database has a list of security numbers, and when a card is activated at the data terminal the amount printed on the card is associated with one of those security numbers.)

Comparing these scenarios illuminates the importance of the term "associating" and illustrates why it must be construed in conjunction with the three terms originally submitted. n4
n4 Of course, with a "variable" or pure "customer choice" card, no dollar amount can be associated with a security number until the customer selects an amount and activates or recharges the card for that amount. As noted, the parties do not dispute that the patent terms define this type of transaction.

Claim 1 of the '114 patent states that as part of the system there is a host computer with an input port, and a data terminal "connectible to the input port for associating, at the host computer an amount of call authorization to a security number of a calling card . . . ." '114 patent, col. 6, l. 11-16 (emphasis added). Similarly, Claim 1 of the '768 patent describes a method in which calling card account in the database is activated "by associating an active call authorization amount with the particular pre-paid calling card account." '768 patent Reexam Cert, col. 1, l. 35-37 (emphasis added).

"Associating" is an active verb, which must mean something. If, as TGIP argues, cards could have a preset amount printed and coded on the card, along with that card's identifying or security number, then what is left to associate by the host computer or the data terminal? After Claim 1 of original application for the '114 patent had been rejected as obvious in light of two earlier patents, the applicant stated:

Claim 1 has been amended to further emphasize several of the above-identified features and concepts that are neither described nor obtained by Schilling, taken by itself or in combination with Kamil . . . For example, Claim 1 now describes . . . The data terminal is now described as the device in the system which is used to associate an amount of call authorization to a security number of a calling card using the data transmitted between the terminal and the host computer.

Amendment to First Office Action, 5/18/1995, p. 8 (Bates No. TGIP 006428), Ex. 7 to Defendants' Responsive Brief [Doc. # 207, Attachment # 7, p. 9 of 11].

To define the terms at issue so broadly as to encompass the system of scenario 1 above, would simply ignore this statement to the PTO, and would define "authorizing" as simply meaning "validating." The prosecution history makes it clear that such a construction was rejected by the PTO. n5 The court will define these related terms as follows:

"Call authorization amount" as used in the '114 patent, Claims 1, 6, and 7, and "amount of call authorization" as used in the '114 patent, Claims 1 and 6, mean: "a monetary amount to be used to pay for call service."
be associated with a caller and also obtained by the disclosed "communication receiver" to perform the method described in claim 15. ('140, 2:12-19; 5:51-56; Fig. 4 (402)).

In contrast, VTech contends its proposal is consistent with the intrinsic evidence, including the specification and prosecution history ('140, 1:42-48), while Motorola's proposed definition is not supported by the disclosure in the specification. According to VTech, Motorola's use of the word "associated" is vague, consistent with Motorola's attempt to extend the scope of its user interface patents beyond what the specification enables, i.e. pagers and pager systems. VTech takes issue with Motorola's use of the word "associated" based merely on a statement made in the prosecution history. VTech contends that in response to a rejection by the Patent Office based upon the Sato prior art reference, Motorola Enhanced Coverage Linking clarified what it meant by the term "call-back number:" "The "call-back number" of the instant application is a telephone number associated with the person sending a page." (VTech Ex. 16, pg. 70) (emphasis in original).

There is some support for VTech's construction, "a phone number entered by a sender." Support for VTech's position is found in the Background section: "By utilizing numeric display paging, callers could dial a single telephone access number to send a call-back number (entered by the caller using, for example, a tone dialing telephone set) that the page recipient could then call to contact the caller by telephone (emphasis added)." ('140, 1: 44-49). And "[u]pon receiving the call, the paging control center 106 prompts the caller to enter a call-back number. . . . (emphasis added)." ('140, 3:60-62).

However, the phrase proposed by VTech requires action on the part of a sender (a second party in the claim), The claim in general and the surrounding claim language in particular, however, is directed toward the receiver. Further, the claim element in question is the "received" call back number. The file history quote noted by both parties emphasizes not how a call back number is created but rather what a call back number is ("a telephone number associated with the person sending a page").

Moreover, the exact phrases that VTech and Motorola have proposed are not found in the intrinsic record. In contrast, the exact phrase "a telephone number associated with the person sending a page" is supported by the intrinsic record. The Applicant made the remark during prosecution regarding the preferred embodiment: "the 'call-back number' of the instant application is a telephone number associated with the person sending a page." Ex. JJ (Paper 4 at 8). However, the examples listed in Col. 1:4-53 are not necessarily a person because they include "offices." Sometimes a page sender may not be a person, but a machine, or an automated dialer. Therefore, the Court removes the reference to "person" and construes the disputed phrase as "a telephone number associated with a page sender."

c. The Court's Construction

The Court construes the term "received call-back number" to mean "a telephone number associated with a page sender."

1. The Language of Claim 1.

The crucial clause of claim 1 requires a "call cost register means, including a digital display, for providing a substantially instantaneous display of cumulative call cost in dollars and cents." Because we can dispose of this appeal by construing only the "call cost register means," we need not and do not construe other, unrelated clauses except to the extent they can help us establish the requirements attributed to a call cost register means by the '463 patent. We therefore focus our attention on reviewing the construction of this clause, and this clause only.

According to claim 1, the call cost register means provides "a substantially instantaneous display of cumulative call cost in dollars and cents." Thus, it appears that a call cost register means functions to display current, accurate information about the cost of a call. It is not immediately clear, however, what the limitation "substantially instantaneously" requires. NTI and United suggest that it requires displayed information about the cost of the call at the same instant that charges accrue. Phonometrics argues, however, that it simply requires the display of accurate cost information immediately upon termination of the call. Fortunately, we need not rely solely on the words used in this means clause to determine the requirements of this limitation, for there are other clauses in claim 1 that inform our construction of the call cost register means and further define the functions attributed to it by the patentee. Specifically, the final three clauses of claim 1 provide
such information.

The first of these three clauses requires an "initial cost transfer means . . . for applying the complete initial fixed charge data from said charge selector means to said call cost register means substantially instantaneously upon resetting of said call timing means and said call cost register" (emphasis added). Thus, when the device is reset, the "initial fixed charge data" is transferred "substantially instantaneously" from the charge selector means to the call cost register means and displayed there via the digital display.

Claim 1 further requires (emphasis added) an incremental cost transfer means for applying the complete incremental charge data from said charge selector means to said call cost register means substantially instantaneously upon completion of timing out the initial call interval . . . and for again applying the complete incremental charge data from said charge selector means to said call cost register means substantially instantaneously upon completion of timing out of each incremental call interval following said initial call interval.

According to this clause, if the call is still in progress when the initial call interval has expired, the "incremental charge data" is transferred to the call cost register means and displayed there "substantially instantaneously." Additional incremental charges are transferred to the call cost register means "substantially instantaneously" upon the passage of additional call intervals. This process of transferring successive interval costs continues throughout the duration of the call.

The limitations in these clauses are revealing. The repeated use of the limitation "substantially instantaneously" to convey the immediacy by which the call interval cost information is transferred to the call cost register means supports our interpretation that the register displays cumulated costs as they accrue, in real time, and not only once the call has ended. A word or phrase used consistently throughout a claim should be interpreted consistently. Thus, as each cost increment is accrued, it is transferred to and displayed "substantially instantaneously" by the call cost register means. The phrase "substantially instantaneously" clarifies that the display in the register is current throughout the duration of the call; the call cost register does not merely display the cost after the call has ended.

Furthermore, the final clause addresses what occurs upon call termination; the claimed device includes a "termination means for interrupting operation of said computer apparatus, with the cumulative call cost held in and displayed by said call cost register means, upon operation of said switch by replacement of the calling telephone." It is especially significant that, at the point at which the call is terminated, the apparatus does not perform a calculation to determine the total cost of the call. Thus, the cost displayed in the register must be accurate at all times during the call, so that regardless of the point at which the call is terminated, the cumulative cost displayed in the register will be accurate without further calculation. Phonometrics's description of its claimed device as a "calculator" is therefore misleading; rather, the claimed device is simply a continuous counting device, for no provision is made for any calculation upon completion of a call.

When the claim itself is considered in its entirety, it becomes clear that the call cost register means has two separate and equally important functions: (1) it provides the caller with real time, accurate information about the cost of the call via digital display as the long distance charges accrue during the call, and (2) it reflects the total cost of the call via the same digital display after the call has terminated. Phonometrics argues that only the second function is claimed, or that only this second function is important for determining infringement. We disagree. Both functions are claimed explicitly in the '463 patent, and both are significant for construction.

2. The Written Description.

The language used throughout the specification preceding the claims supports this construction of dual functions of the call cost register means. For example, the written description explains that the call cost register means operate so that "the cumulative cost of a single call is displayed in the single call cost register . . . to continuously remind the caller as to the cost of the call as the call progresses and to indicate the total cost of the call at the completion." Col. 3, ll. 27-31 (emphasis added). This description of the operation of the call cost register means in a preferred embodiment supports our construction of the claim language: the call cost register means clearly provides information about the cost of the call while the call progresses. Although claims are not necessarily restricted in scope to what is shown in a preferred embodiment, neither are the specifics of the preferred embodiment irrelevant to the correct meaning of claim limitations. See Markman, 52 F.3d at 979, 34 U.S.P.Q.2D (BNA) at 1329. Phonometrics of course argues that additional limitations cannot be imported into a claim from the written description. We may, however, construe a specifically claimed limitation in light of the specification,
which is all we do here.

Similarly, the written description carefully explains the importance of the initial and incremental cost transfer means for the real time operation of the device:

When the party called is reached, the 90-volt pulse derived from the telephone line upon the lifting of the receiver of the called party substantially simultaneously clears the elapsed time indicator and starts the indicator counting time. Further, substantially instantaneously the single call cost register is cleared and loaded with the 3-minute charge indicated on the set charge selector. . . . Should the call exceed three minutes, the elapsed time indicator causes the per-minute overtime charge to be added to [the] cost register[], and this is repeated at further 1-minute intervals during the call. At the conclusion of the call, all counting stops and the displays in the cost register[] and elapsed time indicator are retained.

Col. 3, ll. 3-19 (emphasis added, internal figure references omitted). Thus, the specification further clarifies the way in which the claimed device operates, adding each incremental charge to the call cost register means as each interval elapses, to provide real time long distance charge information while the long distance call is in progress.

Phonometrics, however, objects to the district court's construction of the call cost register means -- that it displays the mounting cost of a call in progress -- observing that the phrase "in progress" appears nowhere within the language of claim 1. While Phonometrics is correct that this phrase does not appear in the claim itself, that fact does not render erroneous the construction given the claim by the district court. In fact, when the claim is considered properly as a whole, we think it clear that the '463 patent is limited to a device which displays the cumulative cost of a long distance call both as charges accrue during the call and after the call has been terminated.

3. The Prosecution History.

Finally, the prosecution history supports our understanding that the call cost register means performs two distinct functions by displaying cumulated costs both during the call and upon its termination. During prosecution of the '463 patent, the applicants specifically emphasized the functions of the cost transfer means in distinguishing over the prior art:

In addition, and as clearly set forth in Claim 10 [now claim 1 of the '463 patent], the apparatus of the present invention instantaneously transfers the three minute charge information to the cost register when the call is completed by the receiving party lifting the called telephone, and the incremental one minute charges are applied to the cost registers substantially instantaneously upon the timing out of each one minute interval. In the Fletcher device, and other similar prior art apparatus, the call charge information requires considerable time for entry and may well result in an erroneous charge recording if the calling telephone is hung up after only a minor increment of a charge interval is completed. This operational error is entirely obviated by the cost computer apparatus of the present invention. Accordingly, it is submitted that Claim 10 affords distinctive and patentable differences, in comparison with the prior art of record, and should be allowed.

Amendments to Application No. 229,711, April 4, 1973, p. 12 (emphasis added). Thus, the in-progress transfer of accrued costs to the call cost register means increased the inherent accuracy of the device compared to the prior art Fletcher device. By the applicants' own statement, the in-progress and instantaneous transfer of incremental costs was an important function for patentability. The function is clearly set forth by the claim language as viewed in light of the written description and the prosecution history, and cannot be ignored by us here.

Our independent review of the claim language thus reveals that the district judge's construction of claim 1 of the '463 patent with respect to the functions of the call cost register means was supported by the language of the claim itself, the rest of the specification, and the prosecution history. We hold that claim 1 of the '463 patent requires a call cost register means which functions both to provide accurate cost information while the call progresses as well as total cost information once the call has ended.

GO BACK

504

C.4.f. "call distributor"
According to Katz, "call distributor" means "hardware and/or software to receive and have the capability to direct calls." Katz Brief at 74. Verizon appears to allege that "call distributor" means "a switch for routing calls." See Verizon Brief at 100.

"Call distributor" means "hardware and/or software to receive and have the capability to direct calls." See Lucantoni Decl. P 29. This interpretation is consistent with the claim language and the specification. See 863 patent, Col. 4:15-31 ("the communication facility C is connected to the processing systems P1-Pn through an associated series of automatic call distributors AC1 through ACn. Each of the automatic call distributors AC1-ACn accommodates one hundred lines from the communication facility C and accordingly, may accommodate and queue up to 100 calls. Each of the automatic call distributors AC1-ACn may take various forms as well known in the prior art, functioning to queue incoming calls for connection to a lesser number of lines. In the disclosed embodiment, from each of the call distributors AC1-ACn, fifty lines are connected respectively to the individual data processing systems P1-Pn through an interface 20 and a switch 21. Thus, in the disclosed embodiment, each of the automatic call distributors AC1-ACn can accommodate one hundred lines, fifty of which may be active in association with one of the processing systems P.").

E. "Call Having a First Message"

Claims 1 and 18 of the '932 Patent refer to a system or method for handling a "call having a first message," in which a processing system receives and processes the "first message" to select a narrowband switch and generates and transmits a "second message" based on that selected switch. In Vonage, the Court adopted Sprint's proposed construction of "first message" in these claims to mean a signaling message that is distinct from the second message. See 518 F. Supp. 2d at 1322-23. Based on that ruling, Sprint now argues that "call having a first message" should be construed to mean a call having a signaling message that is distinct from the second message. Big River seeks to construe this phrase to mean the original signaling message created by the call. The Court rejects Big River's construction.

The Court begins with the language of the claims, at it must. Big River notes that the claims require that the "second message" be based on a selection made from processing of the "first message," which necessarily requires that the "second message" come after the "first message;" thus, Big River argues that the claims impose a temporal limitation. The Court agrees with Sprint, however, that because that sequence is dictated by the claim, "first" and "second" need not be further defined to incorporate that sequence. Moreover, the fact that the "first message" comes earlier in time than the "second message" does not bear on whether the "first message" is required to be the original message in the call.

The Court also does not agree with Big River that the language "call having a first message" somehow associates the "first message" with the entire call in a temporal fashion. Instead, the use of that language would appear to contradict Big River's construction, as a patentee intending Big River's meaning could more easily have referred to a call generally (which must of course have signals, and therefore a first-in-time signal as well) and the processing of the "original" or "first" message of that call. The use of the phrase "call having a first message" suggests that "first message" refers to something other than the original signaling message of the entire call, using "first" to distinguish its role from that of the "second" (or "third" or "fourth") message discussed in the claims.

Big River also cites portions of the specification that indicate that signaling messages are created when calls are placed. Those references do not use the term "first message," however, and they do not suggest that the message processed in the claims must be the original message of the call. To the contrary, the specification specifically notes that the element from which the processor receives the "first message" may be a switch in another network ('650 Family at 8:49-51), which would mean that the first-in-time signaling message for the call took place within that other network, and not within the claimed system.

Finally, the Court rejects Big River's argument based on the patent application's prosecution history. In the cited references, the applicant distinguished prior art by noting that the present invention routes the signaling message to the processor instead of routing it to a switch first. The applicant did not state that the invention required processing of the original message of a call, and the claims in the application at that point did not include the term "first message" at any rate.
Accordingly, the Court construes "call having a first message" in these claims to mean a call having a signaling message that is distinct from the second message.

506

B. "Call pod"

The term "call pod" initially appears in claim 1 of the '611 patent. Callpod contends that "call pod" should be construed to mean "a portable device which forms conference calls among a plurality of call participants." Defendants claim that "call pod" should be construed as "a portable device with at least two headset ports." Alternatively, Defendants recommend that "receptacles" or "plugs" be used in place of "ports" in its construction of the term as both are found within the patent description.

The claim language itself does little to resolve this issue. Each of the independent claims use the term "call pod" and states that the call pod is "for interconnecting a plurality of headsets." (JA, Ex. 1, '611 patent, claims 1, 9, & 18). However, nothing in the claims specifically suggests that the headsets require ports to achieve the interconnection. Fortunately, while the claim language is inconclusive, the specification expressly defines "call pod" as a "portable telephone device which forms conference calls among a plurality of call participants, at least two of which are proximate the call pod." (JA, Ex. 1, '611 Patent, at 2:23-25.) Defendants claim that this definition does not satisfy the precision requirement in 35 U.S.C. § 112 because Callpod's proposed definition could refer to any mobile telephone with a speaker function. However, the reference to headsets throughout the patent would resolve any such confusion and provide sufficient clarity and precision for a person skilled in the art to know what the invention actually concerns. Moreover, even when a different meaning from what the specification provides could be attached to the term at issue, "the inventor's lexicography governs." Phillips, 415 F.3d at 1316. Therefore, the Court will construe "call pod" to mean "a portable device which forms conference calls among a plurality of call participants."

<td>('861 Patent, 861 claims 1, 2, 3 and 11); ('465 Patent claim 1)</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Plaintiff argues that its definition is supported by the specification describing call reports in the context of users operating elevator cars in which a first call report can "indicate a conveying destination (upwards or downwards) or a boarding floor" and a second call report indicates a "destination floor." ('465 Patent col. 4:59-67.) Plaintiff further argues that another embodiment of a "call report" is a "destination call report," which is defined in the specification as including "data regarding not only the boarding floor, but also the destination floor." (Id. col. 6:18-19.).

Defendants counter that the term "call report" is invalid based on its ambiguity. Defendants emphasize that, at a minimum, the construction of "call report" must include some limitation concerning it to use for controlling the elevator control.

With respect to Defendants' indefiniteness argument, the issues before the Court with respect to this term are whether it is indefinite, and if not, what its proper construction should be. "If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, [the Federal Circuit has] held the claim sufficiently clear to avoid invalidity on indefiniteness grounds." Exxon Res. & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001). "A claim will be found indefinite only if it is insolubly ambiguous, and no
narrowing construction can properly be adopted . . ." Praxair, Inc. v. ATMI, Inc., 543 F.3d 1306, 1319 (Fed. Cir. 2008) (internal quotation marks and citation omitted). In contrast, a claim term is definite if it can be given any reasonable meaning. See Young v. Lumenis, Inc., 492 F.3d 1336, 1346 (Fed. Cir. 2007) (citing Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1347 (Fed. Cir. 2005)).

A reasonable meaning for the term "call report" can be derived from the specification. As cited by Plaintiff above, the specification describes a "call report" to be "for example, analog electrical signals of defined current strength, voltage, frequency, period, etc." ('465 Patent, col. 5:37-40.) The specification further provides that a "call report" includes both a "boarding floor" and a "destination floor" for a passenger. (See id. col. 4:59-67; id. col. 6:18-19.). Based on these descriptions, the Court finds that the term "call reports" is not ambiguous as its meaning could be discerned by a person of ordinary skill in the art.

Despite rejecting Defendants' indefiniteness argument, the Court recognizes that Defendants present a valid limitation that the term "call report" should be restricted to information "used to control the elevator control." The express words of the claims themselves are clear that "call reports" are generated in order to be used by the elevator control. (See '861 Patent, col. 12:33-34) ("having at least one elevator and an elevator control for controlling the at least one elevator by a call report"); (id. col. 12:51-52) ("converting said destination signal into a call report for use by the elevator control in controlling the elevator"); ('465 Patent, col. 11:7-8) ("having at least one elevator control by way of at least one call report"); (id. col. 11:23-25) ("for converting the destination signal into at least one call report and for controlling the elevator control by way of the call report"). In these references, "call reports" are explicitly described as being used by the elevator control in performing its function. In light of this limiting language contained in the claims themselves, the Court concludes that the term "call report" means "a signal providing passenger conveying information used to control the elevator control."

**508**

VI. "a call state, being at least one of the group consisting of active and hold states" / "a plurality of communication ports, each supporting at least one of the group of switch connections consisting of video in, video out, audio in and audio out"

The two disputed phrases from the '500 patent are interrelated, and must be construed together. Claim 1 of the '500 patent is representative of the use of both phrases.

1. A teleconferencing system comprising:
   
   (a) a plurality of AV devices, each capable of
      
      (i) originating and reproducing
      
      (1) user related audio and video signals;
   
   (b) a plurality of communications ports, each supporting
      
      (i) at least one of the group of switch connections consisting of
      
      (1) video in, video out, audio in and audio out; and
   
   (c) at least one communication path,
      
      (i) arranged for transport
      
      (1) of audio and video signals,

   wherein the system is configured to

   (i) to control a communication connection
(1) between two of the AV devices,

(2) over the communication path,

(ii) by creating,

(1) as a result of a call request,

(2) at least a first call handle,

i. associated with one of the two AV devices and, thereafter,

(3) at least a second call handle,

i. associated with the other AV device,

(4) each call handle defining,

i. for its respective AV device,

ii. a call state, being at least one of the group consisting of active and hold states; and

iii. the port switch connections involved in the communications connection.

'500 patent at 41:51-42:11 (emphasis added).

The claims of the '500 patent relate generally to the mechanics of placing and connecting a videoconference call between two AV devices (CMWs) using the invention described in the Specification. The description of the preferred embodiment illustrates the general process for how a videoconference call is connected.

First, before a CMW can participate in a videoconference call, it must connect to the AVNM and register the types of collaborative services it provides—such as videoconferencing or data sharing—in a central directory, or "service server." Spec. at 20:66-21:1. During registration, the CMW can specify "the audio/video ports physically connected to the particular CMW into which the user is logged in." Id. at 21:18-19. Based on the information provided by the CMW, the AVNM creates a data record called a "port abstraction, wherein each port represents an addressable bidirectional audio/video channel." Id. at 20:42-44.

In the preferred embodiment, a CMW has four physical connections to the AV switch: video in, video out, audio in, and audio out. Id. at 20:35-41. A CMW need not make all four of these connections available in its port abstraction, however. Instead,

[c]lient programs can specify which of the 4 physical connections on its ports should be switched. This allows client programs to establish unidirectional calls (e.g., by specifying that only the port's input connections should be switched and not the port's output connections) and audio-only or video-only calls (by specifying audio connections only or video connections only).

Id. at 20:57-63. Moreover, not all devices participating in a conference must support all four connections:

The system architecture also accommodates the situation in which the user's desktop computing and/or communications equipment provides varying levels of media-handling capability. For example, a collaboration session -- whether real-time or asynchronous -- may include participants whose equipment provides capabilities ranging from audio only (a telephone) or data only (a personal computer with a modem) to a full complement of real-time, high-fidelity audio and full-motion video, and high-speed data network facilities.
When a user initiates a videoconference from a CMW, the caller's CMW sends a call request to the AVNM, specifying the address of the callee's CMW. The AVNM then looks up the callee in the service database. Id. at 22:3-17. If the callee has registered a videoconference service, the AVNM proceeds to create two "call handle" records, and associates one call handle with each CMW's port abstraction. Id. at 22:54-61. The call handle records include information about the state of the call. Id. 23:11-20. If a CMW is connected to a call, the call handle will have an "active" state. Id. If a CMW places a call on hold, the associated call handle will be changed to a "hold" state. Id. A CMW has a separate call handle for each videoconference call it engages in, and can have multiple call handles at any one time. Id. at 23:7-10 ("Each port can have an arbitrary number of callhandles bound to it, but typically only one of these call handles can be active at the same time."). For example, if a CMW is connected to one videoconference and has two more videoconferences on hold, the CMW will have a total of three call handles associated with its port abstraction.

Based on this overall understanding of how a call is placed in the preferred embodiment, the court now turns to the construction of the disputed terms.

A. "a call state, being at least one of the group consisting of active and hold states"

CPI argues that the phrase "a call state, being at least one of the group consisting of active and hold states" should be construed to mean "the call state of the call handle must have at least one of two possible states; active (in a call) or on hold (connected but not transferring images or sound)." Tandberg argues that the phrase should be construed as follows:

Call State: the status of both audio and video connections indicating whether each connection is active or hold.

Active State: a call state in which information is exchanged over a dedicated physical connection between the caller and the callee.

Hold State: a call state permitting the caller to answer incoming calls or initiate new calls without releasing a previous call.

The parties' proposed constructions differ in two respects. First, the parties dispute whether a call state must have the ability to be simultaneously "active" and "hold," or whether the state may be either "active" or "hold" individually. Second, the parties dispute whether an "active" call is one where information is exchanged over a dedicated physical connection. The court has already concluded, in the context of construing "A V path," supra, that calls need not be connected over a dedicated physical connection.

Turning to whether the call state must be able to simultaneously be active and hold, the phrase "configured to" in claim 1 indicates that the following elements are a recitation of the claimed system's capabilities. Claim I thus requires that the system have the functionality of creating a call handle which defines "a call state, being at least one of the group consisting of active and hold states." A system with the capability of creating a call handle with a call state of "active" would fall within the literal scope of the claim, as would a system with the capability of creating a call handle with a call state of simultaneously "active" and "hold." The phrase "at least" is most reasonably understood as broadening the claim to include systems with call states being simultaneously "active" and "hold," as well as either individually, rather than requiring the call state to be simultaneously "active" and "hold." The court's construction is consistent with the Specification, which clearly contemplates that the call state will toggle between "active" and "hold," but will not be both simultaneously. See Spec. at 23:11-20. The phrase "a call state, being at least one of the group consisting of active and hold states" is therefore construed to mean "a call state, which is 'active,' 'hold,' or both 'active' and 'hold' simultaneously."

n2 The court takes up the meaning of "configured to" in more detail in its order denying Tandberg's motion for summary judgment of invalidity under 35 U.S.C. section 112.
7. The 298 Patent and the 456 Patent contain multiple references to the term "caller." Both parties agree that the ordinary meaning of "caller" is "one who calls." (Def. Op. Br. at 19; Plf. Op. Br. at 21). Relying on the description of the preferred embodiment, Paymentech suggests that the term be construed to mean "a bill payer using a touch tone telephone." (Def. Op. Br. at 19). However, the preamble to Claim 1 of the 298 Patent states that "a caller places a call using said telephone." (Plf. App., Exh. 1 at 16) (emphasis added). Thus, Paymentech's suggested definition creates redundancy and should not be adopted by the court. See Power Mosfet Technologies, L.L.C. v. Siemens AG, 378 F.3d 1396, 1410 (Fed. Cir. 2004) (interpretations that render language of the claims superfluous are disfavored). By contrast, Claims 1 and 6 of the 456 Patent state that "a caller begins a session by using a telecommunications [network] line to initiate a spontaneous payment transaction to a payee.["] (Id., Exh. 3 at 42) (emphasis added). The court has construed "telecommunications line" to mean "a system of wires and other components to transmit messages between users by various devices such as telegraph, cable, telephone, radio, or television." Because the "telecommunications lines" and "telecommunications network lines" described in the 456 Patent are not limited to telephones, it would be impermissible to adopt the restrictive definition advocated by Paymentech. See Arlington Industries, 345 F.3d at 1327 (a court is seldom justified in importing limitations from the preferred embodiments to restrict the meaning of a claim term).

3. "Caller ID"

The disputed claim term "caller ID" appears in claims 1, 2, 4, 7, 25, 35, 36, 43, and 44 of the '416 Patent and claims 1, 2, 4, 5, 8, 10, 13, 14, 17, 34, and 35 of the '186 Patent. Kyocera proposes the following construction of "caller ID":

Conventional number and number/name caller id, ANI, video caller identifying data, fax header caller identifying data or alternate manually entered caller identifying data, where "conventional number and name/number caller id" is transmitted in the conventional manner between the ringing signals from the terminating central office. "Caller ID" does not include a unique identifier associated with a wireless portable communication device.

(Kyocera Br. 19.) Intellect Wireless, however, argues that Kyocera's proposed construction is unnecessarily narrow and improperly limited to a preferred embodiment. Instead, according to Intellect Wireless, the plain and ordinary meaning of "caller ID" is "data which identifies a telephone number associated with the device of the message originator." (Intellect WirelessResp. 16.) The conflicts in the parties' constructions center around three primary disputes. First, Kyocera believes that the inventor provided an "express definitional statement" of "caller ID" in the specifications, which Intellect Wireless disputes. Second, Kyocera argues that "[a] 'unique identifier' pertains explicitly to a device, whereas 'caller ID' refers to the telephone number of a person" (Dkt. No. 216 ("Kyocera Reply") at 13); Intellect Wireless, in contrast, disagrees that the "caller ID" cannot be associated with the message originator's device. Finally, Intellect Wireless challenges Kyocera's position that the "caller ID" must be transmitted in the "conventional manner."

a. Inventor Did Not Expressly Define "Caller ID"

Kyocera predominately bases its definition of the term "caller ID" on the following description of caller ID in the specifications' "ANI Detector Used in a Paging Center" embodiment:

Hereinafter, the generic term caller id shall be used interchangeably to describe conventional number and number/name caller id, ANI, video, fax header or alternate manually entered caller identifying data.

'186 Patent, col.8 ll.28-31. According to Kyocera, this language is an"express definitional statement" indicating that the inventor acted as his own lexicographer in defining "caller ID." (Kyocera Br. 20.) As explained above, however, although "[a] patentee may act as its own lexicographer and assign to a term a unique definition that is different from its ordinary and

In this case, the court disagrees with Kyocera that the above-quoted excerpt from the specifications constitutes an express definition of caller ID. The asserted independent claims in the patents in suit recognize that the "caller ID . . . identifies the telephone number of the message originator." '186 Patent, col.46 ll.49-51; '416 Patent, col.46 ll.44-46, col.50 ll.33-35. Kyocera's construction, however, includes additional types of caller ID not contemplated by this claim language, such as "video" and "name caller id."

Additionally, the specifications present various descriptions of caller ID, thereby suggesting that Kyocera's purported definition is merely one of several illustrations rather than an express definition. In one embodiment, for example, the specifications refer to caller ID separately from ANI: "The stored voice communications device includes a means for receiving transmitted voice messages, receiver identifying control information, and source identifier information such as caller id, ANI, synthesized caller id, DTMF, image, or the like." '186 Patent, col.26 ll.13-15 (emphasis added). Notably, this excerpt appears after the inventor purportedly defined "caller ID." If, as Kyocera contends, the term "caller ID" already embraces ANI, the inventor would not have made this distinction between ANI and caller ID.

A more general definition of caller-identification information 6 also appears later in the patents' specifications:

[C]onsidered broadly, caller-identification information may be solely data which identifies a telephone number associated with the telephone unit utilized to place a call, or the telephone number associated with the telephone unit utilized to place the call in combination with alphabetic characters identifying a name associated with that particular number in a telephone directory (i.e., a telephone directory data base). In either event, whether the directory name is provided or not, this information can be considered to be the "caller-identification information."

Id. at col.35 l.66-col.36 l.8. Consequently, the court does not agree with Kyocera's position that the above-quoted excerpt from the specifications constitutes an "express definitional statement" of "caller ID."

--- Footnotes ---

6 The court notes that Kyocera does not appear to dispute that "caller-identification information" refers to "caller ID." (See Kyocera Reply 12.)

--- End Footnotes ---

b. "Caller ID" Can Be Associated with the Message Originator's Device

The court similarly is unpersuaded by Kyocera's position that the "caller ID" is associated only with the calling party, not that party's telephone device. As quoted above, the specifications instruct that "caller-identification information may be solely data which identifies a telephone number associated with the telephone unit utilized to place a call." Id. at col.35 l.66-col.36 l.2. Additionally, according to the specifications, ";[t]ypically Caller ID data transmitted includes either 7 digit or 10 digit numeric data corresponding to the calling party's telephone," id. at col.20 ll.28-30, and ";[s]uch caller-identification information which may be received includes numeric information corresponding to the telephone number of telephone 13 utilized by call originator 11," id. at col.37 ll.16-18.

The references cited in the specifications also indicate that the plain and ordinary meaning of "caller ID" is "data which identifies a telephone number associated with the device of the message originator," as proposed by Intellect Wireless. Specifically, in an October 23, 1995 news release listed in the specifications' References Cited section, AT&T announced its caller ID services for cellular customers in Washington state, explaining that caller ID "display[s] the telephone numbers of incoming calls." (Intellect Wireless Resp., Ex. L at T020172.) U.S. Patent No. 5,559,860 ("'860 Patent"), also identified in the References Cited section, similarly discloses a "caller ID processor" and "caller ID memory" to store "identifying data," which in one embodiment "is the telephone number of the calling party." '860 Patent, col.8 l.1-5; see also id. at Abstract.

The prosecution history does not support a different construction. According to Kyocera, the inventor "surrendered" "a unique identifier associated with a wireless portable device" during the prosecution of the '186 Patent. (Kyocera Reply 13.)
This surrender, Kyocera argues, demonstrates that "a 'unique identifier' pertains explicitly to a device, whereas 'caller ID' refers to the telephone number of a person." (Id.)

As discussed above, the doctrine of prosecution history disclaimer applies "where the patentee has unequivocally disavowed a certain meaning to obtain his patent." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). "For example, an amendment that clearly narrows the scope of a claim, such as by the addition of a new claim limitation, constitutes a disclaimer of any claim interpretation that would effectively eliminate the limitation or that would otherwise recapture the claim's original scope." Schindler Elevator Corp. v. Otis Elevator Co., 593 F.3d 1275, 1285 (Fed. Cir. 2010). In this case, the amendments to the claims identified by Kyocera do not "clearly narrow[] the scope of the claim" to constitute a disavowal of claim scope.

As support for its prosecution history disclaimer argument, Kyocera directs the court to a 35 U.S.C. § 102 anticipation rejection by the examiner in October 2006 and the inventor's subsequent amendments to the claims. In the rejection, the examiner stated:

Regarding claim 33, Metroka discloses a wireless communication device (see Figure 1) comprising:

- a receiver . . . operably coupled to receive, over a wireless communication connection . . . call data including a message . . . and a unique identifier associated with the wireless portable communication device, the message including visual image data, the call data optionally including associated caller identification information . . . .

(J.A. at 186FH000874.) The inventor made several amendments in response to this rejection, including deleting the phrase "unique identifier associated with the wireless portable communication device" and adding "caller ID automatically provided by a communications network that identifies the telephone number of the message originator." (Id. at 186FH000974.)

As Intellect Wireless correctly notes, whether the rejection was premised on the "'unique identifier' limitation or some other element or combination of elements" is not apparent from the examiner's comments in the October 2006 office action. (See Intellect Wireless Resp. 18.) Furthermore, the phrase "caller ID automatically provided by a communications network that identifies the telephone number of the message originator," which was added in the amendment, does not unambiguously disavow the association of the "caller ID" with the message originator's device and therefore does not clearly exclude "a unique identifier associated with the message originator's device" from the claim scope. To the contrary, as discussed below, the court finds that "automatically provided" refers to the transmission of the "caller ID" without entry by the message originator. For this transmission to occur, the "caller ID" presumably would be associated with the message originator's device. Thus, when viewed in the context of the entire amendment, the court finds that the patentee did not expressly disavow an embodiment of "caller ID" which is a "unique identifier associated with the wireless portable communication device."

The prosecution history for the parent '264 Patent, also relied upon by Kyocera, is similarly ambiguous. In the September 2006 office action cited by Kyocera, the examiner rejected then-pending claim 192 of the '264 Patent's application as obvious under 35 U.S.C. § 103 offering limited explanation:

Regarding claim 192, Baehr discloses a method of communicating information from a calling party connected to a telephone network, to a called party having a portable communication device that is pageable by a paging system in communication with a message center, such message center in communication with the telephone network, comprising the steps of:

- receiving at the message center caller identification information, pertinent to the telephone of the calling party;
- transmitting the caller identification information from the message center to the paging system; and
- transmitting the caller identification information from the paging system to the portable communication device . . . .

(Kyocera Br., App. Vol. 10 at KA00803-804.)
In response to that rejection, the inventor amended the entire claim, including deleting the phrase "receiving at the message center caller identification information pertinent to the telephone of the calling party" and replacing it with "receiving at the message center . . . message originator identification information provided automatically by the communications network as a caller ID identifying the telephone number of the message originator." (Id., App. Vol. 10 at KA00786-787.) Again, like the excerpts from the prosecution history of the '186 Patent discussed above, the addition of the phrase "receiving at the message center . . . message originator caller identification information provided automatically by the communications network as caller ID identifying the telephone number of the message originator" does not clearly disavow unique identifiers associated with a device. The court, therefore, will not exclude "a unique identifier associated with a wireless portable communication device" from its construction of "caller ID."

c. "Caller ID" Need Not Be Obtained in the "Conventional Manner"

Kyocera also contends that the claimed "caller ID" must be transmitted in the "conventional manner," i.e., "between the ringing signals from the terminating central office." According to Kyocera, because the phrase "conventional number and number/name caller id" in the "express definitional statement" of "caller ID" is a "potentially ambiguous term," the court should look to the specifications' discussion of the conventional transmission of caller ID to clarify the ambiguity. (Kyocera Br. 20.) The court does not agree with Kyocera on this point.

First, the asserted claims contain no reference to the "conventional" transmission of caller ID. Instead, they merely state that the "caller ID" is "automatically provided by a communications network" and describe "the message originator sending the caller ID . . . to the message center." See, e.g., '186 Patent, col.46 ll.43-56. Second, because the court does not find that the description of "caller ID" from the "ANI Detector Used in a Paging Center" embodiment constitutes an express definition of the term "caller ID," that description's reference to "conventional number and number/name caller id" does not warrant reading Kyocera's proposed "conventional manner" limitation into the claims. Finally, even assuming that Kyocera's proposal for the term "caller ID" was considered to be an express definition, that definition nevertheless does not support requiring the caller ID to be transmitted in the "conventional manner." If the specifications had expressly defined "caller ID," as Kyocera contends, these additional "clarifications" propounded by Kyocera presumably would be unnecessary. Moreover, based on the court's interpretation of the phrase "conventional number and number/name caller id," the court believes that one of ordinary skill in the art would have found that "conventional" does not refer to how the caller ID is transmitted but rather describes what type of information the caller ID contains--in this case, the caller's name and/or number. For these reasons, the court declines to include Kyocera's "conventional manner" limitation in its construction of "caller ID."

The court accordingly finds that Intellect Wireless's definition of "caller ID" is consistent with the plain and ordinary meaning of the claim term as demonstrated by the intrinsic evidence. Consequently, "caller ID" is "data which identifies a telephone number associated with the device of the message originator."

TGIP argues that the term "calling card" in the '114 patent should be construed to mean: "a body portion typically formed of cardboard or plastic on which information capable of being used to obtain telephone service is displayed, printed or stored." Defendants propose "a card used to make calls on a telephone network." TGIP states that the term "calling card" should not be construed in the '768 patent, and that only the term "prepaid calling card accounts" should be construed.

TGIP's definition implies that a "calling card" could be of almost any material and be formed in almost any shape. Defendants agreed that they have no dispute over the material from which the card is made, nor what its shape it is. Tr. pp. 61-62.

TGIP stated it understood Defendants to be arguing that a "calling card" was something that had to be physically present to make a call, but it turned out that was not an issue either. Tr. p. 63.

Since neither the physical composition and structure of a card nor its location during use are disputed issues, it appears that
the claim language itself describes a calling card. "[E]ach of said calling cards having a security number associated therewith that must be entered at a telephone to obtain access to the telephone network." '114 patent, col. 6, 11.6-9. The specification describes the calling card in the preferred embodiment having a security number stored on a "read-only memory stripe" and possibly also "in cleartext under a suitable blackout." '114 patent, col. 2, 11.36-39. A similar description is found at '114 patent, col. 3, 11.42-48. The same construction was given to the PTO during the application process. "Claim 1 now describes that the calling card has a security number associated therewith that must be entered 'at the telephone' to obtain access to the telephone network." Amendment to First Office Action, 5/18/1995, p. 8 (Bates No. TGIP 006428), Ex. 7 to Defendants' Responsive Brief [Doc. # 207, Attachment # 7, p. 9 of 11].

At the hearing Plaintiff gave this description of a calling card, and Defendants agreed that this was a proper definition. Tr. p. 66, l. 4 - p. 67, l. 1. Plaintiff then began to argue that a calling card should not be defined as having a security number which was used to obtain access to a phone network or system. "But it doesn't have to be a security number, your Honor. It could be a PIN number. It could be a tracking number." n6 Tr. p. 68, 11. 7-9; see also Tr. p. 71. Arguing over semantical differences of common homonyms is not claim construction.

--- Footnotes ---

n6 Plaintiff's counsel was honest in admitting that Plaintiff simply did not want to be pinned down. Tr. p. 70, 11. 14-19. The court understands that if patentees commit to a construction they may lose the flexibility to sidestep invalidity claims. See James M. Amend, Patent Law: A Primer for Federal District Court Judges 19-20 (1998). But at some point the court has to construe the claims, and it is incumbent upon the parties to present their best evidence and arguments at the Markman hearing, not on appeal.

--- End Footnotes ---

Counsel could not identify a single reference in the patent or prosecution history that hints at a calling card, which does not have a security number (or access information as defined below) associated with it, either before or after activation, which must be used to obtain access to the phone system or network. Plaintiff's argument that "calling card" has different meanings in the different claims is without support in the record, and flies in the face of the rule that ordinarily the same term in different claims of a patent has the same meaning. This argument also contradicts the admission in TGIP's brief that all claims require that "they [calling cards] be used to access a telephone network." TGIP Br., p. 24 [Doc. # 200, p. 28 of 37].

The fact that calling cards may be used in various way to obtain access in the different systems described by the claims does not imply that the term "calling card" should be defined differently. For example, the fact that the security number or password could be memorized and used after throwing away the physical card does not mean that the card did not exist initially.

The court recognizes that defining a term as it is defined in the claim could result in some redundancy if the definition is substituted for the word defined. But when one side is obviously planning on focusing at least part of its case on that term, such a definition will be more clear than simply leaving the issue open to the arguments of counsel. The court will define this term as follows:

"Calling card" means "a card, which may be made of various materials and in various shapes, which has associated with it a combination of numerals, letters, and/or characters (sometimes called a security number or code) that can be entered at a telephone to obtain access to the telephone network or system."
"calls."

When limitations in the body of a patent claim rely upon, and derive antecedent basis from, the claim preamble, the preamble may act as a necessary component of the claimed invention. Bicon, Inc. v. Straumann Co., 441 F.3d 945, 952 (Fed. Cir. 2006). In order to be limiting, the preamble must recite essential structure that is important to the invention or necessary to give meaning to the claim. Id. citing NTP, Inc. v. Research In Motion, Ltd, 418 F.3d 1282, 1305-06 (Fed. Cir. 2005), cert. denied,-U.S.-, 126 S. Ct. 1174, 163 L. Ed. 2d 1141 (2006). However, patent claim preamble language that merely states the purpose or intended use of the invention is generally not treated as limiting the scope of the claim. Bicon, Inc., 441 F.3d at 952.

Defendants cite Pitney Bowes, Inc. v. Hewlett Packard Co., 182 F.3d 1298 (Fed. Cir. 1999) to argue that the preamble of claim 1 is necessary to give meaning to the claim. However, Defendants' reliance on Pitney Bowes is misplaced. In that case, the term at issue appeared in the preamble as well as the claims, and was necessary to discerning some of the claim language. Pitney Bowes, 182 F.3d at 1306 (stating that "the term 'spots' is initially used in the preamble . . . then appears twice in each of the independent claims. That the claim term 'spots' refers to the components that together make up the images of generated shapes on the photoreceptor is only discernible from the claim preamble.") By contrast, "calls" appears once in the preamble of Claim 1 and does not reappear in the body of the claim. Further, it is not necessary to discern any of the claimed terms or understand the claimed method. The claimed method for providing access to a mobile user may be properly understood without reference to the type of communication awaiting access.

Even if the preamble were limiting, the Court would still elect not to construe "calls" because the plain and ordinary meaning of the term is consistent with its meaning within the patent. Accordingly, the Court will not construe the term "calls."

B. Whether the patents are limited to a self-contained camera?

In his previous claim construction, Judge Farnan construed the term "electronic camera" to mean a "self-contained, portable electronic camera, with the capability to take still pictures, the components of which are contained in a single housing." Canon Construction, 2004 U.S. Dist. LEXIS 17489, 2004 WL 1941340, at *9. St. Clair contends that Judge Farnan's claim construction is correct and should not be altered because it is consistent with the plain and ordinary meaning of the word "camera," as well as with the specification and prosecution history of the patents-in-suit. Defendants contend that this construction is incorrect because Judge Farnan was not fully apprised of the applicability of the prosecution history of the '219 patent and did not consider that some of the claimed "cameras" include a remote control device. Defendants also contend that Judge Farnan used a "dictionary-based approach" to claim construction which the Federal Circuit has since rejected. According to Defendants, a proper construction of the terms "electronic camera" and "digital camera" should not be limited to a self-contained device. In this regard, Defendants propose that the terms "electronic camera" and "digital camera" be construed as "electronic equipment that may be self-contained or not, and has the capability to take still pictures." (D.I. 259 at 24)

After considering the parties' arguments in light of the claim language, specification, and prosecution history, I agree with the claim construction proposed by St. Clair and adopted by Judge Farnan in the Canon litigation. I do not read the Federal Circuit's decision in Phillips to forbid the use of dictionaries in informing claim interpretation. Rather, Phillips cautions
against a heavy reliance on dictionaries to the exclusion and/or contradiction of the specification, which is "the single best
to the meaning of a disputed term," and is itself "a dictionary when it expressly defines terms used in the claims or
when it defines terms by implication." Phillips, 415 F.3d at 1321 (internal citations and quotation marks omitted). In his
decision, Judge Farnan consulted a dictionary to inform the ordinary meaning of the term "camera," but he also emphasized
the specification and prosecution history of the patents-in-suit, which I agree are consistent with the ordinary meaning of the
term "camera" and describe a self-contained, portable device.

For example, the common specification of the patents-in-suit notes that the object of the invention is "to provide an
electronic still camera that is efficient in design and permits extended periods of portable operation." '010 patent, col. 2 lines
59-61 (emphasis added). This is consistent with other statements in the specification referring to the compression hardware
and software as being incorporated "in the camera." '010 patent, col. 10 lines 48-55. It is also consistent with statements
made during the prosecution history which distinguish the claimed device from prior art systems by its self-contained
housing and portability. See, e.g., JCCCDefs. Ex. 17, '219 patent 8/25/97 Amend. at 8 ("The claimed device instead stores a
plurality of computer-ready digitized images on a removable mass memory element in the device housing.") (emph

Defendants contend that the reference to a remote control device in claim 15 of the '459 patent and Figure 6C means that the
camera is not necessarily self-contained, portable, or contained in a single housing. In this regard, Defendants contend that
"claim 15 requires that the remote control -- which is not in the camera body -- be part of the claimed 'camera."
(D.I. 259 at 25) I do not read claim 15 in the manner proposed by Defendants. First, claim 15 refers to a camera "further comprising
remote activation means for selectively activating said camera." '459 patent, col. 15 lines 17-19 (emphasis added). In my
view, this phrasing does not claim a remote control within the camera itself. To the contrary, I agree with St. Clair that the
"[t]he patents' description of how the Roberts camera could receive and process remote commands does not transform a
physical remote control into the camera." (D.I. 283 at 31-32) Rather, the patent describes how the camera processes external
signals inside the body of the camera as depicted in Figure 6C, which shows a remote signal outside the camera activating
an internal switch. '010 patent, col. 4 lines 28-30 ("Upon receipt of the externally generated 'shoot' command, the relay
switch 32 is activated and provides internal switch closure.").

Defendants also contend that I should depart from Judge Farnan's previous ruling that the phrase "in an electronic camera"
is implicit in claim 16 of the '459 patent. However, I am not persuaded that such a departure is justified.

In sum, I recommend that the terms "electronic camera" and "digital camera" be construed as a "self-contained, portable
electronic camera, with the capability to take still pictures, the components of which are contained in a single housing."

B. Camera Base

The preambles to all six claims contain the language 
"[a] remote control apparatus for a rotating camera base...." Lectrolarm
argues that the preambles are limitations of the claims and proposes that "camera base" should be construed to mean
"television camera base." The Defendants argue that the preambles are not limitations of the claims, and would interpret
"camera base" to mean "a base capable of supporting a camera." n6

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n6 If the preambles are not claim limitations, as the Defendants argue, it is not clear why the Defendants have proposed a
definition for the preambles.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -
1479 (Fed. Cir. 1994) ("terms appearing in a preamble may be deemed limitations of a claim when they give meaning to the claim and properly define the invention"). The preambles to claims one through six of the '088 patent give meaning to the claims. For example, claim two recites "an input means for inputting the operating data for the automatic operation of said rotating camera base." U.S. Patent No. 4,974,088, Column 11:38-45. The words "said rotating camera base" refer back to the "camera base" in the preamble, and are only properly understood if the accompanying description of the camera base in the preamble is read as a limitation of the claim. All six of the claims include the language "said rotating camera base" referring the reader back to the description of the rotating camera base in the claims' preambles.

Because the preambles are limitations of the claims, the court must construe the disputed language. The plain language of the term "camera base" is "camera base." Neither the specification nor the prosecution history indicates that the patentees desired a different definition of this term. The Defendants have identified no reference to the base of the apparatus in the specification that contemplates any use other than in conjunction with a camera.

The Defendants attempt to use the specification to support their view by arguing that the "'088 Patent does not describe any aspect of the camera itself, apart from the existence of zoom, focus, and iris motors. Instead the focus of the '088 Patent is the base itself and the control box, not what is on the camera base." (D.'s Br. at 46.) As the title of the invention states, the patent is for a "Television Camera Base." U.S Patent No. 4,974,088 (emphasis added). Patenting an invention for a base for television cameras does not require discussing the details of the television cameras that will be mounted on that base.

The inventors, by the plain language used in the claims, limited patent '088 to bases for cameras. Nothing in the specification or prosecution history indicates otherwise. The court sees no reason to use a definition other than the plain meaning of the words and construes "camera base" to mean "television camera base."

Camera Mechanism

The Court construes "camera mechanism" to mean "the functional components of the motion detector camera." Defendants' proposed construction limits the camera to a film-camera, a limitation the Court has already rejected. Defendants' proposed construction also includes the limitation that the camera mechanism "includes a stand-alone [off-the-shelf] camera that can be used independently when removed from the housing of the motion detector camera." Defendants argue the Court should adopt this limitation because Plaintiffs do not argue against it, nothing in the claims excludes off-the-shelf cameras, and Figure 7 depicts such a camera. The specification does not describe the camera mechanism in Figure 7 as an off-the-shelf camera. The claim does not address whether the camera mechanism can be an off-the-shelf camera. Defendants do not present any reason that the jury should specifically be instructed that the camera can be an off-the-shelf camera. Accordingly, the Court rejects this limitation of Defendants' construction.

B. "Camera Means" (First Clause of Claim 1) and "Camera" (Claim 3)

Plaintiff's Proposed Construction: A generic term referring to any suitable reader that can read a body part and generate an electronic representation of the body part.

 Defendants' Proposed Construction: A light sensitive device that receives a visual image and records the image on film or translates the image into signals.

The dispute here is whether "camera" or "camera means" should be narrowly construed to mean an optical device, i.e., a light-sensitive device that receives a visual image, or broadly construed to mean a generic body part reader. Plaintiff argues that in the claims at issue, the Patentee deliberately used the term "camera means" to encompass more than just a camera. The doctrine of claim differentiation supports this argument wherein Claim 8 states that the "camera means" is a video camera and Claim 3 describes the additional elements of a lens and camera as part of the "camera means." Furthermore, the
specification teaches that "camera means" is a generic term for the fingerprint reader by describing the reader as: "[a] video camera or suitable replacement," '474 Patent at 8:55-56; "any suitable reader that can render a valid picture of the fingerprint," id. at 6:20-22; "any device that can convert an image to a picture form," id. at 9:21-22; and "some form of reader or transducer," id. at 2:63-64.

Defendants respond that although the specification notes that other suitable fingerprint readers could be used, the claims do not recite a "reader," they recite a "camera," and thus Plaintiff should be limited to what they claimed. Looking closely at the claim language itself, it is clear to the Court that "camera means" is used broadly, and encompasses more than just a video camera. It is also clear, however, that the term does not refer to non-optical devices. Although the specification generally states that "[a] video camera or suitable replacement" can be used, id. at 8:55-56, it specifically teaches that "[t]he reader utilizes an optical scanner" id. at 6:7. Reading the claim in the context of the entire patent, one of ordinary skill in the art at the time of the invention would have understood that another suitable fingerprint reader would be another optical device. Therefore, in accordance with Defendants' proposed construction, the Court finds that the terms "camera means" and "camera" as used in the claims of the '474 Patent refer to "a light sensitive device that receives a visual image and records the image on film or translates the image into signals."

7. Candidate georeferenced maps

Dependent claim 2 of the 698 patent provides:

The method of claim 1, wherein the ascertaining further comprises:

- examining a plurality of candidate georeferenced maps with boundaries that are proximate to the geographic coordinates, and

- inspecting the candidate georeferenced maps to determine which contains the geographic coordinates and is usable to make the flood zone determination for the real property.

The parties dispute what the term "candidate georeferenced maps" means. The plaintiff contends that no construction is necessary. Alternatively, the plaintiff suggests that the term should be construed to mean "georeferenced maps that may be of interest." The defendant contends that the term means "two or more raster FEMA map images containing the listed insets that intersect with the selected grid-rectangle containing the property latitude and longitude or other coordinate set that defines the position of the property on the earth's surface." The court adopts the plaintiff's alternative construction for this term.

2. "cannot be reliably predicted"

The parties dispute whether the phrase "cannot be reliably predicted" mean that there must be perfect security.

The description of clock skipping and clock decorrelation in the specification also indicates that "cannot be reliably predicted" is not limited to perfect security. The claim language "cannot be reliably predicted" adequately reflects the variable effectiveness of the technique in different situations, and thus, the Court declines to further construe the phrase.

i. "processing frequency capability"
The plaintiffs propose "the range of speeds at which the CPU can operate." The defendants propose "fastest safe operating speed at which the CPU can operate."

As discussed in the previous section, "processing frequency" is not limited to the "fastest safe operating speed." In addition, "capability" is not limited to a range or to the fastest speed. Accordingly, the Court construes the term to mean "the speeds at which the CPU can operate."

f. "refractory metal forming a cap to prevent evaporation of said fuse portion when said fuse portion is exposed to a directed energy source to increase the vapor pressure under the cap to produce an explosive removal of said fuse portion"

i. the structure of the cap

The parties do not appear to dispute that the term "cap" is the layer of an optically absorptive refractory transition metal formed above the interconnect. The cap does not include a passivation layer, as the claim recites that it is the refractory metal that forms the cap.

ii. "to prevent evaporation . . . to increase the vapor pressure under the cap to produce an explosive removal"

The court must decide whether the claim limitation "to prevent evaporation" means to prevent evaporation "from the top of the fuse portion," as is urged by EMI, or to "prevent all significant evaporation from the fuse portion," as is advocated by Cypress.

Neither the claim language, nor the specification, suggests that the claim language should be limited as sought by the parties. The patent does not specify that the cap should prevent evaporation "from the top of the fuse." Nor does the patent teach that the cap should prevent "all significant evaporation from the fuse portion." The claim language can be interpreted on its face. The court declines to construe the term "to prevent evaporation . . . to increase the vapor pressure under the cap to produce an explosive removal."

iii. cause of the explosion

The parties agree that an increase in vapor pressure must cause the explosive removal of the fuse material. The parties appear to disagree, however, on the degree of causation required for the increased vapor pressure to induce the explosion. Cypress argues that the increased vapor pressure must be "the proximate cause" of the explosion. EMI states that the increased vapor pressure must be "a proximate cause" of the explosion, but that other forces may contribute to producing the explosion.

The patent examiner rejected claim 1 twice, and allowed the claim only when the inventors emphasized the function of the absorptive layer in inducing an explosion. The applicants explained that the absorptive cap "transfers the heat or energy . . . to the underlying material and permits a vapor pressure to accumulate." In distinguishing their claimed invention from the prior art, the applicants stated that the art of record "generally calls for melting the fuse material, and nowhere is seen to suggest building up an explosive vapor pressure under a cap." Based on these statements, the examiner allowed the claims, remarking that "the ability of the refractory metal to prevent evaporation of the underlying metal and cause explosive removal is an unexpected result which is not taught or suggested by the prior art."

The applicants succeeded in overcoming the examiner's rejections by emphasizing that the absorptive layer induces an explosion by preventing evaporation of the metal layer. Clearly, the increase in vapor pressure must proximately cause the explosive removal of the fuse portion. Neither the claims, specification, nor prosecution history, however, limit the explosion-inducing force to increased vapor pressure alone. Thus, the court holds that under the terms of the patent, increased vapor pressure must proximately cause the explosive removal of the fuse portion, but that other forces may contribute to the explosion. No judicial construction is required for the term "to prevent evaporation . . . to increase the vapor pressure under the cap to produce an explosive removal."
2. Data Transmission Device Capable of Connecting Directly to a Communication Network

The parties dispute the construction of the phrase "capable of connecting directly." The defendants contend that this term should be construed so that "connecting directly" means that the data transmission device "can be connected to a communication network without requiring a separate unit (such as a computer or modem) between the data transmission device and the network." The defendants further contend that PHT's proposed construction is "overly broad and impermissibly recaptures claim scope that was disclaimed during prosecution in order to obtain allowance of the claims." (D.I. 40, at 17); see Elekta Instrument S.A. v. O.U.R. Scientific In'tl, Inc., 214 F.3d 1302, 1308 (Fed. Cir. 2000).

In response, PHT asserts that the phrase should be construed so that "capable of connecting directly" means that the data transmission device "is capable of transmitting data from the data logger to a communication network site without the data being processed by or accessed on an intervening computer." According to PHT, Claim 22 only excludes an intervening computer. It does not exclude the possibility a device located between the data logger and communications network, such as an external modem. (D.I. 45, at 4 n.6.) PHT argues that its construction is supported by the specification and prosecution history of the patent, noting that the preferred embodiment expressly includes an external modem. (D.I. 39, at 10-11.) PHT further argues if the court adopts the defendants proposed construction then claim 22 would not cover the preferred embodiment, and "[a] claim interpretation that excludes a preferred embodiment from the scope of the claim 'is rarely, if ever, correct.'" Id. (quoting Globetrotter Software, Inc. v. Elan Computer Group, Inc., 362 F.3d 1367, 1381 (Fed. Cir. 2004)).

PHT correctly states the law of the Federal Circuit. Indeed, an interpretation that excludes the preferred embodiment "require[s] highly persuasive evidentiary support." Elekta, 214 F.3d at 1308. The defendants, however, contend that this is the "rare case" in which the evidence shows that the asserted claims do not cover the preferred embodiment. See Transcript of Markman hearing, dated April 19, 2005 ("Tr."), at 23-24; Elekta, 214 F.3d at 1308. According to the defendants, PHT disclaimed coverage of the preferred embodiment with unambiguous claim amendments and prosecution history statements, pointing out that "arguments made during prosecution regarding the meaning of a claim term are relevant to the interpretation of that term in every claim of the patent absent a clear indication to the contrary." Southwall Techs., Inc., 54 F.3d at 1579.

Here, the examiner rejected certain claims during prosecution as being obvious in light of U.S. Patent No. 5,128,552 (the "Fang patent"). In response, the applicants cancelled some of the original claims, amended claims, and distinguished the Fang patent. Specifically, the applicants amended claim 22, adding the "data transmission device capable of connecting directly to a communication network" limitation. The applicants also asserted that their invention was different from the Fang patent. The defendants argue that the applicants' asserted distinctions compel the court to adopt their proposed construction. The court disagrees.

After reading the prosecution history, the court is not convinced that the applicants "disclaimed scope of coverage, by using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Texas Digital Systems, Inc. v. Telegenix, Inc., 308 F.3d 1193, 1204 (Fed. Cir. 2002) (citing Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1324 (Fed. Cir. 2002). For example, the applicants told the patent examiner that "[a] particularly useful feature [in regard to portability] is the construction of the monitor to allow direct access to a communications network without requiring connection via a separate unit, such as a personal computer." (D.I. 42 Ex. C, at 11.) While the court could consider this statement as a possible disclaimer of an external modem, the applicants further explained the difference between their invention and the Fang patent, stating:

Fang provides no suggestion of a handheld unit, and certainly does not suggest the use of a data transmission device with a handheld unit that allows direct connection from the unit to a communication network. Without such direct connection capability, a user would have to download the data to a separate processor before it could be transmitted to a remote destination site. This would require the user to carry, in addition to the monitor itself, a portable computer (or other portable processing unit), or to simply wait until he or she reaches a place where a computer with a modem (not to mention the appropriate software) is available.

(Id. at 12) 5 (emphasis added). The emphasized language from the prosecution history describes direct connection capability

- 997 -
in relation to downloading data to a separate processor. That is, the applicants told the patent examiner that without the
direct connection capability of their invention a user would have to carry a portable computer. Thus, the applicants used the
direct connection capability to distinguish their invention over the Fang patent, because the Fang patent teaches a personal
health monitor that includes a programmable computer, or laptop computer, while the 985 patent teaches a personal
health monitor that is "truly ambulatory" and does not require the data to be downloaded to a separate processor. (Id. at 11.) At
most, the court finds that the disclaimer issue is arguable. As such, the court cannot say that the applicants "used words or
expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope." Texas Digital, 308 F.3d at
1204. Accordingly, the court will construe the phrase "capable of connecting directly" to mean "capable of connecting
without requiring a separate data processor." The court, therefore, construes the phrase "data transmission device capable of
connecting directly to a communication network" to mean "a device that transmits data and is capable of connecting to a
communication network without requiring a separate data processor."

5 The applicants made these comments with respect to claim 1. However, as noted by the defendants and the applicants,
claim 22 is similar to claim 1 in that it contains the "capable of connecting directly" limitation. (D.I. 40, at 18 n.6.)

The parties dispute whether the display must display all information in multiple orientations, and whether the display must
be "oriented properly for reading." Mallinckrodt argues that not all information need be properly oriented for reading, such
as graphics, and therefore only some information needs to be reoriented. E-Z-EM argues that the display is "tilt
compensating" and the same information that is displayed in one orientation must also be displayed in a second orientation.
Mallinckrodt's argument is twofold. First, the claim does not require that all of the displayed information be displayed in a
first and second orientation, primarily because of the absence of the word "said" before the second occurrence of
"information." Second, "oriented properly for reading" is an unnecessary limitation because, according to the argument, it
would preclude the display of graphics, which need not be "oriented properly for reading." According to Mallinckrodt, only
text would need to be "oriented properly for reading," yet the preferred embodiment and dependent claims expressly
contemplate the display of graphics. See 710 patent, Claim 4 ("wherein display is a matrix of evenly-spaced pixels which
can be selectively activated to, in combination, for[m] graphics or characters for display"). Mallinckrodt further argues that
E-Z-EM's proposal introduces ambiguity because a person of ordinary skill in the art would not be able to know when a
display is properly oriented.
E-Z-EM argues that the Summary of the Invention requires that a display be "tilt-compensating" and "always oriented properly for reading." '710 patent, 3:36-45. E-Z-EM also argues that a later limitation in the claims requires that all of the information on the display be "flipped" because it states that "said display is responsive to said tilt angle signal to display said display information in said first orientation in response to a first range of values . . . ." Id. at 21:40-45. E-Z-EM renews its injector head argument, asking the Court to insert the limitation that is display the activities of the injector head. Finally, E-Z-EM argues that the invention's purpose to solve the problem in the prior art would be thwarted unless all of the information in the display were reoriented. The Background of the Invention explains a particular problem with the prior art:

Unfortunately, operators have found it cumbersome . . . to read the injector head gauges and displays, for several reasons, not the least of which is the necessary tilting of the injector head between the upward, filling position to the downward, injection position, . . . and at some tilt angles, rendering the gauges or displays difficult to read.

'710 Patent, 1:55-62. According to E-Z-EM, if only some of the displayed information were "reoriented properly for reading" on the injector display, then the injector display would fail to overcome the prior art. Therefore, to solve the problem with the prior art, E-Z-EM urges the Court to adopt a construction that would require that all displayed information be shown in two or more orientations.

Reviewing the patent figures demonstrates that not even the preferred embodiment would satisfy E-Z-EM's proposal. "[A] claim interpretation that excludes a preferred embodiment from the scope of the claim is rarely, if ever, correct." On-Line Techs., Inc. v. Bodenseewerk Perkin-Elmer GmbH, 386 F.3d 1133, 1138 (Fed.Cir. 2004) (quotation marks omitted). First, it is highly unlikely that Figs. 13B & 13C represent all of the available information regarding the "activities and status of operation" of the injector. It does not indicate the angle of tilt, whether the injector is operating in programmed mode, or whether the injector is inhibiting motion. Second, it is clear that not all information on the display is reoriented when the injector is tilted. For example, the image of the syringe is not "flipped," as E-Z-EM's construction would require.

The Court finds persuasive E-Z-EM's argument that the Summary of the Invention requires the additional limitation that the display be "oriented properly for reading." A display that reorients information by 90 degrees, yet remains difficult to read, would satisfy the claim language but would be beyond the scope of the invention. Mallinckrodt objects on the basis that it would preclude the display of graphics or require that graphics be reoriented because of the word "reading." E-Z-EM's proposed language, however, comes directly from the Summary of the Invention: "The injector head includes a tilt angle sensor for detecting the tilt angle of the head, and uses this tilt angle to choose one of two display orientations. As a result, the display is always oriented properly for reading." '710 patent, 3:40-43. The Court, however, agrees that the invention does not require that all information about the injector be included on the display. Nor does the invention require that all information on the display change orientations when there is a change in tilt angles.

The Court construes the limitation to mean, "an electronic display displaying at least some information regarding the activities and state of operation of said injector head, said display capable of displaying at least some information in at least a first and a second orientation so that said information is oriented properly for reading."

4. "Plurality of radio transceivers capable of communicating on the plurality of communications channels and capable of providing paging signals for mobile units." The transceivers can be commanded to provide any one of several functions upon receipt of instructions from the central control station, including the function of establishing a communication connection between a mobile unit and the central control station. ( 554 patent, col. 31, Ins. 1-5)
4. card data (Claim 32)

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>Alexsam's Proposed Construction</th>
<th>Humana's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>card data</td>
<td>no construction is needed.</td>
<td>data contained on the card,</td>
</tr>
<tr>
<td></td>
<td>Alternatively, information</td>
<td>including activation data</td>
</tr>
<tr>
<td></td>
<td>related to the card</td>
<td>encoded on the card</td>
</tr>
</tbody>
</table>

Primarily, the parties dispute whether "activation data" needs to be encoded on the card. Alexsam seeks to broadly construe "card data" as any "data related to the card" that is used in the transactions being processed. In contradiction to the very term, Alexsam argues that "card data" includes even data that is not contained on the card, so long as it is related to the card.

Humana seeks to add a limitation of "activation data" being included on the card. Humana argues that activation of cards at POS terminals is a key aspect of the invention. See '608 patent, 2:15-18. Further, it argues that the "unique identification number" is the only card data relevant to activation, and the claim expressly includes this number as being part of "card data." Id., cl. 32. Furthermore, Humana argues that a scope disavowal by the inventor during prosecution of the '608 patent mandates the limitation. Humana points out that in overcoming the Stimson 2 prior art, the Applicant argued:

Thus, the present invention recognizes, and claims, the unique advantage of providing a system which can be used flexibly with a variety of different encoded cards that include, as part of the information contained on the card, a unique identification number which includes a bank identification number approved by the ABA for use in a banking network, thus allowing the existing point of sale system in place at a retailer, and the existing banking network and existing bank processing hubs, to be used to activate or recharge phone cards, electronic gift certificates and other card types and functionality described and claimed in the instant application.

Amendment dated June 24, 1999, '608 patent prosecution history, at 11-12.

Further, Humana notes that in the Notice of Allowability for the '608 patent claims, the Examiner stated that "the applicant discloses a multifunction card system which has means for receiving activation data from an unmodified point-of-sale device when the card is swiped through the point-of-sale device which is not found in the prior art of record." See Examiner's Notice of Allowability dated August, 5, 1999, 608 Patent Prosecution History. Therefore, Humana argues that POS activation was a basis for the Examiner's allowance of the '608 patent claims.

Alexsam's response is that Claim 32 is different from all other claims. Alexsam points out that Claim 32 and dependent claim 33 were never rejected over the Stimson prior art. The Examiner rejected these two claims over a different prior art, Pritchard, 3 and the disclaimers made in response to the Office Action that Humana relies upon, according to Alexsam, do not apply to these two claims. Alexsam's argument is that the Examiner did not reject claims 32 and 33 in light of Stimson because these claims did not involve activation, while all the other rejected claims did. Along the same lines, Alexsam argues that Claims 32 and 33 should be differentiated from claims that expressly include the activation data as part of the unique identification number. See, e.g., '608 patent, clts. 1, 9, 16. The Court agrees. In construing claim terms the Court first looks to the claims themselves. See Phillips, 415 F.3d at 1312 ("the claims of a patent define the invention to which the patentee is entitled the right to exclude"). There is nothing in Claims 32 and 33 that requires activation. The Court is not persuaded Humana's argument that the Examiner's comments read an implied limitation into these claims. First, the prior art that the examiner rejected these claims over, Pritchard, had nothing to do with activation. Secondly, even if the Court were to look to the argument that the patentee made to overcome the Stimson prior art, the statement made by the patentee clearly includes "other card types and functionality described and claimed in the instant application." Similarly, the Court

"Card data" means "data contained on the card."

525

10. "card key"

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>FotoMedia's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;card key&quot;</td>
<td>Information for identifying image data</td>
<td>a unique identifier that is created at the time the postcard is sent and which includes information for retrieving the electronic postcard data from a Card Database and an Image Database</td>
</tr>
</tbody>
</table>

Fotomedia responds by asserting that any reference to a Card Key and the Card or Image Database in the specification is merely a description of an embodiment. It presents two arguments. First, Fotomedia notes that claim 9 of the '936 patent recites a card key that "identifies the digital image." Fotomedia argues that referring to the digital image should be different from referring to the electronic postcard, and, therefore, the construction of card key cannot be limited to a postcard. Second, it argues that the defendants' proposed definition of card key imposes an unclaimed temporal limitation - "at the time the postcard is sent." Despite Fotomedia's position, neither of its arguments explains why the description of "card key" in the specification should not be considered the inventor's definition. The Court adopts the patentee's own language for these terms.

The "Card Key" is "a unique identifier that is created at the time the card is sent and which is the information required for retrieving the electronic postcard data from a Card Database and an Image Database."
K. '472 Claim 18: "electrically cardioverting the heart by discharging said selected magnitude of stored energy through said
delivery electrodes into the heart of the wearer."

The step of "electrically cardioverting the heart by discharging said selected magnitude of stored energy through said
delivery electrodes into the heart of the wearer" is another disputed element of the method stated in Claim 18. However,
unlike the step of "sensing an abnormal cardiac rhythm," the "cardioverting" element recites the acts that accomplish the
cardioverting function. The clause "by discharging said selected magnitude of stored energy through said delivery electrodes
into the heart of the wearer" sufficiently describes how the heart is cardioverted. Thus, 35 U.S.C. § 112 P 6 does not control
this element and there is no basis for limiting the scope of the claim to the disclosures in the specification. Nonetheless, St.
Jude renews its argument that the patentee has at least implicitly limited the definition of the word "cardioverting" to the
treatment of atrial, and not ventricular, arrhythmias.

To support the contention that "cardioverting," as used in a step of the method claim, should be limited to atrial
cardioversion, St. Jude cites the same intrinsic evidence discussed above in Section II-A of this entry. St. Jude also points
out a few additional instances in the specification where the description discusses atrial arrhythmias or the discharge of
cardioverting energy "in or about the heart, as in the right atrium." '472 Patent, col. 7, ll. 42-43; see also, e.g., col. 6, ll. 2-5
("the discharge capacitor feeds directly to a catheter 72 implanted in or about the atrium 74 of a heart"); col. 8, ll. 1-7 ("the
discharge capacitor 78 discharges through the heart 76 of the patient via atrial catheter 72.").

For the reasons discussed in detail above regarding Claim 1, the court finds that the step of "cardioverting the heart" as used
in Claim 18 is not limited to atrial cardioversion.

8. "carrier [recovery]" and "clock recovery"

Wi-LAN's Proposed Construction          Defendants' Proposed Construction
carrier [recovery]:                        carrier [recovery]:
"synchronizing the local oscillator to the  "recovery of the carrier signal"
carrier frequency of the received signal"

clock recovery:                           clock recovery:
"synchronizing the sampling clock to the  "recovery of the clock"
timing of the received signal"

Claim 7 requires that "the width of the frequency band is chosen so that neither carrier nor clock recovery is required at the
second transceiver." The terms "carrier" and "clock recovery" are also used in the construction of the term "wideband
frequency channels" in claim 1. Defendants argue that the claim language uses carrier and clock recovery generally and
does not limit those terms to any particular known technique. Wi-LAN argues that the terms are limited to a particular
 technique that is implicitly defined in the context of the prior art receiver shown in FIG. 1b.

There are numerous references to clock and carrier recovery in the specification and not one instance restricts the types of
clock or carrier recovery that should be avoided. See '222 patent, 2:19-24; 4:55-63; 6:30-33; 6:46-50; 12:45-50; 13:5-7;
13:17-19; Figure 1b. The specification provides only that the use, in general, of "clock recovery" and "carrier recovery" is
not required by the present invention. It does not provide that certain specific techniques or methods of "clock recovery" or
"carrier recovery" are not required. The Court finds that the terms should not be limited to a particular embodiment or
method, particularly when the claims and specification do not support such a limited interpretation. Thus, the Court rejects
Wi-LAN's proposed constructions and finds that they are an attempt to improperly restrict those terms to only one of the
many ways of performing the clock or carrier recovery that were well-known at the time the application leading to the '222
patent was filed. The Court finds, however, that Defendants merely rephrase and rearrange the terms to be construed, and
such a construction is not helpful in this instance.

One of skill in the art would understand the term "carrier recovery" to generally mean the process of extracting a phase-coherent reference carrier from a received carrier waveform or providing an estimate of the carrier phase from the received signal. One of skill in the art would understand the term "clock recovery" to generally mean the process of determining the clock of the received signal or recovering clocking information from the received data. Thus, both clock and carrier recovery derive the carrier phase and clock, respectively, from the information-bearing signal.

The Court construes the term "carrier recovery" to mean "process of determining the carrier phase of the received signal." The Court construes the term "clock recovery" to mean "process of determining the clock of the received signal."

The dispute is over the meaning of the term "carrier signal." The plaintiff contends that the term means a signal modulated to carry data. Joint Claim Construction Brief, Exh. A. The defendants, by contrast, argue that "carrier signal" should be limited to an analog baseband TV signal or main or secondary channel of an AM or FM radio signal. Id.

The distinction is explained in the affidavit of Dr. Stephen Castell, offered by the defendants. According to Dr. Castell:

12. As [a] television frame is recorded, it must be converted to a mode that can be transmitted. Television uses a signal to carry the picture. Generally speaking, in the broad field of electronics, a signal is a measurable quantity such as a voltage. In traditional television technology, an analog signal is modified by increasing or decreasing voltage over time. These variations correspond to how light or dark part of the picture is, for example. . . . Circuitry in the television interprets the variations to reproduce the picture on the screen.

17. The "baseband" television signal is the television video signal, including the scan lines, the blanking intervals, and the sync pulses, in an "unmodulated" form that is used to drive the electron beam(s) in a television. If the images did not need to be broadcast over long distances (such as through the atmosphere), the television camera could send an unmodulated, baseband signal to a television set. But, since television is broadcast over long distances, the baseband television signal is sent over on a radio frequency (RF) wave.

18. An RF wave is an electromagnetic wave that cycles a certain number of times per second that is characteristic of the radio spectrum. The more times per second the wave cycles, the higher the frequency. . . .

19. To use the RF wave, the television signal must modulate it. This is done by modifying the RF wave using the television signal. . . .

20. However, an RF wave modulated with a video signal cannot be directly used to drive the electron beam in a television. It must first be demodulated back to the baseband video signal.

The parties conceded at the Markman hearing that there are two carrier signals—(1) the low frequency baseband television signal, and (2) the higher frequency RF wave that broadcasts the television signal through the atmosphere to distant locations. See Record, p. 24, lines 5-23; p. 73, lines 7-23; p. 110, line 14-p. 111, line 12. The issue for construction is which "carrier signal" is referred to in the claims at issue.

I agree with the plaintiff that the term "carrier signal such as a television or commercial radio carrier signal" means a signal modulated to carry data. I reject the defendants' position that the low frequency baseband signal is the carrier signal as that term is used in the claims of the '094 Patent.
My conclusion is based on the plain language of the claims themselves. In particular, claim 8 states that it concerns "a method for broadcasting data to a television set using a carrier signal such as a television or commercial radio carrier signal." '094 Patent, col.22, lines 21-23. Broadcast means the "transmission of a radio or television program or signal." The American Heritage Dictionary of the English Language, 167 (1971), and a transmission is "the sending of modulated carrier waves from a transmitter." Id. at 1364 (emphasis added). Combining the two terms, to broadcast is to send radio or television signals by a modulated carrier wave. Thus, it is the modulated radio frequency wave that is broadcast, not the low frequency baseband television signal. In addition, the claim deals with broadcasting "to a television set." According to Dr. Castell, the baseband television signal is "made to modulate the appropriate RF frequency for transmission"; it is not broadcast to a television set. Castell Declaration, at P23(4). It is the RF wave that is transmitted to a television set and demodulated to reproduce the baseband television signal. Id. at PP23(4)-23(6). Also, the claim states that the broadcast is accomplished "using a carrier signal such as a television . . . carrier signal." '094 Patent, col. 22, lines 22-23 (emphasis added). Significantly, the claim does not say that the broadcast is accomplished using a "baseband television signal" or even a "television signal," as it would to express the construction advanced by the defendants. To the contrary, the broadcast is accomplished using a television or commercial radio carrier signal. The carrier signal utilized to broadcast a television signal is a modulated radio frequency wave.

My conclusion also finds support in the specification. For example, the specification provides that a "data stream is inserted into the vertical blanking interval (VBI) of the television broadcast signal transmitted from the central station and is subsequently broadcast over the ether to be received by the receiver stations. . . ." '094 Patent, col. 4, lines 18-22 (emphasis added). Significantly, the data is inserted into the "television broadcast signal," or baseband television signal, and not the carrier signal. By contrast, the claims specify that they concern a method for broadcasting using a carrier signal such as a television carrier signal. Thus, when the inventors meant to describe the baseband television signal, into which the data is inserted, they used the term "television broadcast signal," but when they meant to describe the modulated RF signal used to broadcast the data through the atmosphere, they used the term "carrier signal such as a television or commercial radio carrier signal."

Nor is the term "carrier signal" limited to a radio frequency signal. To the contrary, the specification provides that "the TV broadcast signal can be delivered by any one of a number of known methods including VHF/UHF transmission[,] microwave transmission, satellite transmission, fibre optic transmission." '094 Patent, col. 15, lines 50-54.

I construe the term "carrier signal such as a television or commercial radio signal" to mean a signal modulated to carry data.

I construe the term "broadcasting data . . . using a carrier signal such as a television or commercial radio carrier signal" to mean transmitting data by means of a signal modulated to carry data.

I construe the term "data stream broadcast over a carrier signal" to mean a data stream broadcast by means of a signal modulated to carry data.

I construe the term "receiving data . . . using a carrier signal such as a television or commercial radio carrier signal" to mean receiving data broadcast by means of a signal modulated to carry data.

I construe the term "broadcasting the data stream within the carrier signal" to mean broadcasting a data stream by means of a signal modulated to carry data.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

1 The defendants do not dispute the statement contained in the plaintiff's opening brief that although the claims contain differing language--i.e., "using a carrier signal"; "over a carrier signal"; and "within a carrier signal"--"the parties dispute over these phrases is solely a reflection of their differences regarding the definition of 'carrier signal.'" Broadcast's Opening Claim Construction Brief, at p. 18. Therefore, I accept the parties' concession that there is no significance in the varying formulations of the expression.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - -
1. Carrier traps ('943 patent, claim 1, 4, 9, 11; '437 patent, claims 1, 7, 13, 15)

Plaintiff initially contended that "carrier traps" are "ions that trap electrons and cause flashing," while Defendants initially contended that they are "traps for electrons or holes." At the Markman hearing, the court proposed a construction of "traps that capture electrons and thereby impede the movement of holes." Defendants agreed to this construction, while Plaintiff argued that the court's proposed construction is essentially correct, but that the construction should specify that carrier traps "cause flashing." Markman Tr. 166:8-168:14. The sole remaining issue for the court, therefore, is whether the construction proposed by the court at the Markman hearing should specify that carrier traps cause flashing.

Plaintiff argues that the essence of the invention is preventing flashing and, therefore, that this construction should specify that the carrier traps to which the claim term refers are those that cause flashing. As Defendants point out, however, the patent does not define "flashing," and Plaintiff did not purport to identify what "flashing" means to a person of ordinary skill in the art in its briefing or at the Markman hearing. Because the term "flashing" is not a term that a jury would readily understand, and because Plaintiff has not offered a meaning of the term that a jury would understand, the court declines to include this undefined term in the construction of this term.

Moreover, based on the briefing and the parties' arguments at the Markman hearing, the "flashing" phenomenon that the specification describes as being prevented in the inventions of the '437 and '943 patents (see '437 patent, 2:10-17; '943 patent, 1:57-64) is caused by traps capturing electrons and thereby impeding the movement of holes to the P-N junction. As the '943 specification explains:

> The present invention is based on the realization that the flashing is caused by hot electrons generated by photons of visible or ultraviolet radiation which are captured by these electron traps in the passivation layer. The trapped electrons suppress the infrared response by recombining with photogenerated minority carriers (holes for the N-type base) before they are collected in the semiconductor P-N junctions of the device.

'943 patent, 2:56-63; see also '437 patent, 1:47-53. The court's construction, therefore, takes into account the "flashing" phenomenon described in the patents and referenced by Plaintiff.

The court, therefore, construes "carrier traps" to mean "traps that capture electrons and thereby impede the movement of holes."

2. Carrier Wave

Lectrolarm proposes that "carrier wave" should be construed to mean:

> The term carrier wave is completely synonymous with the term carrier, which, to one skilled in the art in 1988, means wave. A carrier wave is a continuous electromagnetic wave, of sinusoidal or non-sinusoidal form, capable of being modulated or impressed with a signal.

Defendants propose that the court should construe carrier wave to include only the second sentence of Lectrolarm's proposed definition minus the word "electromagnetic." The IEEE Dictionary defines "carrier wave" as a synonym for "carrier." IEEE Dictionary, at 136. The IEEE Dictionary gives several definitions for carrier. Definition (5)(A) explicitly states that it applies to the use of the word "carrier" as a synonym for "carrier wave" and defines the terms as "a continuous frequency capable of being modulated or impressed with a signal." IEEE Dictionary, at 134-135.

The first sentence of Lectrolarm's proposed definition of carrier wave is superfluous. Although the IEEE Dictionary defines "carrier wave" as a synonym for "carrier," making this statement in the court's claim construction does not clarify the term.
for the fact finder. Similarly, whether "carrier" is a synonym for "wave" does not clarify the term for the fact finder. The court will not adopt the first sentence of Lectrolarm's proposed construction of "carrier wave."

The court next considers the use of the word "electromagnetic." The IEEE Dictionary defines "electromagnetic waves" as:

(1) Waves characterized by variations of electric and magnetic fields. Note: Electromagnetic waves are known as radio waves, heat rays, light rays, etc., depending on the frequency. (2) (radio wave propagation) Waves characterized by temporal and spatial variations of electric and magnetic fields.

IEEE Dictionary, at 346. The parties agree that the modulating and demodulating circuits are connected electrically (Pl.'s Br. at 39.); therefore, it must be possible for the carrier wave to be an electrical signal. The IEEE Dictionary definition does not include electrical pulses within its recitation of examples of electromagnetic waves. Lectrolarm has presented no arguments for including the word "electromagnetic" in the definition of "carrier wave." Therefore, the court will not adopt Lectrolarm's proposed inclusion of the word "electromagnetic" in the definition of "carrier wave."

The court notes that, although the IEEE Dictionary definition of "carrier wave" does not specify whether a "carrier wave" can be sinusoidal or non-sinusoidal, the parties agree that the definition should include the language "of sinusoidal or non-sinusoidal form." Neither the specification nor the prosecution history narrows the scope of the term "carrier wave" from its ordinary meaning to a person of skill in the art. Consistent with the IEEE Dictionary, the court defines "carrier wave" as "a continuous wave, of sinusoidal or non-sinusoidal form, capable of being modulated or impressed with a signal."

---

8. "(2.2) Carrying out preliminary data signal processing"

The phrase in question comes from Step 2 of the method, normal synchronization, and, in context, reads:

[M]aintaining said normal synchronization comprises the substeps of:
(2.1) conducting a framed synchronization with fine frequency synchronization, and

(2.2) carrying out preliminary data signal processing.

'216 Patent at 9:34-40. Further, the specification discloses:

A frequency correction value produced by the central control unit 31 from the actual (current) frequency measurement is supplied to the synchronization processor 28. By means of this preprocessing of the data signal any impairment of error-free decoding in the case of frequency shifts exceeding 200 Hz is completely eliminated. Such frequency shifts are to be expected from the Doppler effect and from oscillator drift.

Id. at 7:63-8:2 (referring to Fig. 2). "The central control unit 31 prescribes to the synchronization processor 28 which synchronization step is to be activated. The control unit reads out the responses of the synchronization processor, interprets them and supplies the setting values to the corresponding components, as for example a correction for a local oscillator." Id. at 5:16-21 (referring to Fig. 2).

HTC assails the lack of any real description of what "[c]arrying out preliminary data signal processing" means and where it is performed. HTC contends:

The specification merely discloses that "this preprocessing" results in "[a] frequency correction value produced by the central control unit 31." ['216 Patent at 7:63-8:2]. The specification further discloses that, as a result of this unknown "processing," the frequency correction value "completely eliminates . . . any impairment of error-free decoding in the case of frequency shifts exceeding 200 Hz." [Id.] Thus, the '216 patent only describes the goal of substep (2.2) — an ambitious goal at that. But neither the '216 patent nor the claims specifies [sic] what acts implement that goal. . . . [T]he acts claimed by substep (2.2) are impossible to discern.

HTC's Reply [Dkt. # 156] at 24. In the alternative, HTC proposed that the phrase be construed as "preprocessing a data signal to generate a frequency correction value to be used in further signal processing of that data signal." Chart at 3. IPCom proposes that the phrase means, "preprocessing data signals to account for frequency shifts during communication." Id.

The Court disagrees with HTC's contention that the phrase is incapable of construction. As the specification discloses, preliminary data signal processing is performed by the central control unit 31 when it analyzes the actual, or real-time, frequency signal received from the base station and produces a frequency correction value to the synchronization processor 28. Using that frequency correction value, the synchronization processor 28 can then perform whichever synchronization step the central control unit 31 orders. Because the central control unit 31 supplies a frequency correction value for each step of synchronization, frequency shifts do not impair the cell phone's ability to decode the signals it receives.

The Court construes "(2.2) carrying out preliminary data signal processing" to mean "measuring the actual frequency from the base station and calculating a frequency correction value for use by the synchronization unit."

The fourth element of independent claim 1 recites the step of "carrying out processing operations in response to said position information." Adobe proposes that this phrase be construed to mean "carrying out processing operations using position information generated by the pen-tablet unit, which is substantially higher in resolution than that of the displayed image data."

The underscored portion of Adobe's proposed construction relates to dependent claim 4, which recites "[a] process as in claim 1 in which the step of using the circuit responsive to pen position comprises generating pen position information to a resolution substantially higher than that of the image data." The court agrees with Adobe that the position information used in the processing operations recited in the fourth element of independent claim 1 must be pen position information substantially higher in resolution than that of the displayed image data. "Said position information" recited in that element
refers to the pen position information recited in element 1. Dependent claim 4 expressly recites the step of generating pen position information to a resolution substantially higher than that of the image data.

The court does not, however, agree with Adobe that the phrase "carrying out processing operations in response to said position information" means using higher-resolution position information generated by the pen-tablet unit. Claim 4 recites the step of using the circuit coupled to the pen-tablet unit, rather than merely the pen-tablet unit, to generate the higher-resolution pen position information.

534

2. Cartographic data

The term "cartographic data" appears throughout the '873 patent. Plaintiff continues to argue that the '873 patent pertains only to automobile navigation: it defines "cartographic data" as "map data." On the other hand, defendant, pursues the argument that the '873 patent is also relevant to marine and aircraft: it defines "cartographic data" as "data relating to maps or charts." For the same reasons that I restricted the definition of "thoroughfare" to "public road," I restrict the definition of "cartographic data" to "map data." I am satisfied that the '873 patent concerns only automobile navigation and I will not broaden the meaning of critical terms in this patent to include terminology pertaining to marine or air craft.

GO BACK

535

B. "case base knowledge engine"

Claim 26 contains the term "case base knowledge engine": "interpreting the electronic message using a rule base and case base knowledge engine." The specification provides a description of case base processing:

"An attribute setting rule is used when a satisfied condition is useful in subsequently matching the E-mail message 11 to stored case models of the case base 34 . . . . The application of the attribute setting rules produces a case model of the E-mail message 11 (i.e., an index of features useful in comparing the E-mail message 11 to the stored case models of the case base 34). Specifically, when attribute setting rules fire, specific attributes of the case model of the E-mail message 11 are flagged (i.e., set true). Thus, when a search of the case base 34 is required, the flagged attributes of the case model are used to search the stored case models of the case base 34."

(‘947 patent, 6:42-44, 6:53-61) (emphasis added). Bright Response's proposed construction is "a knowledge engine that processes electronic messages by comparing them to a stored set of exemplar cases." The defendants argue that this term means "a knowledge engine that compares an incoming set of facts (a 'problem') with a stored set of exemplar cases representing past 'problems' to obtain a set of prior cases which are used to formulate an appropriate action."

The parties disagree on whether the stored exemplar cases must be past problems or may they include anticipated problems. In support of limiting the term's scope to past problems, the defendants cite the following passage from the Background of the Invention: "A help desk application utilizing a case based reasoning system, see U.S. Pat. No. 5,581,664 to Allen et al., has been described which compares an incoming set of facts (a 'Problem') with a stored set of exemplar cases (a case base). . . . The case base is stored in the form of case attributes representing past 'problems.'" (‘947 patent, 2:41-48). The defendants argue that this language expressly defines case base and restricts its meaning. But this discussion of case base is written in the context of explaining the functionality of the Allen reference, not the present invention. The patent describes Allen as prior art and distinguishes it from the claimed invention. (See '947 patent, 2:52-53 ("Unfortunately, [Allen] has several drawbacks.").) The defendants also argue that the prosecution history supports limiting case base to past problems. In response to a PTO rejection, the patentees explained that a case base reasoning system "compares an incoming set of facts (a 'Problem') with a stored set of exemplar cases (a case base)" and cited the portion of the specification discussing the Allen reference. Notably, however, the patentees omitted the sentence that stated, "The case base is stored in the form of case attributes representing past 'problems.'" In all, the court concludes that the prosecution history contains no clear and unmistakable disavowal of case bases containing anticipated problems. See Omega Eng'g, Inc v. Raytek Corp., 334 F.3d

- 1008 -
Next, the defendants contend that the case base knowledge engine "compares an incoming set of facts (a 'Problem')" to the case base, while Bright Response asserts that the "electronic message" is compared. The defendants cite the portion of the prosecution history, quoted above, that contains the "incoming set of facts" language. But the passage that immediately follows states, "The specification describes in detail an example of a case base knowledge engine for interpreting electronic messages . . . In that example, an incoming message ("a presented model") is compared to each of a set of stored case models . . . ." Furthermore, the claim language itself explains that the electronic message is being interpreted. (947 patent, claim 26, step b ("interpreting the electronic message using a . . . case base knowledge engine")). The defendants also argue that Bright Response's proposed construction excludes the preferred embodiment, which compares flagged attributes. The specification describes an embodiment of the case base knowledge engine's operation:

The application of the attribute setting rules produces a case model of the E-mail message 11 (i.e., an index of features useful in comparing the E-mail message 11 to the stored case models of the case base 34). Specifically, when attribute setting rules fire, specific attributes of the case model of the E-mail message 11 are flagged (i.e., set true). Thus, when a search of the case base 34 is required, the flagged attributes of the case model are used to search the stored case models of the case base 34.

(947 patent, 6:53-61). Thus, the defendants contend that Bright Response's "incoming message" proposal excludes the embodiment above. But comparing flagged attributes is subsumed within the broader "processing electronic messages" construction. Also, the scope of this term should not be limited to the flagged attributes comparison embodiment. Therefore, the court construes "case base knowledge engine" to mean "a knowledge engine that processes electronic messages by comparing them to a stored set of exemplar cases."

3. "Cash Value"

The next term is "cash value." The plaintiff argues that this term means "a value measurable in dollars (or other currency)." The defendant proposes "a value accumulated in an account that is (i) personal to each consumer, (ii) determined by accumulating credit values, (iii) to which the consumer receives access and (iv) measured in dollars transferred to the consumer directly or placed in the consumer's account."

The defendant correctly derives its proposed construction from the prosecution history. There, the patentee explicitly defined "cash value." Response to Office Action, February 26, 1997, at 3. In addition, the defendant points out that its proposed construction is the exact same construction that the plaintiff offered in a prior case in this Court. See Defendant's Responsive Claim Construction Brief, Ex. BB. The plaintiff, on the other hand, argues that the defendant's proposed definition incorporates limitations from other portions of the claims and is unnecessarily cumbersome.

The court rejects the plaintiff's arguments. The patentee defined this term in the file history, and, therefore, the court adopts the defendant's proposed construction.

1. Catalog/ Product Catalog

'683 Patent, Claims 3, 26, 28, 29

'516 Patent, Claims 1, 2, 6, 9, 21, 22, 29

a. Words of the Claim
Claim 3 of the '683 Patent claims an electronic sourcing system comprising:

at least two product catalogs containing data relating to items associated with the respective sources;

means for selecting the product catalogs to search;

means for searching for matching items among the selected product catalogs…

'683 Patent at 25:10-15 (emphasis added). Claims 26, 28 and 29 of the '683 Patent claim a method comprising the steps Of:

maintaining at least two product catalogs on a database containing data relating to items associated with the respective sources;

selecting the product catalogs to search;

searching for matching items among the selected product catalogs…

2 Claim 29 incorporates Claim 28.

Claims 1, 2 and 6 of the '516 Patent claim an electronic sourcing system comprising:

a collection of catalogs of items stored in an electronic format;

a first set of pre-determined criteria associated with said collection of catalogs;

a second set of pre-determined criteria associated with items from each of said catalogs;

a catalog selection protocol, said catalog selection protocol relying on first set of pre-determined criteria to selected less than said entire collection of catalogs, and including a matching vendor identification code with a subset of said collection of catalogs, wherein said subset of catalogs includes both a vendor catalog from a predetermined vendor and a second catalog from a predetermined third party that is one of a manufacturer and a competing vendor, said predetermined third party selling items corresponding to items in said vendor catalog; and

a search program, said search program relying on said second set of criteria to select specific items from said catalogs determined from said catalog selection protocol.

'516 Patent at 23:44-64 (emphasis added). Claim 21 and 22 claim an electronic sourcing system comprising:

a requisition module including data fields, user-generated criteria entered into at least one of said data fields to generate at least partial criteria corresponding to a desired item;

a catalog collection searching module, said searching module including a collection of catalogs of items stored in an electronic format, a catalog selection criteria used to select less than said entire collection, said searching module being used to generate additional search-module criteria for said data fields of said requisition module;

a multiple purchase order generation module, said purchase order generation module creating multiple purchase orders from a single requisition created with said user-generated criteria and said search-module criteria;

wherein each of at least two catalogs include a generally equivalent item from a different source, said requisition module

a collection of catalogs of items stored in an electronic format;

a first set of pre-determined criteria associated with said collection of catalogs;

a second set of pre-determined criteria associated with items each of said catalogs;

a catalog selection protocol, said catalog selection protocol relying on first set of pre-determined criteria to select less then said entire collection of catalogs, and including a matching vendor identification code with a subset of said collection of catalogs, wherein said subset of catalogs includes both a vendor catalog from a predetermined vendor and a second catalog from a predetermined third party;

a search program, said search program relying on said second set of criteria to select specific items from said catalogs determined from said catalog selection protocol; and

a cross-reference table linking a vendor item catalog number from said vendor catalog with an item catalog number from said predetermined third party.

b. Specification

The most significant disagreement between the parties is whether a "catalog" must be published by a vendor. The specification provides:

A feature of the present invention is the ability to search multiple catalogs from different suppliers. For example, catalog database 36 can contain the catalog or catalogs published by a vendor Distributor. . . Catalog database 36 can further contain catalogs published by some of the vendor manufacturers. . . Catalog database 36 can further contain catalogs published by outside suppliers, whether manufacturers or other distributors, listing such vendor's products different from those in the Distributor's catalogs.

'683 Patent, 4:46-59 (emphasis added). In briefing, Lawson argued that it is essential that the construction of "catalog" require that it be "published by a vendor." At oral argument, ePlus stated that it objected to the inclusion of "published by a vendor" because the specification quoted above makes clear that a catalog may be published by a supplier, manufacturer or distributor, among others. The parties' disagreement over whether a catalog must be published by a vendor was resolved when they agreed, at oral argument, that the term "vendor" includes suppliers, distributors, and manufacturers.

Additionally, the specification outlines what is generally-included in a catalog. It provides that catalogs "preferably include such information as part number, price, catalog number, vendor name or I.D., and vendor catalog number, as well as textual information and images of or relating to the catalog products." '683 Patent at 4:38-42.

c. Proper Construction

Based on the fact that a catalog is published by a vendor and includes the type of information outlined in the specification above, "catalog" and "product catalog" mean: an organized collection of items and associated information, published by a vendor (which includes suppliers, manufacturers, and distributors), which preferably includes a part number, price, catalog
number, vendor name, vendor ID, a textual description of the item, and images of or relating to the item. That construction is consistent with the ordinary meaning of the term as used in the words of the claim and the specification.

b. “catalog file”
The digital jukebox described in the 302 patent includes “a catalog file including data for each stored song representing the identity of said song and the location in said computer memory of the digital data representing said song.” Opening Brief, Ex. 1 at 5:18-19 (emphasis added). The specification states that it includes seven fields: title, classification (genre), song address (where the song is stored in the jukebox), song size, graphics address, graphics size, and play count. Id. at fig. 2; 2:56-58. Plaintiffs contend that “catalog file” means “a file that includes information associated with songs.” Opening Brief at 7. Defendants contend that catalog file should be construed as “a data structure made up of song records, with each song record having the fields set forth in Figure 2.” Resp. Brief at 6. In other words, defendants contend that the catalog file must include, for each song, data in each of the seven fields. Plaintiffs argue that the claim does not require that there be data in each field or category for each song.

Defendants’ proposed construction amounts to an impermissible attempt to read the preferred embodiment in figure 2 as a limitation of the claim. Nazomi Comm., Inc. v. ARM Holdings, PLC, 403 F.3d 1364, 1369 (Fed.Cir.2005). The plain language of the claim shows that the catalog file need have only two of the fields depicted in figure 2: “the identity of said song and the location in said computer memory of the digital data representing said song.” Opening Brief, Ex. 1 at 8:55-58. Defendants’ proposed construction disregards the claim language itself, which is the first place to look when construing disputed terms. See Hockerson-Halberstadt, 222 F.3d at 955. The Court therefore construes the term “catalog file” as “a file that includes information identifying a song and the location of the digital data representing the song in the computer memory.” The same construction applies to the term “catalog file” in claims 2 and 10 of the 889 patent.
The parties' proposed constructions are as follows:

**Plaintiff**
- System of characters or symbols that represent categories.

**Defendant**
- A code representing a category to which a network page is or could be assigned.

The parties dispute whether the term "categorization code" refers to an entire "system" of codes or to the individual codes that correspond to each category. The term "categorization code" appears in dependent claims 19, 20, 25, and 30:

19. The method of claim 1, further comprising providing a categorization code that can be used to label the page with the categorization label that indicates the categories to which the page is assigned.

20. The method of claim 19, wherein said categorization code comprises an indicium for each of said categories.

25. The method of claim 19, wherein said categorization label further includes an identifier to indicate that said label is part of said categorization code.

30. A computer implemented method for categorizing a network page, comprising:

   - providing a list of categories, wherein said list of categories include a category for transacting business and a category for providing information, and wherein said list of categories include a plurality of categories based on the copyright status of material on a page;
   - providing a categorization code for labeling the network page with a categorization label, wherein said categorization label indicates a set of categories and subcategories to which the network page is assigned, and wherein said categorization label indicates the copyright status of material on the network page; and
   - controlling usage of the network page using the categorization label and the copyright status of the network page.

(13:40-45; 14:3-5; 14:16-33) (emphasis added.) The language of a patent's claims are "generally given their ordinary and customary meaning," Phillips, 415 F.3d at 1313. Furthermore, the claim term is read in the context of both the particular claim in which it appears and in the context of the entire patent. Id.

These claims reveal a system of characters that represent categories to which network pages can be assigned. Specifically, dependent claim 20 refers to a categorization code as comprising "an indicium for each of said categories" to which a page is assigned. (13:44-45.) For claim 20 to make sense, the term "categorization code" must contemplate a system that can comprise the categorical indicia. Likewise, dependent claim 25 refers to an "identifier" to indicate that the categorization label is part of the categorization code. Defendant's proposed construction is nonsensical when posed alongside claim 25. If a "categorization code" is merely a two-letter indicium of a particular category to which a page has been labeled, then the categorization code should constitute part of the categorization label rather than the label constituting a part of the code. The specification provides further light for interpreting claim 25:

The categorization label for a page preferably also includes an identifier, such as a combination of several characters or symbols, to indicate that the characters or symbols that follow are part of a categorization code system.

(7:8-11.) This portion of the preferred embodiment directly speaks to dependent claim 25 of the specification, and uses the term "categorization code system" where the claim uses "categorization code." According to the patent, the terms are used interchangeably, and is further evidence that the inventors intended the term "categorization code" to mean a code system.

Defendants cite the example of coding a pornographic web page, where the patent states: "The categorization label would be 'coexvimu,' which indicates: Commerce (co); Explicit (ex); Visual (vi); and Multimedia (mu). The Explicit category 42, identified by the 'X' icon and the 'ex' code, . . . " (7:48-54.) While the specification also uses the term "code" when referring to individual category symbols, this is not in conflict with recognizing that the term "categorization code" refers to the system of as a whole. The patent repeatedly refers to these individual codes as "indicia":

- 1013 -
The list of categories includes at least one different indicium for each category. The indicium is preferably a universal symbol or icon that is not associated with any one language, but it may also include a combination of letters, numerals, or other characters, or symbols. The indicia preferably used are universal icons and two-letter or two-numeral indicia, as shown in FIG. 1. Thus, the indicia for commerce are "co" and the "$" symbol, while the indicum for "Public Domain" is "01."

(6:3-11.)

The preferred embodiment further states: "The method also includes the step of providing the creator with a categorization code that can be used to tag or label each page or site . . . . and is preferably the indicia shown in FIG 1." (6:63-7:1.) Figure 1 of the '459 patent displays the three "tiers" of categories and the fourth category comprising copyright status, and the various categories within the tiers. Accordingly, "categorization code" as used in this instance cannot constitute a singular code or category, but must represent the entire system of codes displayed in Figure 1 of the '459 patent.

Defendant also points to portions of the provisional patent applications which referred to the term "categorization code" as both a system and as the individual string of codes as evidence that the term could mean an individual code. (E.g., Yahoo! Reply Decl. Kevin A. Smith Ex. 15 Fig. 1 ("The iics copyright code can simply be typed in at the end of the categorization code . . . .").) The provisional applications that the defendant points to, however, did not use the term "categorization label." Rather, they used the term "categorization code" to also mean what is now defined as the "categorization label." While the provisional patent applications may have used the term "categorization code" to express multiple meanings, the '459 patent claims and specification are consistent in their usage of the term.

Finally, the preferred embodiment generally speaks about the "categorization code" as something that the network page creator "uses" to assign categorization labels to network pages. (See 6:63-65; 7:1-3; 7:12-15.) This conception of "categorization code" aligns with a systemic view of the term, and is incompatible with a construction that limits the term to one particular set of characters or symbols in code.

Therefore, the term "categorization code" means "System of characters or symbols that represent categories."

4. Categorization Label

The parties' proposed constructions are as follows:

<table>
<thead>
<tr>
<th>Plaintiff</th>
<th>Defendant</th>
</tr>
</thead>
<tbody>
<tr>
<td>Tag indicating the category or categories to which a page is assigned.</td>
<td>The complete code string</td>
</tr>
<tr>
<td>representing all the categories to which a network page is assigned.</td>
<td></td>
</tr>
</tbody>
</table>

Defendant's proposed construction clearly is contrary to the preferred embodiment of the invention with respect to the words "complete" and "all." The specification states that: "The categorization label preferably consists of the indicia for all of the categories to which the page is assigned." (7:3-4) (emphasis added). According to the preferred embodiment, therefore, it is not necessary that the categorization label include the indicia representing every category to which the page has been assigned. Plaintiffs also point to dependent claim 22, which states: "The method of claim 20, wherein said categorization label includes the indicia for each category to which a page is assigned." (13:48-50.) Furthermore, independent claim 30, which includes both terms "categorization code" and "categorization label," makes clear that the categorization label need not contain the indicia of all the categories to which a network page is assigned:

30. A computer implemented method for categorizing a network page, comprising:

providing a list of categories, wherein said list of categories include a category for transacting business and a category for providing information, and wherein said list of categories include a plurality of categories based on the copyright status of material on a page;
providing a categorization code for labeling the network page with a categorization label, wherein said categorization label indicates a set of categories and subcategories to which the network page is assigned, and wherein said categorization label indicates the copyright status of material on the network page; and

controlling usage of the network page using the categorization label and the copyright status of the network page.

(14:17-33) (emphasis added.)

Plaintiff argues that the defendant's proposed construction also improperly reads "categorization code" and "code string" into independent claim 1 of the '459 patent. Specifically:

1. A computer implemented method of categorizing a network page, comprising:

   Providing a list of categories, wherein said list of categories include a category for transacting business and a category for providing information, and wherein said list of categories include a category based on copyright status of material on a page;

   assigning said network page to one or more of said list of categories;

   providing a categorization label for the network page using the copyright status of material on the network page; and

   controlling usage of the network page using the categorization label and the copyright status of the network page.

   19. The method of claim 1, further comprising providing a categorization code that can be used to label the page with the categorization label that indicates the categories to which the page is assigned.

(‘459 patent 12-13) (emphasis added.) "[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." Phillips, 415 F.3d at 1314-15. Dependent claim 19 adds the limitation of "further comprising a categorization code," which presumably is not contained in independent claim 1. While independent claim 30 includes both "categorization label" and "categorization code," independent claims 1 and 31 do not require a "categorization code." The court will not import a dependent claim into independent claim 1 by importing the term "categorization code" to the term "categorization label."

Furthermore, the language of the specification, which was quoted only in part by the defendant, states that: "The indicia for the categories are preferably placed in an unbroken code string in the following order: first tier, second tier, third tier, and copyright-status categories." (7:15-18) (emphasis added). The specification further states that: "An example of such a categorization label is a single, simple character string consisting of the two-letter or two-numerical indicia for all of the categories to which the page is assigned." (7:5-8) (emphasis added). It does not appear, therefore, that the preferred embodiment is the only embodiment of the categorization label, and the court will not interpret the term "categorization label" to require a "code string."

Finally, because the patent does not limit its claims to placing only one categorization label on a network page, it is clear that each label does not need to include every category to which a page is assigned in order for the patent to function. A network page creator could assign a network page two categorization labels, each indicating only some of the categories to which a page is assigned. Furthermore, the specification provides that a network page designer can communicate the categories to which a page is assigned directly to search engines rather than include those categories in the categorization label. (6:50-58.) This clearly contemplates that a categorization label might not include every category to which a network page is assigned.

Defendants object to plaintiff's including the word "tag" in their proposed construction of the term "categorization label." While the word "tag" may be a term of art, "a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history." Honeywell Intern., Inc., 452 F.3d at 1318. In the specification, the patent clearly uses the words "tag" and "label" and "mark" in the verb form interchangeably. (6:55-53, 6:63-65.) The construction suggested by plaintiff, however,
uses the word "tag" as a noun, which is not supported by the patent language as being synonymous with a "label." Additionally, the preferred embodiment somewhat confusingly also states that "The method also includes the step of providing the creator with a categorization code that can be used to tag or label each page or site." (6:63-65.) Substituting the word "tag" for "label" in the definition adds nothing to enlighten the jury. To the contrary, it would just add another word which arguable would have to be defined. Since the plaintiff asserts that the patent uses the terms "tag" and "label" interchangeably, this construction provides the same meaning while avoiding possible confusion. Furthermore, this construction makes clear that the label need not include every category to which a page is assigned.

Therefore, the term "categorization label" means "Label indicating a category or categories to which a page is assigned."

541

Cause, causing, all forms of "cause"

The term cause is a common word with no peculiar meaning in the 290 patent. Accordingly, the Court concludes "cause" means "bring about."

GO BACK

542

B. "Causing a Quantity of Digital Data Resident on a Source Storage Medium to Be Transferred to a Computer System Having a Destination Storage Medium"

The parties next dispute the meaning of the phrase "causing a quantity of digital data resident on a source storage medium to be transferred to a computer system having a destination storage medium," which represents the first of the three steps of the method described in Claim 1. See '776 Patent, col. 17, Ins. 14-16. The parties agree that the phrase "a quantity of digital data" means "an amount of digital data," and that the phrase "source storage medium" means a "computer storage medium that is the point of origin of the data being transferred." See JCCS, Appx. A, at 4 (terms 14-15). Within this phrase, the parties principally dispute the meaning of the terms "causing," "computer system," and "destination storage medium."

1. "Causing"

Defendant defines "causing" as used in Claim 1 as "effecting by command or request." JCCS, Appx. A, at 4 (term 13). Plaintiff defines "causing" as "effecting by command, authority, or force." Id. Plaintiff contends that defendant's proposed definition is truncated, and that an effect can be "caused" even if there is no explicit command or request. Defendant argues that plaintiff, through its proposed definition, is attempting to interpret "causing" so as to include actions by either the user of the software described in the patent or a computer other than the destination computer.

Defendant's concerns, in so far as claim construction is concerned, are misplaced. Neither proposed definition speaks to who or what is doing the "causing." Indeed, even under defendant's proposed definition a user or computer other than the destination computer may be able to "command" or "request" a certain result. Whether the limitations of the claims as a whole require the "causing" step to be initiated by the destination computer is simply not affected by either party's proposed construction of "causing." That being the case, defendant's proposed construction is adopted, as that construction is consistent with the ordinary definition of the term. See MERRIAM-WEBSTER ONLINE (available at www.m-w.com/cgi-bin/dictionary?book=Dictionary&va=causing); OXFORD ENGLISH DICTIONARY (2d ed. 1989) (online edition available at www.dictionary.oed.com/cgi/entry/50034905?query_type=word&queryword=causing&first). 

2. "Computer System"

The parties also dispute the meaning of the term "computer system." Plaintiff contends that the appropriate definition of this term is "any combination of hardware, software, documentation, and manual procedures that are combined to perform a specific function." JCCS, Appx. A, at 4 (term 17). Defendant contends that the appropriate definition is simply a "personal computer or workstation." Id. The Court adopts defendant's proposed construction of this term.
The specification clearly contemplates a "computer system" in accord with defendant's proposed definition. In setting forth the preferred embodiment, the specification describes a computer system as comprising a bus to which are connected a central processing unit, random access memory, a serial port, and a data storage medium (such as a hard disk)--i.e., a single personal computer or computer workstation. See ’776 Patent, col. 3, lns. 18-31. This constitutes the complete description of the computer system. Importantly, the specification describes data transmission occurring between two such systems through modems which, although attached to each computer system, are outside of the system. See id., lns. 32-38. This construction also makes sense in light of the claim limitations, which discuss transfer of data to a computer system that has a destination storage medium--i.e., a hard disk or similar storage device.

8 The specification's reference to the possibility that the modules described in the patent could be implemented directly in hardware, "as in the form of add on circuitry for a 'virus free' modem," ’776 Patent, col. 10, lns. 26-27, does not alter this conclusion. Nothing in this brief sentence leads to the conclusion that a modem is itself a "computer system" as that term is used in the patent, and any such conclusion is belied by the explicit description of such a system earlier in the specification.

The extrinsic evidence also supports this construction. In his rebuttal report, plaintiff's expert Eugene Spafford states that the term "computer system" encompasses various systems other than a simple personal computer or workstation, including interconnected computer systems, channel processors, and distributed computer systems. See Pl.'s Br., Ex. 11, Decl. of Professor Eugene H. Spafford, Appx. 1, Rebuttal Expert Report of Professor Eugene H. Spafford, PP 18-21 [hereinafter "Spafford Rebuttal Report"]. In his deposition, however, Dr. Spafford testified that the specification's use of "computer system" referred to a single computer, see Def.'s Br., Ex. 12, Deposition of Eugene Spafford, at 68-69 [hereinafter "Spafford Dep."], and that a modem as referred to in the specification and as understood in 1990 would not be considered either part of a computer system or such a system in its own right, see id. at 69. He also conceded that the patent nowhere mentions the terms "channel processors," "interconnected computer systems," or "distributed computer systems," other types of systems which Spafford contends in his report are types of "computer systems" as used in the patent. See id. at 99-100. Further, Dr. Stephen Melvin, plaintiff's expert in the Hilgraeve case, opined in his report on plaintiff's behalf in that case that

[t]he only type of system that is described in the ’776 Patent is a personal machine . . . . Generally speaking, this class of computer systems is the only type that needs protection from viruses. There are other types of computer systems, such as unattended servers, that typically don't need this protection. They are used to simply relay information, they are not under the control of an ordinary user and they don't execute any software except pre-installed applications. There is no support to indicate that the patentees intended to cover these types of systems. Furthermore, there is no figure, and no teaching of how to apply the claims to an unattended server.

Def.'s Br., Ex. 13, Expert Report of Dr. Stephen W. Melvin in Hilgraeve Corp. v. Symantec Corp., at 8 [hereinafter "Melvin Expert Report"]. Dr. Melvin further notes that, as used in Claim 1, "[t]he computer system is a desktop personal computer or workstation[]." Id.

Accordingly, the Court adopts defendant's proposed construction of the term "computer system."

3. "Destination Storage Medium"

The parties next disagree about the meaning of the term "destination storage medium." Plaintiff contends that the term means "a computer storage medium that is the intended endpoint of the transfer of digital data." JCCS, Appx. A, at 4 (term 18). Defendant counters that the term should be defined as "a computer storage medium that is the target of the transfer of data as a result of the causing step." Id.

The Court finds that defendant's proposed construction should prevail. As defendant correctly notes, construing destination storage medium as plaintiff does would permit the invention to operate outside of the computer system. For instance, the source storage medium could transfer the data to the computer, which would then transfer the data to a peripheral storage device such as a thumb drive. Under plaintiff's proposed construction, only the thumb drive would be the "destination
storage medium," even though it is only connected to, but not part of, the computer system identified in the patent. Plaintiff's construction would allow two separate transfers of data to be collapsed into only one transfer, and for the destination storage medium to be located outside of the "computer system" identified in the patent. The language of the patent does not permit this interpretation. See '776 Patent, col. 3, lns. 38-44 ("It will further be assumed that the data to be transmitted is initially stored on storage medium 24a of system 12 and after transmission will also be stored on storage medium 24b of system 14. Thus, storage medium 24a may be considered the source storage medium while storage medium 24b may be considered the destination medium."); id., col. 6, lns. 17-21 (emphasis added) ("In this regard, the local [computer] system 14 has the capacity for causing a transmission of digital data resident on the remote system 12 (e.g., hard disk storage medium) to be transmitted to the local system.").

Accordingly, the Court adopts defendant's construction of this term.

4. The Phrase as a Whole

In light of the construction given the individual terms above, the complete phrase "causing a quantity of digital data resident on a source storage medium to be transferred to a computer system having a destination storage medium" means: "effecting by command, authority, or force, the transfer of digital data resident on a source storage medium to a personal computer or workstation having a computer storage medium which is the target of the transfer of data as a result of the 'causing' step."

1. "CD Reader" and "Recordable CD Drive"

The terms "CD Reader" and "Recordable CD Drive" appear together in dependent Claims Four and Eight of the '531 Patent. The language of Claims Four and Eight mirror each other and state the following: "The method [system] of claim 1 [claim 5] which further allows a user to repeatedly add and interchange recordable CDs between a CD reader and a recordable CD drive using sessions." ('531 Patent, col. 6, ll. 41-43; '531 Patent, col. 8, ll. 7-9).

Optima urges the Court to construe these terms based on their "plain meaning," which, Optima contends, limits them to drives capable of reading or recording CDs only. Roxio, on the other hand, avers that these terms should be construed more broadly to include all drives that are capable of reading and recording Write-Once-Read-Many (WORM) discs. 2

--- Footnotes ---

2 The acronym 'WORM' is used to refer to various storage media that is capable of being written once by a computer that has the appropriate capabilities and then read many times. Although recordable CDs are one type of WORM media, there are many different types of WORM media that are not CDs, including 130mm magneto-optical drives and 300mm optical disks. (Expert Report of Dr. Scott Brandt, p. 6.) Indeed, a floppy disc written upon once with the ability to write on the disc permanently disabled might also be a WORM disc.

--- End Footnotes ---

Each party's proposed claim construction of "CD Reader" and "Recordable CD Drive" is as follows:

<table>
<thead>
<tr>
<th></th>
<th>Optima's Proposed Claim</th>
<th>Roxio's Proposed Claim</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;CD Reader&quot;</td>
<td>A CDROM player capable of reading but not writing CDs.</td>
<td>A disc drive capable of reading Write-Once-Read-Many (WORM) discs.</td>
</tr>
<tr>
<td>&quot;Recordable CD Drive&quot;</td>
<td>A CD player/recorder capable of both reading and writing CDs.</td>
<td>A disc drive capable of recording Write-Once-Read-Many (WORM) discs.</td>
</tr>
</tbody>
</table>

To support its constructions, Roxio argues that Optima equates recordable CDs with WORM discs several times within the '531 Patent. For example, Roxio cites to the following statement in the '531 Patent: "Recordable CD can not be directly
interfaced with the operating system because they are WORM (Write Once Read Many) devices." (Roxio's Opening Claim Construction Brief, p. 17, citing '531 Patent, col. 1, ll. 12-14). This "equation" of recordable CDs to WORM discs, Roxio argues, leads to the conclusion that the terms at issue should be construed to include all WORM discs and not be limited to CDs.

The Court rejects Roxio's contention that the '531 Patent equates recordable CDs to all WORM discs. As both parties in the instant case are aware, recordable CDs are a type of WORM discs. Optima merely chose to clarify this relationship in the '531 Patent and, by doing so, did not equate one with the other. Thus, the Court finds that the terms "CD Reader" and "Recordable CD Drive" are accorded their ordinary meaning and are limited to drives that are capable of reading and recording CDs only, respectively, not other WORM discs.

The parties also dispute whether the term "CD Reader" is 'a drive that can only read CDs, or whether it is a drive that is capable of reading CDs but that also can perform other tasks, such as recording CDs. Optima urges the former construction based on the term's "plain meaning." (Pl.'s Opening Markman Brief, p. 10). Roxio, however, argues the latter construction because "any drive that can write CDs can also read them." (Roxio's Opening Claim Construction Brief, p. 17-18, citing Compton Decl., Ex. E, P 15).

The Court finds that the claim language of the '531 Patent compels a construction of "CD Reader" that limits this term to drives that are able only to read CDs. Roxio's argument is logically flawed. Although it may be correct that any drive that is able to write CDs also can read them, it does not follow that the opposite is true." Moreover, the decision by Optima to include the terms "CD Reader" and "Recordable CD Drive" in the '531 Patent demonstrates its desire to distinguish the two. The ordinary meaning of "CD Reader" is a drive that only reads CDs. The ordinary meaning of "Recordable CD Drive" is a drive that can both read and write CDs.

7. Cell

A cell is a group of one or more digital words.

2. "Cell analysis instrument" (claim 21)

Cytyc contends that a "cell analysis instrument" is "a device, not including a microscope station, that performs measurements or analysis of at least one cell feature on a specimen preparation, such as a specimen slide." TriPath's proposed definition is, "an instrument that automatically conducts a detailed assessment or examination of one or more cells to determine its nature or essential features." The disagreement centers on three issues. First, whether a cell analysis instrument is or includes a microscope station; second, whether it performs "measurements"; and third, whether it conducts assessments automatically or requires human input.

The above discussion of "microscope station" resolves the first issue. A "cell analysis instrument" is not, and does not include, a microscope station. Therefore, the remainder of this section will focus on the second and third issues.

The claims provide little guidance as to whether the cell analysis instrument performs measurements. Claim 21 states that the cell analysis instrument produces "analysis", but does not provide any further details. 969 patent at col. 14, 1. 33. Similarly, claim 24 states that the cell analysis instrument produces "analysis data." Id. at col. 14, 1. 49.

The specification is more helpful. As mentioned above, the specification lists examples of four types of cell analysis instruments. Id. at col. 9, 11. 25-30. The only type that it describes in detail is a particular brand of laser scanning cytometer, the CompuCyte LSC(tm) ("LSC"). Id. at col. 9, 1. 27.
The description states that the

LSC can scan slides stained with fluorescent dyes to measure the constituents and morphology of cells on the slide and generate a computer database file containing a set of constituent values, morphology values and slide position values of every cell found by it on the slide.

Id. at col. 9, 11. 39-44 (emphasis added). This passage indicates that the patentee intended a cell analysis instrument to conduct measurements.

Moreover, the sentence introducing the four types of cell analysis instruments begins, "There are at least four types of instruments." Id. at col. 9, 11. 35 (emphasis added). The words "at least" make clear that the four listed types are examples; they are not the outer limits of the claims. The patentee does not define any specific method of analysis that the claimed "cell analysis instruments" must use. Therefore, to interpret "cell analysis instrument" as one that does not perform measurements would not only contradict the example in the preferred embodiment, but would improperly limit the scope of the claim. See Phillips, 415 F.3d at 1323 (warning against confining the claims to the embodiments in the specification when those embodiments are merely "exemplary in nature").

The claims are silent as to whether a "cell analysis instrument" operates automatically or requires human input. Again, the description of the LSC provides the only detailed example of how a cell analysis instrument functions. The LSC clearly allows some human interaction. For example, the user may move the slide to view areas of interest and annotate the positions of specific cells while the slide is on the stage. Id. at col.9, 11. 61-62; col. 10, 11. 2-4. However, it does not appear that human interaction is required in order for the LSC to perform the analysis. Another embodiment specifically automates the movement of the microscope to locations of interest. Id. at col. 10, 11. 6-14.

Since much of the description of the LSC is written in the passive voice, it is difficult to discern whether a machine or a human is conducting the analysis. See id. at col. 9, 1. 34 -- col. 10, 1. 5. However, the specification is clear that the purpose of the "cell analysis instrument" is to perform "analysis", an activity that can be conducted with or without human interaction. The claims and the specification do not restrict the methods by which the "cell analysis instrument" can perform its analysis. Thus, I will not read into the claims a limitation that a "cell analysis instrument" must conduct analysis either automatically or with human input.

In sum, a "cell analysis instrument" is a device, not including a microscope station, that performs measurement or analysis of at least one cell feature on a specimen preparation, such as a specimen slide.

2. Cell separation process

<table>
<thead>
<tr>
<th>Disputed Claim Language</th>
<th>Synopsys's Proposed Construction</th>
<th>Magma's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cell separation process</td>
<td>a process which assigns a cell a location or an approximate location on the physical placement area</td>
<td>method of assigning locations to cells such that they do not overlap</td>
</tr>
</tbody>
</table>

The phrase "cell separation process" appears in claims 1, 6, and 11 of the '114 patent, each time as part of the longer phrase "executing a cell separation process according to the netlist." (See '114 Patent at 6:56-7:3, 7:13-28, 8:5-22.) The parties agree that the "cell separation process" involves assigning a location to the cells, but dispute whether the cells are assigned to specific, as opposed to approximate, locations, and whether cells may overlap in any way.

In the initial portions of the '114 patent specification, one possible reading of the language is that the "cell separation process" assigns specific locations to cells but does not require that the cells be spaced apart from each other. For example, the "Summary of the Invention" section of the '114 patent states:
[A] cell separation process assigns (x,y) locations to each of the cells. The cell location information is supplied to the synthesis tool, which can then make changes to the netlist thereto. In the present invention, the size of the placement area is allowed to be scaled according to the new netlist. Next, the cells of the netlist are spaced apart according to a spacing algorithm.

(See '114 Patent at 2:16-23.) Additionally, in the "Detailed Description" portion of the specification, which describes a preferred embodiment of the invention, the inventors reiterate that "cell separation" and "spacing" are separate steps of the patented process. (See id. at 3:14-20, 3:41-47.) According to the specification, "[t]he cell separation process takes each cell in the netlist and assigns a pair of (x,y) coordinates" which are "used to specify the location of each cell relative to a two-dimensional boundary area in which the circuit is to be placed." (See id. at 3:16-20.) The placement of cells during the "cell separation process" is "a best estimate guess," after which "the netlist is tweaked to optimize the design." (See id. at 3:27-32.) Only thereafter does the "spacing" of the cells occur, followed by a separate step of partitioning the cells "in order to better 'spread' them apart." (See id. at 3:41-48.) The above-cited language arguably suggests that the "cell separation process" includes the step of assigning a location to each cell, but does not include the step of ensuring that the cells are "spaced apart." 13

Elsewhere in the specification, however, in a more detailed description of "cell separation" found in a description of a preferred embodiment, the specification expressly states that "[c]ells must be assigned locations so that they do not overlap each other, they all fit within some overall bounding figure, and the total wiring cost is minimized." (See id. at 5:23-25 (emphasis added)). The cell separation process determines "an assigned (x,y) position . . . denoting the approximate centerpoint of the cell." (See id. at 5:27-28.) The specification further explains that, in the spacing step, the partition walls are changed "in order to improve the spacings between the cells." (See id. at 5:32-35 (emphasis added)). Although the above-cited language appears in the description of a preferred embodiment, (see id. at 4:59-61), the provision that, during cell separation, "[c]ells must be assigned locations so that they do not overlap each other," read in context, describes a requirement of the invention rather than an optional aspect of the preferred embodiment.

Nonetheless, Dr. Harris attests, "[t]o one with ordinary skill in the art, it would make no sense to require that the cells are completely non-overlapping" at the conclusion of the cell separation process. (See Harris Decl. P 134.) He further attests that while "it is true that the precise x,y locations for the centerpoints of two cells need to be different (because one cannot have two cells that have precisely the same centerpoint), this does not mean that the entire area of the cells must or should be non-overlapping." (See id.) According to Dr. Harris, "it is typical during rough placement, that cells are assigned overlapping locations, and this overlap is usually dealt with during detailed placement." (See id. P 138.)

Even if it is "typical" for cells to overlap during rough placement, the specification of the '114 patent expressly states, as noted, that "[c]ells must be assigned locations so that they do not overlap each other." (See '114 Patent at 5:23-25.) The Federal Circuit has held that "the specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor" and, in such instances, "the inventor has dictated the correct claim scope, and the inventor's intention, as expressed in the specification, is regarded as dispositive." See Phillips v. AWH Corp., 415 F.3d 1303, 2005 WL 1620331 at *8. Accordingly, the Court concludes that the "cell separation process" must result in assignment of cells to locations such that they do not overlap each other in any way.

With respect to whether the cells are assigned to precise locations during the "cell separation process," the specification repeatedly states that the cells are assigned "(x,y)" locations during the cell separation process. (See, e.g., '114 Patent, Abstract and 2:17-18, 3:16-17, 5:12-14, 5:25-28.) Synopsisys's argument that the locations nonetheless may be approximate is based entirely on one sentence in the specification: "The output from cell separation process 306 is a number of cells, each of which has an assigned (x,y) position 307 denoting the approximate centerpoint of the cell." (See id. 5:25-28.) As Dr. Sarrafzadeh suggests, however, where a cell has an irregular shape, its precise centerpoint may be difficult to determine, and the cell nonetheless is assigned to a precise (x,y) location, which location is intended to represent the "approximate
centerpoint" of the cell. (See Sarrafzadeh Decl. P 43; see also '114 Patent at 5:25-28.) Synopsys fails to explain how a cell can be assigned to specific (x,y) coordinates and still be assigned only an "approximate" location.

Accordingly, the Court will adopt Magma's construction of "cell separation process" and construe the term as "a method of assigning locations to cells such that they do not overlap."

Cell stuff information

Ciena argues that the term should be construed as "information indicating the location of cells that enable the receiving node to remove them." Ciena contends that its construction of "cell stuff information" reflects the ordinary meaning of the term as evidenced by the specification. In support of its argument, Ciena points to Column 10, Lines 35 through 37 of the specification that state, "[a]ny cell can be used for stuffing as long as the location is indicated so that the receiving node can remove it."

Claim 3 of the patent is an independent claim that discloses a method comprising, among other things, "transmitting from the first node the series of [Asynchronous Transfer Mode] data cells in the round robin order, the first node inserting at least one inverse multiplexing control cell that contains cell stuff information into each frame."

Claim 4, a dependent claim of claim 3 reads, "The method of claim 3, wherein the cell stuff information includes stuff code indicating the location of stuff cells inserted in a respective frame." If the Court were to adopt Ciena’s construction, claim 4 would effectively read, "The method of claim 3, wherein the information indicating the location of cells that enable the receiving node to remove them includes stuff code indicating the location of stuff cells inserted in a respective frame."

Furthermore, the excerpt from the specification is described in the context of one embodiment of the invention and does not support Ciena’s construction of the term. The term “cell stuff information” should retain its ordinary meaning. Accordingly, the Court construes the term as “information relating to cell stuffing.”

"cellphone" / "cellular telephone"

The term "cellphone" or "cellular telephone" appears in the independent claims. Claim 50 of the '783 patent states in part, "a cellphone having a portable housing of a size and weight for being handheld by a person and adapted for placing and receiving person-to-person telephone calls to and from remotely located telephones." The plaintiff proposes that "cellphone" and "cellular telephone" mean "a portable telephone capable of communicating wirelessly in a cellular system or satellite system." In contrast, the defendants contend that these terms mean "a device capable of communicating wirelessly via a cellular or satellite network and including an antenna, a transmitting/receiving section, a microprocessor, a memory, a dialing pad, a microphone, and a speaker."

The defendants argue that the components comprising the cellphone must be enumerated to allow the fact finder to determine if those components are in the claimed "housing." This argument is based in part upon the Alltel defendants' proposed claim construction of "housing," in which Minerva allegedly disclaimed housings with slides or hinges. The defendants also quote the following passage from the specification in support of their proposed construction:

Referring more particularly to the figures, the entertainment and communication device, generally designated 100, includes a cellular telephone or satellite accessible telephone or the like, hereinafter referred to collectively as a "cellphone", having a dialing pad 101 . . . . The cellphone includes a microphone 103 and a speaker 125 . . . . The cellphone also includes a dialing memory 113, a dialing section 114, a transmitting/receiving section 115, an antenna 119 and a ring signal capturing
The microphone 103 and speaker 125 are connected through an audio signal processing section 108 to the microprocessor 112 of the device 100.

(‘783 Patent, 1:52-2:3) (emphasis added).

Minerva disputes the need to enumerate the cellphone's components. The plaintiff points out that some of the dependent claims add limitations indicating that the cellphone includes "a microphone, a speaker, . . . and a memory" (‘783 Patent, Claim 50) and a microprocessor (‘783 Patent, Claim 32). These additional limitations would be redundant if the term "cellphone" were construed to include a microphone, speaker, memory, and microprocessor. Furthermore, the written description does not assert that the individual cellphone components, deemed necessary by the defendants, are novel or required.

As shown in the quoted passage above, the specification does describe the cellphone as having a dialing pad, microphone, speaker, a dialing memory, transmitting/receiving section, and an antenna. The court finds that an ordinary artisan would recognize that a cellphone requires these components, and they are not optional features of a preferred embodiment. However, despite the enumeration of a microprocessor, the specification's language does not clearly state that the cellphone includes a microprocessor; some of the cellphone's components are merely connected to the microprocessor of the claimed portable entertainment device. (See ’783 Patent, 1:67-2:6 ("The microphone 103 and speaker 125 are connected . . . to the microprocessor 112 of the device 100. The dialing memory 113, dialing section 114, transmitting/receiving section 115, ring signal capturing section 122 and dialing pad 101 are also connected to the microprocessor 112 . . . .") (emphasis added)) For the reasons provided above, the court construes the terms "cellphone" and "cellular telephone" to mean "a device capable of communicating wirelessly via a cellular or satellite network and including an antenna, a transmitting/receiving section, a memory, a dialing pad, a microphone, and a speaker."

549

"Cells"

"Frames"

"Packets"

The constructions of these terms are somewhat interdependent, so the Court finds it useful to discuss them together. Alcatel's proposed construction for "cells" is "data formatted in accordance with ATM standards." Cisco's proposed construction for "cells" is "fixed length packets/frames." Alcatel's proposed construction for "frames" is "data formatted in accordance with the frame relay standards." Cisco's proposed construction for "frames" is "formatted set of data, not limited to frame relay." Alcatel's proposed construction for "packets" is "cells of data formatted in accordance with the ATM standards." Cisco's proposed construction for "packets" is "formatted set of data, not limited to ATM."

Alcatel argues, supported by testimony from its expert, that the term "cells" have an ordinary and common meaning to persons skilled in the art, which is data formatted according to the ATM standards. See Lucantoni ’032 Decl., at P 45. In the specification, the term "cells" is also defined in accordance with this construction. In particular, the patent states, "ATM networks are cell switching networks that transfer fixed length packets or 'cells' in a time multiplexed manner . . . ." Valizadeh, at 1:15-16; see also Valizadeh, at 1:45-48.

Cisco does not point to any place in the specification where the term "cells" is used in a context other than an ATM network. Nevertheless, Cisco's puts forth two arguments to refute Alcatel's proposed construction. First, Cisco claims that because the term "cells" is not explicitly referred to in connection with an ATM network in claim 12, as opposed to claims 3, 9, 13, and 17, which clearly refer to an ATM network in the same context as the term cells, then "cells" was not intended to be limited to data formatted only in accordance with the ATM protocol. However, if, as Alcatel argues, "cells" has an ordinary and accustomed meaning to one of ordinary skill in the art as referring only to ATM networks, then simply omitting the phrase ATM network in claim 12 does not amount to an explicit intention by the inventor to define cells in a different manner. See, e.g., Apple Computer, Inc. v. Articulate Sys., Inc., 234 F.3d 14, 21 n.5 (Fed. Cir. 2000) (in order for a patentee to define terms in a way that differs from the common understanding of those skilled in the art, "a patentee must deliberately and
clearly point out how these terms differ from the conventional understanding”). Nonetheless, Cisco's expert, once again in direct contrast to Alcatel's expert, claims that "[o]ne of ordinary skill in the art would understand from this that the term 'cells' alone refers to a set of data formatted for some form of network, but not only for an ATM network." Acampora '032 Report, at 9.

In looking at the dictionary definition of the term to resolve this dispute, the relevant definition of "cell" is described as follows: "A packet with fixed length. Notes: 1. Each cell has a 5 octet header and 48 octets of data. 2. This definition is specific to asynchronous transfer mode (ATM). See also: asynchronous transfer mode; cell relay." IEEE Dictionary, at 141 (6th ed. 1996) (emphasis added). 14 Therefore, in accordance with this definition, as well as the description of the term "cell" in the patent specification, the Court acknowledges that the common understanding of "cells" to one of ordinary skill in the art is specific to an ATM network. Furthermore, the patent does not indicate an intention to define this term differently from its customary meaning. Therefore, the Court construes the term "cells" in the '032 patent claims as "fixed length packets 15 formatted in accordance with ATM standards."

14 See Alcatel's '032 Responsive Brief, Ex. A.

15 As discussed further below, the Court construes "packets" as "formatted set of data."

Unlike the term "cells," the terms "frames" and "packets" are not ordinarily limited to one particular type of network. See Acampora '032 Report, at 7-8; Lucantoni '032 Decl., at PP 42, 47; IEEE Dictionary, at 428, 740 (6th ed. 1996).

Nevertheless, Alcatel argues that in the context of this patent, "frames" are limited to data formatted in accordance with the frame relay standards, and "packets" are limited to data formatted in accordance with the ATM standards.

The term "frames" is used in claims 3, 5, 6, 7, 9, 10, 12, 13, and 17. Claims 3, 12, 13, and 17 specifically refer to frames "according to a frame relay protocol," whereas the remaining claims using the term "frames" make no such reference. Therefore, this would imply that when the claims intend to limit the term "frames" to being "in accordance with the frame relay protocol," it is explicitly stated.

As before, Alcatel argues that despite the varying use of language among the claims, the term "frames" is always used in the specification as relating to a frame relay network. Since, according to Alcatel, the patent only involves ATM networks or frame relay networks, whenever the patent is using the term "frames" it is referring to data operating according to the frame relay standards. See Lucantoni '032 Decl., at P 42. Such construction is supported by the examples used in the preferred embodiment. See, e.g., Valizadeh, at 3:11-13, 3:61-65. However, were the Court to adopt Alcatel's proposed construction of "frames," it would be limiting the claim term solely based on the examples given in the preferred embodiment, which is inappropriate in this instance. See Rhine, 183 F.3d at 1346; Electro Med., 34 F.3d at 1054. Furthermore, as Cisco points out, there are parts of the specification where the term "frames" is used without necessarily referring to a frame relay network. See Valizadeh, at 1:45-65, 2:12-16, 2:25-27.

Therefore, the Court construes the term "frames" as "formatted set of data."

With regard to "packets," both parties agree that the customary use of the term does not refer only to ATM networks. 16 However, Alcatel argues that the term, as it is used in the claim, is only referring to data formatted according to ATM standards.

16 According to the IEEE Dictionary, "packet" is defined as "a unit of data of some finite-size that is transmitted as a unit." Id. at 740 (6th ed. 1996).
The term "packets" is found only in claim 6, and is used in the following manner: "a receive processor to assemble packets received from a plurality of receive channels of the network into frames, each frame being assembled based upon a respective set of the packets." Valizadeh, at 6:45-48. Nowhere in the text of claim 6 does it require that the packets come from an ATM network.

Alcatel argues, in similar fashion to its previous arguments, that the patent discloses only one type of common-carrier network, an ATM network, and thus when packets are referenced in claim 6, they must come from an ATM network. Furthermore, in the background section of the patent, the language could be read to imply that packets are synonymous with cells, as the term is used in this patent. Specifically, the patent states: "ATM networks are cell switching networks that transfer fixed length packets or 'cells' in a time multiplexed manner using a plurality of virtual paths ('VPs') and virtual channels ('VCs') defined within the physical transmission medium of the network." Id. at 1:15-20. Alcatel argues that the language "packets or 'cells'" indicates a clear intent to use the word "packets" as the equivalent of "cells," which, as this Court has previously acknowledged, refers only to data formatted in accordance with ATM standards.

Nevertheless, Cisco puts forth a more plausible interpretation that the phrase was simply describing "cells" as "fixed length packets," which would accord with Cisco's proposed definition of the two terms. Moreover, this explanation comports with the definition of "cells" in the IEEE Dictionary as noted above, which is "a packet with fixed length." Id. at 141 (6th ed. 1996).

With nothing more, the intrinsic evidence does not indicate a desire of the patentee to define "packets" more narrowly than its customary definition. 17 That notwithstanding, at first glance, a closer reading of claim 6 creates a problem with Cisco's proposed construction. Cisco argues that both "packets" and "frames" should be construed as "formatted set of data." However, by defining "frames" and "packets" identically, claim 6 effectively reads, "a receive processor to assemble [formatted sets of data] received from a plurality of receive channels of the network into [formatted sets of data], each [formatted set of data] being assembled based upon a respective set of the [formatted sets of data]."

17 Once again, both parties have submitted declarations from their experts that provide conclusory opinions as to what they each believe a person of ordinary skill in the art would interpret the term to mean in the context of the claim. Again, each experts' opinion is in direct contrast with the others, and essentially just restates the respective parties' opinion.

Normally, the Court will not construe a term to have its ordinary or accustomed meaning "where the term or terms chosen by the patentee so deprive the claim of clarity that there is no means by which the scope of the claim may be ascertained from the language used." Johnson Worldwide Assoc's., 175 F.3d at 990; see also K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1363 (Fed. Cir. 1999). Nevertheless, the Court finds that Cisco's proposed construction does not create this result. Claim 6 clearly intends to assemble a set of data formatted in a certain way into a set of data formatted in a different way. "Proper claim construction . . . demands interpretation of the entire claim in context, not a single element in isolation." Hockerson-Halberstadt, Inc., 183 F.3d at 1374. The term "packets" is used in the claim simply to distinguish that formatted set of data from "frames," which is a set of formatted in a different way from "packets," without requiring either set of data to be formatted in a particular way. This is in contrast to the use of the term "cells" in other claims, which is used to describe a set of data formatted specifically in accordance with ATM standards. Thus, the Court finds that the term "packets" has the same meaning as the term "frames," but the two terms are used in conjunction in claim 6 in order for one of ordinary skill in the art to recognize that the two terms refer to formatted sets of data that are formatted differently from each other.

Therefore, the Court construes the term "packets" as "formatted set of data."

B. The "Center Conductor" of a "Coaxial Cable"

The biased cable apparatus described in Claim 2, and incorporated in claims 3 through 5, describes a "coaxial cable having a
center conductor and a conductive shield." Monster Cable captures the meaning of the reference to the "center conductor" as merely "a material which readily transfers voltage, that is surrounded by a conductive shield." Quest seeks the predictably more restricted construction of "a conductive material that runs through the middle of the coaxial cable, 'is concentric with the outer conductive shield' of the coaxial cable' and carries the voltage varying electrical signal." The parties thus dispute whether the center conductor must be concentric with, or merely enclosed by, a conductive shield, and whether the center conductor must (or merely may) carry a voltage varying electrical signal.

1. Concentricity of the Center Conductor and Conductive Shield

As discussed in the analysis of "coaxial cable" above, the "center conductor" need not be concentric with the outer conductor. "Center" can be read broadly as in the "middle part" rather than representing a point equidistant from all points on the conductive shield. See Webster's Third New International Dictionary 362 (1986) (defining "center" as either "[a] point equidistant from all points on a circumference" or "middle part in contrast to sides, boundaries, outskirts, circumference, or peripheral features"). Other than the reference to this conductor as the "center conductor" and the preferred embodiment of the bias cable apparatus depicted in figure 9, the patent contains nothing that would limit the meaning of "center" to the more narrow definition requiring equidistance. The fact that the inventor chose the term "center conductor" rather than "inner conductor" in some instances does not make the inventor "his or her own lexicographer" of the term "center," as there is no indication that the patentee disclaimed a broader meaning of the word. See Texas Digital, 308 F.3d at 1204 (to interpret terms as inconsistent with their ordinary meaning, the patentee must disavow or disclaim a broader scope of coverage by using words of "manifest exclusion or restriction").

As a matter of law, Monster Cable is entitled to the broader meaning of "center." See NTP, Inc. v. Research in Motion, Ltd., 392 F.3d 1336, 1346 (Fed. Cir. 2004) (holding that "[i]n the absence of an express intent to impart a novel meaning to the claim terms, the words take on the full breadth of the ordinary and customary meanings attributed to them by those of ordinary skill in the art"); Linear Tech. Corp. v. Impala Linear Corp., 379 F.3d 1311, 1324 (Fed. Cir. 2004) (holding that where "simultaneously" can mean both "occurring" and "existing" at the same time, the term must be construed to encompass both definitions); Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 326 F.3d 1215, 1222-23 (Fed. Cir. 2003) (holding that the term "remote location" could refer not only to locations far apart and distant from one another, but to locations "separate by intervals greater than usual," including two locations within a single room).

"Center conductor" is thus construed on the basis of the clarity of the intrinsic record and the ordinary meaning alone. To capture the concept of the non-equidistant center (i.e., "the middle part in contrast to sides"), this court construes the "center conductor" to be "enclosed by" the conductive shield. 8

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

8 Plaintiff's proffered construction of a center conductor "surrounded by" an outer conductor would confuse rather than illuminate coaxial cables where a helical conductor is involved, such as in the 787 Patent.

2. Voltage Varying Electrical Signal

The claim terms expressly state that the voltage communicated along the center conductor is a "voltage varying electrical signal." 416 Patent, col. 9, lines 27-28. Based on a reading of the term "coaxial cable" as including at least two conductors, Monster Cable argues that there can be additional center conductors which do not carry the electrical signal. This reading of the patent is foreclosed by the court's construction of coaxial cable, described above, as limited to two conductors. There can be no question that the voltage communicated across the center conductor is a "voltage-varying electrical signal," as this reflects the specific invention claimed by the patentee. Id. Though the patent specifications refer repeatedly to "digital electrical signals" and "digital signals," claims 2 through 5 refer to a "voltage varying electrical signal" as the antecedent for "said electrical signal." See 416 Patent, col. 9, line 28; col. 10, line 2. See also 416 Patent, col. 2, lines 60, 63-4, 66-7; col. 3, line 38. In describing the specifications in figure 9, the patent states that the digital signal "has a voltage that changes with respect to an approximately constant ground reference voltage," i.e., a signal that is "voltage varying." See 416 Patent, col. 7, lines 24-6. In addition, the bias means described in claim 2 and incorporated in claims 3 to 5 refers to "bias voltage being larger than any peak-to-peak voltage of the voltage varying electrical signal." Id., col. 10, lines 15-17.
This reading of the patent is supported by the prosecution history, in which the inventor amended the preamble of what became claim 2. See Teleflex, 299 F.3d at 1326 (holding that the prosecution history can influence claim interpretation). In response to Office Action by the United States Patent and Trademark Office rejecting all of the inventor's claims, the patentee amended the claim for the biased cable apparatus to add the language "voltage varying." Req. for Judicial Notice at MON 7. "The prosecution history gives insight into what the applicant originally claimed as the invention, and often what the applicant gave up in order to meet the Examiner's objections." Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 978 (Fed. Cir. 1999) (quoting Lemelson v. General Mills, Inc., 968 F.2d 1202, 1206 (Fed. Cir. 1992)). By amending his claim to add "voltage varying" in accordance with the Examiner's instructions, the inventor of the 416 Patent gave up his right to claim that his apparatus used any form of "voltage."

Thus, for the reasons stated above, the court construes "center conductor" as "a conductive material which is enclosed by the conductive shield of a coaxial cable and which carries the voltage varying electrical signal."

3. "Central channel." A radio frequency channel assigned to carry control signals to establish, as opposed to maintain, communication connections between the central control station and the mobile units. (554 patent, col. 31, lns. 23-36)

8. "central computer"

<tbody>
<tr>
<td>Central computer</td>
<td>A computer and software system server that is centrally located</td>
</tr>
</tbody>
</table>

The issues surrounding the construction of this term are similar to the above construction of "local computer." Anthurium intends to include both a direct and indirect aspect, while the defendants seek to impose a geographic limitation. The patent again uses abstract terminology to describe various aspects of the invention. Here, both parties agree that MOM refers to the "central computer." As indicated above, the Court agrees with Anthurium's construction.

Claim 1 clearly indicates communication between the central computer and both the local and remote computers. The specification supports a direct or indirect connection with the local and remote computers. See '998 Patent, col. 1 ll. 46-59, col. 4 ll. 52-65. Furthermore, the specification does not import a geographic limitation on the term. The defendants again make a claim differentiation argument concerning the use of "local," "central," and "remote" to modify computer. Here, as above, the specification simply does not support such a limitation. The defendants, in making their argument, are improperly interpreting the specification. The specification describes the MOM as a more of a hub or nerve center, as Anthurium argues. See id. at col. 4 l. 62-col. 5 l. 6. There is simply no reason to impart an ambiguous geographic limitation upon the term.
The Court defines "central computer" as follows: "A computer capable of communicating, either directly or indirectly, with a local computer and a remote computer."

4. Means-Plus-Function Analysis

In their briefing, the parties agreed that "central computer means" and "remote terminal means" were not means-plus-function elements, while "keypad means," "modem means," "display means," "local memory means," "further memory means," "means coupled to said memory means and to said keypad means," "means responsive to information stored in the further memory means," and "logic means" were means-plus-function elements. The Court questioned how this could be so at the Markman hearing, and the parties analyzed the terms both ways.

Claim 3 includes:

a central computer means in which plural blocks of information are stored at respectively corresponding locations each of which locations is designated by a predetermined address therein by means of which a block can be selected, each of said blocks comprising a first portion containing information for display and a second portion containing information not for display but including the complete address for each of plural other blocks of information . . .

662 patent, col. 6, 11. 15-24.

The use of the word "means" in the claim (particularly as used in the phrase "means for") raises a presumption that the means-plus-function limitation applies. York Prods., Inc., 99 F.3d at 1574; Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996). The means-plus-function presumption may be rebutted, however, if the claim uses the word "means" but specifies no corresponding function for the "means," or if the claim recites a function but also includes a definite structure to perform entirely the recited function. Sage Prods., Inc. v. Devon Indus., Inc., 126 F.3d 1420, 1427-28 (Fed. Cir. 1997); Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996). The Court must determine, as a matter of law, whether to apply the means-plus-function analysis.

Whether there is definite structure recited in the claim language may be evidenced by a lack of alternate structures disclosed in the specification. See Turbocare Division of Demag Delaval Turbomachinery Corp. v. General Electric Co., 264 F.3d 1111, 1120-21 (Fed. Cir. 2001). In Turbocare, the Federal Circuit found that a claim including the term "compressed spring means" recited too much structure to perform the means-plus-function. Id. Nothing in the specification disclosed anything other than a "spring" or a "compressed spring" to perform the function of the "compressed spring means." Id. at 1121. This result differed from the court's prior decision in Unidynamics Corp. v. Automatic Prods. Int'l, Ltd., 157 F.3d 1311, 1319-22 (Fed. Cir. 1988). In that case, the court found that the term "spring means" was written in the means-plus-function format. Id. The Federal Circuit decided that the use of the word "spring" did not preclude the means-plus-function limitation because the specification demonstrated that a "spring" was only one example of a "spring means." Therefore, the Federal Circuit found that the phrase "spring means" was broader than a "spring" as generally recognized in the mechanical arts. See Turbocare, 264 F.3d at 1120 (distinguishing Unidynamics, 157 F.3d 1311).

Accordingly, I find that the "central computer means" is not a means-plus-function claim. The functions of the central computer are stated in the claim language, however, the claim recites the entire structure necessary to perform the claimed function. Sage, 126 F.3d at 1427-28. That structure is a computer.

The function of the central computer means as asserted in the claims is storing blocks of information. The computer also communicates with the remote terminals. The specification discloses a "computer" for performing these functions. The term "computer" is the only structure described in the specification, and there is no indication that the patentee wished the term "computer means" to be broader than a "computer." If the term "computer" does not tell us what the computer is, then the claim would be indefinite. See S3 Inc. v. Nvidia Corp., 259 F.3d 1364, 1367 (Fed. Cir. 2001) (quoting In re Donaldson Co., 16 F.3d 1189, 1195 (Fed. Cir. 1994) ("if an applicant fails to set forth an adequate disclosure, the applicant has in effect failed to particularly point out and distinctly claim the invention as required . . ."). If possible, patents should be construed in order to preserve their validity. Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1557 (Fed. Cir. 2001)
The Special Master construed the term "a central computing device" to mean "a single server or higher-end machine at the top of the hierarchical relationship which stores, processes and transmits information to and from multiple remote computing devices." (F&R at 32) He viewed the parties' dispute over the meaning of the term "a central computing device" as two-fold and divided his analysis accordingly. First, he said the parties disputed whether or not the term can be read to mean that the central computer is at the top of the hierarchical computer network (XFormity) -or- whether there is no hierarchical relationship between the central and remote computers (B-50). Secondly, he stated the parties disagreed over whether the term "central computer" refers to one (XFormity) or multiple (B-50) computers. These arguments were raised by B-50 in its objections to the Special Master's final report. Both points are addressed below.

1. Hierarchical Relationship

With respect to the first dispute -- whether or not the claim describes a hierarchy between the central and remote computers -- the Special Master relied on the plain meaning of the claim language read in the context of the entire patent and found that the term should be construed to describe a hierarchical relationship between the central computer and the remote computer in which the central computer "is at the top of the hierarchical relationship." (F&R at 21-22) In its objections to the Special Master's report, B-50 opposed this construction, arguing that "there is nothing in the patent claims that requires either the central computing device' or the multiple remote computing devices to be at the top (or, for that matter, at the middle or bottom) of the hierarchy." (B-50's Obj. at 2)

Upon de novo review of this issue, the Court finds the Special Master's construction to be correct and based on sound principles of claim construction. The Special Master explains in his final report that the hierarchical relationship is "required" by the claim language which recites a "central" computer. (F&R at 21) The term "central," he states, "must have some meaning different that adds to the term "computing device[s]."" (Id. at 21-22) The Special Master's conclusion is grounded in solid claim construction practice. Specifically, a court must construe claims to give meaning to all terms of the claim and avoid rendering any claim language mere surplusage. Merck & Co., Inc. v. Teva Pharm., USA, Inc., 395 F.3d 1324, 1364, 1372 (Fed. Cir. 2005); Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1119 (Fed. Cir. 2004). Thus, to comport with proper claim construction practices, "central" must add some consequence to the term "computing device[s]."

To determine its meaning, the Special Master properly viewed the term "central" in light of the specification. From the specification, he gleaned that "central" connotes more than a "geographic indicator" because the specification indicates that the "central computer" can be moved to any one of the other locations and still be "central." (F&R at 22) The fact that the specification recited that the central computer can be moved and still retain its "central" designation confirmed to the Special Master that "it is at the top of the hierarchical relationship with respect to the other computers." (Id.) The Court agrees with this analysis and conclusion. Claims must be interpreted in view of the specification which can supply understanding of unclear terms. Phillips, 415 F.3d at 1315. The specification "provides context for understanding the meaning of the terms to one of skill in the art at the time of invention." Innovad Inc. v. Microsoft Corp., 260 F.3d 1324, 1332 (Fed. Cir. 2001) Moreover, looking to the specification for guidance on claim terminology comports with long settled claim construction practice which requires that claim terms be construed from the perspective of a person of ordinary skill in the art "in the context of the entire patent" as opposed to "the context of the particular claim in which the disputed term appears." See Phillips, 415 F.3d at 1313.

The Special Master next addressed an argument made by B-50 that the remote and central computing devices "need not be in a hierarchical relationship" because the specification indicates that data transfers occur in a variety of ways. In dismissing this contention, the Special Master referred to the claim language and found that the phraseology "transferring point-of-sale data to a central computing device from multiple computing devices at multiple remote locations" defined "a relationship between at least the central computing device and the other computers" and indicates that "all of the data is transferred . . . to a central computing device." (F&R at 22-23) This claim verbiage, in turn, reinforced his conclusion that the "central
computing device" is at the top of a hierarchical relationship with the remote computers. (F&R at 22-23) The grammatical arrangement of words in a sentence -- the syntax of the claim language -- must be examined to properly interpret a claim term. See Credle v. Bond, 25 F.3d 1566, 1571 (Fed. Cir. 1994). Here, the Special Master correctly relied on the foregoing choice of words describing data being transferred to a central computer from the remote computing devices -- to find that the claim described a hierarchy of computers with the central computer at the top.

In summary, relying primarily on the plain wording of the claims while looking to the specification for context, the Special Master used settled claim construction principles to find that the claim described a hierarchical relationship between the central computer and the remote computers in which the central computer "is at the top of the hierarchical relationship." The Court agrees with and adopts the Special Master's conclusion on the hierarchical relationship between the computers. B-50's objections on this point are accordingly overruled.

2. "A Central Computer"

The parties' second dispute over this term involves whether the Special Master correctly construed "central computing device" to mean one, as opposed to multiple devices. When the Special Master initially apprised the parties of this construction by circulating his draft report, B-50 objected on several grounds. Two of those grounds are included B-50's objections to the Special Master's final report and will be addressed by this Court. First, B-50 complains that the construction of "one" device contradicts the plain language of the specification which expressly states that "embodiments of the invention contemplate multiple central computing devices if needed. . . . " (B-50's Obj. at 2; 851 patent, col. 4 Ins. 51-54) (emphasis added) Second, B-50 contends that the Special Master's singular construction contravenes the general rule that the use of the indefinite article "a" or "an" in patent parlance means "one or more" when -- as in the 851 patent -- used in open-ended claims containing the transitional phrase "comprising." (B-50's Obj. at 3-4 (citing KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000)).

In addressing the foregoing arguments, the Special Master first acknowledged that the specification does conflict with the claim language by disclosing that there can be one or more central computers. But he did not find this contradictory disclosure in the specification determinative of the issue. Rather, he determined that "other parts of the specification, and inherent network theory, suggest this disclosure [in the specification] may be problematic." (F&R at 27 citing to 851 patent at Col. 5) He concluded that the conflicting language "cannot overcome the clear public notice found in the claim and the concession made by B-50 about how to construe the article a' in a related dispute." (Id.) The Court agrees with the Special Master's assessment of the effect of conflict between the statement in the specification and the claim language. Although the specification is a vital part of the intrinsic record, it "should never trump the clear meaning of the claim terms." Pixon, Inc. v. PlaceWare, Inc., 2004 U.S. Dist. LEXIS 15808, No. C 03-02909-SI, 2004 WL 1769024, at * 2(N.D. Cal. Aug. 2, 2004) (citations omitted); see also RF Del, Inc., v. Pacific Keystone Techs., Inc., 326 F.3d 1255, 1265 (Fed Cir. 2003) ("courts may not use the teaching of the specification to contradict the clear language of the claims").

With respect to B-50's second argument that its use of the article "a" or "an" in conjunction with the term "central computing device" necessarily required a construction that the patent claimed multiple central computing devices, the Special Master disagreed. Instead he looked directly to the claim language which he concluded implied only one device. By examining the claims, he determined that the "general rule" regarding the use of "a" or "an," relied on by B-50, was inapplicable in this context because the claim language evinced a "clear intent" to claim only a single "central computing device." (F&R at 24-27) He reasoned that in drafting the claims, B-50 had used the article "a" in several other places in the claims to signify a singular meaning. He referred to method step (b) which addresses "defining a custom report format," method step (c) which recites generating "a custom report," and method step (d) which refers back to "the generated custom report." (F&R at 25) He referred to B-50's briefing which contended that "a custom report" meant only one report. (Id.) (emphasis added) From this and other examples of B-50's use of "a" in both the independent and dependent claims to mean "one" -- as opposed to more than one -- the Special Master found that it was consistent that B-50's use of the term "a" in conjunction with central computing device likewise meant "one."

The Court agrees. His reasoning is based on solid claim construction analysis. When an identical term appears in multiple claims within a patent the term should be interpreted consistently within all claims. See CVI/Beta Ventures, Inc. v. Tura L.P., 112 F.3d 1146, 1159 (Fed. Cir. 1997)("We are obliged to construe the term elasticity' consistently throughout the claims"); Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995). The Special Master bolstered his conclusion that "a" meant "one" by pointing out B-50's repeated use of terms that clearly signal "multiple" when referring to more than
one. As examples, he referred to B-50's use of terms in the claims to describe multiple structures such as "multiple computing devices," "one or more formats," and "at least one of the report formats." (F&R at 26) In other words, B-50 knew how to specify multiples when it so chose.

Upon de novo review, the Court finds that the Special Master's construction of a single central computing device is sound and should be adopted. B-50 is correct that the Federal Circuit has held that the use of the indefinite article "a" in conjunction with the word "comprising" creates a presumption that the article means "one or more." But, as noted by the Special Master, the Federal Circuit has also held that this presumption can be overcome when the patentee evinces a clear intent to limit the article to the singular. Scanner Techs. Corp. v. ICOS Vision Sys. Corp., N.V., 365 F.3d 1299, 1304 (Fed. Cir. 2004) (citing KCJ, 223 F.3d at 1356). Further, the Federal Circuit precedent on this issue specifically holds that "a" may suggest "one" but can mean "more than one" depending on the context in which it is used. Elkay Mfg. Co. v. Ebeco Mfg. Co., 192 F.3d 973, 977 (Fed. Cir. 1999) (other citations omitted) (emphasis added). The Special Master examined B-50's use of the term "a" within the context of the other claim language, using the method described above, and found the "clear intent" to claim a single computer. The Court agrees with this construction and adopts it as the construction of the Court. B-50's objections as to this point are overruled.

In summary, the Court adopts the Special Master's construction of the term "a central computing device" and construes the term as follows: "a single server or higher-end machine at the top of the hierarchical relationship which stores, processes and transmits information to and from multiple remote computing devices."

III. "conferencing control" / "central control manager"

The phrases "conferencing control" and "central control manager" appear in claim 15 of the '654 patent:

15. A method of conducting a teleconference among a plurality of participants, comprising the steps of:

   (a) initiating a video conference, from one of a plurality of workstations, using a video conferencing control included within each of the plurality of workstations, the video conferencing control establishing communication with a central control manager to set up AV paths along a first network over which the video conference can be conducted;

   (b) capturing video images and spoken audio of the participants for transmission in the form of AV signals over the AV paths during the video conference;

   (c) reproducing the video images and spoken audio on at least one first monitor, positioned near each workstation, from the AV signals received over the AV paths during the video conference;

   (d) initiating a data conference, during the video conference, using a data conferencing control included within each of the plurality of workstations, the data conferencing control establishing communication with the central control manager to set up requested data paths along a second network over which the data conference can be conducted; and

   (e) sharing data, among the plurality of participants, during the data conference, such that data received over the data paths is displayed on at least one second monitor included within each workstation.

'654 patent at 43:20-44:23. As the two terms are related to each other, the court will construe them together.

A. "conferencing control"

CPI proposes that the phrase "conferencing control" should be construed to mean "video or data conferencing software and/or hardware at a workstation." Tandberg proposes that the phrase should be construed to mean "software executed by the workstation that initiates all collaborative sessions by setting up appropriate services and paths via the central control manager." The parties' constructions differ in two respects. First, Tandberg's construction requires that the conferencing control set up all services and paths via the central control manager. Second, CPI's construction allows the conferencing
control to be made up of hardware and/or software, while Tandberg's construction requires that the control be made up exclusively of software.

The phrase "conferencing control" does not appear anywhere in the specification of the patent. The parties agree, however, that the element in the preferred embodiment corresponding to the conferencing control is the Collaboration Initiator. See Spec. at 18:51-52 ("The central component of the Collaborative Multimedia Workstation software is the Collaboration Initiator 161.").

Tandberg argues that CPI's proposed construction is too vague because it says nothing about what the conferencing control does. Without some further restriction, "video conferencing software and/or hardware" might encompass any part of the workstation that is involved in a videoconference: the keyboard, the monitor, the camera, the CPU, and the operating system, as well as any special-purpose software or hardware associated exclusively with videoconferencing. CPI's construction is indeed too broad because it fails to account for the claim language. The phrase "conferencing control" has two elements. First, the term relates to "conferencing"—both videoconferencing and data conferencing. Second, the term encompasses the notion of "control." The surrounding claim language indicates that the control, at a minimum, must include setting up video and data conferences. See id. at 43:25-28 ("the videoconferencing control establishing communication with a central control manager to set up AV paths along a first network over which the video conference can be conducted") (emphasis added); id. at 44:5-9 ("the data conferencing control establishing communication with the central control manager to set up requested data paths along a second network over which the data conference can be conducted") (emphasis added). Moreover, "control" has broader meaning than "initiation"; the conferencing control is used to facilitate as well as initiate calls. See Spec. at 18:35-41 ("[conference control] Software 160 allows the user to initiate and manage (in conjunction with the server software) videoconferencing, data conferencing, multimedia mail and other collaborative sessions."). The court therefore finds that the conferencing control must be able to "control"—i.e., initiate and facilitate video and data conferences.

Tandberg is also correct in arguing that the "conferencing control" must "set[] up appropriate services and paths via the central control manager." The claim language already expressly includes this limitation, however, and adding it to the definition of "conferencing control" would be redundant. See '654 patent at 43:25-28, 44:5-9.

Turning to whether the control may consist of hardware or software, the specification clearly indicates that videoconferencing functionality may be implemented in hardware as well as software. See Spec. at 18:5-8 ("Given the proximity of Side Mount device 850 to the user, and the direct access to audio/video I/O within that device, various additional controls 820 can be provided at the user's touch (all well within the capabilities of those skilled in the art)." The "Side Mount" device is, in the preferred embodiment, a piece of additional hardware which is connected to a desktop computer or workstation. Id. at Fig 18B. Limiting the phrase "conferencing control" to software would exclude this disclosed embodiment, which is disfavored unless the claims present a compelling reason to do so.

Finally, the court notes that the hardware and software comprising the conferencing control must be present at each workstation. '654 patent at 43:23-24.

The court therefore construes the phrase "conferencing control" to mean "hardware and/or software at each workstation which is used to initiate and facilitate videoconferencing, data conferencing, and other collaborative sessions."

B. "central control manager"

CPI argues that the phrase "central control manager" should be construed to mean "software and/or hardware that establishes and manages connections for a video conference." Tandberg argues that the phrase should be construed to mean "A special purpose computer which manages the audio and video switching circuitry, the state of the call, and selectively establishes connections between physical ports on different workstations." The parties' constructions differ in three respects. First, Tandberg's construction requires that the central control manager be a "special purpose computer." Second, Tandberg's construction requires that the control manager manage "audio and video switching circuitry"—a physical AV switch. Third, Tandberg's construction requires that the central control manager establish connections between physical ports on different workstations. The phrase "central control manager" does not appear at any point in the specification. The parties agree, however, that the corresponding element of the preferred embodiment is the Audio Video Network Manager, or AVNM. See Spec. at 18:54-57 ("When the Collaboration Initiator is started, it exchanges initial configuration information with the Audio Video Network Manager (AVNM) 60 (shown in FIG. 3) through Data Network 902.").
1. Special Purpose Computer

The basis of Tandberg's argument that the "central control manager" is a special purpose computer is somewhat unclear. Tandberg notes that the AVNM in the preferred embodiment consists of software running on the MLAN server, and then cites WMS Gaming, Inc. v. International Game Technology, 184 F.3d 1339, 1348 (Fed. Cir. 1999) for the proposition that "[a] general purpose computer, or microprocessor, programmed to carry out an algorithm creates a new machine, because a general purpose computer in effect becomes a special purpose computer once it is programmed to perform particular functions pursuant to instructions from program software" (internal quotations omitted). In WMS Gaming, the Federal Circuit found that the district court had improperly construed a means-plus-function claim element more broadly than the structure disclosed in the specification. Id. In correcting the district court, the Federal Circuit limited the invention to the disclosed embodiment—a computer programmed to run the claimed algorithm. Id. at 1349 ("the structure disclosed for the 'means for assigning' limitation of claim 1 of the Telnaes patent is a microprocessor programmed to perform the algorithm illustrated in Figure 6.").

CPI does not dispute that, to the extent the central control manager includes software, the software must run on a computer. Indeed, CPI's proposed construction recites as much structure as the construction adopted in WMS Gaming—computer hardware and software configured to perform the steps of establishing and managing connections for a video conference. Labeling such hardware and software a "special purpose computer" does not aid in understanding the claims.

2. Audio and Video Switching Circuitry

As discussed supra in the context of "AV path," the claimed invention is not limited to analog AV networks with physical AV switches. Digital AV signals may be transmitted jointly with the data over a packet-switched network, in which case there is no need for dedicated audio and video switching circuitry. Tandberg's proposed construction is therefore too narrow.

3. Connections Between Physical Ports

For the same reason, the claim does not require that the central control manager establish actual connections between physical ports on two or more workstations. In the case of digital AV signals transmitted over a packet-switched network, Tandberg does not argue that the physical connection to the workstation will change during the course of initiating and connecting a videoconference call. The connection between the workstations is purely logical. Also, as the Polycom court noted, one of the disclosed embodiments allows for a wireless connection to a workstation. See Spec. at 38:49-67. Tandberg's proposed construction is therefore too narrow.

CPI's construction is too broad in two senses, however. First, the central control manager must be able to manage connections for both video and data conferences. '654 patent at 44:5-9 ("the data conferencing control establishing communication with the central control manager to set up requested data paths along a second network over which the data conference can be conducted").

Second, the control manager must be "central." Tandberg argues that the word "central" requires that the central control manager reside computer which is physically separate from the workstations. CPI counters that the central control manager can be logically distinct and "central"-brokering communications among multiple workstations—without residing on a physically separate machine. The court agrees that nothing in the claim language requires the central control manager to be physically separate, but agrees with CPI's apparent concession that it must be distinct in some way from the conferencing control, which is separately recited in the claim. In addition, claim 15 requires that a single central control manager have the capability of coordination communications among multiple workstations: claim 15 recites a plurality of workstations, each with a conferencing control, but only a single central control manager to set up paths among them. '654 patent at 43:20-28.

The court therefore construes the phrase "central control manager" to mean "hardware and / or software that is distinct from the conferencing control and that is capable of establishing and managing video and data connections for multiple workstations."
f. "Central controller operatively connected"

Claim 1 discloses the following:

A central controller operatively connected to each said communication interface circuit and said surgeon's control panel, said central controller transmitting to said plurality of self-contained pieces of surgical equipment commands entered manually on the surgeon's control panel and transmitting to said surgeon's control panel status of the surgical control heads for display on said displaymeans.

'688 Pat. col.19 l.63-col.20 l.3. Claim 10 makes a similar disclosure. See id. at col.21 ll.4-12. The Parties shifted the focus of their dispute with regard to this term following the Markman hearing.3 They agree that a "central controller" is a "computer," but they contest two other aspects of the term. (See Agreed-Upon Constructions Chart 2-3.) First, whether "a central controller" means one or one or more computers, and second, whether such computer(s) are "operatively connected" or merely "connected" to the communication interface circuits and the surgeon's control panel. (Id.)

3 The Court notes that the Parties have abandoned their dispute with regard to the rest of this term. (See Agreed-Upon Constructions Chart 2.)

The Court adopts KSEA's proposed construction with regard to the number of computers. KSEA correctly states that in open-ended claims containing the transitional phrase "comprising," the general rule is that the singular pronouns "a" and "an" mean "one or more." See Baldwin Graphic Sys., Inc. v. Seibert, Inc., 512 F.3d 1338, 1342-43 (Fed. Cir. 2008) (citations omitted). This rule suggests that Claims 1 and 10 disclose one or more "central controllers," which the Parties agree are "computers." S&N has provided no argument in support of its bare assertion in the Agreed-Upon Constructions Chart that the general rule does not apply here.

The Court also finds that the "central controllers" are "operatively connected" to the communication interface circuits and the surgeon's control panel, as the patent clearly expresses. See Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1119 (Fed. Cir. 2004) ("While not an absolute rule, all claim terms are presumed to have meaning in a claim." (citing Pickholtz v. Rainbow Techs., Inc., 284 F.3d 1365, 1373 (Fed. Cir. 2002))); (see also Hr'g Tr. 88 (counsel for S&N conceding that "[w]e don't think it really matters between connected or operatively connected."))

The Court construes the "central controller operatively connected" term as disclosing one or more "central controllers," which are construed as "computers." The Court also construes this term as teaching that the "central controllers" are "operatively connected to the communication interface circuits and the surgeon's control panel."
Alliance Gaming Corp., 504 F.3d 1356, 2007 U.S. App. LEXIS 22807 at *9 (Fed. Cir. Sept. 27, 2007) ("In the patent claim context the term 'comprising' is well understood to mean 'including but not limited to.'"). "A" denotes "one or more than one." Norian Corp. v. Stryker Corp., 432 F.3d 1356, 1359 (Fed. Cir. 2005).

Defendants agreed that there could be more than one central data facility. Their request for "a single location" in the construction of this term is merely a way of stating their position that each central data facility needed to perform all three functions (digitizing, compressing, and storing video programs). Tr. at p. 53, l. 21 - p. 54, l. 5.

USVO argues that Time Warner's proposed construction would import limitations from the preferred embodiment into the claim. Figures 1 and 2, which show all three functions at one location, do represent a preferred embodiment. However, both the Summary of the Invention and the Abstract also state that all three steps—digitizing, compressing, and storing—happen at the first location.

The Abstract of the '792 patent states that "program signals are digitized, compressed, and stored at the first location, and transferred to the remote location on request of a viewer." This description is echoed in at least two other places in the specification: first in the Summary of the Invention, col. 2, ll. 7-9 ("The program signals are digitized, compressed, and stored at the first location"); and later in the Description of the Preferred Embodiment, col. 3, ll. 7-16 ("The central data facility 10 includes a central processor 20 connected to one or more mass storage devices 22...The video programs are digitized and compressed in a digitizing processor 26, and transferred to the central processor 20 for retention in mass storage devices 22."). Figures 1 and 2 clearly show that the central data facility encompasses the digitizing processor 26, the central processor 20, and the mass storage device 22.

At the hearing, USVO suggested that this was simply poor wording by the applicant and that Claim 1 states only that the central data facility has "means for storing digital compressed versions of video programs." Tr. at p. 56, ll. 8-10; '792 Patent, col. 7, ll. 43-44. "Poor wording" is not a convincing argument to ignore the plain language of the specification.

While the specification indicates that the central data facility digitizes, compresses, and stores the video program, Claim 1 only recites a central data facility which stores the digitally compressed program. This is part of a "comprising" claim, so the claimed system must have at least "a central data facility" that has "means for storing digital compressed versions of video programs." Time Warner argues that "central data facility" is vague, and must be more than a storage place for videos. The patentee does not have to describe every feature of a facility; this is especially true in the context of a "comprising" claim. It is also possible for a patentee to disclose, but decline to claim, subject matter. "[T]his action dedicates that unclaimed subject matter to the public." Johnson & Johnston Assoc. v. R.E. Serv. Co., 285 F.3d 1046, 1054 (Fed. Cir. 2002).

Claim 1 states only that the central data facility stores programs that are digitized and compressed. There is no good basis for including other limitations. The court will therefore define this term as follows:

"Central data facility" means "a location where digital compressed versions of video programs are stored."
component of a computer. A "central processing computer" would have to contain a central processing device (or unit) and other components as well.

I adopt the following definition: "a device that receives, processes, and presents data by having, interconnected for operation, at least a central processing device and a memory device."

Plaintiffs offer "a device or computer which can perform an operation, action, or function, or a device or computer which can perform more than one operations, actions, or functions [sic]." 3 Given that a computer is a device, plaintiffs' definition seems to reduce to: "a device which can perform one or more operations, actions, or functions." That definition is so broad as to encompass many manufactured items.

Defendants put forward:

a device that receives, processes, and presents data by having, interconnected for operation, a memory device and at least one user input and one user output device and containing the circuits required to interpret and execute instructions.

The language of the claims makes plain that the central processing computer is the computer that collects data from the various point-of-sale devices, banking transaction terminals, customer communications devices, etc. It is the pivot point between the service provider and the account holder, and so is in the middle of -- "central" to -- the apparatus. 4

4 The patent at various times uses the phrase "central transaction processing computer." See, e.g., '725 Patent, Col. 44:67. These two phrases appear to be synonymous.

Neither the description of the invention, nor the claim language, nor the preferred embodiments, nor the prosecution history imposes any limitation on the type or nature of computer that can perform the "central processing computer" function. In fact, the patent places virtually no restrictions on the type of device that the central processing computer could be: "[it] may be a mainframe computer, a mini-computer, a micro-computer, a server computer… and/or any other suitable computer or computer system." '725 Patent, Col. 22:24-29.

Defendants' definition is closer to being correct, but includes some unnecessary limitations. There is no need for a "user input and "user output" (I/O) device on the computer; a server or mainframe computer (which may be a central processing computer according to the patent itself) do not necessarily have components beyond a processor and memory. Of course, for the protocol to work, the central processing computer must be connected to a communications network, but that fact is adequately stated in the claims themselves. Therefore, removing the references to input and output devices, and replacing the phrase "containing the circuits required to interpret and execute instructions" with the phrase "central processing device," I reach the following definition: "device that receives, processes, and presents data by having, interconnected for operation, at least a central processing device and a memory device."

D. "Central Processing Device"

"Central Processing Device" is construed as "That part of a computer containing the circuits required to interpret and execute instructions."
execute instructions."

This definition, propounded by defendants, is found in the McGRAW-HILL DICTIONARY OF SCIENTIFIC AND TECHNOLOGICAL TERMS, 356 (6th ed. 2003). It meets the first rule of patent construction -- that the plain meaning of a term shall be used to define it.

This definition is also consistent with plaintiffs' use of the term throughout the patent. For reasons that are not entirely clear to this Court, plaintiffs use this term interchangeably with the more common "central processing unit" (CPU) and with the term "central processing computer." Indeed, in most instances, plaintiffs use the word "unit" or "computer" rather than "device." For example, the illustrations in Figures 1, 4, 7, and 11 of the '725 patent include "central processing computers." Figure 8 depicts three "CPU's." The "SUMMARY OF THE INVENTION" refers repeatedly to a "central processing computer." '725 patent, col. 3-12. The "DESCRIPTION OF THE PREFERRED EMBODIMENT" section refers repeatedly to various "central processing units" and "central processing computers." Id., col. 12-44. In fact, the first time this Court sees mention of a "central processing device" is in a subsection of the "DESCRIPTION OF THE PREFERRED EMBODIMENT" section describing the patent claims, at column 46, line 12.

In any event, "device" and "unit" strike me as essentially equivalent, and my intuition is borne out by the DICTIONARY OF SCIENTIFIC AND TECHNOLOGICAL TERMS, p. 226, which defines "unit" as, "An assembly or device capable of independent operation, such as a . . . computer subassembly that performs some inclusive operation or function." The interpretation and execution of instructions is most certainly an "inclusive operation or function."

Defendants' proposed definition also comports with the definition of the term "processing" that was stipulated by the parties. Both sides agree that "processing" means "operating on data or information, or to perform a series of actions or operations directed toward a particular result." A processing "device" is, therefore, something that accomplishes "processing" as defined by the parties. In a computer, that device is the "central processing unit."

Defendants' effort to further limit the definition by suggesting that the word "central," as used in the phrases, "central processing device" or "CPU," is somehow analogous to the word's use in the phrase "central computer means" that was the subject of discussion in British Telecomms. PLC v. Prodigy Commun's. Corp., 189 F. Supp. 2d 101, 112-13 (S.D.N.Y. 2002), is misplaced. First, that case involved a "means plus function" claim, which is manifestly not the case here. Second, nothing whatever in the specifications suggests the existence of some central computer or bank of computers, as was the case in British Telecom.

Plaintiffs' effort to broaden the definition beyond the one proposed by defendants is equally misguided. "Something that processes something" defines nothing. In connection with this Markman proceeding, I have processed a great deal of information. That does not mean that the term "central processing device" as used in the '725 patent could be read onto my brain.

560

2. "central processing location"

Claim 14 claims the following step:

transmitting compressed, digitized data representing a complete copy of at least one item of audio/video information at a non-real time rate from a central processing location

The parties dispute the proper construction of the phrase "central processing location" as that phrase is used in Claim 14 of the '863 patent. The phrase "central processing location" is used in the claim but it is not used elsewhere in the specification.

Courts may give a definition to a phrase which is only used in a claim if: a) the individual words in the phrase have well-recognized meanings to those skilled in the relevant art; and b) the court is able to discern a definition which the court, with reasonable confidence, finds would be understood by one skilled in the art based on the language of the claim and the other intrinsic evidence. See Bancorp Services v. Hartford Life Insurance Co., 359 F.3d 1367, 1372 (Fed. Cir. 2004).
To determine what "central processing location" means to those skilled in the relevant art, the Court turns to a standard dictionary prepared by the Institute of Electrical and Electronics Engineers ("IEEE"). The IEEE defines "centralized computer network" as: 1) a computer network configuration in which a central node provides computing power, control or other services; and 2) A computer network in which a central node provides all network control functions and services to other nodes. IEEE 100: Authoritative Dictionary of IEEE Standard Terms, 154 (7th ed. 2000).

Thus, it is reasonable to characterize that in the field of data communications, the phrase "central processing" is generally understood by skilled artisans as a computer network configuration in which a single system at the hub distributes data to multiple peripheral dependent systems belonging to the network. In contrast, a system in which "processing" is distributed over multiple locations, would be understood by skilled artisans as a "decentralized system." Id. The term "central" does not refer to any particular geographic location. It refers to a functional location.

The step of Claim 14 under consideration discloses "transmitting" from a central processing location. Claim 14, contains specific limitations governing this transmitting step. These limitations are introduced using the transitional phrase "wherein the transmitting step comprises." The transmitting step is then prescribed as, among other limitations, inputting an item having information into "the transmission system," followed by "sending" the information to the local distribution system." The Court finds that the phrase "transmission system" as used in Claim 14 is the "transmission system" which the Court previously defined in its December 14 Order. (December 14 Order at Section IA3.) Accordingly, the "central processing location" is a limitation which defines the functional location of the "transmission system."

The Court construes the phrase "central procession location" as follows:

- a single transmission system, as previously defined, from which compressed, digitized data, representing a complete copy of the at least one item of audio/video information, is transmitted at a non-real time rate to at least one of a multiple of local distribution systems.

1. Central Processing Means

The meaning and validity of the phrase "central processing means" in claim 14 is a matter of debate between the parties. Lutron contends that "central processing means" is a means plus function limitation, but argues that the specification does not name the structure required to perform the specified functions, thus rendering claim 14 invalid. Genlyte argues that the phrase is not a means plus function limitation, and that even if it is, the specification clearly links structure to perform the stated function.

As stated above, if an element of a claim uses the word "means," a presumption arises that the language is a means plus function limitation. A party may rebut the presumption by showing that the claim either mentions no function to be performed by the means or recites sufficiently definite structure for performing the desired function. See Rodime PLC v. Seagate Technology, Inc., 174 F.3d 1294, 1302 (Fed. Cir. 1999). The language of the "central processing means" element of claim 14 states that the function to be performed by the "central processing means" element is "controlling directly the light intensity of the associated lights in the room." Therefore, the question this Court must answer is whether "central processing means" recites sufficiently definite structure to avoid invoking a means plus function limitation.

As an initial matter, it is noted that simply because the phrase "central processing means" was found to be a means plus function limitation in claim 6, the Court is not bound to reach the same conclusion here. As the Federal Circuit stated in Cole, the Court must determine on an element by element basis whether § 112, P6 applies. See Cole, 102 F.3d at 531. Therefore, merely because "central processing means" is a means plus function element in claim 6, that does not necessarily mean that the same is true in claim 14.

As stated above, when construing the meaning of a disputed claim, the Court must analyze the intrinsic evidence, which includes the claims, the specification, and the prosecution history. Whether a claim recites definite structure may be evidenced by a lack of alternate structure disclosed in the specification. See British Telecomms. PLC v. Prodigy

In this case, the specification recites no alternate structure for performing the stated function of controlling directly the light intensity of the associated lights in the room, and Lutron contends that because the phrase is presented as "central processing," and not "central processor," the phrase describes function, not structure. However, the intrinsic evidence does indicate that "central processing means" recites sufficiently definite structure.

If one skilled in the relevant art would understand "central processing means" to be a central processing unit, then sufficiently definite structure exists to avoid implication of § 112, P6. The U.S. PTO rejected the application of the '731 patent several times for indefiniteness. However, despite studying claim 14 in detail, the U.S. PTO never rejected the patent for indefiniteness in using "central processing means" in the language of claim 14. While this does not end all questioning of the structure of "central processing means," the prosecution history is relevant as intrinsic evidence that "central processing means" is not indefinite.

Additionally, at col. 3, ll. 11, the specification referred to the central processing unit 42 of the microcontroller 44 contained in the multi-room controller 12 as "central processing means." While the specification does not refer to the individual light control 10 which is the subject of claim 14, the phrase "central processing means" appears to be synonymous with central processing unit 42.

Perhaps even more telling is the fact that in its First Amended Answer and Counterclaims, Lutron acknowledges that the individual light control of claim 14 contained "central processors" for directly controlling the light intensity of associated lights in a room. In making its counterclaims against Genlyte, Lutron describes prior art which Lutron claims Genlyte failed to disclose to the U.S. PTO, and alleges that the Lightolier "Lytemode" System and the Lightolier "Scenist" System contained several features in common with the claimed elements of the '731 patent, including "central processors in the individual light controls for directly controlling the light intensity of associated lights in the room." Therefore, even Lutron acknowledges that "central processing means" recites sufficiently definite structure for performing the function of directly controlling the light intensity of associated lights in the room.

Accordingly, the "central processing means" element of claim 14 does not invoke § 112, P6, as one skilled in the relevant art would understand "central processing means" to be "a central processing unit." Thus, "central processing means" is construed to be "a central processing unit."
a. **"central processing unit"**

The first term for construction is "central processing unit." The plaintiffs propose "an electronic circuit that controls the interpretation and execution of programmed instructions." The defendants propose "the central electronic circuit in a computer that controls the interpretation and execution of programmed instructions." There are two main disputes - 1) whether the circuit needs to be in a computer and 2) whether the circuit needs to be the "central electronic circuit."

In support of their construction, the plaintiffs argue that the specification teaches that the microprocessor can be used in applications other than a computer (e.g., HDTV and automobiles). ’336 patent, 9:61-10:12. The plaintiffs also observe that the specification states that the microprocessor can be part of a multiprocessor system and, therefore, no one CPU is the "central electronic circuit" for the computer. See ’336 patent, 11:64-12:4. The defendants, on the other hand, argue that they did not intend to limit the use of the CPU to a computer. They assert, however, that a CPU must be part of a computer chip.

The parties appear to agree that one of ordinary skill in the art would understand that a computer chip or other integrated circuit can be used in various devices, such as automobiles or televisions. The Court construes the term to mean "an electronic circuit on an integrated circuit that controls the interpretation and execution of programmed instructions."

---

564

1. Central Processing Unit

The parties do not disagree as to the meaning of the term "central processing unit" in Claims 1, 8, and 13. The term "central processing unit" is construed to mean a key component of a computer, which contains circuitry to interpret and execute program instructions.

---

565

Disputed Claim Language

"A central processor section … for determining a range to said target derived from said flight time of said laser pulses to said target and said flight time of said reflected laser pulses from said target."

Analysis

Defendants contend the elements of the central processor section are not specified, nor is any microprocessor, algorithm or the like specified in the claim. I agree. Because the term "central processor section" is unclear, I look for meaning in the specification. It describes a microcomputer that places flight times of received laser pulses in a "stack," and compares successively received pulses to those already in the stack. '910 patent, col. 17, lines 3-20. Each place in the "stack" must represent a flight time, so when a relatively large number of pulses occupy one "slot" in the "stack," that "slot" represents the flight time indicative of the distance to the target.

Plaintiff argues that in the preferred embodiment for the central processor section, "the processor compares time-of-flight information stored in memory to locate the time-of-flight information that occurs with the greatest frequency, and uses these signals to determine a range to the target." '910 patent, col. 17, line 3 - col. 18, line 30. I also agree with Plaintiff. Plaintiff's description is general while Defendants' description focuses on the specifics of the "stack" mechanism. In the end, both parties describe the same process.

I construe the disputed claim language in the general sense that Plaintiff uses to describe the preferred embodiment of the disputed claim. As stated above, while Defendants may overcome the heavy presumption that the claim terms embody their ordinary meaning and attempt to narrow the meaning of the terms, they "cannot do so simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history." CCS Fitness, Inc., 288 F.3d at 1366. Here, Defendants point to the preferred embodiment of the '910 patent specification to impermissibly narrow the
meaning of the claim to include the stacking mechanism. But "limitations from the specification are not to be read into the claims." Comark, 156 F.3d at 1186. "While ... claims are to be interpreted in light of the specification and with a view to ascertaining the invention, it does not follow that limitations from the specification may be read into the claims." Id. Therefore, I decline to incorporate the specification language that describes the stacking mechanism into the disputed language of Claim 8.

CONSTRUCTION: A processor compares time-of-flight information stored in memory to locate the times-of-flight that occur with the greatest frequency, and uses the most frequent times-of-flight to determine a range to the target. Neither a specific microcomputer nor anything that puts received laser pulses in a "stack" is required.

2. "central server"

Southwest argues that the term means "an electronic device capable of organizing and manipulating data located at headquarters," whereas 3T argues that the term means "in a network, a device or computer system that is dedicated to controlling or directing a processing station." Thus, Southwest proposes a construction for the term "central server" that is similar to its proposed constructions for the terms "controller" and "data processing system" in the '405 patent. Southwest bases its argument on the following phrase: "As may be seen, data processing system 10 may include data processing system 12 which may also be referred to as central server 12. Data processing system or central server 12..." '673 patent, 8:2-5. Thus, Southwest argues that the specification equates the terms "data processing system" and "central server" with the only difference being that the "central server" is located at headquarters.

3T argues that the plain and ordinary meaning of the term "server" is narrower than the terms "processing station" or "processing system." 3T bases its proposed construction on the dictionary definition of "server." See IEEE Standard Dictionary of Electrical and Electronic Terms, pp. 972-73 (6th ed. 1996) (server: "in a network, a device or computer system that is dedicated to providing specific facilities to other devices attached to the computer network"). 3T argues that the specification's use of the term is consistent with its plain and ordinary meaning. For example, in the Summary of the Invention, the patentee describes the role of the central server in creating site specific coupons. See '673 patent, 3:57-67. Further, the central server "tells the remote processing which generalized coupon templates and which site specific information files should be downloaded by that specific site." Id. at 3:65-67.

The Court finds that, similar to the rationale set above in the '405 patent on terms relating to data processing system, the patentee used different terms in claiming its invention to give different scopes to its claimed invention. The term "central server" was intended to mean something different than other related terms, such as data processing system, and the Court finds that these different terms should be given different meanings. See Innova/Pure Water, 381 F.3d at 1119. Southwest's proposed construction eliminates the meaning of the term "server" by essentially equating its construction to the terms "controller," "data processing system," central processing station," and "central processing system." The Court also finds that the term "server" is narrower than the terms "processing station" or "processing system," and is narrower than Southwest's proposed construction. Further, the Court finds that the "central server" as used in the specification and claims is connected via a network to each of the plurality of remote sites. See '673 patent, 3:59-67, 6:23-28, 8:2-7, 8:31-34. Thus, consistent with the specification and the term's generally understood meaning, the Court construes the term "central server" to mean "a computer system that is dedicated to communicating over a network with the processing station at each of the plurality of remote sites."
WeddingChannel argues that a central server is a computer system that provides services to other computers on a network. In contrast, the Knot takes the position that a central server is a computer unit that provides such services.

WeddingChannel argues that a person of ordinary skill in the art understands: (1) that a "server" is a computer system (i.e., a combination of hardware and software) (Adler Ex. F; Ligler Decl. P 29), and (2) that a server can be configured as a single computer unit standing alone or as multiple computer units working together. (Ligler Decl. P 31).

WeddingChannel argues that its interpretation is supported by the language of claim 1, which describes the central server as comprising a CPU, memory (i.e., hardware), and various instructions (i.e., software). It should be noted that the language of claim 1 does not impose any limitation concerning the physical configuration of the central server.

WeddingChannel argues that its interpretation is further supported by the language of claim 35, which claims a "computer system" comprising a central processing unit, a memory, and various instructions. WeddingChannel asserts that these claim 35 elements are largely identical to those characterized as a "server" in claim 1. On this basis, WeddingChannel concludes that server is a computer system.

The Knot argues that WeddingChannel's construction of the term "server" ignores the fact that the preamble to claim 1 already recites "a computer system," and that WeddingChannel's construction leads to the allegedly impermissible circular result that the computer system described in the preamble is comprised of two computer systems --i.e., the remote server and the central server. See Harris Corp. v. IXYS Corp., 114 F.3d 1149, 1152 (Fed. Cir. 1997) (rejecting a proposed construction on the grounds that it was circular). In support of this interpretation, the Knot points out that the '753 specification only describes and shows a single computer as the server having the elements recited in claim 1, and it specifically states that such server has a "standard computer configuration." Furthermore, the Knot argues that Figure 1 illustrates a single computer with multiple CPUs; the illustration does not suggest that a given server can be comprised of more than one computer unit.

The Knot also argues that if the inventors intended the claimed central server to be a "computer system," they would have specified as much, as evidenced by the use of the term "computer system" in the preamble of claims 1, 5, and 35. See '753 Pat. at col. 11, l. 39, col. 12, l. 7, col. 14, l. 63. Likewise, in new claims 109, 111, and 126 of the '540 continuation application, WeddingChannel apparently used "computer" when it wanted to indicate an individual unit and "computer system" when it wanted to indicate a combination of such computer units. (Qualey 2d Supp. Decl. Ex. 21 at LO002091-2092, LO002094).

In its reply to the Knot's supplemental brief on claim construction, WeddingChannel argues that none of the '540 continuation claims say or suggest that a server is not a type of computer system. Rather, these continuation claims merely reflect the fact the term "computer system" is a broader term than "server," and not every computer system is necessarily a server.
The submissions of the parties demonstrate that the word "server" as used in the claim is ambiguous - i.e., it could be read to mean that a server is a "computer system" or to mean that a server is a single computer unit. Under such circumstances, it is particularly appropriate to consult extrinsic sources. See, e.g., DeMarini, 239 F.3d at 1323. The extrinsic evidence proffered by WeddingChannel resolves this ambiguity. First, Dr. Ligler states that persons of ordinary skill in the art understand that a "server" is a "computer system." (Ligler Decl. P 29.) Furthermore, WeddingChannel has provided an excerpt from the Random House Webster's Computer & Internet Dictionary 3d ed., which states that a "computer system" is merely a "complete, working computer." (Adler Decl. Ex. F.) This dictionary definition suggests that the Knot's distinction between a single, physically integrated computer unit and a computer system consisting of spatially separate components is not one that would be recognized by one of ordinary skill in the art. On the basis of this extrinsic evidence, WeddingChannel's construction of the term "central server" is adopted.

C. "Central Station"

<table>
<thead>
<tr>
<th>Plaintiff's Construction</th>
<th>Defendant's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>One or more computers or other data processing devices operated together in order to deliver video on demand service to a user site.</td>
<td>A station in a single location, remote from the user site, where video products (such as movies and video games) and date used to limit viewing of the video products are stored.</td>
</tr>
</tbody>
</table>

The core dispute between the parties is whether the "central station" must be situated in a "single location" (Defendant's position) or not (Plaintiff's position).

In support of its construction, Plaintiffs relies largely on the fact that the specification, in describing the prior art, incorporates by reference the '387 patent, which, according to Plaintiff, shows a "central data station" that includes both a "host computer" and "memory modules" that are each distinct data transmission sources. (D.I. 64 at 6.) The specification of the patent-in-suit further describes the '387 patent as including a "host computer" that transmits data "in conjunction with other electronics." ('402 patent at 1:31-35.) Finally, Plaintiff notes that the specification of the '402 patent describes the data link connecting the "central station" and "user site" as possibly being a fiber optic link, publically switched link, telephone link, satellite wireless link, or cable television link, which one of skill in the art would allegedly recognize as being geographically distributed. (See D.I. 64 at 6.) In light of these disclosures, Plaintiff contends that the specification confirms that the central station can include one or more devices and that "there is no geographical restriction in connection with central station." (See D.I. 69 at 6:9-7:10.) Rather, what is important, Plaintiff contends, is that the components of the "central station" possess some level of "logical connectivity" so that they may "work together." (See D.I. 69 at 12:8-19.)

Defendant responds, first, that the specification only appears to disclose an embodiment in which the central station is at a single location. For instance, according to Defendant, by explaining that the "time limit" "can be encoded at the central station," the specification confirms that the limiting data and video product are stored at the same location. (See D.I. 63 at 15-16.) Likewise, according to Defendant, both figures in the patent show the "central station" as being at only a single location and only one transmission path from the "central station" to the "user site." (Id. at 16; D.I. 69 at 46:6-17.) Though pointing to this evidence in the specification, Defendant's principal argument on this claim term appears to be that its proposed construction follows from its construction for the "data stream" terms, which, as explained above, is well supported by the prosecution history. (See supra Part II.A.) Briefly, Defendant contends that "if the video product and limiting data are transmitted together as part of the same data stream, then they must be transmitted from the single location." (D.I. 63 at 16.)

After reviewing the specification and the parties' arguments on this term, the Court concludes that the specification simply
dispute that "predesignated site" meant "to designate beforehand the original or fixed position of a thing." Id. at 811. The system operated over the internet and allowed consumers to print coupons on their home computers. Id. The parties did not contained the phrase "a system for controlling the selection and dispensing of product coupons at a plurality of remote Catalina, the plaintiff had patented a selection and distribution system for discount coupons. Id. at 805. One of the claims Blank relies heavily on Catalina Mkt. Int'l v. Coolsavings, 289 F.3d 801 (Fed. Cir. 2002), in making its argument. In to the metered account will be determined before the account is credited with a dollar amount. Lubrizol Corp., 64 F.3d 1553, 1557 (Fed. Cir. 1995). According to Blank, common sense dictates that any balance credited and the claim should not be read in such a way as to render claim language superfluous. See Exxon Chem. Patents, Inc. v. assignments to the card "during the manufacturing process prior to shipment." In fact, the specification provides for the assignment to the card "during the manufacturing process prior to shipment." WEBSTER’S at 926. Although both parties agree that the correct meaning is "determine beforehand," they disagree as to how far beforehand the certain balance must be determined. Blank proposes that "a certain predetermined balance" should be construed to mean "a value given to a card during the manufacturing process prior to shipment to retailers." (Def.’s Markman Memo. at 18.) Fiala would interpret "a certain predetermined balance" to mean "crediting the metered account with a balance that is fixed and stated prior to crediting of the metered account." (Pl.’s Markman Brief at 30).

The specification conflicts with Blank's proposed meaning. Nothing in the specification indicates that a value must be assigned to the card "during the manufacturing process prior to shipment." In fact, the specification provides for the opposite. "The metered account may have been credited with a certain predetermined balance when the metered account was entered into the digital computer [prior to shipping], but, if not, the digital computer will … credit the metered account with a certain predetermined balance [when the card is activated by the store clerk at the time of purchase]." U.S. Patent No. 5,918,909, Column 20:1-5. The specification supports Fiala's construction and permits giving the card value either before shipment or at the time of activation.

Blank, however, argues that the claim language supports its construction. Blank contends that adopting Fiala's proposed construction of the phrase would render claim language superfluous. Every word in the claim is presumed to add meaning, and the claim should not be read in such a way as to render claim language superfluous. See Exxon Chem. Patents, Inc. v. Lubrizol Corp., 64 F.3d 1553, 1557 (Fed. Cir. 1995). According to Blank, common sense dictates that any balance credited to the metered account will be determined before the account is credited with a dollar amount.

Blank relies heavily on Catalina Mkt. Int'l v. Coolsavings, 289 F.3d 801 (Fed. Cir. 2002), in making its argument. In Catalina, the plaintiff had patented a selection and distribution system for discount coupons. Id. at 805. One of the claims contained the phrase "a system for controlling the selection and dispensing of product coupons at a plurality of remote terminals located at predesignated sites such as consumer stores." Id. at 806. The accused infringer's coupon distribution system operated over the internet and allowed consumers to print coupons on their home computers. Id. The parties did not dispute that "predesignated site" meant "to designate beforehand the original or fixed position of a thing." Id. at 811. The
patent owner, however, argued that the phrase "predesignated site[s]" encompassed Coolsavings.com's system because it predesignated the consumer's computer as the site at which the coupons would be dispensed prior to the actual printing of the coupons. Id. The Federal Circuit held that this argument ignored "the physical dimension indicated by the phrase 'located at' immediately preceding 'predesignated sites'" and that "recognition simply does not amount to predesignation." Id. The court held that "the phrase 'located at predesignated sites such as consumer stores' requires designation of the physical site of the terminal before location of the terminal at a point of sale location." Id. at 811-12.

Fiala's proposed definition, however, would not ignore any of the claim language or any of the necessary implications of that language. Unlike Catalina, there is no additional language with which the court must concern itself other than "a certain predetermined balance" and, thus, no danger that claim language will be rendered superfluous. 1

--- Footnotes ---

1 The court construes "certain" to mean fixed or settled. WEBSTER'S at 222-23. Fiala's proposed definition reflects this definition rather than ignoring it.

--- End Footnotes ---

Claim terms are given their ordinary and customary meaning absent some contrary meaning indicated in the specification or the prosecution history. Johnson Worldwide, 175 F.3d at 990. As discussed above, the specification supports the ordinary meaning of predetermined as determined beforehand. The prosecution history indicates no intent to vary from the ordinary and customary meaning. There is no indication that a person of ordinary skill in the art at the time of invention would have understood predetermined to mean determined before shipping as opposed to determined before the crediting of the account. Nothing supports the imposition of additional limitations not found in the claim language itself. The court, therefore, reads the claim language as supporting Fiala's interpretation rather than Blank's interpretation.

Having considered the claim language, specification and prosecution history, the court construes "a certain predetermined balance" to mean: "crediting the metered account with a balance that is fixed and stated prior to crediting of the metered account." The evidence before the court indicates that a person of ordinary skill in the art would have so defined "a certain predetermined balance" at the time the patent was prosecuted, and this interpretation is consistent with the clear meaning of the claim language.

571

C. "Certifying"

The final disputed term is the word "certifying," as used in paragraph (c) of claim 1 of the '954 patent. Plaintiffs assert that "certifying" should be defined in accordance with its plain and ordinary meaning as "confirming formally as true, accurate and genuine." In the context of the '954 patent, then, "certifying" would mean applying a verifiable digital cryptographic signature to show receipt by the outside agency. Defendants argue that "certifying" should be interpreted as meaning "to establish incontrovertibly (i) the identity of the party providing the receipt and (ii) that the contents of the receipt, particularly the time indication, are correct and have not been falsified." The short answer to defendant's contention is that claim 1 itself indicates that the "certifying" of the receipt is done "by means of a digital cryptographic signature scheme." 17 Thus, the plain language of claim 1 and the patent specification define the meaning of "certifying" without ambiguity as simply meaning applying a verifiable digital cryptographic signature to the time-stamp receipt to show that it was prepared by the outside agency.

--- Footnotes ---

17 See U.S. Pat. No. 34.954, col. 8, ll. 62-64.

--- End Footnotes ---

Moreover, it is clear that "certifying" as used in claim 1 does not indicate that the time in the receipt is correct because such
an indication cannot be done by means of a "verifiable digital cryptographic signature." It is apparent from the preceding discussion of "verifiable" that the application of the "verifiable digital cryptographic signature" only provides proof (i) of the identity of the time-stamping agency and (ii) that the document has not been altered since the application of the time-stamp. The specification explains that the proof of the veracity of the time-stamp itself relies upon an additional aspect of the invention, namely the receipt-linking method, in which the time-stamping agency adds data from adjacent receipts to the document's time-stamp to prove the veracity of the time-stamp. Claims 1-4 do not recite the elements of the receipt-linking method; those are recited in claim 14. Any attempt to read a requirement of proof of the veracity of the time in the receipt from claim 14 into claim 1 is improper. See Environmental Designs, 713 F.2d at 699. Accordingly, the term certifying as used in claim 1 does not include proof of the veracity of the time in the receipt.

III. Conclusion

In summary, the Court construes the disputed elements of claim 1 of the '954 patent in the following way. "Outside agency" is defined as "some entity or something other than the originator of the digital document to be time-stamped." "Verifiable" as used in "verifiable digital cryptographic signature" is defined in accordance with its plain and ordinary meaning as "possible to prove the truth of with evidence or testimony." In the context of the '954 patent, a "verifiable digital cryptographic signature" means the provision of significant evidence of the identity of the agency that applied the digital signature. Finally, "certifying" is defined in accordance with its plain and ordinary meaning as "confirming formally as true, accurate and genuine." In the context of the '954 patent, "certifying" means applying a verifiable digital cryptographic signature to show receipt by the outside agency. "Certifying" does not include confirmation of the truth or accuracy of the time in the receipt. An appropriate order has issued.

3. "change in membership status"

EMC asks the Court to construe this term as either: "change in membership status" or "a change in status resulting from an act affecting the member, such as the member being removed from the set." HP proposes (in its opposition brief): "Exclusion of a physical mass storage device from a logical set of mass storage devices (and, in certain circumstances, the writing of data onto the remaining physical mass storage devices in the logical set)."

The claim language indicates that when there is a change in membership status, "other ones of said plurality of mass storage devices that remain members of said logical set" are assigned new membership signatures and the set is assigned a new substantially matching global identifier. The specification states that "[w]hen a member of the set undergoes a change in membership status the [sic] (e.g., removal of a physical mass storage device), a new membership signature is assigned to each remaining physical mass storage device in the set." 497:2/45-49. Thus, removal is only one possibility of status change. Indeed, the written description states: "whenever any event occurs to change the membership of any of the drives in the set . . . ." 497:2/23-26 (emphasis added). Removal or addition of a storage device occurs in the preferred embodiment. Finally, dependent claim 2 limits the change in membership status to "the removal of said member from said logical set." Importing that limitation into independent claim 1 would render claim 2 superfluous. The Court therefore will not import "exclusion of a storage device" into the construction of this term. Similarly, there is nothing in the claim that requires writing data onto or updating the membership of the remaining physical mass storage devices in the logical set.

Accordingly, the Court construes "change in membership" as "a change in status resulting from an act affecting a member of the set, such as a member being added or removed from the set."

"for changing the flow"
Claims 7, 13, and 15 of the '057 patent and claims 4, 11, and 13 of the '362 patent contain the term "for changing the flow of said data collection applications." The parties point to the same portion of the specification to support their suggested definitions:

1.6 Logical Flow of Applications

The logical flow of your application is controlled by a parameter common to each answer field: the Go To parameter. This parameter determines the next question to be asked in the application. Each question is also assigned a Sequence Number used by the GoTo parameter. In the example of FIG. 1.1 above, question 1's GoTo parameter would be simply "Next Question." Question 2's GoTo parameter, being the final question of this short application, would be "End Program."

'057 Patent at 19:64-20:6. The above quoted language describes how "flow" is controlled by a "parameter" that determines the "next question." Typhoon suggests that the definition of "for changing the flow" is "for changing the logical order of inquiries." However, as the above quoted language clearly demonstrates, the "logical order" of questions is only altered in response to the user's answer to the previous inquiry. Further, the specification suggests a process where a change in "logical order" extends to the "next question." Thus, Typhoon's general definition including the term "logical order" is overly broad. The specification describes a specific question-by-question process whereby a change in answer to a current question may result in a different subsequent question. See id. at 19:51-54 ("Consequential libraries . . . hold lists of answers and can affect the flow of the application. That is, the next questions asked are dependant upon the previous answer selected.") Therefore, Defendants' proposed construction correctly identifies the scope of "flow." Accordingly, "for changing the flow of said data collection application" is defined as "changing the next question presented from the data collection application depending on the response to the previous question."

C. Changing a [the] Hardware Configuration (Claims 1, 9, 10, 16)

PCTEL contends that the term means "the electrical/physical properties of circuitry." Agere and USR contend that the term is indefinite under § 112, P 2. Alternatively, Agere argues that the term means "changing the relative physical arrangement of non-programmable structures on the modem board; not merely changing the use of those structures as provided." USR asserts that the term should be construed as follows: "mechanically changing the arrangement of electrical interconnections of physical, non-programmable structures on the data communication apparatus."

PCTEL's interpretation once again solely relies upon the declaration of expert witness Dr. Wicker. As explained above, PCTEL's proposed construction is problematic because it has no intrinsic support in the '561 patent, the prosecution history, or even the ordinary meaning of "hardware" or "configuration" as taken from technical dictionaries. Furthermore, this construction provides no guidance with regard to differentiating a hardware configuration from software changes, which appears to be a crucial distinction which the patentee relied upon to obtain the '561 patent. Finally, PCTEL's proposed construction is flawed because it seeks to read "hardware configuration" out of the claims by construing it no differently than "hardware related operating parameter."

Agere and USR's proposed construction relies heavily upon technical dictionaries available at the time the patent was issued. Claim terms mean what they say and have the ordinary meaning that would be attributed by one skilled in the relevant art. See Texas Digital Systems, Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202 (Fed. Cir. 2002) (citing several cases for this proposition). The Federal Circuit recently reaffirmed that dictionaries, encyclopedias, and treatises are particular useful resources to assist the court in determining the ordinary meaning of claim terms. Phillips v. AWH Corp., 415 F.3d 1303, 2005 WL 1620331, *15 (Fed. Cir. 2005). However, the Phillips court warned that "heavy reliance on the dictionary divorced from the intrinsic evidence risks transforming the meaning of the claim term to the artisan into the meaning of the term in the abstract, out of its particular context, which is the specification." 415 F.3d 1303, [WL] at *14. Thus, in determining the "ordinary meaning" of a claim term, the district court must initially focus on "how the patentee used the claim term in the claims, specification, and prosecution history." Id. If these sources of evidence prove unhelpful, then courts may turn to dictionary definitions to illuminate the "ordinary meaning" of the claim term. Id.
In order to overcome the "heavy presumption" in favor of the ordinary meaning, such evidence must express "manifest exclusion." See Teleflex Inc. v. Ficosa North American Corp, 299 F.3d 1313, 1326 (citation omitted). In Texas Digital Systems, the court stated: "if the meaning of the words themselves would not have been understood to persons of skill in the art to be limited only to the examples or embodiments described in the specification, reading the words in such a confined way would mandate the wrong result . . . " 308 F.3d at 1205; see also Teleflex, 299 F.3d at 1326 ("[t]hat claims are interpreted in light of the specification does not mean that everything in the expressed in the specification must be read into all the claims . . . ") (citation and quotation marks omitted). "Generally, particular limitations or embodiments appearing in the specification will not be read into the claims." Loctite Corp. v. Ultraseal Ltd., 781 F.2d 861, 867 (Fed. Cir. 1985), overruled on others grounds by Nobelpharma AB v. Implant Innovations, 141 F.3d 1059 Fed. Cir. 1998) (cited by Texas Digital Systems 308 F.3d at 1204).

Here, there is no genuine dispute that the claim language, the specification, and the prosecution history are not helpful in ascertaining the ordinary meaning of "changing a [the] hardware configuration." Therefore, the Court is permitted to examine technical dictionaries to determine the "ordinary meaning" of the claim term. Agere and USR assert that the ordinary meaning of "hardware" is "physical equipment used in data processing, as opposed to computer programs, procedures, rules and associated documentation." n4 (Malz Decl, Ex. 10 at AL 15292 and AL 15296, IEEE Standard Dictionary of Electrical and Electronics Terms, (1984) & (1988)). Agere and USR also assert that the ordinary meaning of "configuration" must include an arrangement of parts. (Tang Decl., Ex. 10, SAMS Modern Dictionary of Electronics (1984)) (defining "configuration" as "the relative arrangement of parts (or components) in a circuit); (Tang Decl., Ex. 8, IEEE Standard Dictionary of Electrical and Electronics Terms (1984)) (defining "configuration" as "their geometrical arrangement including the size of the wires and their relative positions with respect to other conductors and the earth"). Based on these definitions, the Court finds that the ordinary meaning of "hardware configuration" would necessarily included a "physical arrangement."

---- Footnotes ----

n4 Other dictionaries provide similar definitions. See McGraw Hill Dictionary of Electronics and Computer Technology (1984) (defining "hardware" as "physical, tangible, and permanent components of a computer or a data processing system").

---- End Footnotes ----

However, PCTEL also takes issue with other language that Agere and USR attempt to include in their proposed constructions. First, Agere and USR's proposed construction restricts the scope of the claim by including the term "non-programmable." Second, Agere and USR's proposed construction requires that the structures that constitute the "hardware configuration" be "on" the modem board. Third, USR's interpretation seeks to limit the scope of the claims to only "mechanical" changes. The Court will discuss the inclusion of each of these proposed terms in turn.

1. Non-Programmable

USR asserts that the inclusion of "non-programmable" is directly supported by the patent specification which indicates that the programmable part of the modem, the software in microprocessor 40 that controls the other components, is separate from the hardware being configured which is incapable of running software and thus non-programmable. '561 patent, 10:38-57. USR also asserts that the ordinary meaning of hardware in technical dictionaries specifically notes a difference between, software which is programmable, and hardware, which is not.

PCTEL responds that a preferred embodiment of the patent discloses a modem that uses duplicate circuits for achieving two different impedances. '561 patent, col. 10:34-46. According to this embodiment, one circuit for providing first impedance is connected to a first port or a microprocessor, and a second circuit for providing a second impedance is connected to a second port of the microprocessor. PCTEL asserts that this preferred embodiment discloses that the microprocessor is programmed to select between the two ports depending upon the impedance needed for the country in which the modem is to be used. PCTEL argues that Agere and USR's proposed construction excludes a preferred embodiment of the '561 patent, and thus is too narrow.

The Court agrees with Agere and USR that the consensus of technical dictionaries makes clear that "hardware" differs from "software," which is programs. (Tang Decl., Ex. 8, IEEE Dictionary (1984)) (noting that "hardware" is "physical equipment
used in data processing, as opposed to computer programs, procedures, rules and associated documentation”); (Tang Decl., Ex. 9, Dictionary of Computers, Information Processing & Telecommunications (1987) (same)). Furthermore, despite PCTEL's assertion to the contrary, the Court does not find that the specification discloses a preferred embodiment that describes programmable hardware. Rather, an examination of the preferred embodiment supports USR's position, namely, that the programmable microprocessor is clearly separate from the "non-programmable" hardware. '561 patent, col. 10:34-46. Hence, the Court concludes that "hardware configuration" should be construed as "non-programmable."

2. "On" the Modem

Agere and USR assert that the hardware must reside on the data communication apparatus on the '561 specification. In support of their argument, they contend that the specification does not identify an embodiment where the hardware components are not within the "data communication apparatus 10." PCTEL responds that Agere and USR's proposed construction should be rejected because no such limitation can be found in the claims.

The Court agrees with PCTEL. USR's implicit argument that the scope of the claims is limited to the examples set forth in the specification is contrary to law. "A patentee may claim an invention broadly and expect enforcement of the full scope of that language absent a clear disavowal or contrary definition in the patent's specification." Home Diagnostics, Inc. v. Lifescan, Inc., 381 F.3d 1352, 1357 (Fed. Cir. 2004). Here, the specification contains no such disavowal or contrary definition. Thus, the Court will not limit the "hardware configuration" to being "on" the modem board.

3. "Mechanical Change"

USR asserts that a change in the arrangement of the various hardware components of the '561 patent would require a mechanical switch which changes the circuit paths by movement of the connector of a switch. USR contends that such a mechanical switch would not be present on programmable structures such as a microprocessor. USR concludes that its interpretation is consistent with the '561 patent specification and prosecution history because a change in line impedance and changing a set of resistors for transmit signal line level could be performed by a mechanical switch, such as a relay. In support of its arguments, USR relies exclusively on its expert witness Dale Walsh.

PCTEL responds that while the patent discusses using mechanical switches to change modem speed options, asynchronous or synchronous communication modes, and other options, these options have nothing to do with configuring for country of intended use. PCTEL asserts that country specific parameters are changed by the microprocessor and arrange the modem hardware. '561 patent, col. 10:38-57. PCTEL also notes that the patent itself refers to switching or circuit logic, which is not mechanical switching, but rather solid state. '561 patent, col. 10:48-51.

The Court agrees with PCTEL that the patent does not require a mechanical switch to change the arrangement of the various hardware components of the '561 patent. It appears, as noted by PCTEL, that the specification explicitly allows for the hardware configuration to be changed through the use of circuit logic, which is clearly distinguished from mechanical switching. '561 patent, col. 10:46-51. In any event, "particular limitations or embodiments appearing in the specification will not be read into the claims." Loctite Corp., 781 F.2d at 867. The word "mechanical" is found nowhere in the patent claims. Thus, the Court will not read such a limitation into the claims.

In sum, given the considerations discussed above, the Court construes "changing the hardware configuration" as changing the physical arrangement of non-programmable structures.

In Paragraph (4) Of Claim 20 Of The '998 Patent - "Changing The Stored Sound Waveform In Accordance With Changes Made In The Visually Displayed Waveform By The Step Of Editing"

Macromedia contends that this phrase (hereinafter the "changing the stored sound waveform phrase") should be construed to mean "making different or modifying the sound characteristics of the stored sound waveform in accordance with changes made in the visually displayed waveform." (D.I. 243 at 14). Adobe contends that the changing the stored sound waveform phrase should be construed to mean "overwriting the stored waveform stored in the computer RAM memory to reflect a
change in the sound characteristics of the waveform in accordance with changes made in the visually displayed waveform." (D.I. 305 at 28).

In construing the changing the stored sound waveform phrase, the Court has reviewed the specification and the prosecution history. (See D.I. 248, Ex. B, '998 Patent, Col. 1, lines 33-40; D.I. 248, Ex. C). Based on a review of these sources, the Court concludes that changing the stored sound waveform is directed to overwriting the original waveform stored in the computer RAM memory. Accordingly, the Court construes the changing the stored sound waveform phrase to mean "overwriting the stored waveform stored in the computer RAM memory to reflect a change in the sound characteristics of the waveform in accordance with changes made in the visually displayed waveform."

---

**576**

- "channel" is construed to mean "a path for transmitting electrical signals."

Lucent contends that this term means "a path for transmitting electrical signals." (D.I. 396 at 10.) Defendants contend that this term means a virtual circuit connection established in the network between 'end user terminals." (D.I. 395 at 9; D.I. 385 at 16.)

In view of the Court's conclusion that the claims of the '810 and '811 patents are not limited to packet-switching network comprised of virtual circuits, the Court rejects Defendants' proposed construction. Accordingly, in the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

---

**577**

B. "First" and "Second" Channels

Covad asserts that the Court should construe each of the first and second channels of claims 1 and 21 as: "An amount of bandwidth isolated for communications that may be either unidirectional or bi-directional." Bell Atlantic argues that the Court should construe each of the first and second channels of claims 1 and 21 as: "A one-way path between communicating entities." Both parties agree that the terms "first" and "second" require that there be two distinct channels and that the meaning of the term "channel" depends on the context in which it is used. The parties also agree that one type of channel contemplated by the '786 patent is the frequency division multiplexed channels shown in Figures 4 and 10 of the '786 patent. 10

---

10 Frequency division multiplexed channels are regions of the available spectrum reserved for a particular communications task, usually by isolating a range of frequencies using electronic filters.

---

The '786 patent repeatedly refers to "channels" by the reference numbers 302, 304, 306, 302', 304', and 306'. The patent explains that ADSL transceivers use "frequency multiplexing to divide the available loop bandwidth into three channels 302, 304, and 306 (see FIG.4)." See col. 8, ll. 20-23. Figures 4 and 10 show that channels 302, 304, 306, 302', 304', and 306' all correspond to "bands of frequencies" -- i.e., bandwidths - along the communications spectrum. See Figs. 4, 10 (attached). There are numerous references to these frequency channels scattered throughout the specification. See, e.g., col. 8, ll. 15-26; col. 8, ll. 44-65; col. 9, ll. 8-10; col. 12, ll. 17-20.

The '786 patent repeatedly refers to a bi-directional channel in the singular, which would clearly contradict Bell Atlantic's proposed definition of channel as a "a one-way path between communicating entities." In one instance, the patent states that" … the two-way control channel may be unacceptably slow …." Col. 2, ll. 29-30 (emphasis added). In another instance, the patent refers to "a small … two-way reverse control channel upstream on the ISDN packet data network between the
subscriber and the central office." Col. 8, ll. 24-26 (emphasis added). Another reference states that "the frequency channel represented by range 302 in FIG.4 thus establishes a 2-way channel used to provide standard POTS service or ISDN (2B+D) service over the ADSL line." Col. 8, ll. 44-46 (emphasis added). The prosecution history also refers to bi-directional channel 302 in the singular. In the July Amendment, Bell Atlantic explained to the PTO that "the bandwidth provided by channel 302 provides connectivity for conventional telephone services, usually below 4Khz." 11 July Amendment, at 12 (emphasis added).

11 Conventional telephone service is a bi-directional channel previously described as POTS.

Bell Atlantic states that there is no dispute that, even under Covad's proper construction of "channels," the two "channels" called for by claims 1 and 21 are present in the accused ADSL systems. Thus, regardless of how this Court rules on Covad's "channel" construction, the Court must deny Covad's motion of noninfringement as to it's ADSL systems if this Court rejects Covad's other two proposed constructions regarding "mode" and "selectivity."

Bell Atlantic argues that the Court should rely on extrinsic evidence from the Telecommunications Primer for the proposed definition of "channel" to be applied: "A one-way path between communicating entities." E. Bryan Carne, Telecommunications Primer: Data, Voice and Video Communications, at 35. Bell Atlantic also directs the Court's attention to the definition of "circuit" defined in the text as "the combination of two channels, one in each direction, between communicating entities." Id. Bell Atlantic, therefore, argues that based on extrinsic evidence, a path allowing communication from point A to point B is one channel, and a path allowing communication from point B to point A is a different channel. 12

12 This same text, however, under a section addressing "frequency-division multiplexing," states that "[a] channel is defined by its center frequency, and its bandwidth, or by its upper- and lower-frequency limits." Id. at 223.

Bell Atlantic states that the patent refers to channels not separated from one another in frequency. The specification notes that, "alternatively, a fractional T1 interface and control software could be used at the subscriber end to provide separate multiplexed carriers or channels of up to 24 DS-O's on a regular trunk." Col. 14, ll. 34-37. The specification also states that "each of the channels can be combined with others in the 1/0 DSC 15 serving the homes or the 1/0 DCS 14 on the LAN end and thereby connected to the LAN over a single T1 link." Col. 8, ll. 6-9. Plaintiff further relies on extrinsic evidence in the form of expert testimony in support of the assertion that there are various ways of implementing multiple channels in a transmission system, such as separating them by frequency, by time, or through the use of echo cancellation. See Bell Atlantic's Brief, at 4.

The patent explicitly refers to a two-way or bi-directional channel in the singular, therefore, an analysis of the intrinsic evidence alone will resolve any ambiguities with regard to the reference to the first and second channels of claims 1 and 21. Bell Atlantic's proposed definition of "channel" from The Telecommunications Primer is in direct conflict with the language of the patent, as the inventors clearly intended "channel" to encompass both one-way and two-way segments of bandwidth. Thus, the Court finds that each of the first and second channels of claims 1 and 21 mean: "An amount of bandwidth isolated for communications that may be either unidirectional or bi-directional."
unidirectional or bi-directional communications. The district court noted that various phrases in the specification described "two-way" channels, and reasoned that "the inventors clearly intended 'channel' to encompass both one-way and two-way segments of bandwidth." However, Bell Atlantic contends that the first and second channels are instead "one way paths." We agree with Bell Atlantic on this aspect of the interpretation of the "channel" limitation.

First, the language of the claims supports Bell Atlantic's contention that the first and second "channels" are intended to encompass only one-way communication. Claims 1 and 21 both describe a first transceiver "transmitting or receiving signals, at a first transmission rate, on a first channel, and transmitting or receiving signals, at a second transmission rate, on a second channel." '786 patent, col. 17, ll. 9-12 (emphasis added). The use of the word "or" demonstrates that each transceiver either transmits or receives on a single channel, but not both simultaneously. Thus, the language of the claims themselves supports a construction of the first and second "channels" that excludes bi-directional or two-way communications.

Second, the written description defines the first and second channels as those that support one-way communication. Throughout the written description, the specification discusses the data channels as either "upstream" or "downstream" channels. '786 patent, col. 2, l. 60; col. 3, l. 57; col. 7, l. 48; col. 8, l. 57; col. 12, ll. 10-29. Indeed, the written description notes that in conventional ADSL systems, "channels 304 and 306 are unidirectional." '786 patent, col. 9, l. 8 (emphasis added). Other passages refer to the "unidirectional" nature of the downstream or upstream channels. '786 patent, col. 9, l. 50. Thus, it is clear that the specification defines by implication the first and second channels as supporting only unidirectional communication.

Covad nevertheless contends that the specification and prosecution history also use the term "channel" to refer to bi-directional communications. Therefore, Covad reasons that the term as used in claims 1 and 21 must be construed to encompass both unidirectional and bi-directional communications. It is true that the specification refers to a "two-way" or bi-directional channel in numerous instances. '786 patent, col. 2, ll. 29-30; col. 8, ll. 24-26; col. 8, ll. 44-46; col. 13, l. 7. It is also true that during prosecution history, the patentees stated that "channel 302 provides connectivity for conventional [bi-directional] telephone services." However, in each of these instances, it is evident that the statements regarding the bi-directional channels refer to only the prior art control channel, the signaling channel, or the POTS channel. Conversely, wherever the specification discusses the first and second (upstream and downstream) data channels referenced in the claims at issue, it is clear that the communication is unidirectional.

"In circumstances such as this, where the language of the written description is sufficient to put a reader on notice of the different uses of a term, and where those uses are further apparent from publicly-available documents referenced in the patent files, it is appropriate to depart from the normal rule of construing seemingly identical terms in the same manner. This entirely accords with the public notice function of claims." Pitney Bowes, 182 F.3d at 1311, 51 U.S.P.Q.2D (BNA) at 1170. Thus, although the term "channel" may encompass both unidirectional and bi-directional communications, it is clear that the first and second data channel limitations in claims 1 and 21 support only unidirectional communications.

b. Frequency Separated Channels

The district court also held that the first and second "channels" are "an amount of bandwidth" or "bands of frequencies" or "frequency channels." In other words, the district court determined that the channels must be separated by frequency. Bell Atlantic contends that the ordinary meaning of the term "channel" is not limited to communication paths separated by frequency. Indeed, as understood by one of ordinary skill in the art, the ordinary meaning of the term "channel" is quite broad. Within the realm of DSL technology, technical treatises refer to channels separated by frequency ("frequency division multiplexing"), channels subdivided by time ("time division multiplexing"), channels separated by "echo cancellation" techniques, and channels subdivided by various "modulation" techniques. See, e.g., E. Bryan Carne, Telecommunications Primer 223 (Prentice Hall 2d ed. 1999); Michael Busby, Demystifying ATM/ADSL 37, 53-54, 205-206 (Wordware 1998).

However, the '786 patent specification defines the first and second channels, by implication, as amounts of bandwidth, and thus, communication paths separated by frequency. The summary of the invention references the upstream and downstream channels. '786 patent, col. 2, l. 59; col. 3, l. 57. The written description of the preferred embodiments notes that the upstream and downstream channels are illustrated in Figure 10 as channels 304' and 306'. '786 patent, col. 12, ll. 10-21. Figure 10, discussed above, illustrates the upstream and downstream channels as channels separated by frequency.
Moreover, the specification states that "the ADSL/AVRs used in the present invention are a modification of, and an improvement over, conventional ADSL." '786 patent, col. 8, ll. 15-17 (emphasis added). The specification notes that conventional transceivers use "frequency multiplexing to divide the available loop bandwidth into three channels 302, 304 and 306." '786 patent, col. 8, ll. 20-22. In numerous other passages, the specification describes the channels in conventional ADSL systems as separated by frequency. '786 patent, col. 8, l. 20; col. 8, l. 44; col. 8, l. 60; col. 9, l. 43; col. 10, l. 46. The specification notes that the ADSL/AVR system of the present invention is similar to conventional ADSL systems. '786 patent, col. 10, ll. 60-61. Furthermore, the written description states that the channelization between the upstream and downstream channels is illustrated in Figure 10. '786 patent, col. 12, ll. 19-21. Both Figure 4 (conventional ADSL channelization) and Figure 10 (bi-directional mode channelization) show that data channels 304, 306, 304', and 306' correspond to bandwidths separated by frequency.

Moreover, the patentees stated during prosecution that "in the present invention, the transmission bandwidth of channels 302, 304, and 306 are controlled for various modes." (emphasis added). This statement further demonstrates that the channels used in the present invention are defined by an amount of bandwidth. Thus, the only type of channels contemplated by the '786 patent are those that occupy an amount of bandwidth those that are separated in frequency. Nowhere does the specification discuss channels created by time-division multiplexing or echo cancellation. Indeed, in the one reference to time division multiplexing, the specification states:

'A down-stream control signal to the subscriber (not shown in Fig. 4) is time division multiplexed with the 1.544 mbps video signal on the 100-500 Hz carrier. This down-stream control signal, together with the digitized information and overhead, occupies a bit rate band of about 1.6 mbps.

'786 patent, col. 8, l. 66 to col. 9, l. 4 (emphasis added). The specification refrains from identifying the time-division multiplexed signal as a "channel," instead referring to it as a "signal."

Our construction does not limit the term "channel" through inferences drawn from the description of a preferred embodiment. Johnson Worldwide, 175 F.3d at 992, 50 U.S.P.Q.2D (BNA) at 1612. Neither does this case involve the "varied use of a disputed term." Id. at 991, 50 U.S.P.Q.2D (BNA) at 1611. Instead, the written description "provides guidance as to the meaning of the claims, thereby dictating the manner in which the claims are to be construed, even if the guidance is not provided in explicit definitional format." Scimed, 242 F.3d at 1344, 58 U.S.P.Q.2D (BNA) at 1065. Because the patentees used the term "channel" throughout the entire patent specification, consistent with a single meaning, they defined that term "by implication." Vitronics, 90 F.3d at 1582, 39 U.S.P.Q.2D (BNA) at 1577; see also Hockerson, 222 F.3d at 955, 55 U.S.P.Q.2D (BNA) at 1490. Thus, in addition to being unidirectional, the first and second channels described in claims 1 and 21 also constitute an amount of bandwidth, and as such, are channels that are separated by frequency.

3. "channel estimator"

Wi-LAN's Proposed Construction

"a device for computing the amplitude and/or phase distortions of a received signal"

Alternative: "a device for computing amplitude and/or phase differences in the received signal caused by the wireless channel"

Defendants' Proposed Construction

"a device for estimating one or both of the amplitude and the phase differential of the received signals to produce as output one or both of the difference in amplitude or phase between received data symbols"

The construction for this term is largely related to the construction for the terms relating to "amplitude and phase differential." In light of the Court's prior constructions, the only term to be construed is the "channel estimator" term itself. As previously stated, the claimed channel estimator estimates the phase differential of the transmitted signals by sampling the amplitude envelope of the signals. See '222 patent, 11:1-28. There may be distortions to the amplitude and phase of the
transmitted signal caused by the channel. However, the Court finds that estimates of the "amplitude" and the "phase
differential" are used to correct for distortions over the channel, not that the channel estimator itself directly computes or
measures the distortions. See '222 patent, 9:43-61. Accordingly, the "phase differential" of the received signal is supplied to
the "pre-distorter" to correct for "phase distortion over the channel." Id. The Defendants' construction largely recites most of
the subsequent language following the term to be construed, and therefore the Court rejects Defendants' construction as
being unhelpful. Again, the Court rejects Wi-LAN's proposal to equate the term differential to distortion. The Court finds
that the language of the claims and specification are clear that the channel estimator may compute an estimated phase
differential and estimated amplitude, but it is not necessarily a device for computing distortions. See '222 patent, 9:43-61.
The channel estimator of the '222 patent first obtains an estimated amplitude of the received signal by sampling the
amplitude envelope, which is then used to obtain an estimated "phase differential" to correct for the channel's effects on the
received signal. '222 patent, 11:10-19. The specification provides that the channel estimator is for "estimating the channel."
See '222 patent, 10:67-11:1. Further, the plain language of the term "channel estimator" implies that it is a device that
estimates the channel. Wi-LAN's expert confirms that the goal of the channel estimator is to estimate the channel, and more
particularly to estimate the effect of the channel on information symbols. Thus, the Court construes the term "channel
estimator" to mean "a device that estimates the effect of the channel on the transmitted signals."

580
B. "channel forming region"

Plaintiff proposes that "channel forming region" be construed to mean "the region of a semiconductor device in which the
channel may form." Defendants argue that the phrase means "an amorphous silicon region that is later formed into a channel
after irradiation."

The proposed definitions differ in two important respects. First, defendants contend that the entire region is converted into a
"channel" after irradiation takes place. Plaintiff contends, instead, that "channel" refers to the actual path that current takes
through the channel forming region when the transistor is in use. Second, defendants' construction requires that the channel
forming region subsequently be exposed to laser radiation. Plaintiff's construction does not.

With respect to the first point, although the specification is not entirely consistent in its use of "channel" and "channel
forming [or formation] region," it does make clear that the two are not necessarily coextensive: ":[i]n the channel formation
region, it is the interface with the gate insulating film which operates as a channel in practice." 358 patent at 8:58-60.
Although the specification describes only a particular embodiment, and, as defendants noted at oral argument, other
embodiments may exist in which current flows through the entire channel forming region, defendants' construction would
limit the scope of the claims to a case not even discussed in the specification. Their proposed construction is therefore too
restrictive.

With respect to the second point, it is certainly true that the patent frequently discusses crystallizing the amorphous silicon
regions through irradiation. See, e.g., id. at 8:60-62 ("the intrinsic amorphous silicon layer which becomes the channel
formation region must be crystallized sufficiently [through irradiation.]"); id. at Abstract ("the channel formation region . . .
[is] exposed to laser radiation."). Indeed, the stated purpose of the invention is to permit the creation of thin-film transistors
with silicon regions that are accessible to laser radiation after the structure of the transistor is completely formed. Id. at
1:62-66 (the invention "make[s] it possible to crystallize a channel formation region and to activate the Ohmic contact
region of the source and drain by laser irradiation after the device structure of a thin film transistor is completed.").

The fact that the invention provides for the possibility of irradiation, however, does not mean that irradiation is required in
order for a channel-the conductive path through the channel forming region-to form. The specification makes clear that not
all transistors formed by the patented process need be irradiated. Instead, individual transistors can be irradiated or not
depending on the desired electrical characteristics: "[t]he laser radiation is directed to the source, drain regions and to the
channel formation region of desired one or more of the amorphous silicon TFTs." 258 patent at 5:9-11 (emphasis added).
Also, "desired one or more of the amorphous silicon TFTs can be made to have desired electrical characteristics." Id. at
5:34-36 (emphasis added). Finally, "a system comprising the substrate on which amorphous silicon TFTs and polysilicon
TFTs are fabricated can be manufactured without relying on different manufacturing processes." Id. at 5:45-48. As this last
sentence makes clear, where a large number of TFTs are made using the patented process, only some of them need be
converted from amorphous silicon to polysilicon through the additional step of laser irradiation.

The specification also uses the phrase "channel formation region" in a manner suggesting that the channel formation region exists prior to irradiation: "the channel formation region can be activated and crystallized by laser irradiation after the device structure of the amorphous silicon thin film transistor has been completed." Id. at 5:2-5. While the channel formation region can be "activated" by irradiation, it exists before any irradiation takes place.

The dependent claims underscore this distinction. Claim 26 covers "[a] method according to claim 3 further comprising a step of irradiating at least the channel region with a laser after the formation of the source and drain regions." Id. at 16:7-9. By implication, the invention claimed in claim 3 does not include the step of "irradiating . . . the channel region." n2

n2 Defendants attempt to downplay the significance of the dependent claims by noting that the phrase "channel region" is different from "channel formation region." The court finds the reference to be sufficiently clear to support the conclusion that the independent claims do not implicitly contain a step of irradiation.

Defendants argue that the phrase "channel forming region," as a matter of common English usage, "suggests that the term means a region that is not yet a channel, but in which a channel will be formed." Defs.' Response at 13. The court agrees, but as defendants' own articulation suggests, the channel forming region is not transformed into a channel, but rather is the region "in which a channel will be formed" once current begins to flow through the transistor. See id. The phrase "channel forming region" is quite similar to the name for another circuit element, "light emitting diode," which also describes an event (the emission of light) which occurs when the circuit element is in use.

The court therefore adopts plaintiff's construction of "channel forming region," which means "the region of a semiconductor device in which the channel may form."

581

2. Disputed term in AMD's '893 patent: "Channel-free region," "channel free zone" (claims 1, 2, 4)

This patent describes a Metal Oxide Semiconductor Field Effect Transistor ("MOSFET"). The disputed term, "channel-free region" (or "channel-free zone" 7), appears in claims 1, 2 and 4.

7 The parties agree that "channel-free region" and "channel-free zone" have the same meaning.

1. An insulated gate field effect device comprising:

a first conductivity type semiconductor substrate having a main surface; said semiconductor substrate having a concave surface formed on said main surface extending to a prespecified depth below the main surface; an insulating film formed on said concave surface; a conductive gate electrode formed above said insulating film, overlying the concave surface; first and second impurity regions of a second conductivity type respectively formed in the substrate, in the vicinity of said main surfaces, self-aligned to and positioned at one side and the other side of said gate electrode respectively; and a first conductivity type region located in said semiconductor substrate between first and second impurity regions for defining a channel region and a channel-free region extending conformably under and along said concave surface;

wherein the depth of said concave surface is set to a value which ranges between one and two times the depth of said first and second impurity regions, and

- 1055 -
wherein the concave surface is continuously curved in the vicinity of at least one of the first and second impurity regions to produce smooth merger of a conforming first depletion region formed around the at least one impurity region and a conforming second depletion region formed in the vicinity of the gate electrode so that excessive field concentration will not develop in the vicinity where the first and second depletion regions meet.

2. An insulated gate field effect device according to claim 1, wherein one of said first and second impurity regions constitutes a drain region of said insulated gate field effect device, the other of said first and second impurity regions constitutes a source region and wherein the concave surface is continuously curved at least in the vicinity of the drain region, where the channel-free region develops during an off state of the device, to produce smooth merger of the conforming first depletion region which develops in the vicinity of the channel-free region and the drain region and the conforming second depletion region formed in the vicinity of the gate electrode so that excessive field concentration will not develop in the vicinity of the channel-free region.

4. An insulated-gate field effect transistor comprising:

- a substrate having a substantially planar main surface and a concave surface portion extending continuously from the main surface to a predetermined depth below the main surface;
- an insulating layer conformably disposed on the main surface and the concave surface portion;
- a gate conformably disposed on the insulating layer, overlying the concave surface portion, the gate having opposed first and second sides;
- implanted source and drain regions disposed within the substrate and self-aligned to the respective first and second opposed sides of the gate; and
- a channel-region formed between the source and drain regions, for defining a channel that conducts current between the source and drain regions when the transistor is in a turned-on state;
- wherein a channel-free zone develops in the substrate, under the gate and between the source and drain regions, when the transistor is in a turned-off state; and
- wherein the gate and concave surface portion are curved at least in the vicinity of the channel-free zone such that a smoothly curved depletion zone boundary will develop in the vicinity of the channel-free zone when the transistor is in the turned-off state.

A MOSFET is a type of transistor. Transistors regulate the amount of current in a circuit. Figure 9 of the '893 patent illustrates a MOSFET. The basic features are the source (labeled "4" in Fig. 9), where current enters the transistor; the drain (5), where the current leaves the transistor; and the gate (21), which starts and stops the flow of current. When the transistor is turned on, current flows from the source to the drain through a channel (13). When the voltage is sufficiently high, the channel retracts, creating a "pinch-off" region at the drain. Figure 9 illustrates the retraction at Lg1 and labels this area "channel-free length."

[SEE FIGURE 9 IN ORIGINAL]

Figure 4 illustrates the '893 patent. The claimed invention of the '893 patent was to improve the design of the MOSFET by introducing a curved structure. The curved surface made the channel longer than the conventional MOSFET without making the transistor larger. As Figure 4 illustrates, the "pinch-off" region (Lg2) is longer than in a conventional MOSFET. See 4:3-8 ("By comparing Fig. 4 to Fig. 9, it can be seen that . . . the distance Lg2 between the end of channel region 12 and the drain 5 is longer than the distance Lg1 indicated in Fig. 9.").
The parties dispute the meaning of "channel-free region." They agree that the channel-free region encompasses the pinch-off region, but disagree as to whether it can also include the rest of the area between the source and drain. AMD's proposed construction is: "The terms 'channel-free region' and 'channel free zone' refer to areas where there is no channel." In other words, AMD argues that when the transistor is turned off, a channel-free region exists between the source and drain.

Samsung proposes the following construction: "Area without a channel and through which current flows between the channel and the drain." According to Samsung, the channel-free region describes only the pinch-off region. In Samsung's view, when the transistor is turned off, there is no "channel-free zone" between the source and drain.

Samsung's proposed construction contradicts the claim language. Claim 4 teaches that "a channel-free zone develops in the substrate, under the gate and between the source and drain regions, when the transistor is in a turned-off state[]." 4:18-21 (emphasis added). Samsung's construction would render this language in claim 4 meaningless because, according to Samsung, the channel-free region does not exist when the transistor is turned off.

Samsung cites documents from the prosecution history showing that during the prosecution of the '893 patent, AMD referred to the areas Lg2 and Lg1 as "channel-free zones." See, e.g., Haskett Decl., exs. 17 (July 7, 1992 Amendment at 3, 4), 19 (Nov. 10, 1992 Response to Office Action at 3). These documents are not instructive: it is undisputed that "channel-free zone" includes the pinch-off regions Lg1 and Lg2. The prosecution history cited by Samsung does not demonstrate that while prosecuting this patent, AMD limited the scope of this term to encompass only regions Lg1 and Lg2.

Samsung also objects that AMD's construction will be confusing to jurors because it suggests that a "channel-free region" exists anywhere a channel is absent. The Court disagrees. Read in the context of claims 1, 2, and 4 it is clear that the channel-free region exists in the substrate between the source and drain, and not elsewhere in the transistor.

Accordingly, the Court adopts AMD's construction.

I Claim Construction

As described above, the problem addressed by the patent is the issue of channel latency. See '074 patent, col.1 ll.42-67. The object of the invention is to accelerate the decoding process through a system that identifies and assembles a "channel map" that replicates from the MPEG-2 PMT all of the information necessary to identify and acquire a program. By requiring the replication of this information instead of waiting to receive the PMT as it appears in the datastream, "the time required by [the] decoder . . . to identify and acquire a program being transmitted on [a] selected sub-channel . . . is advantageously reduced." '074 patent col.7 ll.40-42.

Resolution of the issues of infringement and invalidity requires that we address three issues of claim construction at the outset. First, we address the construction of "channel map information." We must determine whether the "channel map information" must replicate the four data fields constituting the program number, PCR_PID, elementary_PID, and stream_type data from the MPEG PMT. The Commission found that the channel map must replicate these four data fields. Funai advocates the Commission's reading of the claims in order to avoid invalidity on the basis of anticipation and obviousness, whereas appellants advocate a broader reading of the claims so as to support their invalidity arguments.

The '074 patent does not define the term "channel map information," nor does this term appear to have any ordinary English meaning. To locate a user's selected program, claims 1 and 23 require identification and assembly of channel map information, and require that

said channel map information replicates information conveyed in said MPEG compatible program map information and said replicated information associates a broadcast channel with packet identifiers used to identify individual packetized datastreams that constitute a program transmitted on said broadcast channel.
'074 patent col.11 ll.36-41, col.14 ll.19-24 (emphases added). Funai argues that the claim language here references "MPEG compatible program map information," and that "channel map information" must be construed with reference to the MPEG-2 standard. Appellants challenge the Commission's reliance on the MPEG-2 standard, and argue that there are several MPEG standards and that the '074 patent does not expressly limit itself to the MPEG-2 standard. In appellants' view, the claims only require that packet identifiers (or elementary PID), one of the four data fields, be part of the channel map.

The claim language referring to "MPEG compatible program map information" must refer to the MPEG-2 standard. As the Commission noted, the '074 patent appears to define the term "MPEG standard" as the MPEG-2 standard. See '074 patent col.1 ll.18-21 ("One such widely adopted standard is the MPEG2 . . . image encoding standard, hereinafter referred to as the 'MPEG standard.'"). The MPEG-2 standard is specifically referenced in numerous places in the specification, and the specification makes no reference to any other MPEG standard. See, e.g., id. col.1 ll.18-25, col.2 ll.55-59, col.7 ll.49-57.

Appellants' own expert, Dr. Wechselberger, acknowledged that the multiple references in the '074 patent to the "MPEG standard" refer to the MPEG-2 standard. Moreover, we agree with the Commission that the fact that the MPEG-2 standard was the standard used for digital television broadcasts in the United States at the time of the filing of the patent itself suggests that one of ordinary skill in the art would understand the disputed claim terms of the '074 patent to refer to the MPEG-2 standard. See LG Elecs., Inc. v. Bizcom Elecs., Inc., 453 F.3d 1364, 1375 (Fed. Cir. 2006) ("Although we have concluded that the patentee did not expressly adopt the . . . industry standard, that standard remains relevant in determining the meaning of the claim term to one of ordinary skill in the art at the time the patent application was filed, and it is treated as intrinsic evidence for claim construction purposes . . .."). rev'd on other grounds, Quanta Computer, Inc. v. LG Elecs., Inc., 553 U.S. 617, 128 S. Ct. 2109, 170 L. Ed. 2d 996 (2008).

Thus, we agree with the Commission that the claims require associating the program with all of the identifiers conveyed in the MPEG-2 program map information that are necessary to "constitute a program." '074 patent col.11 ll.36-41, col.14 ll.19-24. At the evidentiary hearing, the expert witnesses agreed that the MPEG-2 standard requires, at a minimum, four data fields--the program number, PCR_PID, stream type, and elementary_PID data--in order to "identify individual packetized data streams that constitute a program." See App. 28,438-39, 28,467-68, 31,841-43, 32,431. 4

--- Footnotes ---

4 The ALJ also examined the text of the MPEG-2 standard itself, and concluded the same. See Initial Determination, slip op. at 44.

--- End Footnotes ---

Appellants cryptically argue that dependent claims 2 and 10 demonstrate that the channel map information in independent claim 1 does not include all four data fields. Claim 2 recites that the "channel map information further associates an individual program with a corresponding program clock reference (PCR) value." '074 patent col.11 ll.42-45. Appellants state that "the presence of a dependent claim that adds a particular limitation gives rise to the presumption that the limitation in question is not present in the independent claim." Appellants' Br. 43 (quoting Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005)) (en banc). Thus, because dependent claim 2 adds the limitation that the channel map information associates an individual program with a PCR value, the presumption is that independent claim 1 must not require "channel map information" to include the PCR value. Appellants assume that the PCR value and the PCR_PID are the same. However, the Commission points out that the PCR value (referenced in claim 2) and the PCR_PID are not the same. See Initial Determination, slip op. at 42 ("[T]he PCR_PID field constitutes a 'packet identifier.' The Program Clock Reference values identified by the PCR_PID constitute a datastream of program specific information that relates to a particular program."). The reply brief does not disagree. We conclude that claim 2 states an additional limitation beyond the claim limitations of independent claim 1.

Likewise, claim 10, which depends from claim 1, requires that the

channel map information further associates a datastream type indicator

with an individual packetized datastream, said datastream type indicator identifying whether said individual packetized datastream contains at least one of a) audio information, and b) video information.
1. **Construction of "channel region"**

Resolution of the meaning of this claim term requires a determination of what area the channel region encompasses in the claimed thin film transistor. Plaintiff asks the court to construe the term to mean "an area--labeled 79 in figure 6H of the '463 patent--between the source and drain regions through which the current path between the source and drain electrodes is formed; the channel region includes but is not limited to the current path between the source and drain electrodes." In other words, plaintiff would have the court define the channel region as including the entire area of semiconductor material between the source and drain regions. It bases its proposed construction in part on the court's construction of the term in Acer, addressing the '941 patent, which has the same specification as the '463 patent. Defendants do not propose a specific definition for the term channel region and instead focus on identifying where the channel region would be located in the accused products.

A few initial matters deserve mention. Plaintiff's proposed construction includes a definition of channel agreed to by the parties in Acer, namely "the current path between the source and drain electrodes." Although defendants challenge the construction in their reply brief, dkt. # 321 at 9-18, they do not ask the court to construe the term "channel" and I will not do so. I am not convinced that construction of the term "channel" is necessary to resolve the parties' dispute, which relates to identifying where the channel forms in the accused products, that is, the channel region, as opposed to the channel itself.

Plaintiff also would have the court specifically define the channel region as the area between the source and drain regions, as the court did in Acer. All but two of the independent claims of the '463 patent describe the channel region as being "between" the source and drain regions. Figure 6H also labels the space between the source and drain regions as the channel region. However, it seems unnecessary to construe the term channel region as meaning the area located between the source and drain regions, when independent claims 1, 5, 12 and 13 of the patent specify that the channel region is between the source and drain regions, when independent claims 1, 5, 12 and 13 of the patent specify that the channel region is between the source and drain regions. Construing channel region to include this same language would make the explicit limitation in claims 1, 5, 12 and 13 superfluous. Further, because claims 8 and 14 do not state that the channel region is between the source and drain regions, construing channel region more specifically may add an unintended limitation to claims 8 and 14. Finally, although Figure 6H depicts the channel region between the source and drain regions, the specification makes clear that this is only a preferred embodiment of the invention. Golight, 355 F.3d at 1331 ("limitations from the specification are not to be read into the claims").

Plaintiff's proposed construction of "channel region" would include the vertical path that the electrical current takes from the source region to the channel and then back up to the drain region. Defendants contend that the channel region consists only of the bottom portion of the area that runs along the gate electrode where the channel is formed. According to defendants, the channel region in the accused products is the AL layer, a narrow layer (about 20 nanometers thick) of high-quality semiconductor material immediately above the gate insulation layers. The AL layer is not in contact with the source and drain regions because a separate protective layer (the AH layer) lies between the AL layer and the source and drain regions. Although plaintiff agrees that the accused products have both an AL and AH layer, it contends that nothing in the '463 patent limits the channel region to one layer and that together, the AH and AL layers constitute the channel region in the accused products.

I agree with plaintiff that nothing in the claim language or specification indicates that the channel region should be limited to one layer of semiconductor material. I am not persuaded by defendants' argument that the patent specification's reference to a semiconductive layer (singular) means that the channel region can never consist of two layers (plural). Neither the
patent claims nor the specification includes such a limitation. The patent also does not define the extent of the area making up the channel region. However, as the court concluded in Acer, it seems apparent that the channel region must at least include the channel itself. The parties agree that the channel is at least a layer of semiconductor material along the gate insulating layer that is rendered conductive by the gate electrode. It also is undisputed that when a voltage is applied to the gate electrodes of a thin film transistor, electric charge flows from the source region through the channel region to the drain region. Therefore, as the court did in Acer, I will construe the term channel region to mean an area that includes but is not limited to the channel.

Defendants attempt to distinguish the channel region in the accused products on the grounds that the AH layer, which is the layer in contact with the source and drain regions, is a lower quality semiconductor material that adds resistance and degrades the performance of the thin film transistor. However, it is undisputed that in the accused products, current flows through both the AH and AL layer from the source region to the drain region. Whether that current is slowed or impeded by an intermediate layer is irrelevant. Nothing in the '463 patent requires the claimed channel region to transmit current without an intermediate layer degrading the overall performance. In fact, the specification does not contain any discussion of the differences between a single layer and a multiple layer channel region. If the patent intended the claimed channel region to maximize current flow or conductivity by using only one high quality layer of material in the channel region, it would have contained some discussion on the matter. Also irrelevant is defendants' claim that manufacturing the AL layer takes significantly more time than manufacturing the AH layer. The patent is silent with respect to the desired speed at which the channel region should be manufactured.

In sum, I decline to limit the term "channel region" by adding performance and manufacturing related requirements not claimed by the patent. Therefore, plaintiff is entitled to summary judgment with respect to whether the accused products satisfy the requirement in claims 1-7 and 12-13 that the channel region be in contact with the source and drain regions.

B. "Operator" and "Channel Select Designation"

Many claims in the '952 patent use the word "operator" together with the phrase "channel select designation." It appears, for example, in claim 11 as follows:

A system for controlling a television receiver capable of tuning from a multi-channel input a television channel corresponding to a preassigned channel tuning designation upon receipt of a channel tuning control signal, the system comprising:

memory means for storing at least one operator-assigned channel select designation for at least one of said channel tuning designations;

operator-actuated control means for generating a control output signal comprising one of (a) a first data set representative of a desired channel select designation for one of said channel tuning designations, and (b) a second data set representative of a desired viewing channel identified by an operator selected one of said channel select designations;

processor means for receiving said control output signal from operator-actuated control means, and upon receipt of said first data set, causing said memory means to store said desired channel select designation as corresponding to said one channel tuning designation, and upon receipt of said second data set, retrieving from said memory means the one of said channel tuning designations corresponding to said operator selected channel select designation, and generating said channel tuning control signal to correspond to said one channel tuning designation;

wherein said memory means includes means for initially storing a channel select designation for each of said channel tuning designations which is identical thereto;

said operator-actuated control means including means for generating a memory clear signal;

said processor means including means for receiving said memory clear signal, and in response thereto, clearing said
memory and restoring therein said channel select designation for each of said channel tuning designations which is identical thereto.

(Doc. # 1, Exh. A at col. 18 (emphasis added)).

Beery contends - as he did during the Gemstar litigation - that a "channel select designation" is a control signal for picking a channel tuning designation which may be programmed into memory by a viewer, or by someone else, such as the cable service operator. In this manner, Beery argues that the term "operator" when used with the phrase "channel select designation" includes not only a person actually operating the system, such as the viewer, but also third parties such as cable service providers.

Thomson argues that proper definition of the phrase "channel select designation" was established by the courts during the Gemstar litigation and must therefore be limited to a television control system that allows the operator, the viewer, to program his or her own selected labels for tuning a television receiver to a television channel by the operator or another viewer. Thomson explains that this definition applies to the phrase "channel select designation" in all its various forms including, "operator-assigned channel select designation" and "operator selected channel select designation" and "desired channel select designation."

The prior conclusion, supra, § VIA, that collateral estoppel does not preclude construction of the '952 patent claim language in this case does not mean that the Gemstar courts' claim construction must be rejected; it simply means that this Court is not required to accept it under the doctrine of collateral estoppel. Thus, the Gemstar courts' claim construction provides insight into the proper construction of the phrase "channel select designation," at least to the extent that the '952 patent claims use this phrase in the same manner as the '734 patent. This it certainly does, and Beery seems to acknowledge this through his recognition that the '952 patent "includes the text of the '734 patent ...." (Doc. # 192 at 8).

Beery, however, further asserts that the '952 patent includes "the additional text in the '947 [patent], and many new claims present in neither the '734 nor the '947 [patents]." Id. He argues, "Thomson attempts to shoe-horn the '947 and '952 into the '734, as though the '952 never existed." (Doc. # 268 at 7). This contention is well taken.

The question is whether the '952 patent claim language reaches beyond the text of the '734 patent sufficient to justify Beery's expansion of the phrase "channel select designation" to include a channel tuning designation by a viewer or someone else, such as a cable operator. The phrase "channel select designation" as it appears in the '952 patent claims must be understood to include tuning designation by operators, viewers, or third-parties like cable television service providers. Looking first to the claim language, little clue is given to whether the phrase "channel select designation" only includes operators or viewers who enter tuning designations. This is because the phrase is conjoined with other terms such as "desired channel select designation" (claim 5) or "operator-assigned channel select designation" (claim 11) or "operator selected channel select designation" (claim 30). Reading these phrases only in the context of their surrounding claim language does not provide any meaningful guidepost to its meaning. Consequently, the specification must be consulted. See Zebco Corp., 175 F.3d at 990 (and cases cited therein).

The '952 patent specification describes a broader array of inventions incorporating the tune-by-label function than the '734 patent describes. One such invention involves programming by a cable service provider. The '952 patent specification states:

A further alternative to programming the control system through a data port is to program the system through the cable itself. Such an alternative might be useful, for example, where the cable service company itself wishes to program its subscriber's control systems to match the designation it uses for channels which it provides, or the designations used by local newspapers in providing program information. One cable channel may be reserved for transmitting the necessary data. The control system may be made responsive to such channel either on a periodic basis, or upon receiving an instruction program itself from the incoming data stream.

One cable provider may wish to provide multiple programmed series, useful for example where a cable provider serves an area covered by newspapers using different designations in their television listings. While this approach can be implemented in a number of ways, one possibility is to reserve a separate cable channel for each channel designation series. This will in fact enable the user to select the series desired, by tuning to the appropriate channel for programming of the control unit.
(Doc. # 1, Exh. A at col. 13, ll. 13-33).

To accept Thomson's construction and limit the "channel select designation" to operators and viewers, the Court would need to overlook this descriptive language in the specification. Because this explanation illuminates how a cable service provider can program its customers' television control systems with the cable provider's own channel select designations, the specification supports Beery's construction of this phrase. Both the absence of limiting terms in the claim language and this description in specification were sufficient to place a reader on notice that the phrase "channel select designation" was not limited to operators and viewers but also included third parties such as cable service providers. Cf. Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1311 (Fed. Cir. 1999)(seemingly identical claim terms not interpreted same in light of specification and prosecution history).

Accordingly, the phrase "channel select designation" when combined with the word "operator" refers to a control signal for picking a channel tuning designation which may be programmed into memory by a viewer, or by someone else, such as the cable service operator.

4. Claim 10: "channels" "Channels" is construed to mean "communication pathways, each having a pre-assigned frequency, over which cellular telecommunications signals are carried."

2. Character-based Output Device

The phrase "character-based output device" means a device that processes data in the form of characters. It includes devices that process characters even though they may, at times, process data in the form of a bit map.

4. Character-based Representation of Said Color Image

The phrase "character-based representation of said color image" means that the representation is comprised of an array of characters.

5. characteristic

The term "characteristic" appears in claim 11 of the '345 patent. The plaintiff's proposed construction is "a distinguishing feature of a work, such as, beats per minute, length, resolution, artist name, song name, play count or genre." The defendant's counter-construction is "a property that can be determined by analyzing a recording (such as beats per minute, length, or video resolution), as opposed to information about a work such as "artist name" or "song name." After reviewing the briefs and the arguments of the parties, the court construes the term "characteristic" as "a distinguishing feature of a work."
F. Characteristic Impedance

Dependent Claim 15 claims: "The phase shift assembly as claimed in claim 1, wherein the at least first and second stripline sections each have a defined characteristic impedance." (Id., Claim 15, Col. 7, ll. 10-13 (emphasis added).) While Kathrein argues that "characteristic impedance" should be given its ordinary and customary meaning of a "property of a radio-frequency transmission line that is primarily determined by the geometry of the transmission line" (Pl.'s Claim Construction Br. 14), RYMSA contends that the construction of the term "characteristic impedance" should be consistent with the parties' agreed construction of the term "impedance values," i.e., "amounts of opposition to the flow of electric current" (Defs.' Claim Construction Br. 29-30; Notice Re: Undisputed Claim Terms, Ex. 1, Undisputed Claim Terms for '130 Patent, at 2).

The Court agrees with RYMSA that the proper definition of "characteristic impedance" must be consistent with the construction of the term "impedance values" as it is used in Claim 2 of the '130 Patent. Claim terms are normally used consistently throughout a patent, therefore the usage of a term in one claim can often illuminate the meaning of the same term in other claims. Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001). Thus, "impedance" should have the same or similar meaning in every phrase in which it appears.

In support of its construction, Kathrein relies a dictionary's definition of "characteristic impedance" as "a property of antenna transmission lines that is determined primarily by the diameter of the conductors and the spacing between them." (Pl.'s Claim Construction Br. 14, Ex. D, Modern Dictionary of Electronics 111 (7th ed. 1999).) In response, RYMSA argues that because transmission line geometry affects various physical and electromagnetic properties, a construction hinging on geometry may encompass a myriad of other unspecified properties. (Defs.' Claim Construction Br. 29-30.)

The Court finds Kathrein's definition problematic. Kathrein's dictionary definition of characteristic impedance includes reference to the spacing between the conductors and their diameter. (Id.) However, Kathrein has not explained how this is necessarily equivalent to the "geometry" of the transmission line, the phrase it uses in its definition of "characteristic impedance."

RYMSA's proffered construction of characteristic impedance is "the existing amount of opposition to the flow of electric current of a stripline." (Defs.' Claim Construction Br. at 30.) The Court finds RYMSA's use of the phrase "of a stripline" redundant when read in the context of the claim. Because the claim language states that each stripline has a defined characteristic impedance, it is unnecessary to add the descriptor "of a stripline." Further, the term "existing" by itself does not explain to a jury how "impedance value" differs from "characteristic impedance" because the latter term would be defined as "the existing impedance value."

The definition of characteristic impedance is closely related to, but not the same, as the definition of "impedance value." The parties agree that the definition of impedance values is "amounts of opposition to the flow of electric current." An impedance value is a calculable number that represents characteristic impedance. Characteristic impedance, on the other hand, is the amount of opposition to the flow of current that exists at any point as the electrical signal moves down a transmission line. (Id. defining characteristic impedance as "[t]he ratio of voltage to current at every point along a transmission line on which there are no standing waves"). Generally speaking, it could differ at different points. However, in the context of Claim 15, the Court's construction of "characteristic impedance" reads: "The phase shift assembly as claimed in claim 1, wherein the at least first and second stripline sections each have a defined [amount of opposition to the flow of current that exists at any point as the electrical signal moves down a transmission line]."

The Court adopts Defendants' construction of "loop characteristic parameters" as "values representing the electronic characteristics of the particular wire loop." The only dispute here is that Plaintiff's argue for the language "a function of" instead of "representing," so Plaintiff's proposed construction reads "values that are a function of the electronic characteristics of the particular wire loop. Plaintiff supports its construction with a citation to the specification. See '323
("Prior to initiating transport of modulated data over the loop 220, signals are exchanged over the loop 220 between the COT unit 232 and the CPE unit 242 to adapt the ADSL units to the electronic characteristics of the particular wire loop 220. For example, loop loss characteristics, which are a function of loop length, wire gauge, wire composition, and other factors, are exchanged. This exchange of information is often referred to as handshaking.") (emphasis added). But Plaintiff is mischaracterizing this language in the specification. The portion of the specification upon which Plaintiff relies explains that the electronic characteristics themselves are a "function" of the physical properties of the wire, such as "loop length, wire gauge, [and] wire composition"; it does not state, as Plaintiff argues, that "loop characteristic parameters" are a "function of" the electronic characteristics.

Therefore, since Plaintiff's reliance on the intrinsic record is misplaced, there is no clear support for either "a function of" or "representing" in the intrinsic record. However, Defendants use of "representing" is consistent with the plain meaning of a "parameter" according to various dictionary definitions. See Merriam-Webster's Collegiate Dictionary 898 (11th ed. 2006) (defining "parameter" as "something represented by a parameter: a characteristic element") (emphasis added); Webster's Third New International Dictionary 1638 (Merriam-Webster Inc., 1993) (defining "parameter" as "an arbitrary constant characterizing by each of its values some member of a system (as of expressions, curves, surfaces, functions) <we now develop an equation which, for suitable choice of a ~, will represent either a parabola, an ellipse, or a hyperbola—School Mathematics Study Group>") (emphasis added). So the Court concludes that "loop characteristic parameters" should be construed as "values representing the electronic characteristics of the particular wire loop."
physical properties. The specification explains that the relevant data includes "[o]verhead data of the condition, characteristics, status, and the like, of the individual blocks," including "an indication of how many times the block has been programmed and erased, voltage levels to be used for programming and/or erasing the block, whether the block is defective or not, and, if so, an address of a substitute good block, and the like." Id., col. 2, Ins. 56-63. Later, the specification distinguishes this type of overhead data from the type that may be stored with user data, explaining that "the overhead information that is stored in a block along with a sector of data is limited to information about the data itself and does not include physical overhead information about the block or its operation," id., col. 13, Ins. 61-64, while "information about the physical block is stored in another block," id., col. 14, Ins. 6-7. Additional examples of "this type of information about the physical block" include "experience cycles, numbers of pulse or voltages required to program or erase the block of cells, defects within the block, and like information," "flags including an indication that the user data block is a good one," voltage for programming or erasing the user data block and data indicating the wear of the user data block, id., col. 14, Ins. 1-4, 35-47, Fig. 9.

One example in the specification is silent about whether the "characteristic" involves a physical characteristic of the block. Figure 10 illustrates "an overhead record for a user data block that has exceeded its useful lifetime." Id., col. 14, Ins. 66-67. The figure shows a block of data containing "FLAGS," and "SPARE UNIT, BLOCK ADDRESS." The specification explains that the "SPARE UNIT, BLOCK ADDRESS" portion of Figure 10 specifies "the spare block's address." The specification says nothing about whether the address must be physical.

Although logical block addressing does not fit well in any of the three possible groups of data, it must fit somewhere, which means the question is where it fits best. I conclude that the best fit is with the group including "characteristics of" the blocks. Although the specification emphasizes that the data tends to relate to physical characteristics of the block, it refers to "addresses" generally in its example and does not suggest any reason for excluding logical addresses, which are at least indirectly about the physical block (each logical address is ultimately tied to a physical location when the controller "translate[s the] logical block address to a physical one." Id., col. 18, Ln. 30.

Moreover, treating logical block addresses like physical ones makes sense in light of the stated purpose of the invention, which includes avoiding "frequent rewriting of the overhead data, each time the user data is rewritten into the block" and "reduce[ing] the amount of time necessary to access and read the block overhead data." Id., col. 3, Ins. 3-7. Because a logical address is tied to a piece of user data in much the way a physical address would be and enjoys the same sort of stability, it would make sense to store logical addresses outside the user data block. I conclude that both logical and physical addresses are "characteristics of" user data blocks.

Characterized as being a member of one category selected from a plurality of categories and Characterized in the display as being a member of a category selected from a plurality of categories

Sklar contends one of ordinary skill in the art reading the claims, the specification, and the file history would understand the terms have their plain ordinary meaning. If the terms require construction, Sklar proposes the terms should mean "a category is a collection of items having a common characteristic, and being a member of one category is one item in one category where more than one category exists." The Court, however, modifies Sklar's proposed construction and construes the terms to mean "one characteristic of an item is that it is a member of at least one category, where multiple categories exist." Microsoft argues that the terms should be construed to mean "the method identifies each item as being a member of one category and as not being a member of one or more other categories. A category is a collection of items having a common characteristic, such as 'electric' cars available for sale or web pages with the term 'Oakland Raiders.'" Microsoft seeks to add the limitation that items in categories have common characteristics and that each item cannot be a member of more than one category. Microsoft claims its interpretation is consistent with the embodiment described in Fig. 11 of the patents-in-suit. Microsoft attempts to incorporate unnecessary limitations into the claims through a restrictive definition of "category," requiring that each item in the category have a common characteristic. Microsoft points to the specification as providing a basis for its interpretation: "Using the category labels and item labels, a display area can efficiently be populated, while giving the user an indication of the overall organization of the data in the database." '843 patent, Col. 11:8-10 (emphasis added). The specification, however, describes categories in more detail than Microsoft alludes to: "each label represents either an item or a category, where an item label represents an individual
item, while a category label represents an entire category of items." '843 patent, Col. 4: 46-48 (emphasis added). There are examples in the patents-in-suit of items being grouped together based on a common characteristic and examples of items being grouped together simply because they are displayed on a map in close proximity. '843 patent, Col. 7:48-49. There is no reason to incorporate the limitations of one embodiment and not the other when the claim language requires neither. Microsoft seeks to add the limitation that an item be "characterized" as being a member of only one category and as not being a member of one or more other categories. The claims do not require that an item is a member of only one category. To the contrary, the patents-in-suit teach that an item can be in more than one category. '843 patent, Col. 7: 38-41 ("the system could be designed to allow a record to be in more than one cluster"). Microsoft has provided no viable argument requiring an item to belong in one category and no others. Accordingly, the Court construes this term as set forth above.

The main issue before the district court involved whether claim 1 should be construed such that the "first monitor" and "second monitor" perform their ascribed functions simultaneously. Claim 1 of the '453 patent, in relevant part, requires:

A photographic self-portrait installation comprising a video-photo installation including a video-camera for viewing a subject user, characterized by a first monitor for reproducing a real-time image of the user as a background on the monitor screen, . . . [and] a second monitor for displaying a composite of a user-created frozen real-time image as a background and at least one user-selected computer-digitised image from the memory store as a foreground, . . .

The district court set forth its partial claim construction in a verbal ruling during an October 18, 2001, hearing on cross-motions for summary judgment. At that hearing, the court stated its conclusion that "the claim limitations require two monitors which display different images at the same time: a real-time image on the first monitor and a frozen image on the second monitor." In a subsequent order dated October 31, 2001, the district court granted summary judgment as to the patent infringement claim in favor of Foto Fantasy "for the reasons stated by the Court in its rulings during the October 18, 2001 hearing."

Photomagic has timely appealed to this court, principally challenging the district court's claim construction. We have jurisdiction pursuant to 28 U.S.C. § 1295(a)(1).

II

A

This court reviews without deference a district court's grant of summary judgment. Cortland Line Co. v. Orvis Co., 203 F.3d 1351, 1355 (Fed. Cir. 2000); Ethicon Endo-Surgery, Inc. v. United States Surgical Corp., 149 F.3d 1309, 1315, 47 USPQ2d 1272, 1275 (Fed. Cir. 1998). A district court's claim construction is a question of law which we review de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 USPQ2d 1169, 1174 (Fed. Cir. 1998) (en banc).

B

The principal and dispositive issue on appeal involves the district court's partial claim construction, which requires that the first and second monitors display "different images at the same time." Photomagic contends in this appeal that the district court improperly imported a limitation derived from the embodiment described in the specification into claim 1 because the "temporal and functional 'time reference'" limitation at issue has no basis in the claim language or written description.

The district court - relying in part on the written description - concluded that, if claim 1 were not construed such that the claimed "first monitor" and "second monitor" did not perform their functions simultaneously, the second monitor would be rendered superfluous. Thus, to avoid a claim construction in which "the second monitor, in effect, has no function separate from the first," the district court ruled that "in light of the specifications as well as a review of the other claims . . . the claim limitations require two monitors which display different images at the same time: a real image on the first monitor and a
C

This court has frequently described certain fundamental principles governing the process of claim construction. "The starting point for any claim construction must be the claims themselves." Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305, 51 USPQ2d 1161, 1165 (Fed. Cir. 1999). After reviewing the claim language, it is then appropriate for a court to consider the rest of the intrinsic evidence, beginning with the specification and concluding with the prosecution history, if in evidence. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 USPQ2d 1573, 1576 (Fed. Cir. 1996) (citation omitted); Markman v. Westview Instruments, Inc., 52 F.3d 967, 979, 34 USPQ2d 1321, 1329 (Fed. Cir. 1995) (noting rule that claims be read in view of the specification). However, "if the claim language is clear on its face, then [a court's] consideration of the rest of the intrinsic evidence is restricted to determining if a deviation from the clear language of the claims is specified." Interactive Gift Express, Inc. v. Compsure, Inc., 256 F.3d 1323, 1331, 59 USPQ2d 1401, 1406-07 (Fed. Cir. 2001). Finally, we have frequently emphasized the rule that "particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments." Electro Med. Sys. S.A. v. Cooper Life Sci., 34 F.3d 1048, 1054, 32 USPQ2d 1017, 1021 (Fed. Cir. 1994); see also Laitram Corp. v. NEC Corp., 163 F.3d 1342, 1347, 49 USPQ2d 1199, 1203 (Fed. Cir. 1998) ("[A] court may not import limitations from the written description into the claims.").

D

Beginning by considering the claim language, we cannot discern in the express language of claim 1 any requirement that the respective functions of the first and second monitor be performed simultaneously. Nor can we discern any ambiguity or lack of clarity in the language of claim 1 sufficient to necessitate resort to the written description. Accordingly, our consideration of the written description is appropriately restricted "to determining if a deviation from the clear language of the claims is specified." Interactive Gift Express, 256 F.3d at 1331, 59 USPQ2d at 1406-07.

Turning to the specification, we address Foto Fantasy's contention that the language used to describe the claimed invention required the district court to import a temporal limitation. Foto Fantasy relies on language from the written description which states that the claimed invention "gives the user versatile control over its operation and the resultant print, the user being able to select and reselect the real time image to be recorded and to select and reselect the digitized image prior to the ultimate decision to print the resulting montage." Foto Fantasy argues that "in order to achieve these asserted advantages and allow this comparison, the booth must have two monitors, each of which displays a different image, one being the real time image and the other being the frozen composite image." While acknowledging the general rule forbidding the importation of limitations from the description of the preferred embodiment, Foto Fantasy urges application of the narrow exception that states "when the preferred embodiment is described in the specification as the invention itself, the claims are not necessarily entitled to a scope broader than that embodiment" (quoting Modine Mfg. Co. v. United States Int'l Trade Comm'n, 75 F.3d 1545, 1551, 37 USPQ2d 1609, 1612 (Fed. Cir. 1996)).

Footnotes

We find Foto Fantasy's argument unpersuasive. As an initial matter, we find Foto Fantasy's invocation of the exception articulated in Modine inapposite. In Modine, a numerical range necessary to the definition of an indefinite claim limitation was contained in the sole embodiment of the relevant claim described in the specification. 75 F.3d at 1551 (concluding that the ambiguous claim language "relatively small" should be read in light of the numerical range of "about 0.015-0.040 inch" included in the written description). This is not an analogous case. Claim 1 recites a first and a second monitor as well as the ascribed functions of the first and second monitor. We can find nothing in claim 1 that is sufficiently ambiguous or undefined to require us to resort to the written description in construing the claim. See Renishaw PLC v. Marposs Societa per Azioni, 158 F.3d 1243, 1248, 48 USPQ2d 1117, 1121 (Fed. Cir. 1998) ("If we need not rely on a limitation to interpret what the patentee meant by a particular term or phrase in a claim, that limitation is 'extraneous' and cannot constrain the
claim.

2 It is not clear to us that this is a case where the written description is "described as the invention itself." However, because we reject Foto Fantasy's argument on other grounds, we assume, arguendo, that the '453 patent does present such a case. Accordingly, we specifically do not decide the question of whether this is a case "where the patentee describes an embodiment as being the invention itself and not only one way of utilizing it." Autogiro Co. of Am. v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 398, 155 USPQ 697, 703 (Ct. Cl. 1967); see also Modine, 75 F.3d at 1551, 37 USPQ2d at 1612.

Additionally, it appears clear to us that the language relied upon by Foto Fantasy describing the advantage of "versatile control" not only does not require - but fails even to imply - any "comparison" of the real-time and frozen images. A description of the "selection" and "resele action" process precedes the language upon which Foto Fantasy relies. This description explains that "if the frozen montage [i.e., composite image] is acceptable to the user," the user may cause it to be printed by "depressing" the "print button." "If, however, the frozen montage is unacceptable, it can be released and the user can reseselect a montage of acceptable form for subsequent printing." Thus, as described in the specification, the user's determination during the "reselection" process is limited to whether the frozen image is "acceptable" or "unacceptable," not - as Foto Fantasy asserts - whether the frozen image is better or worse than the real-time image. Accordingly, the written description does not support Foto Fantasy's contention that the asserted advantage of "versatile control" or the described "selection and reselection" process requires that the user be able to compare the real-time and frozen images. Thus, we cannot find that the written description provides the necessary "evidence to indicate that . . . limitations must be imported into the claim[] to give meaning to disputed terms." Constant v. Advanced Micro-Devices, Inc., 848 F.2d 1560, 1571, 7 USPQ2d 1057, 1065 (Fed. Cir. 1988); see also Specialty Composites v. Cabot Corp., 845 F.2d 981, 987, 6 USPQ2d 1601, 1605 (Fed. Cir. 1988) ("Where a specification does not require a limitation, that limitation should not be read from the specification into the claims.") (citation omitted).

In sum, we conclude that the language of claim 1 requires only that the apparatus have a first and a second monitor, the first of which "reproduces a real time image of the user as a background on the monitor screen" and the second of which "displays a composite of a user-created frozen real time image as a background and at least one user-selected computer-digitised image from the memory store as a foreground." Neither the claim language or the written description necessitates interpreting the claim to specify the simultaneous performance of these two functions. 3 We therefore hold that the district court erred by ruling that "the claim limitations require two monitors which display different images at the same time."

3 Because claim 1 was drafted using the recognized term of art "comprising" in the transitional language, it is an "open" claim that must be construed as including the recited elements, but not excluding additional, unrecited elements. See generally Georgia-Pacific Corp. v. United States Gypsum Co., 195 F.3d 1322, 1327-28, 52 USPQ2d 1590, 1595 (Fed. Cir. 1999). Thus, there is no basis for concluding that the first and second monitors may not, in addition to performing their ascribed functions, also perform additional functions. Accordingly, the first monitor may - at some time or period of time during operation of the apparatus - perform the function ascribed to the second monitor and vice versa so long as each monitor also performs the functions ascribed to it by the claim.

Finally, we note that Foto Fantasy also urges on appeal that the district court's claim construction was appropriate because it was necessary to prevent invalidity and also that the district court's construction was strongly supported by the '453 patent's prosecution history. The record before us indicates that the district court declined to hear argument on these issues, and the extent to which the district court relied on Foto Fantasy's invalidity and prosecution history arguments - if at all - is not reflected in the record before us. Accordingly, this court's holding is limited to the conclusion that neither the language of
claim 1 nor the written description justified construing the claim to include the limitation that the first and second monitors perform their ascribed functions simultaneously.

1. "characterized in that the B-mode image is displayed within said blood flow display region while said blood flow display region is moved"

Plaintiffs' construction: comprising a B-mode image which is displayed in the blood flow display region while the blood flow display region is moved

Defendant's construction: characterized in that the B-mode image is always displayed in place of the blood flow image within the blood flow display region while the blood flow display region is moved, and the blood flow image is never displayed within the blood flow display region while the region is moved

Plaintiffs' construction of this term is minimal. The only difference between their construction and the term itself is a replacement of the word "characterized" with the word "comprising," an alteration they assert is appropriate given the court of appeals' explanation that "comprising" is synonymous with "including," "containing" and "characterized by." Plts.' Br., dkt. # 52 at 16 (citing Mars v. H.J. Heinz Co., L.P., 377 F.3d 1369, 1376 (Fed. Cir. 2004), and Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997)). However, there is no indication that such a substitution of a less common synonym of "characterized by" is of any value in understanding the meaning of the '294 patent. In effect, plaintiffs are arguing for no construction at all.

On the other hand, defendant seeks to add the limitation to the claim language that, when the blood flow display region is moved, only the B-mode or grayscale image is displayed. In support of its position, defendant relies on the patent specification and several types of extrinsic evidence. Defendant starts with the "Summary of the Invention," which explains that "the B-mode image is displayed in place of the blood flow image while the blood flow display region is moved, and the blood flow image is displayed while the blood flow display region is stopped." '294 pat., col. 1, Ins. 61-65. This statement supports defendant's construction that, when the blood flow display region is moving, only the B-mode image will be displayed. In fact, it is difficult to imagine a less precise explanation of how the patented invention works.

Plaintiffs attempt to rebut defendant's argument with general statements about the importance of avoiding the importation of a preferred embodiment into the claim language. However, that is not what is happening here. The cited passage from the Summary of the Invention was made in the context of a discussion of "the present invention." Therefore, it is appropriate to apply this limitation to the invention as a whole. Verizon Services Corp. v. Vonage Holdings Corp., 503 F.3d 1295, 1308 (Fed. Cir. 2007) ("When a patent thus describes the features of the 'present invention' as a whole, this description limits the scope of the invention."); Honeywell International, Inc., v. ITT Industries, 452 F.3d 1312, 1318 (Fed. Cir. 2006) (written description discussing "this invention" and "the present invention" may limit claim scope); C.R. Bard, Inc. v. United States Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004) ("Statements that describe the invention as a whole are more likely to be found in certain sections of the specification, such as the Summary of the Invention.") Finally, given the unequivocal language of this portion of the specification, it is not necessary to evaluate whether the preferred embodiment or extrinsic evidence support such a limitation as well.

Court's construction: "characterized in that the B-mode image is displayed within said blood flow display region while said blood flow display region is moved" means "characterized in that the B-mode image is always displayed in place of the blood flow image within the blood flow display region while the blood flow display region is moved, and the blood flow image is never displayed within the blood flow display region while the region is moved"

A First Gate Drive Circuit for Charge Pumping a Node
The Court first addresses the term "a first gate drive circuit for charge pumping a node." ST argues that the term should be construed as "a first circuit that drives a power transistor by alternately taking on charge and delivering charge to the gate of the transistor in a repetitive process." Motorola asserts that the term should be construed as "a first charge pump that delivers charge to the gate of the MOS power transistor by shifting the negative side of a first capacitor from a lower voltage to a higher voltage, wherein said capacitor is not an external capacitor."

The Court declines to accept either proposed construction and instead construes the term to mean "a first circuit that drives a power transistor by raising the electrical potential in an additive, charge transfer process in the manner of a pump." First, the Court does not simply replace the term "gate drive circuit" with "charge pump" because of ambiguities that may be added. Motorola admits that it cannot find a dictionary definition for "charge pump," and the Court is not willing to insert a term having unknown boundaries. Therefore, the Court's construction describes the gate drive circuit's function "in the manner of a pump" without exchanging one ambiguous term for another. Second, ST's description of "alternately taking on charge and delivering charge to the gate of the transistor in a repetitive process" is also inadequate. The purpose of the first gate drive circuit is to raise the transistor's electrical potential to an appropriate level, not simply to deliver charge. The Court replaces that part of ST's proposed construction in order to more accurately describe the first gate drive circuit's purpose.

A. Is "charge sink means" a means plus function clause?

The inquiry into the meaning of this claim language begins with examination of whether "charge sink means" describes a means for performing a function under 35 U.S.C. § 112, para. 6 (1988). Under section 112, an inventor may use functional language to describe an invention. However, title 35 limits the scope of a means-plus-function claim to the "corresponding structure, material, or acts described in the specification and equivalents thereof." 35 U.S.C. § 112. The different statutory rule for construing means-plus-function claims requires this court to determine whether this claim which recites some structure falls within the ambit of section 112.

The Federal Circuit has clarified that the recitation of some structure does not remove a claim from the ambit of section 112. Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1536 (Fed. Cir. 1991). This court, however, must still confront the question of how much recitation of structure removes a claim from the interpretive requirements of section 112, paragraph 6.

Several other courts have confronted this issue. In Fairchild Semiconductor Corp. v. Nintendo Co., 1994 U.S. Dist. LEXIS 3853, 30 U.S.P.Q.2D (BNA) 1657 (N.D. Cal.), aff'd, 39 F.3d 1197 (Fed. Cir. 1994) (table), another district court interpreted the language "chute means including a locking means having a detent for engaging said locking recess of said cartridge means to hold said cartridge means in a received position" to include a means-plus-function term. The court first noted that the application used the word "means." Id. at 1660. The court then noted that the word "locking" was unintelligible without reference to a function. While accepting that the claim contained structure such as "a detent," the court nonetheless applied section 112 to the term "locking means." Id.

In AMP, Inc. v. Fujitsu Microelectronics, Inc., 853 F. Supp. 808 (M.D. Pa. 1994), still another district court interpreted "bus solder tail means" to fall outside a means-plus-function format. The court found the words "bus solder tail" described a specific structure rather than a function. Id. at 820.

This court's analysis of the application of § 112 begins with examination of the '485 patent's claim language. The claim expressly uses the term "charge sink means." The word "means" is a significant term of art. The Federal Circuit's decision in Laitram suggests that the use of the word "means" presumptively places one within section 112. 939 F.2d at 1536. Inventors are not likely to use such an important legal term unless they intend to place themselves within the ambit of section 112.

The additional language in element d of claim 1 does not set forth a discernible structure. Instead, this additional language describes the location of the charge sink means, not its structure. For example, element d indicates that the "charge sink means" is "buried within" the semiconductor material and "disposed for receiving excess charge." These additional words identify the location of the charge sink means. They do not provide sufficient structure to overcome the presumption that the inventor intended to invoke the rules of § 112 by using the term "means."
Significantly, even Loral's expert witness described a "charge sink means" as a way of performing a function. The court asked Dr. Barbe to define "charge sink means." Dr. Barbe responded: "It is a way for removing excess charge from the light sensing element which is collecting the charge." Transcript at 211. Loral's own expert and one skilled in the art understood "charge sink means" to describe a function rather than a structure. Transcript at 211-12. In sum, this court determines that the term "charge sink means" falls within the rules of the sixth paragraph of section 112.

Having determined "charge sink means" describes a means-plus-function element, the court turns to interpreting those words with reference to the structure described in the specification. Valmont Indus., Inc. v. Reinke Mfg. Co., 983 F.2d 1039, 1042 (Fed. Cir. 1993). The structure, material or acts described in the specification and equivalents thereof set the bounds of this means-plus-function claim. Id. 1

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
1 However, the final inquiry as to whether an accused element is "an equivalent thereof" is a question of fact. D.M.I., Inc. v. Deere & Co., 755 F.2d 1570, 1575 (Fed. Cir. 1985).

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

The specification of the '485 patent describes and depicts only one charge sink means. Figure 1 shows a region of highly doped semiconductor material, 14, surrounded by a depletion region, 27, created upon application of a bias to the highly doped region of semiconductor material. The specification further describes the charge sink means as a region formed on the surface of a layer of semiconductor material with an epitaxial layer of semiconductor material formed over the top of the charge sink means and first substrate layer.

The specification describes formation of the charge sink region. The first step implants or diffuses an N type impurity into the first layer of P type semiconductor material to form a high conductivity N + type region. Next, additional P type semiconductor material is formed over the first layer to cover the charge sink region. The specification then notes that application of a potential forms a depletion region around the charge sink region.

Loral's expert, Dr. Barbe, as noted earlier, viewed the charge sink means in functional terms. When the court asked Dr. Barbe to describe the structure associated with that function, he testified: "The structure, the basic structure is a -- one embodiment of the structure, which is shown in figure one of the ["674] patent, is a P/N junction, which is created beneath the light sensing element." Transcript at 211-12. In similar terms, he described the charge sink means as the highly doped region, numbered 14 in Figure 1 of the '485 patent, and its associated depletion region. Transcript at 68.

Dr. Barbe agreed that differences in the type of impurities in the semiconductor substrate occur only at the PN junction between region 14 and regions 11 and 12. Dr. Barbe proceeded to testify in argumentative fashion obviously geared to the outcome of litigation. In this vein, he tried to encompass the depletion region within the structure of the charge sink means. He argued that a bias applied to the charge sink region forces electrons out of the surrounding area to form the depletion region. According to Dr. Barbe, this area constitutes structure and is part of the charge sink means. To the contrary, a depletion region exists at any P/N junction regardless of the application of a bias. In the claimed invention, the depletion region functions to receive excess charges flowing out of the light sensing element. Transcript at 105. As conceded by Dr. Barbe, the depletion region is a region influenced by the application of bias, not a region characterized by a different structure. The depletion region is a functional region, not a structural region.

Dr. Bower convincingly underscored this precise point. On several occasions, he stressed that the depletion region is not structure. During direct examination, he specifically stated that the depletion region is not structure. Transcript at 136-37. Dr. Bower explained that the doping of the semiconductor material defines atomic structure. This doping makes the semiconductor material N or P type, Transcript at 137. The free electrons do not obey the boundaries defined by the P and N type materials. Instead they "spill over" the boundary between P and N type material. Id.

During cross-examination, Dr. Bower emphasized that "structures are three-dimensional entities that have geometrical definition that are put into the semiconductor, or built on the semiconductor, and it is applying voltages to those that allow us to cause free carriers to move and congregate in certain areas, or disburse." Transcript at 177. In understanding the structure to be built, one skilled in the art would look to those things that form three-dimensional structures, formed through the use of masks, and processes using those masks. Id. These structures, when given a bias, then function to create depletion
regions. Id. The depletion region is an area defined by the function of the structures. In these areas, the structures exert control over free carriers.

Thus, this court concludes that the specification describes the structure of the charge sink means as a region of semiconductor material doped opposite from its surrounding semiconductor material. The charge sink means does not include its associated depletion region.

Claim 3 specifically describes a charge sink means as a region of opposite conductivity to its surrounding semiconductor material. This specific description of the charge sink means in claim 3 does not suggest that the charge sink means in claim 1 is broader than that of claim 3. In this patent, claim 3 does not describe an invention distinct from claim 1. In other words, the doctrine of claim differentiation does not operate to distinguish the more specific language in claim 3 from the language of claim 1. As the Federal Circuit has noted, the doctrine of claim differentiation cannot override the limitations resulting from application of the rules for interpreting means-plus-function limitations. Laitram, 939 F.2d at 1538. In the '485 patent, claim 3 buttresses this court's reading of claim 1 by describing more specifically the structure of the "charge sink means" as disclosed by the structure in the specification.

XVI. "Charger"

The Court next turns to the term "charger" from claims 9 and 10 of the '925 patent.

A. The Parties' Proposed Constructions

Black & Decker asserts that the term "charger" simply means "charger" and notes that it adopts the plain and ordinary meaning. Bosch argues that the Court should construe the term as "a device that receives the DC output voltage from the first power source and transforms that DC output voltage to a voltage equal to an input voltage of the battery to charge the battery."

B. The Parties' Arguments

Claim 9 of the '925 patent requires a "charger to charge said secondary rechargeable direct current power source from said first power source." Black & Decker contends that "charger" should simply have its plain and ordinary meaning, which Webster's New World College Dictionary, 4th Ed. (1999) provides as "an apparatus used to charge storage batteries." Bosch agrees that the "charger" charges batteries, but seeks to include additional limitations. Bosch, however, fails to point to any portion of the intrinsic record that requires a limitation on the term "charger" beyond its plain and ordinary meaning. The language of the claim itself plainly sets forth the scope of the term "charger" -- an apparatus that charges the secondary rechargeable direct current power source from the first power source. Adopting Bosch's proposed construction would render claim 9 of the '925 patent nonsensical and incorporate limitations into the claim that are not present. Accordingly, the Court adopts Black & Decker's proposed construction of "charger" which is "charger, having its plain and ordinary meaning, which is 'an apparatus used to charge stored batteries.'"
6. "a chassis comprising a front panel"

This term appears in the '408 patent claims 1 and 9. Rackable contends that "a chassis comprising a front panel" means a "frame or housing for the general purpose computer including the main board and including a front panel providing access as claimed." Supermicro asserts that "a chassis comprising a front panel" means "a frame or housing including a front panel."

The essence of the dispute is whether the "chassis" is for a general purpose computer, or whether it is simply any frame or housing. Again, Rackable argues for the narrower, more specific construction, and Supermicro the broad one.

Rackable argues that the claims themselves refer to "the computer" and the various components of the computer, supporting its construction. It further asserts that the specification and the "summary of the invention" explicitly state that the chassis is for a general purpose computer, and not simply any frame or housing. Additionally, Rackable argues that the embodiments support its construction, and demonstrate a chassis built up with certain components, including a main board.

In response, Supermicro argues that Rackable's construction is too limiting. Even if it were a chassis for a computer, Supermicro notes that contrary to Rackable's construction, it should not be construed only as a frame or housing for a "general purpose computer" or server. It argues that Rackable is attempting to import an inappropriate limitation into the term.

The court indicated at the hearing that Rackable's reference to "computer" in its construction of the term was redundant, given the fact that the broader context of the claim is the computer itself. In response to the court's inquiries, Rackable indicated agreement with Supermicro's construction. Because claims must be construed in a manner that avoids such redundancies, the court adopts Supermicro's definition, and construes the term "a chassis comprising a front panel" as a frame or housing including a front panel. See Unique Concepts Inc. v. Brown, 939 F.2d 1558, 1562 (Fed. Cir. 1991) (merging one element into another is improper because it renders claim language redundant).

---

599

A. "chip memory apparatus"

The parties dispute the term "chip memory apparatus," which appears twice in dependent claim 15 (col. 8:13-27) (emphasis added):

15. A semiconductor chip memory apparatus for storage of pre-recorded audio, said memory apparatus adapted for use with a solid state audio player, said apparatus comprising:

   a plurality of memory cells for storing digital data therein;

   address shift register for receiving serial data corresponding to addresses of memory locations; data shift register for outputting serial data read from selected memory locations;

   said chip memory apparatus including a housing, said housing including a graphics display area for inclusion of indicia pertaining to said pre-recorded music; and

   said housing including a hole disposed at an end thereof, whereby said apparatus may be transported by means of a carrying device attached through said hole.

The parties' proposed constructions are shown below:

<table>

<td>inserted into an accompanying audio</td>
</tr>
</tbody>
</table>

- 1073 -
"A device that includes a player, wherein the memory chip is not an audio player.

As mentioned at the claim construction hearing, LSI believes that because "chip memory apparatus" appears in the preamble, it should not be construed. On top of this, LSI contends that the preamble as a whole is not limiting because it merely recites a purpose or intended use for the invention. These arguments are unpersuasive. While the term "chip memory apparatus" does indeed appear in the preamble of claim 15, it also appears in body of the claim. This fact alone distinguishes the Federal Circuit decision cited by LSI, which involved a term that appeared exclusively in the preamble. IMS Tech. Inc. v. Haas Automation, Inc., 206 F.3d 1422, 1434 (Fed. Cir. 2000). Moreover, IMS Tech involved the amorphous term "control apparatus." 206 F.3d at 1434. The term disputed here -- "chip memory apparatus" -- presents concrete questions of whether and to what extent the apparatus should be limited to memory chips. Indeed, this dispute boils down to just that question.

As framed by the parties at oral argument, this construction centers on whether the "chip memory apparatus" can itself be an audio player. SanDisk argues that the "chip memory apparatus" cannot be an audio player. LSI argues the opposite. Thankfully, the claim language provides clear guidance on this issue. The disputed "chip memory apparatus" is found in claims 15 through 19 (see cols. 6:50-8:12, 8:13-45). As described in claim 15, a "chip memory apparatus" is used "for storage of pre-recorded audio, said memory apparatus adapted for use with a solid state audio player" (col. 8:13-15) (emphasis added). This language is notably different from claims 1 through 14, which cover a "memory chip" that is "adapted for insertion into an associated audio player."

These differences between claims 1 through 14 (the "memory chip" claims), and claims 15 through 19 (the "chip memory apparatus" claims) support two presumptions under the doctrine of claim differentiation: (1) a "chip memory apparatus" is not simply a "memory chip" and (2) a "chip memory apparatus" does not need to be "adapted for insertion into" an audio player. Rather, it need only be "adapted for use with" an audio player. As such, SanDisk's proposed construction directly contradicts the language of the claims.

Finally, nothing in the language of claim 15 prevents the "chip memory apparatus" from itself being an audio player. This does not mean, however, that the audio player mentioned in claim 15 can be the apparatus itself. Recall that the preamble described the "chip memory apparatus" as "adapted for use with a solid state audio player" (col. 8:13-16) (emphasis added). A person having ordinary skill in the art at the time the patent application was filed would have understood this language to mean that the "chip memory apparatus" and the audio player were not one and the same. Rather, the "chip memory apparatus" must be adapted for use with a separate audio player.

In sum, whether or not the "chip memory apparatus" can itself be an audio player is besides the point. Even if it was, this would not satisfy the limitation in claim 15 that the "chip memory apparatus" be adapted for use with a separate audio player. As such, the term "chip memory apparatus" is construed to be "a device that includes memory on a semiconductor chip that is adapted for use with a separate audio player."

b. Choosing a dynamic model for the plant from a group of specimen sequenced-dynamic-factory models

The parties dispute the limitation "choosing a dynamic model for the plant from a group of specimen sequenced-dynamic-factory models." ITI submits that this phrase should be interpreted to mean selecting a representation or simulation that is marked by change of a manufacturing plant that has fabrication sequences and which makes a variety of products using different machines. Defendants suggest that the Court should construe the limitation as "selecting a dynamic model from a group of models. Creating or selecting data or data files that describe the manufacturing plant (for example, process flows, products, equipment, residence times, yields, equipment failure or repair rates, setup time requirements, start rates, lot sizes, dispatch schemes, or initial positions of lots) is not 'choosing a dynamic model.'"

The parties agree that the ordinary meaning of "dynamic model" is a representation or simulation marked by change. It is unclear why defendants do not use this definition in their proposed construction, but it is sufficient that they acknowledge the agreement in their brief. See Defs' Brief at 9. The primary difference between the parties' proffered definitions seems to
be that defendants wish to insert an exclusion to show that there is a distinction between the model itself and the data files that go into the model. ITI, in contrast, maintains that although a model is chosen, that model has certain data associated with it, and the claim does not exclude the possibility of creating or selecting data. During oral argument, defendants clarified that they are not asserting that the invention cannot use data files, but are simply arguing that the selection of data files in a particular model is not the act of choosing a model from a group of models for a particular simulation. Defendants contend that the specification and prosecution history confirm their reading of the claim language.

According to the specification, the invention provides a standard class of specimen models for distributed factories which have fabrication sequences. Members of this class are called sequenced-dynamic-factory (SDF) models. The class is defined by sets of fundamental rules for the definitions of fabrication sequence, queues, scheduling rules, batching, set-up times, yield, reliability, and other variables. A choice of rules from each set defines an individual model... An individual model from the class above is chosen; the choice is based upon the match between the dynamic characteristics of the model and those of the factory.

U.S. Patent No. 4,796,194. col. 5, lines 34-47.

Turning to the prosecution history, claim 18 was amended to specify that a dynamic model is chosen "from a group of specimen sequenced-dynamic-factory models." Feb. 22, 1988 Amendments at 2, Defs' Ex. B. The inventor, Robert Atherton, explained that the change was made to distinguish the present invention from the model used in prior art, specifically, the Dayhoff-Atherton paper. See id. at 4. He explained that the model depicted in the Dayhoff-Atherton paper was "a single, fixed model which is used with different fabrication processes. The fixed model is used with different manufacturing processes by providing a data file that is specific to a particular manufacturing process... There is no selection from a group of specimen sequenced-dynamic-factory models." Id. In Atherton's affidavit attached to the amendments, he further elaborates on the Dayhoff-Atherton model:

In that model "the entire manufacturing plant [is] represented as a queueing network." The queueing network is discussed further in terms of "servers," "service times," and a network of "multiple deterministic paths." The factory is described to the model in terms of the parameters of the queueing network called out in a nomenclature of factory terms. Examples include "residence times, yields, equipment failure or repair rates, setup time requirements, start rates, lot sizes."

Atherton Decl. P 4, Defs' Ex. C.

The Court does not believe that either the specification or prosecution history requires defendants' reading of the limitation. The distinction Atherton made between the current invention and the Dayhoff-Atherton model involved selecting a model from a group of available models as opposed to simply selecting different data for a single model. The specification similarly makes it clear that a model is chosen based on a match between the characteristics of the model and the factory. Defendants' exclusion is unnecessary and an issue for infringement, not claim construction. Taking both sides' positions into account, the Court adopts the following construction: selecting a representation or simulation that is marked by change of a manufacturing plant from a group of such models.

ITI contends that the proper construction of the limitation "the chosen factory-specific model containing descriptions of the dynamic interactions of part lots and machines in the plant" is: the model chosen describes how groups of like parts and machines act upon each other in a real plant. Defendants' position is that the language should be interpreted as: the chosen model contains descriptions of how the type and order of process steps change during the time the model is run.

Defendants maintain that ITI's construction is flawed because it lacks any reference to the "dynamic" nature of the interactions. They emphasize that the dynamic interactions between part lots and machines arise due to changes in the path of the lots through the machines in the factory, i.e., changes in fabrication sequences. The Court agrees with defendants'
reasoning. But defendants' interpretation incorporates the "type and order" language that the Court previously rejected in the context of defining "fabrication sequences." In their response brief, defendants suggest that "dynamic interactions" means changes in the way that the part lots and machines act upon one another.Defs' Resp. at 22. The Court believes this sentence best describes how someone skilled in the technology would interpret the ordinary and customary meaning of the phrase. Incorporating the meaning of "lots" - the specification states that "lots are composed of like parts and follow a fabrication-sequence," U.S. Patent No. 4,796,194, col. 10, lines 66-68 - the Court construes the limitation to mean: the chosen model contains descriptions of changes in the way that groups of like parts and machines act upon one another.

602

a. Cinematic Work

The parties' first disagreement is over the meaning of "cinematic work." The defendants argue that a cinematic work must be an entire motion picture, not just a portion as Bloomstein contends. The defendants reason that the Bloomstein claims' focus on efficiency and periodic references to dubbing foreign films supports the interpretation that the invention must apply to the entire film.

The most applicable plain meaning of a "work" is "something produced by the exercise of creative talent or expenditure of creative effort: artistic production." Webster's New Collegiate Dictionary 1350 (1977). This definition does not clearly limit an artistic work to the entire artistic endeavor. Furthermore, even if the claims should be limited to the context of dubbing a foreign language to a native one, it is possible that the process described in the claims would be applied to dub only portions of the motion picture, leaving other portions in the unaltered language and appearance. See Joint Memorandum, Ex. A at column 8:12-15, column 12:28-32. In light of the plain language of the claims and specifications, the court determines that "cinematic work" is not limited to an entire motion picture, but may be only a portion of a motion picture.

603

The parties' proposed constructions raise two central points of contention: (1) whether the board must be electrically insulated, and (2) whether the board must include conductive paths located on or within the board. DPS urges the Court to adopt both limitations. PDI argues for neither.

In accordance with the principles explained above, the Court begins its analysis by looking at the claim language. The only reference to the term "circuit board" is found in claim 1 of the '516 patent. Claim 1 provides in full:

1. A branch circuit monitor for monitoring parameters of power on each of a plurality of branch circuits extending from a panel board or circuit breaker box, said panel board or circuit breaker box including a plurality of circuit breakers arranged to distribute power from a main line that is terminated within the panel board or circuit breaker box to a plurality of branch circuits, comprising:

   a plurality of non-contact current sensors arranged to monitor currents in wires of branch circuits extending from said panel board or circuit breaker box, said non-contact current sensors surrounding said branch circuit wires; and

   a controller module,

   wherein the controller module is connected to an output of the non-contact current sensors, and wherein the controller module is arranged to process, for each of said branch circuits, currents measured by the non-contact current sensors, and

   wherein said non-contact sensors are mounted on a circuit board positioned near to said panel board or circuit breaker box.

'516 Patent, col. 4, line 52 to col. 5, line 5. The specification does little to expound on the term "circuit board," other than to describe the preferred embodiment as a "printed circuit board." See '516 Patent, col. 4, lines 15-16.
The prosecution history gives some guidance. A claim in the original patent application recited "printed circuit board," however, in a Preliminary Amendment Before Examination, the applicant amended the term to read "circuit board." DPS Memo. in Supp., Ex. M, at 2 (Oct. 18, 2000). The applicant then distinguished a prior art patent by explaining that the prior art "does not disclose or suggest . . . mounting of the non-contact branch circuit current sensors on a separate circuit board." Id. It appears, therefore, that the applicant intended the term "circuit board" to be construed to include more than just printed circuit boards.

Based on the intrinsic evidence in this case, it is appropriate to consider extrinsic evidence to determine what a person of ordinary skill in the art would understand "circuit board" to mean in 2000, on the effective filing date of the application. Phillips, 415 F.3d at 1318. The Court first considers the proposed limitation requiring the board to be insulated. The majority of the definitions presented by the parties require the board to be electrically insulated in some way, and the Court finds that a person with skill in the art would understand "circuit board" to mean an "insulated board." PDI cites two definitions that lack the word "insulated." PDI Resp. 9. Both definitions, however, require a material upon which "chips" or "printed or integrated circuits" can be mounted or installed, which would require some form of electrical insulation.

To support its argument, PDI relies on an article that describes the use of metal circuit boards. See PDI Resp. 10-11. While a metal substrate can be used in a circuit board, even the example cited by PDI shows a metal substrate that is electrically insulated. See PDI Resp. 11 (stating that "[i]nsulated metal substrates have been in use for thirty years"). The Court's construction does not exclude metal circuit boards by requiring the board to be insulated. It merely requires the board, whether it has a metal substrate or not, to be electrically insulated in some way, such as by having an insulating layer, so that electrical components can be mounted on the board and interconnected to form a circuit.

Next, the Court considers the limitation requiring the board to include conductive paths located on or within the board. To begin, the Court finds that it would be inappropriate to import the "printed" limitation found in the preferred embodiment into the claim term "circuit board." See In re Am. Acad. of Sci. & Tech. Ctr., 367 F.3d 1359, 1369 (Fed. Cir. 2004) ("We have cautioned against reading limitations into a claim from the preferred embodiment described in the specification, even if it is the only embodiment described, absent clear disclaimer in the specification."). It is particularly inappropriate given that the word "printed" was removed from the claim language during prosecution, apparently broadening the claim.

While the parties appear to agree that printed circuit boards have conductive paths located on or within the board, the more appropriate question here is whether the term "circuit board" must be interpreted to include only boards with such conductive paths. While the Court recognizes that most circuit boards do have such paths, the Court finds that the term "circuit board" should not be limited only to boards having conductive paths on or through the board. For example, a perf board may have no such conductive paths, but still fit within the Court's construction of "circuit board." Further, the majority of the definitions cited by the parties do not include the conductive path limitation. Accordingly, the Court finds it inappropriate to impose such a limitation on the term "circuit board."

IV. Conclusion

For the reasons stated above, the Court construes "circuit board" to mean "an insulated board on which electrical components are mounted and interconnected to form a circuit."

(a) Claim No. 1 -- Disputed Elements

The key issue is whether this independent claim must be construed in light of Section 112, para. 6. Just about every decision I must make hinges on that determination. I conclude that Claim Number 1 is not a means-plus-function claim. However, I prefer to follow the same format as with the two other patents, and will therefore address myself to the disputed limitations seriatim.

(i) A computer system comprising a plurality of processing elements and a message router in which: (A) each processing element for generating messages, each message comprising an address portion comprising a series of address elements and
a data portion comprising at least one data element, each processing element including a message transfer circuit for transmitting messages over said message router and for receiving messages from said router, said message transfer circuit transmitting each message by serially transmitting address elements and a data element thereof and receiving a message by serially receiving at least a data element thereof;

The first and most important thing to note about this limitation is that it refers to a computer system consisting of certain hardware (two or more processors and a message router), not to a process (wormhole routing). To that extent, IBM is correct: TM has not patented wormhole routing, but rather a system for accomplishing that result. Of course, equivalents of that system will also infringe the patent, but that is a question best left for another day.

Each processing unit in the system -- which everyone agrees is any processor that can generate messages -- is used to generate messages. Each message consists of an address portion and a data portion. There can be as little as one bit of data in the data portion, but the address portion must consist of multiple bits. The limitation does not require that the address consist of just one element; any such construction is contradicted by both the plain meaning of the language used in the limitation (a "series of address elements") and the fact that a later dependent claim (Claim 6) requires that "each address element in each said message constitutes one bit."

The processor must contain a message transfer circuit which can both send and receive messages to and from the message router. The transfer circuit sends messages by serially transmitting the address elements and any data element (serially meaning in sequence, one element after another). It receives messages by serially receiving at least the data portion of the message (this is because the address gradually gets stripped off the head of the message as it moves through the system, so the last processor in line will not receive any portion of the address).

IBM suggests that the use of the phrase "message transfer circuit" in this limitation (and later ones as well) transforms it into a means-plus-function limitation, and is therefore restricted to the specific communications interface unit shown at Figures 6B and 8 of the patent. TM has the better of this argument. Claim 1.A is not a claim for a message transfer circuit, but for a computer system having as one of its component parts a message transfer circuit that does certain things. In other words, the phrase "message transfer circuit" refers to a structure within the computer system. That this structure has a particular function to perform, and must therefore be capable of performing that function, does not transmute a structural component of a computer system into a means-plus-function claim to which Section 112, para. 6 applies.

TM has not here attempted to patent an unspecified "means for routing messages through a computer system without forcing the head of the message to wait for the tail." It cannot be expected to recite an invention without identifying its component parts. Interestingly, TM tried to do so; the prosecution history shows that claim 2 of the preliminary amendment to this patent (which was ultimately canceled) recited "means for serially transmitting message elements and means for serially receiving message elements." (A 2089.) That is not how the patent ended up. As allowed by the Examiner, it requires the use of a circuit to transfer messages. Other courts have held the word "circuit" to be a structural term, see, e.g., Cellnet Data Systems, Inc. v. Itron, Inc., 17 F. Supp. 2d 1100, 1107 (N.D. Cal. 1998). Its dictionary definition -- which IBM cites -- is "An electrical network in which there is at least one path that can be closed," S. Handel, A Dictionary of Electronics 59 (2d ed. 1966), or, alternatively, "A complete wire, radio or carrier communications channel." McGraw Hill Dictionary of Scientific and Technical Terms 302 (3d ed. 1984). Neither of those is a functional definition. Yes, it is a circuit that transfers messages -- that is its function in the invention -- but the fact that a disclosed structural element has a function should surprise no one. Under IBM's reasoning, nearly every patent limitation would qualify for Section 112 para. 6 treatment.

605
Disputed Claim Language

"a circuit for automatically adjusting a noise threshold of said laser light receiver to a level at which said laser light receiver produces an output from said noise light pulses having a constant pulse firing rate."

Analysis
Defendants argue I should construe this claim element in means-plus-function format pursuant to § 112 P 6. Defendants' Memo, 35. I agree. Means-plus-function formatting applies to claim limitations that portray a function to be executed, but provide no instruction as to the structure or materials for executing that function. See CCS Fitness, Inc., 288 F.3d at 1369-70. Because I conclude that this claim element is in that format, I go to the specification to understand the "means" for performing the function embodied by the claim.

The second element of Claim 18 is not written in means-plus-function format, typified by the use of the word "means." Personalized Media Commun. v. Harris Corp., 156 F.3d at 703-704 (citations omitted). Therefore, there is a rebuttable presumption that the element should not be construed according to means-plus-function format. Id. Defendants may rebut the presumption that § 112 P 6 does not apply by "demonstrating that the claim term fails to recite sufficiently definite structure or else recites a function without reciting sufficient structure for performing that function." CCS Fitness, Inc., 288 F.3d at 1369. Also, "in deciding whether [the] presumption has been rebutted, the focus remains on whether the claim as properly construed recites sufficiently definite structure to avoid the ambit of § 112 P 6." Personalized Media Commun. v. Harris Corp., 156 F.3d at 704. To determine whether the claim term recites sufficient structure, I may examine whether the claim term has an understood meaning in the art. See CCS Fitness, 288 F.3d at 1369.

Defendants argue that "circuit" does not have a definite meaning. Defendants' Reply Memo, 20. They cite a Southern District of New York case in which "use of the words 'circuit,' 'interface' and 'units' were means-plus-function claims even though the customary terms 'means' or 'means for' were not used." Id. (citing Apex, Inc. v. Raritan Computer, Inc., 187 F. Supp. 2d 141 (S.D.N.Y. 2002)). That court concluded that the term "circuit" is "so generic that by itself it conveys no structure at all." Id. at 158 (citations omitted).

In 1998, the Federal Circuit decided that a very similar claim element was not in means-plus-function format. The Court held that "video delay circuit" was not limited to the preferred embodiment in the patent specification. Comark Commun. v. Harris Corp., 156 F.3d 1182 (Fed. Cir. 1998). Other district courts are in accord. See Cellnet Data Sys. v. Itron, Inc., 17 F. Supp. 2d 1100 (N.D. Cal. 1998) (The Northern District of California held that "circuit means for recording energy use" was not a means-plus-function claim because one of ordinary skill in the art would understand the claim element as a structural limitation.); Intel Corp. v. Broadcom Corp., 172 F. Supp. 2d 478, 515 (D. Del. 2001) (The District of Delaware ruled that "I/ O circuitry … for providing processed video signal to said I/ O port …" was not in means-plus-function format because it could be reasonably understood by one skilled in the art.

In all three of those cases, the word "circuit" is modified in a way that sufficiently narrows its meaning so one skilled in the art may understand it. "Video delay circuit," Comark, 156 F.3d at 1182, is a phrase in which "video" and "delay" significantly modify "circuit" so that the term is clearly not just any of millions of circuits in existence. Similarly, "circuit means for recording energy use," Cellnet Data Systems, 17 F. Supp. 2d at 1100, can only be understood when the words "for recording energy use" appear. If they did not, circuit would exist in a vacuum. Moreover, the word "circuitry" in "I/ O circuitry … for providing processed video signal to said I/ O port," Broadcom, 172 F. Supp. 2d at 515, can only be understood in light of "I/ O" and "for … port." Otherwise, "circuitry" lies naked in the claim.

In Claim 18, "circuit" similarly is modified by its companion terms in a way that gives it meaning. Without "for automatically adjusting a noise threshold," circuit cannot be understood by one skilled in the art as anything but a universally abundant electrical component. Without the modifying language, a dictionary definition provides little clarification either. Circuit may be "the complete path of an electric current including any displacement current" (6a); or "[a] specified portion of a circuit" (6b); or "an assemblage of electronic elements" (8a). WEBSTER'S 3RD NEW INTERNATIONAL DICTIONARY 408 (3rd ed. 1986). None of these definitions provides more than a murky outline.

If a claim element recites a function without reciting sufficient structure for performing that function, § 112 P 6 may apply. CCS Fitness, Inc., 288 F.3d at 1369. But while the functional phrase "for automatically adjusting a noise threshold" gives "circuit" context, without more it does not provide sufficient structural meaning to withstand application of § 112 P 6. There is no structural context that teaches one how a circuit, which may be as vague as "an assemblage of electronic elements" automatically adjusts a noise threshold.

Pursuant to § 112 P 6, I must go to the patent specification and the prosecution history for clues to the meaning of Claim 18. "One of skill in the art can only reconcile the claim language with the inventor's disclosure by recourse to the specification." Comark, 156 F.3d at 1187.
Defendants state: "this claim element should be construed to require a feedback circuit which adjusts the noise threshold …." Defendants' Reply Memo, 18. Defendants also argue that I should read diode 316, found in the preferred embodiment in the '779 patent specification, into Claim 18. Defendants argue that diode 316 is "at the essence of the circuit for automatically adjusting a noise threshold, [so] the essence cannot be ignored when construing the claim or determining infringement." Defendants' Memo, 38.

While Defendants may overcome the heavy presumption that the claim terms embody their ordinary meaning and attempt to narrow the meaning of the terms, they "cannot do so simply by pointing to the preferred embodiment or other structures or steps disclosed in the specification or prosecution history." CCS Fitness, Inc., 288 F.3d at 1366. Here, Defendants do more than simply point to the specification or prosecution history. They identify a portion of the prosecution history without which the '779 patent likely would not have been approved by the U.S. Patent and Trademark Office. By doing so, the presumption is rebutted.

During the prosecution of the '779 patent, inventor Jeremy Dunne distinguished his invention from the prior art embodied in Frungel's U.S. Patent no. 4,259,592. In an amendment to his '779 patent application, Dunne summarized Frungel's invention in two-and-a-half pages. Amendment to Application for Automatic Noise Threshold Determining Circuit and Method for a Laser Range Finder, U.S. Patent and Trademark Office, 1995 (Amendment). Immediately thereafter, he summarized his invention to distinguish it from patent no. 4,259,592. In his summary relating to Claim 18, Dunne wrote: "The essence of [the] automatic noise threshold section … is a feedback loop that comprises the detected (see detector 314, 316, 322, 324) average noise firing rate …." Id. at 16. Plaintiff and Defendants agree that the "316" of the "detector" of the feedback loop is diode 316. Motions Hearing, U.S. District Court for the District of Colorado, July 18, 2002 (Motions Hearing). See Figure 8, '779 patent. Later in the same document, Dunne writes that "no structure within the cited Frungel patent operates to dynamically use a range/ noise signal that is reflected from the target in order to change a detection threshold as a function of noise pulses that are received …. Frungel purposely does not generate a noise threshold signal." Amendment, 22-23.

The feedback loop that is at the "essence" of Claim 18 of the '779 patent includes diode 316. And without that feedback loop, Plaintiff's laser range finder would not be able to perform the noise thresholding that distinguishes Dunne's invention from the Frungel prior art. Defendants' explanation of the importance of diode 316 in the feedback loop was not overcome by Plaintiff at the motions hearing. Because diode 316 is integral to the feedback loop that is essential to the noise thresholding circuit of Claim 18, I conclude as a matter of law that the thresholding circuit requires diode 316 and the feedback loop.

CONSTRUCTION: A circuit consisting of a feedback loop composed in part of diode 316 that adjusts a noise threshold of a laser light receiver to a level at which a laser light receiver produces an output from noise light pulses having a constant pulse firing rate.

I. THE CLAIM TERM "CIRCUIT INTERRUPTING DEVICE" REFERS TO A DEVICE DESIGNED TO INTERRUPT OR BREAK THE FLOW OF CURRENT IN A SINGLE CIRCUIT.

The parties dispute the construction of the term "circuit interrupting device." Leviton contends that the term should be construed as a device designed to interrupt or break the flow of current in one or more circuits. The Defendants argue the term should be interpreted as a device designed to interrupt or break the flow of current in a single circuit. The Court agrees with the Defendants' construction.

The elements of the claim suggest that the circuit interrupting device interrupts a single circuit with multiple paths. See '558 Patent, Col. 13, ll. 36-40 ("circuit interrupting means . . . breaking electrical continuity between said first and second conductive path means and between said first and third conductive path means") (emphasis added); id. at Col. 13, ll. 41-44 ("reset means . . . for reestablishing electrical continuity between said first and second conductive path means and between said first and third conductive path means") (emphasis added). That the claim term only refers to a single circuit finds further support in the abstract and written specification of the patent. In describing the resettable circuit interrupting device, the abstract states that the "trip portion operates independently of a circuit interrupting portion used to break the electrical
continuity in one or more conductive paths in the device." Id., Abstract (emphasis added). This statement indicates that the device is designed to break multiple electrical paths but says nothing of breaking multiple circuits. The detailed description section of the patent also states that the "present application contemplates various types of circuit interrupting devices that are capable of breaking at least one conductive path at both a line side and a load side of the device." Id., Col. 4, ll. 58-61 (emphasis added). The specification also refers repeatedly to breaking electrical continuity in one or more conductive paths. See, e.g., '558 Patent, Col. 5, ll. 41-43; Col. 5, ll. 56-59; Col 7, ll. 31-35. Once again, the patent only describes breaking the flow of multiple paths, not multiple circuits.

Leviton nonetheless argues that the '558 patent discloses one or more circuits for the circuit interrupting device. Specifically, Leviton states that Figures 1 and 8 of the patent show at least two circuits: "one circuit includes contacts 80 and 60, that is the user accessible load and a second circuit includes contacts 36 and 40, that are the load terminals." Pl.'s Resp. at 7 (Doc. 109). This interpretation of multiple circuits, however, contradicts the language in the specification referring to these portions of the circuit as paths. See, e.g., '558 Patent, Col. 5, ll. 34-37 ("The circuit interrupting and reset portions described herein preferably use electro-mechanical components to break (open) and make (close) one or more conductive paths between the line and load sides of the device."); Col. 6, ll. 12-15 ("The circuit interrupting portion… is used to break electrical continuity in one or more conductive paths between the line and load side of the device."); Col. 6, ll. 36-37 ("The conductive path between the line phase connection 34 and the load phase connection 36 includes…"); Col. 6, ll. 46-48 ("The conductive path between the line phase connection 34 and the user accessible load phase connection includes…"). The patent does not refer to the portions of the device including contacts 80 and 60 and contacts 36 and 40 as comprising separate circuits. Rather, the patent language is consistent in referring to portions of the device including those contacts as comprising multiple paths.

Furthermore, the dictionary definition of "circuit" confirms this interpretation of "circuit interrupting device" as a device designed to break the flow of current in a circuit. Merriam Webster's Collegiate Dictionary 207 (10th ed. 1993) defines "circuit" as "the complete path of an electric current including usu. the source of electric energy." This definition contemplates a circuit as necessarily including an electrical power source in order to complete the electrical path. Claim 3 indicates that the circuit interrupting device is electrically connected to only one power source. See '558 Patent, Col. 13, ll. 23-25 ("first electrical conductive path means . . . capable of electrically connecting to a source of electricity"). The device thus contemplates breaking electrical continuity of a single circuit with multiple paths. See id. and Col. 13, ll. 36-40 ("circuit interrupting means . . . breaking electrical continuity between said first and second conductive path means and between said first and third conductive path means").

The Court therefore holds that the correct construction of the term "circuit interrupting device" used in Claim 3 is a device designed to interrupt or break the flow of current in a single circuit.

B. CIRCUIT INTERRUPTING.

In Claim 3, the term "circuit interrupting" also uses the word "means," followed by a recitation of function, resulting in the rebuttable presumption that the element is a means-plus-function element subject to 35 U.S.C. § 112, P 6. The Court finds that Leviton has again met its burden of showing that the claim recites sufficient structure to perform the claimed function.

First, the term "circuit interrupting" connotes structure. Merriam Webster's Collegiate Dictionary 612 (10th ed. 1993) defines the term "interrupter" as "a device for interrupting an electric current usu. automatically." The Court therefore finds that a person of ordinary skill in the art would understand that the term "circuit interrupting" -- a device -- is a structural term. See Linear Technology Corp. v. Impala Linear Corp., 379 F.3d at 1320. The contextual language of Claim 3 also provides further information regarding the location of the structure, i.e., "between said first and second conductive path means and between said first and third conductive path means." '558 Patent, Col. 13, ll. 37-39. Finally, Leviton's expert, Dr. De La Ree, affirmed that "circuit interrupting" is a structural term well-known and understood by persons of ordinary skill in the art. Dr. De La Ree's opinion was not merely conclusory, as he relied on technical literature and previous patents, which demonstrated that a circuit interrupter is a structural device. Furthermore, the Defendants' expert, Dr. Choma, indicated that the term "circuit interrupting" conveys structure when he stated, "the structure conveyed is little more than the schematic depiction of a controlled switch." Dr. John Choma's Expert Response to Declaration of Dr. J. De La Ree at 10.
Again, that the term may not connote a precise physical structure does not compel a finding of insufficient structure. See CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d at 1370; Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d at 1583. See also Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d at 1359-60 (“[I]t is sufficient if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies the structures by their function.”).

Consequently, the Court concludes that the term "circuit interrupting means" is not subject to the claims limitations in 35 U.S.C. § 112, P 6. The Court will construe the term "circuit interrupting" using standard claim construction rules as set forth in Leviton's Claim Construction chart.

608

2. "Circuit means"

The "circuit means" element of the claim is stated in means-plus-function form; it uses the term "means" and describes the function that the means is to perform. MagneTek argues that this requires this claim element to be limited to the particular type of circuit described in the specification, namely a circuit with a tank capacitor and leakage reactance transformer, as well as the equivalents thereof. Nilssen argues that the term "circuit" by itself recites sufficient structure to avoid the application of § 112, P6. MagneTek essentially argues that the term is far too generic to remove the claim language from § 112, P6.

In CellNet Data Systems, Inc. v. Itron, Inc., 17 F. Supp. 2d 1100 (N.D. Cal. 1998), the court was required to construe the term "circuit means" in the context of a patent for a utility meter of the type used by electric companies. Specifically, the parties disputed the meaning of a claim element described as a "circuit means for recording energy use." Id. at 1106. The court concluded that this could not be considered a "means plus function" element, because those skilled in the art would understand the term "circuit means" as a structural element denoting "the combination of a number of electrical devices and conductors that, when connected together to form a conducting path, fulfill a desired function …." Id. at 1107 (quoting Penguin Dictionary of Electronics (2d ed. 1988)).

The only significant difference between CellNet and this case is that there the specification did not describe any particular sort of circuitry, whereas here it does. See id. at 1107. The distinction is immaterial. In this case as in CellNet, the question is whether the claim recites sufficient structure to avoid the application of § 112, P6. And in this case as in CellNet, the fact that the claim specifies the precise location of the circuit, in addition to the fact that the term "circuit" has a commonly known meaning in the art, are enough to show that the claim is not in means-plus-function format. Id. We construe the term "circuit means" as denoting the combination of a number of electrical devices and conductors that, when connected together to form a conducting path, fulfill a desired function -- in this instance, the function of supplying lamp voltage and current from the inverter to the lamp terminals.

E. '690 Patent, Claim 17 - "circuit means"

Claim 17 of the '690 patent reads as follows:

An arrangement comprising:

- power input terminals across which is provided an ordinary AC power line voltage;
- rectifier means connected with the power input terminals and operative to provide a DC voltage at a set of DC terminals;
- gas discharge lamp having a pair of lamp terminals as well as a pair of thermionic cathodes; such lamp terminal being connected with one of the thermionic cathodes; each thermionic cathode having a pair of cathode terminals;
- inverter means connected with the DC terminals and operative to provide an alternating inverter output voltage at a set of inverter output terminals; and
circuit means connected between the inverter output terminals and the lamp terminals, thereby to provide lamp operating voltage to the lamp terminals; the circuit means having a pair of auxiliary output terminals at which is provided a cathode heating voltage; the pair of auxiliary output terminals being connected with one of the pairs of cathode terminals, thereby to provide a cathode heating voltage there across; the cathode heating voltage having a magnitude that is substantially higher before lamp ignition than it is after lamp ignition.

U.S. Patent No. 5,047,690, Claim 17 (emphasis added).

MagneTek argues that the "circuit means" part of the claim is stated in means-plus-function form, thus requiring the circuit means to be defined as limited to the particular type of circuit described in the specification. While it is true that the claim uses the term "means" and also describes a function for the circuit, we do not agree that § 112, P6 applies. The claim language clearly includes a particularized description of a specific structure, which is more than enough to remove this element from the scope of § 112, P6. We decline to read any limitations from the specifications into the claim language, for these reasons and those previously discussed. The particular language of the claim serves to describe the nature and specifics of the circuit means, but no other limitations are appropriate. We again construe the term "circuit means" as denoting the combination of a number of electrical devices and conductors that, when connected together to form a conducting path, fulfill a desired function -- in this instance, the function of supplying lamp voltage and current from the inverter to the lamp terminals -- with, of course, the other particulars spelled out in the claim element.

"Circuit Means" in the '690 Patent's Claim 17

Round two of this 13-round bout involves claim 17 of the '690 Patent:

A circuit means connected between the inverter output terminals and the lamp terminals, thereby to provide lamp operating voltage to the lamp terminals; the circuit means having a pair of auxiliary output terminals at which is provided a cathode heating voltage.

In this instance the stated function is "to provide lamp operating voltage to the lamp terminals." Again the issue is whether enough structure is cited to perform that function to overcome the presumption of Paragraph 6 applicability.

To negate that presumption Nilssen points to CellNet Data Sys., Inc. v. Itron, Inc., 17 F. Supp. 2d 1100, 1107 (N.D. Cal. 1998) and its finding "that those skilled in the art would understand the term 'circuit means' as a structural rather than a means-plus-function element." That conclusion rests on the dictionary definition of "circuit" as connoting the generic structure of "the combination of a number of electrical devices and conductors that, when connected together to form a conducting path, fulfill a desired function such as amplification, filtering, or oscillation" (id. at 1111, quoting Penguin Dictionary of Electronics (hereafter "Penguin") (2d ed. 1988)). In addition, the court noted that the location of the "circuit means" was specified in the claim (17 F. Supp. 2d at 1111, citing Cole, 102 F.3d at 531). Claim 17 also specifies the location of the circuit means:"connected between the inverter output terminals and the lamp terminals."

Motorola seeks to counter with Relume Corp. v. Dialight Corp., 63 F. Supp. 2d 788, 802 (E.D. Mich. 1999), which decided that the claim language "adaptive clamp circuit means" was in means-plus-function form. But because the Relume plaintiff did not dispute that construction, the court was deprived of an opposing viewpoint that might perhaps have highlighted terms of art in the claim that could communicate sufficient structure to overcome the presumption.

Nonetheless this Court would be wholly unpersuaded by CellNet (and hence by Nilssen) if "circuit means" were the only relevant language in the claim element. Although its own days as a highly trained technician (and in one instance as the author of a modest invention) during the formative--nay, primitive--days of airborne radar have so faded into the dim past as to render any possible claim by this Court to being even moderately "skilled in the art" a serious Rule 10b-5 violation, it takes no electronic sophistication at all to understand that electrical circuits are virtually infinite in number. It is not that "circuit" is nongeneric--it is rather that it is so generic that by itself it conveys no sense of structure at all. To say simply that an electrical circuit will be inserted into another circuit to accomplish a stated function is to afford the skilled reader no sense whatever of the structure of that insertion.
Unsurprisingly, M. Mem. 16-18 (emphasis in original) states that claim 17 should be limited by the specification because "the only structure disclosed in the specification for providing operating voltage to the lamp terminals…is an inductor…with auxiliary windings…" That contention is not at odds with the admonition in Comark, 156 F.3d at 1186 that "limitations from the specification are not to be read into the claims," for that caveat applies to claims that fall on the other side of the "fine line" described in Comark, id.

That argument by Motorola is a bit oversimplistic, because it glosses over the operative language in the claim element that cuts back the otherwise generic and uninformative scope of "circuit means" somewhat by describing it as "having a pair of auxiliary output terminals at which is provided a cathode heating voltage." But unlike the situation in Cole, 102 F.3d at 531, where the element at issue carried with it "such a detailed recitation of its structure, as opposed to its function," here the quoted partial description of the "circuit means" just does not supply enough structure "to perform entirely the recited function" (as is required by such cases as Sage Prods., 126 F.3d at 1427-28). In that respect the situation is much akin to that described in the preceding section, where the reference to a "source means" as "having AC terminals" was not enough to provide a sufficient recitation of structure to take the claim out of Paragraph 6's coverage.

This Court therefore holds that claim 17 of the '690 Patent is also in means-plus-function form. And unlike the claim referred to in the preceding section, no further hearing is required to fine-tune its meaning.

1 This is one of two issues on which this Court respectfully differs with its colleague Judge Kennelly (MagneTek, 1999 WL 982966, at *8-*9).

B. "Circuit Means For Recording Energy Use"

Independent claim 1 of the '623 patent discloses a device for use with an electric meter which has a housing containing "circuit means for recording energy use." According to CellNet, the term "circuit means for recording energy use" means any circuit involved with recording energy use. Itron contends that the term is a means-plus-function element and that it means "a circuit having a sensor for detecting the black mark on the [meter] disc, a microprocessor for receiving this information and storing it in memory."

The parties vigorously dispute whether the above element of claim 1 is a means-plus-function limitation. CellNet argues that the element is not in means-plus-function format despite the fact that the patentees used the words "means for" because there is no corresponding structure in the '623 specification. CellNet also contends that those skilled in the art would understand the term "circuit means" as a structural limitation. Itron, on the other hand, argues that the specific circuitry disclosed in CellNet's separate patent application, which led to the issuance of the '677 patent, may be consulted to understand the structure of the "circuit means" because the patents are related and the "elements and circuitry" disclosed in the separate application were incorporated by reference by the patentees in the '623 patent specification. '623 patent, 4:63-5:4.

Paragraph 6 of 35 U.S.C. §112, which authorizes patentees to claim structural limitations without an express structural description in the claim itself, provides that:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material or acts described in the specification and equivalents thereof.
If the Court determines that a claim element is set forth in means-plus-function format, then the "court must consult the specification to define the structure, material or acts corresponding to this claimed function." Sage Products, Inc. v. Devon Industries, Inc., 126 F.3d 1420, 1428 (Fed. Cir. 1997).

Although there is a presumption that a claim element expressed using the words "means for" is a means-plus-function limitation, the Court must nevertheless make its determination "on an element-by-element basis, based upon the patent and its prosecution history." Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1997). "[T]he mere incantation of the word 'means' in a clause reciting predominantly structure cannot evoke section 112, P 6." York Products, Inc. v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1574 (Fed. Cir. 1996). The cases explain that claim elements are not expressed in means-plus-function format if there is an insufficient disclosure of the function to which the purported means corresponds or if "a claim recites a function, but then goes on to elaborate sufficient structure, material, or acts within the claim itself to perform entirely the recited function." Sage, 126 F.3d 1420 at 1427-28; and Waterloo Furniture Components, Ltd. v. Haworth, Inc., 798 F. Supp. 489, 494-95 (N.D. Ill. 1992).

In this case, the Court finds that those skilled in the art would understand the term "circuit means" as a structural rather than a means-plus-function element. Moreover, those skilled in the art would construe the term "circuit means" to mean:

The combination of a number of electrical devices and conductors that, when connected together to form a conducting path, fulfill a desired function such as amplification, filtering, or oscillation.

Penguin Dictionary of Electronics (2nd Ed. 1988). In addition, the fact that the location of the "circuit means" is specified in claim 1 suggests that the patentees intended to recite a structural element. See Cole, 102 F.3d at 531 (claim language held not to be in means-plus-function format because the word "perforation" provides a sufficient description of structure and because the location of the "perforation means" is specified in the claims).

Furthermore, the absence of a corresponding disclosure of the necessary circuitry in the '623 patent specification indicates that "circuit means" is not a means-plus-function element. Itron contends that the structural details of CellNet's "circuit means" can be imported from the '677 patent. 8 However, Itron has not cited any authority, and the Court has not found any, for the proposition that the structural limitations for a means-plus-function claim element can be imported from a pending patent application. Indeed, the relevant case law disapproves of the importation of substantive claim limitations by reference to other documents. Modine Manufacturing Co. v. United States International Trade Commission, 75 F.3d 1545, 1553 (Fed. Cir. 1996). In Modine, the patentee argued that the term "relatively small" in the '580 patent should be construed to include a diameter up to 0.07 inch because it was defined as such in the specification of the related '311 patent. Id. The specification of the '580 patent incorporated by reference the related '311 patent. Id. The Modine court rejected the patentee's argument that a claim limitation could be imported from a related patent, reasoning that "incorporation by reference does not convert the invention of the incorporated patent into the invention of the host patent." Id.

--- Footnotes ---

8 Itron's proposed definition of the disputed term is based on the circuitry disclosed in the '677 patent.

--- End Footnotes ---

Moreover, the description of the circuit structure in the co-pending '677 patent was clearly considered "nonessential" by the examiner in this case. 9 This fact also weighs against a finding that "circuit means" is a means-plus-function element. Section 608.01(p) of the Manual on Patent Examining Procedure ("MPEP") instructs examiners to require the patentee to amend the specification to include essential material previously incorporated by reference before allowing a patent to issue:

Prior to allowance of an application that incorporates essential material by reference to a pending U.S. application, the examiner shall determine if the referenced application has issued as a patent. If the referenced application has issued as a patent, the examiner shall enter the U.S. Patent No. of the referenced application in the specification of the referencing application (see MPEP § 1302.04). If the referenced application has not issued as a patent, applicant will be required to amend the disclosure of the referencing application to include the material incorporated by reference. The amendment must be accompanied by an affidavit or declaration executed by the applicant, or a practitioner representing the applicant, stating the amendatory material consists of the same material incorporated by reference in the referencing application.
MPEP § 608.01(p) (emphasis added). The MPEP defines essential material as "that which is necessary to (1) describe the claimed invention, (2) provide an enabling disclosure of the claimed invention, or (3) describe the best mode (35 U.S.C. 112)."

9 As discussed earlier, the patentees filed a separate patent application ("the ‘677 application") to claim the circuit structure of their meter modules.

If the patentees were asserting a means-plus-function claim, a disclosure of the circuit structure described in the ‘677 application corresponding to the purported means-plus-function limitation would certainly have been considered essential material because it would have been necessary to describe the invention and to provide an enabling disclosure of the "circuit means." The record indicates, however, that the examiner of the ‘623 application did not even raise the issue of incorporating the material incorporated by reference.

Finally, the prosecution history can be helpful in the determination of whether the patentees intended to assert a means-plus-function claim. Cole, 102 F.3d 524, 531; and Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996). The prosecution history of the ‘623 patent does not contain any evidence that suggests the patentees intended to assert a means-plus-function limitation in claim 1.

In this case, the original 25 claims of the application which resulted in the issuance of the ‘623 patent did not contain any reference to the circuitry used in the device. The patentees filed a separate patent application to claim the circuitry. The specification of the ‘623 patent application does have a very general discussion of the various capabilities of the circuitry in the disclosed device, but there is no specific description of the elements or structure of the circuitry. ‘623 patent, 4:20-53. The ‘623 patent specification, however, does contain a reference to the patentees' separate application which resulted in the issuance of the ‘677 patent:

The elements and circuitry for generating information, such as time of energy use, and thereafter transferring that information to a system for calculating billing rates, for example an electronic meter reader, are described in greater detail in our co-pending application entitled "A System For Use With A Utility Meter For Recording Time of Energy Use," and assigned to the assignee of this application, and which co-pending application is hereby incorporated by reference.

‘623 patent, 4:63-5:4. The "circuit means" limitation was added by the patentees in their Response to the November 23, 1987 Office Action. The amended claims were allowed by the examiner without the need for further action or response by the patentees. 10 The examiner's silence regarding the absence of an adequate disclosure of the structure of the "circuit means" added in the patentees' response is relevant to the issue of whether "circuit means for recording energy use" is a means-plus-function element. The fact that the examiner did not request an amendment to the ‘623 patent specification indicates that he did not believe a means-plus-function limitation was added to claim 1. See MPEP § 608.01(p).

Accordingly, the Court concludes that the term "circuit means" is not a means-plus-function element under 35 U.S.C. § 112, P 6, despite the fact that the patentees used the words "means for," because (1) the word circuit discloses a definite structure; (2) the claims specify where the "circuit means" is located; (3) the ‘623 patent specification contains no disclosure of the
necessary corresponding structure; (4) the corresponding structure cannot be imported from the '677 patent; and (5) the prosecution history indicates that "circuit means" is not a means-plus-function limitation.

2. The Court's Interpretation Of "Circuit Means For Recording Energy Use"

Since the term "circuit means for recording energy use" is not a means-plus-function element, the Court construes the term to mean "a circuit for use with standard electric meters capable of recording information regarding the amount of energy used or consumed." Furthermore, the Court construes the term "circuit means" to mean:

The combination of a number of electrical devices and conductors that, when connected together to form a conducting path, fulfill a desired function such as amplification, filtering, or oscillation.

Penguin Dictionary of Electronics (2nd Ed. 1988). 11 The Court's claim interpretation is based primarily on the disclosures made in the specification. In the specification, the patentees state that their device is designed to be used in standard electric meters in conjunction with a sensor means which is not a part of claim 1. 12 There is no suggestion that the devices can also be used in utility meters other than standard meters. Moreover, the relevant portion of the specification pertaining to the circuitry reads as follows:

The device of the present invention is capable of recording time of energy use, peak demand for energy, and energy load profile data. It is usable with and mountable to standard watthour meters. [P] The device measures time of energy use by detecting the rate of rotation of the meter's disc. A black mark (not illustrated) is located on the lower surface of the disc. Sensor means are mounted within a housing 30 of device 10 to detect the black mark as it rotates past an optical port 32 in the top surface 33 of housing 30. . . [P] The rotating black mark interrupts reflection of infrared light to the sensor means, once each evolution. The phototransistor generates a different signal in response to that interruption. The signals are processed and stored by appropriate circuitry in device 10.

'623 patent, 4:20-37 (emphasis added). Thus, the function of the "circuit means" is not to detect or count the rotations of the meter disc, as Itron contends, but to simply record the signals transmitted by the discussed sensor means.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

11 The Court believes that those of ordinary skill in the art covered by the '623 patent, electrical or mechanical engineers, would have a technical understanding of the word "circuit." Therefore, the Court declines to adopt the general definition of the word, "the path of an electric current," proposed by CellNet. See Webster's Collegiate Dictionary (10th Ed. 1993). 12 An embodiment of the claimed device with the referenced sensor means is described in dependent claim 4 which is not being asserted herein. The sensor means limitation of dependent claim 4 cannot be read into independent claim 1. See Uniroyal, Inc. v. Rudkin-Wiley Corp., 837 F.2d 1044, 1054-55 (Fed. Cir. 1988) ("Where some claims are broad and others narrow, the narrow claim limitations cannot be read into the broad whether to avoid invalidity or to escape infringement.") (citation and internal quotations omitted).

B. an on-screen programming circuit that produces video signals for display on the video monitor.

Raritan argues that the phrase "on screen programming circuit" does not connote structure but rather describes a function. Because the term is not expressed in "means plus function" language, there is a rebuttable presumption that § 112, P6 does not apply. Raritan has not overcome the presumption. The term "circuit" is defined as the combination of a number of electrical devices and conductors that, when interconnected to form a conducting path, fulfill some desired function. It connotes some structure. The adjectival phrase "on-screen programming" gives the structure greater definition. To a person of ordinary skilled in the art, it means a circuit that produces a display on a monitor that allows a user to control a switch.

GO BACK
The Court construes "circuitry" as "electronic components that may include digital circuitry, analog circuitry, software, firmware, or a combination of these elements."

A. Parties' Construction Arguments

Plaintiff seeks a construction of "circuitry" as "digital circuitry, analog circuitry, software, firmware, or a combination of these elements." Plaintiff's argument is that the patentee has been his own lexicographer. The specification states "[t]erminal unit circuitry may include digital circuitry, analog circuitry, software, firmware, or a combination of these elements." '323 patent, 7:44-46. Plaintiff argues that the specification defines "circuitry" here.

Defendants' construction adds the limitation that "circuitry" is also "power-consuming electronic components" in addition to Plaintiff's construction. Defendants argue that the fundamental value of circuitry for the purposes of the '323 patent is that the circuitry consumes power. Defendants cite to the specification for support. See, e.g., '323 patent, 2:1-4 ("signal processing, transmitting and receiving circuitry . . . requires a substantial amount[] of power. For a large central office . . . this power usage is substantial"); see also Claims 1, 7, 16, 24. Additionally, Defendants' construction adds the "may include" language from the specification that Plaintiff's construction leaves out.

B. Analysis

The Court agrees with Plaintiff that the patentee has been his own lexicographer. "[The Court] will adopt a definition that is different from the ordinary meaning when the patentee acted as his own lexicographer and clearly set forth a definition of the disputed claim term in either the specification or the prosecution history.") Edwards Lifesciences LLC v. Cook, Inc., 582 F.3d 1322, 1329 (Fed. Cir. 2009) (internal quotes omitted). However, Plaintiff's proposed construction does not give the full definition expounded in the specification because it takes out the "may include" language. See '323 patent, 7:44-48 ("Terminal unit circuitry may include digital circuitry, analog circuitry, software, firmware, or a combination of these elements"). The "may include" language is important because its presence changes the definition. With the "may include" language, the list of components in the definition is not an exclusive list of components that make up the circuitry. Without the "may include" language, the list is exclusive. The Court believes that the "may include" language should be included in the construction of "circuitry" since it is included in the specification and it makes a meaningful difference. Thus, the Court construes "circuitry" as "electronic components that may include digital circuitry, analog circuitry, software, firmware, or a combination of these elements."

The Court's adopted construction is similar to Defendants' proposed construction except that it removes the "power-consuming" language. The "power-consuming" language introduces ambiguity to the phrase because the circuitry, if interpreted as Defendants' construction, might be required to be "power-consuming" at all times. While it may be fundamentally true that circuitry must have the ability to be "power-consuming," the circuitry in the '323 patent is not required to be power-consuming at all times. See, e.g., '323 patent, 5:25-27 ("Each unit . . . may . . . enter low-power mode by shutting off the now unnecessary sections of signal processing [], transmitting [], and receiving [], circuitry."). Therefore, the Court refuses to read in Defendants' "power-consuming" limitation because it adds ambiguity and is not necessary.

C

Claim 1(b) of the '919 patent recites, "display means connected to the scanner for receiving the appearance signals and aesthetic correction circuitry for interactively introducing aesthetically desired alterations into said appearance signals to produce modified appearance signals." '919 patent, col. 15, II. 37-41 (emphasis added). The phrase, "aesthetic correction circuitry for interactively introducing aesthetically desired alterations into said appearance signals to produce modified appearance signals," does not contain the term "means," and is therefore presumptively not a means-plus-function limitation. Nonetheless, the district court held that the presumption was overcome and proceeded to define the function and
MIT urges that the term "aesthetic correction circuitry" connotes sufficient structure to avoid 112 P6 treatment. We agree.

In contrast to the term "mechanism," dictionary definitions establish that the term "circuitry," by itself, connotes structure. Webster's Third New International Dictionary, 408-09 (1968 ed.) (defining "circuit" as "the complete path of an electric current including any displacement current" and "circuitry" as "the detailed plan of an electric circuit or network (as of a radio or television receiver)"); see also Linear Tech. Corp. v. Impala Linear Corp., 379 F.3d 1311, 1320 (Fed. Cir. 2004) ("Technical dictionaries, which are evidence of the understandings of persons of skill in the technical arts, plainly indicate that the term 'circuit' connotes structure. . . . The Dictionary of Computing 75 (4th ed. 1996) defines 'circuit' as 'the combination of a number of electrical devices and conductors that, when interconnected to form a conducting path, fulfill some desired function.'"); Random House Webster's Unabridged Dictionary 374, def. 9 (2d ed. 1998) (defining circuit as "the complete path of an electric current"); Rudolf F. Graf, Modern Dictionary of Electronics 116 (7th ed. 1999) (defining "circuit" as "[t]he interconnection of a number of devices in one or more closed paths to perform a desired electrical or electronic function");

In two of our prior cases we concluded that the term "circuit," combined with a description of the function of the circuit, connoted sufficient structure to one of ordinary skill in the art to avoid 112 P6 treatment. See Linear, 379 F.3d at 1320 ("[W]hen the structure-connoting term 'circuit' is coupled with a description of the circuit's operation, sufficient structural meaning generally will be conveyed to persons of ordinary skill in the art, and § 112 P6 presumptively will not apply."); Apex Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1373 (Fed. Cir. 2003) ("[T]he term 'circuit' with an appropriate identifier such as 'interface,' 'programming' and 'logic,' certainly identifies some structural meaning to one of ordinary skill in the art."). The claim language here too does not merely describe a circuit; it adds further structure by describing the operation of the circuit. The circuit's input is "appearance signals" produced by the scanner; its objective is to "interactively introduce aesthetically desired alterations into said appearance signals"; and its output is "modified appearance signals." '919 patent, col. 15, II. 29-41. This description of the operation of the circuit is sufficient to avoid 112 P6.

In arguing to the contrary, the dissent appears to misapprehend the strength of the presumption that applies when the term "means" does not appear in the claim. As we stated in Lighting World, 382 F.3d at 1362, "[W]e have seldom held that a limitation not using the term 'means' must be considered to be in means-plus-function form," and "the circumstances must be [unusual] to overcome the presumption . . . ." So too the dissent erroneously suggests that claims cannot avoid means-plus-function limitation unless the claim term denotes a specific structure. But "[i]n considering whether a claim term recites sufficient structure to avoid application of section 112 P6, we have not required the claim term to denote a specific structure. Instead, we have held that it is sufficient if the claim term is used in common parlance or by persons of skill in the pertinent art to designate structure, even if the term covers a broad class of structures and even if the term identifies the structures by their function." Id. at 1359-60. Here, technical dictionaries supply ample evidence that the claim term designates structure.

We conclude that Microsoft has not overcome the presumption that the "aesthetic correction circuitry" limitation is not a means-plus-function limitation.

Microsoft urges that "circuitry" should be limited to hardware whereas MIT urged below that it should include both hardware and software. We conclude that the term "aesthetic correction circuitry" is clearly limited to hardware.

The parties agree that the CTM is the "aesthetic correction circuitry" of the '919 patent. As the Summary of the Invention explains, when the operator views an image of the scanned original on a TV screen, the operator can "manipulate[] the TV image interactively in terms of appearance values, introducing aesthetic corrections and such other changes as desired." '919 patent, col. 3 II. 59-62. The CTM is the device that is used "to correct the input errors" in the image on the TV screen. In the preferred embodiment, it is composed of five modules, each of which corrects a specific type of error.

The specification describes the components of the CTM as hardware components. See id., col. 8, II. 36-38 ("The next step is conversion to LC1C2 form by a hardware implementation of the given transformation, followed by the LC1C2 Color Balance Module, 35."); id., col. 8 II. 48-51 ("The next two modules operate on chrominance in polar coordinates, so that the C1C2 signals must be converted in a hardware Cartesian to Polar Coordinate Converter, 36."); id., col. 9, II. 7-10 ("After Special Correction, hue and saturation are converted back to C1C2 form by a hardware Polar to Cartesian Coordinate Converter, 39, for passage to storage or the display."). Although the specification suggests that certain computations
performed by the CTM can be accomplished with either hardware or software, n6 this reference does not alter the specification's repeated description of the circuit itself as involving hardware. Thus, the specification references do not require that "circuit" be interpreted to include software. Dictionary definitions of circuit in 1982, when the patent application was filed, did not include software. n7 See McGraw-Hill Dictionary of Scientific and Technical Terms 299 (2d ed. 1978) (defining "circuitry" as "[t]he complete combination of circuits used in an electrical or electronic system or piece of equipment"). We conclude that the term "circuitry" in claim 1 is limited to hardware.

n6 See '919 patent, col. 10, ll. 25-29 ("It has proven convenient to use a hybrid analog-digital computer to perform the said computation, but any known form of computation can be used. . . ").

n7 "Software" is defined as "the programs used to direct the operation of a computer," Random House Webster's Unabridged Dictionary 1814, def. 1 (2d ed. 1998), and "hardware" is defined as "the mechanical, magnetic, electronic, and electrical devices comprising a computer system," Id. at 872, def. 5.

Having decided that 112 P6 does not apply to the "aesthetic correction circuitry" limitation and that the term does not include software, we leave it to the district court to define this term with further particularity.

MICHEL, Chief Judge, dissenting.

I respectfully dissent from the majority's vacatur and remand-in-part of the district court's decision on the bases of the trial court's incorrectly construing the claim term "aesthetic correction circuitry" under section 112 and erring in the exclusion of Windows as an infringing product, first suggested two years after the complaint was filed. I believe that in view of its specific language, "aesthetic correction circuitry" was correctly construed as a means-plus-function claim limitation. Nor do the cases relied on by the majority support, much less require, a different disposition. Moreover, I believe that excluding Windows as an infringing product was not an abuse of the trial court's discretion because MIT itself urged, successfully, that discovery be delayed.

I.

The district court correctly interpreted "aesthetic correction circuitry" as a means-plus-function claim despite the absence of the term "means for" in view of the presence of functional language because the limitation fails to recite sufficiently definite structure, as our precedent requires. Thus, the presumption against application of section 112, paragraph 6 was overcome. Indeed, on this record, I find it overcome as a matter of law.

The parties agree that "the term 'circuit[ry]' by itself connotes some structure" to one skilled in the art. Apex, Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1373 (Fed. Cir. 2003) (emphasis added). The issue, however, is whether the "aesthetic correction circuitry" limitation "recite[s] sufficiently definite structure," id. at 1372 (emphasis added); accord Linear Tech. Corp. v. Impala Linear Corp., 379 F.3d 1311, 1319 (Fed. Cir. 2004), which is required to avoid section 112, paragraph 6 in a claim using functional language, even in the absence of "means for."

This "definite structure" requirement is well-established in our precedent. "To invoke this statute [section 112, paragraph 6], the alleged means-plus-function claim element must not recite a definite structure which performs the described function." Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996); see also B. Braun Med., Inc. v. Abbott Lab., 124 F.3d 1419, 1424 (Fed. Cir. 1997) ("Because this limitation . . . does not recite definite structure in support of its function, it is subject to the requirements of 35 U.S.C. § 112, P6 . . . "); Personalized Media Commun., LLC v. Int'l Trade Comm'n, 161 F.3d 696, 704 (Fed. Cir. 1998) ("In deciding whether either presumption ['means for' with stated function presumes that
section 112, paragraph 6 applies, while no 'means for' with stated function presumes that section 112, paragraph 6 does not apply] has been rebutted, the focus remains on whether the claim as properly construed recites sufficiently definite structure to avoid the ambit of § 112, P6.”; Watts v. XL Sys., Inc., 232 F.3d 877, 880 (Fed. Cir. 2000) (“[T]he focus remains on whether the claim . . . recites sufficiently definite structure.”); CCS Fitness, Inc. v. Brunswick Corp., 288 F.3d 1359, 1369 (Fed. Cir. 2002) (“Life Fitness can rebut this presumption if it demonstrates that the claim term fails to recite sufficiently definite structure.”); Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004) (“The presumption that a limitation lacking the term 'means' is not subject to section 112 P6 can be overcome if it is demonstrated that the 'claim term fails to recite sufficiently definite structure.'”) (internal quotations omitted). Indeed, section 112, paragraph 6 is rooted in the definiteness requirement of section 112, paragraph 2: “Congress has provided this statute [section 112, paragraph 6] as a specific instruction on interpretation of the type of claim which otherwise might be held to be indefinite.” Data Line Corp. v. Micro Techs., Inc., 813 F.2d 1196, 1201 (Fed. Cir. 1987); accord Jonsson v. Stanley Works, 903 F.2d 812, 819 (Fed. Cir. 1990); see also Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1536 (Fed. Cir. 1991) (“Absent section 112(6), claim language which requires only a means for performing a function might be indefinite.”). Such a claim would, of course, be invalid under section 112, paragraph 2. Although both Apex and Linear, relied on dispositively and exclusively by the majority, found sufficiently definite structure in the claim language, both are distinguishable from the instant case, in which the claim language is dramatically different.

In Apex, a number of claim limitations using the term "circuit" were at issue. One such representative claim with the representative limitations was:

- a first interface circuit for receiving keyboard and cursor control device signals from the workstation;
- an on-screen programming circuit that produces video signals for display on the video monitor;
- a programmed logic circuit coupled to the first interface that transmits the keyboard and cursor control device signals to the programmable switch and controls the on-screen programming circuit to produce the video signals upon the detection of a predefined input from a user of the workstation, the programmed logic circuit further operating to detect keyboard or cursor control device signals received while the on-screen programming circuit is producing video signals on the video monitor and to control the programmable switch in response to the keyboard or cursor control device signals detected; and
- a second interface circuit disposed between the programmable switch and the selected computer for supplying the keyboard and cursor control device signals routed through the programmable switch to the selected computer.

325 F.3d at 1368; United States Patent No. 5,884,096, col. 13, I. 53 - col. 14, I. 24. In holding that the term "interface circuit" was not a means-plus-function limitation, we explained that "the term 'circuit' with an appropriate identifier such as 'interface,' 'programming' and 'logic,' certainly identifies some structural meaning to one of ordinary skill in the art." Apex, 325 F.3d at 1373 (emphasis added). Moreover, we elaborated that "interface circuit" connotes sufficiently definite structure because "interface" and "interface circuit" are defined in electronics and computing dictionaries so as to "connot[e] specific structures to one of ordinary skill in the art." Id. at 1374. We then remanded the case to the district court for further development of the record and a similar analysis for the remaining "circuit" terms. Thus, not every "adjectival qualification" ("A.Q.");id., connotes sufficiently definite structure for the term "circuit," but rather an "appropriate" A.Q., as demonstrated in Apex by technical dictionaries.

By contrast, the "circuitry" claim limitation in this case recites only the following and nothing more:

- aesthetic correction circuitry for interactively introducing aesthetically desired alterations into said appearance signals to produce modified appearance signals;

'919 patent, col. 15, II. 38-41. Unlike in Apex, here we have no evidence whatsoever that "aesthetic correction" is such an "appropriate" A.Q. that it would connote sufficiently definite structure to one skilled in the art. Indeed, "aesthetic correction" itself may be solely functional language. For example, we were shown no evidence that any technical dictionaries suggest to the artisan a sufficiently definite structure for "aesthetic correction circuitry" or even list such a term. Nor did experts from either side opine that one skilled in the art would understand "aesthetic correction circuitry" to connote sufficiently definite circuit structure. While Microsoft's expert Anthony Johnson stated that one skilled in the art would have understood "aesthetic correction circuitry" to mean "hardware that allows an operator to interactively introduce changes into the
appearance signals to create modified appearance signals," this does not connote definite structure, but merely some unspecified hardware structure. The record on appeal does not reflect the opinion of MIT's expert, Bradley Paxton, regarding the meaning of "aesthetic correction circuitry." Rather, in the paltry portion of his testimony in the appellate record, he merely discusses "circuitry" and the fact that "[c]ircuitry contains a lot of components, including wires." This fails to impart definite structure to "aesthetic correction circuitry" because the components and their arrangements are unstated. The inventor, William Schreiber, explained that "aesthetic correction circuitry" means to one skilled in the art "hardware or software used by the system operator to introduce desired alterations into the appearance signals of an image." Again, this does not elucidate a definite structure, but merely suggests some generic structure, namely, some unspecified arrangement of unidentified hardware components or software. Neither of MIT's experts even attempted to opine that "aesthetic correction" connotes definite structure such that "aesthetic correction circuitry" would suggest a sufficiently definite array of components to one skilled in the art. Thus, I cannot discern sufficiently definite structure from the term "aesthetic correction circuitry" to avoid means-plus-function treatment.

Similarly, in Linear, a representative claim with limitations concerning "circuit" recited:

A circuit for controlling a switching voltage regulator, the regulator having (1) a switch circuit coupled to receive an input voltage and including a pair of synchronously switched switching transistors and

(2) an output circuit including an output terminal and an output capacitor coupled thereto for supplying current at a regulated voltage to a load, the control circuit comprising:

a first circuit for monitoring a signal from the output terminal to generate a first feedback signal;

a second circuit for generating a first control signal during a first state of circuit operation, the first control signal being responsive to the first feedback signal to vary the duty cycle of the switching transistors to maintain the output terminal at the regulated voltage; and

a third circuit for generating a second control signal during a second state of circuit operation to cause both switching transistors to be simultaneously OFF for a period of time if a sensed condition of the regulator indicates that the current supplied to the load falls below a threshold fraction of maximum rated output current for the regulator, whereby operating efficiency of the regulator at low output current levels is improved.

379 F.3d at 1316. In ascertaining that these "circuit" limitations were not means-plus-function limitations, Linear began with the approach of Apex and CCS Fitness: "To help determine whether a claim term recites sufficient structure, we examine whether it has an understood meaning in the art." Id. at 1320. Linear then quoted two dictionary definitions of "circuit," one identical to the dictionary definition in Apex. Yet, while Apex merely concluded from these dictionary definitions that "circuit" connoted "some structural meaning to one of ordinary skill in the art," Apex, 325 F.3d 1364 at 1373 (emphases added), Linear relied on these dictionary definitions, Apex, and certain non-functional, operational claim language to state: "Thus, when the structure-connoting term 'circuit' is coupled with a description of the circuit's operation, sufficient structural meaning generally will be conveyed to persons of ordinary skill in the art, and § 112 P6 presumptively will not apply." Linear, 379 F.3d at 1320 (citing Apex, 325 F.3d at 1373) (emphases added). In its holding, however, Linear also required expert testimony as to whether these descriptions of the circuit's operation conveyed sufficient structure to an artisan: "We hold that because the term 'circuit' is used in each of the disputed limitations . . . with a recitation of the structural meaning generally will be conveyed to persons of ordinary skill in the art, the 'circuit' and 'circuitry' limitations of such claims are not means-plus-function limitations . . . ." Id. at 1320-21 (emphasis added). Thus, not any operational language suffices.

Linear therefore extended the reasoning of Apex such that the use of "circuit"coupled with a description of the circuit's operation may connote "sufficient structural meaning," id. at 1320, to one skilled in the art. In Linear, this description of the first circuit's operation was "for monitoring a signal from the output terminal to generate a first feedback signal." Id. The description of the second circuit's operation was "for generating a first control signal during a first state of circuit operation." Id. at 1316. Similarly, the description of the third circuit's operation was "for generating a second control signal during a second state of circuit operation to cause both switching transistors to be simultaneously OFF." Id. Importantly, however, Linear relied on expert testimony to determine whether these descriptions of the circuit's operation conveyed sufficient structure to one skilled in the art. "That persons of ordinary skill in the art would understand the structural
arrangements of circuit components from the term 'circuit' coupled with the qualifying language of claim 1 was recognized by Linear's expert witness," id. at 1320 (emphasis added), who opined that one skilled in the art "would have an understanding of, and would be able to draw, structural arrangements of the circuit elements defined by the claims." Id. (emphasis added). Thus, in Linear, it was not merely the particular descriptions of the operation of the circuit that connoted sufficient structure, but also the expert testimony that these descriptions conveyed sufficient structure to one skilled in the art because the artisan "would be able to draw[] structural arrangements of the circuit elements." Id.

Here, we face a description of only the circuit's function, not of how it operates with other circuits or devices to carry out that function. Moreover, even assuming we had a description of the circuit's operation, "for interactively introducing aesthetically desired alterations into said appearance signals to produce modified appearance signals," '919 patent, col. 15, ll. 38-41, we were shown no evidence from which to conclude that this description identifies the circuit components or conveys the arrangement of circuit components to one skilled in the art so that he could draw the circuit's elements and their sequence.

In sum, both Apex and Linear relied on additional information in the claim to determine whether the limitation as a whole conveyed sufficiently definite circuit structure, i.e., elements or components and their sequence, to an artisan. Apex relied on dictionary definitions of an accompanying "appropriate" A.Q. that suggested sufficiently definite structure to one skilled in the art. Linear relied on expert testimony that the claim's description of the operation of the circuit connoted definite structure. Here, we have neither a dictionary definition to establish that "aesthetic correction" is an appropriate A.Q. to suggest definite structure nor expert testimony that the accompanying description of the operation of the circuit, if any, connotes definite circuit structure-sequence of particular circuit components-to an artisan so that he could draw on paper the arrangement of the components needed.

A. The Wood '107 Patent - Claim One

In this claim for infringement, the plaintiff asserts that several of the defendants' computers literally infringe Claim one (1) of the Wood '107 Patent. Claim One calls for "a data processing apparatus" comprising of:

- a frame memory, having an output connected to a pixel bus, for presenting pixel data corresponding to locations in a displayed image;
- processing circuitry having an input coupled to the output of said frame memory, for converting said pixel data into a digital form corresponding to display intensity;
- inverting circuitry, for receiving the converted pixel data from said processing circuitry and for inverting the converted pixel data responsive to a cursor control signal;
- a cursor enable circuit coupled to said inverting circuitry, for generating said cursor control signal responsive to a current display location corresponding to a cursor location in the displayed image;
- output circuitry, coupled to said inverting circuitry, for presenting the output of said inverting circuitry to a display device;
- a video processor, coupled to said frame memory for accessing said frame memory and for storing data therein corresponding to an image to be displayed;
- a host processor, coupled to said video processor by way of a host bus, and
- a display device, coupled to said output circuitry.

After the language "processing circuitry," "inverting circuitry," "a cursor enable circuit," and "output circuitry," the defendants would add the term "means." However, Compaq argues that the elements are in structural, not means-plus-
The Wood '107 Patent invents a method for achieving a higher resolution (picture or graphic) "by increasing the density of picture elements ("pixels") within the screen area." The higher the pixel density, the smaller the pixel size, resulting in increased resolution of the displayed image. The higher pixel is generated by cursors. "A cursor is a block of pixels for indicating a particular location in the display area that may be seen on a multi-colored screen. See Wood ['107 Patent - Background of the Invention (1)]. The location of the cursor in the image communicates to the user the context of the desired input. Thus, the picture or graphic is more "accurate and lifelike" to the viewer.

The defendants assert that the elements of Claim One, which discloses a circuitry, should be construed in a mean-plus-function limitations. However, the terms "means," "function" and "means for" are not included in the Claim language. Thus, the presumption in law, that the Claim should not be construed as "means for" language must be overcome by the defendants.

To overcome the presumption that § 112(6) is inapplicable, the defendant relies on the expert report of Marcian E. Hoff. However, the Hoff report does not create a dispute concerning the defendants' machine structure of the defendants' computers as they relate to Compaq's. In this regard, the structure requires: (a) a processing circuitry that is coupled to the frame memory; (b) inventing circuitry that receives the converted pixel data from the processing circuitry and inverts, in response to a cursor; (c) a cursor enable circuit that is coupled to the inventing circuitry that is coupled to the inverting circuitry and generates the cursor control signal claimed; (d) a controller in the defendants' computer coupled to the circuitry that presents the output from the inverting circuitry to a monitor; (e) a video processor coupled to frame memory, or graphics controller; (f) a host processor (microprocessor) coupled to the graphics controller by either a PCI or AGP bus; and (g) a display device (video monitors) coupled to the output circuitry.

The sole question remaining is whether the structure disclosed by Compaq's computers should be limited to the specification by which they perform the function. The Court is of the opinion that they should not. Clearly, the Claim calls for electronic circuitry, not a computer program or other mechanical structures. Therefore, the defendants' evidence fails to overcome the presumption that § 112(6) does not apply.

Accordingly, the Court holds that the Claim elements describe an apparatus and proper interpretation calls for electronic circuitry that performs the tasks as claimed in the invention, without limitation as to the type of electronic circuits. Moreover, because the defendants make, use, offer to sell or sells the same or equivalent apparatus, they infringe Claim One of the Wood '107 Patent. See 35 U.S.C. § 271(a). Summary judgment is appropriate for Compaq on this Claim.  

616

1. Construction of "Call Progress Detector Circuitry for Detecting a Call Waiting Signal"

Plaintiffs contend that the claim language "call progress detector circuitry for detecting a call waiting signal" needs no construction. Defendants contend that this limitation should be construed as "[a] collection of electrical hardware components configured to detect a conventional call waiting system." (Def.'s Handout p. 17. n2)

n2 At the hearing, Defendants submitted copies of a summary of its proposed claim constructions to this Court. (See Defendant IEI's Proposed Claim Construction, Claim Construction Hearing, Friday, March 23, 2007 ("Def.'s Handout").) Although the constructions proposed in this handout differ from the constructions proposed in its claim construction brief, Defendants confirmed that the constructions set forth in the handout constitute its final proposed constructions. (Compare Def.'s Handout p. 17 (providing that "call progress detector circuitry for detecting a call waiting signal" should be construed as "[a] collection of electrical hardware components configured to detect a conventional call waiting system" with Def.'s Cl. Constr. Br. p. 6 (providing that this claim language should be construed as requiring "electronic circuitry (i.e., a collection of hardware components) that is configured to detect a conventional call waiting signal and then output a corresponding signal.").)
The parties' dispute hinges on whether the claim term "circuitry" excludes "software based implementations, such as firmware or a microcontroller that may be programmed with software for accomplishing a particular task." (Def.'s Cl. Constr. Br. p. 7.) Plaintiffs contend that "circuitry" does not exclude so-called "software based implementations" whereas Defendants maintain that such implementations are excluded.

In constructing their argument, Defendants rely on Linear Tech. Corp. v. Impala Linear Corp., 379 F.3d 1311 (Fed. Cir. 2004) and Massachusetts Instit. of Tech. v. Abacus Software, 462 F.3d 1344 (Fed. Cir. 2006). n3 In the Linear Tech. decision, the United States Court of Appeals for the Federal Circuit considered whether certain claim limitations involving the term "circuit" or "circuitry" are means-plus-functions limitations subject to 35 U.S.C. § 112 P 6. n4 The Federal Circuit concluded that, because none of the disputed limitations included the word "means," the rebuttable presumption that § 112 P 6 does not apply was triggered:

[W]hen the structure-connoting term "circuit" is coupled with a description of the circuit's operation, sufficient structural meaning generally will be conveyed to persons of ordinary skill in the art, and § 112 P 6 presumptively will not apply. See Apex Inc. v. Raritan Computer, Inc., 325 F.3d 1364, 1373 (Fed. Cir. 2003) ("[T]he term 'circuit' with an appropriate identifier such as 'interface,' 'programming' and 'logic,' certainly identifies some structural meaning to one of ordinary skill in the art.").

Linear Tech., 379 F.3d at 1320.

The Federal Circuit faced a similar situation in Abacus Software. In that case, the parties disputed whether the term "aesthetic correction circuitry" connoted sufficient structure to avoid § 112 P 6 treatment. Abacus Software, 462 F.3d at 1355. After citing its prior decisions in Linear Tech. and Apex Inc., the Federal Circuit noted that:

The claim language here too does not merely describe a circuit; it adds further structure by describing the operation of the circuit. The circuit’s input is "appearance signals" produced by the scanner; its objective is to "interactively introduce[] aesthetically desired alterations into said appearance signals"; and its output is "modified appearance signals." This description of the operation of the circuit is sufficient to avoid 112 P 6.

Id. at 1356 (citation omitted). The Federal Circuit also rejected the plaintiff's argument that "aesthetic correction circuitry" includes both hardware and software. "Although the specification suggests that certain computation performed by the [Color Translation Module] can be accomplished with either hardware or software . . . [w]e conclude that the term 'circuitry' in claim 1 is limited to hardware." Id. at 1356-57 (emphasis in original).

The Linear Tech. and Abacus Software decisions, however, are not concerned with the precise issue upon which Defendants seek a ruling, i.e., whether the term "circuitry" includes hardware but does not extend to so-called "software based implementations," e.g., programmable microcontrollers. In Linear Tech., for example, the Federal Circuit did not discuss whether "circuitry" includes just hardware, software, or software based implementations. In Abacus Software, the Federal Circuit concluded that "circuitry" excludes software, see 462 F.3d at 1357, but did not consider whether that term also excludes "software based implementations." n5 Accordingly, this Court cannot accept Defendants' argument that limitations involving the term "circuitry" necessarily exclude "software based implementations, such as firmware or a microcontroller

- 1095 -
that may be programmed with software for accomplishing a particular task." (Def.'s Cl. Constr. Br. p. 7.)

n5 Instead, the Federal Circuit appeared concerned with a less fine-grained distinction. See Abacus Software, 462 F.3d at 1357 n.7 (defining "hardware" as "the mechanical, magnetic, electronic, and electrical devices comprising a computer system" and "software" as "the programs used to direct the operation of a computer"). Against this backdrop, the Federal Circuit held that claim limitations involving the term "circuitry" could not be interpreted to include software. Id. at 1356-57 ("Although the specification suggests that certain computations performed by the [Color Translation Module] can be accomplished with either hardware or software, this reference does not alter the specification's repeated description of the circuit itself as involving hardware.")(emphasis added).

In addition, there is no reasonable dispute that the specification and prosecution history of the '771 Patent use the term "circuitry" to refer to programmable microcontroller 412. Specifically, claim 1 references "circuitry to recognize a first signal with a duty cycle or cadence coupled with frequency and level indication of a call waiting SAS signal or a distinctive call waiting SAS signal." '771 Patent, Col. 14, ll. 23-26 (emphasis added). The specification explains that, in the preferred embodiment, this limitation is satisfied by microcontroller 412. Id. at Col. 10, ll. 47-50 ("[T]he principal function of [microcontroller 412] is to receive call progress signals, specifically for the preferred embodiment of the present invention, it is the call progress signal (SAS) alerting signals for CW and DCW."). Finally, the specification points out that microcontroller 412 is programmed. Id. at Col. 10, ll. 60-63 ("The microcontroller 412 is programmed with timing algorithms, which provide the flexibility for recognition of CW and a plurality of DCW signals.")(emphasis added). The prosecution history also uses the term "circuitry" to refer to microcontroller 412. (See Pl.'s Cl. Constr. Br. Ex. C (the "Dec. 12, 2002 Amendment").)

As a result, even if Defendants were correct that one of ordinary skill in the art would understand the claim term "circuitry" to exclude software based implementations, the written description and prosecution history use that term "in a manner clearly inconsistent with the ordinary meaning." See Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1204 (Fed. Cir. 2002) (stating that if the specification uses the words in a manner clearly inconsistent with the ordinary meaning of a dictionary definition, the inconsistent dictionary definition must be rejected); see also Irdeto Access, Inc. v. EchoStar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004) ("It is well-established that the patentee can act as his own lexicographer, so long as he clearly states any special definitions of the claim terms in the patent specification or file history.")(citation omitted). Moreover, to the extent that Defendants seek a construction of "circuitry" that excludes software based implementations such as programmable microcontrollers, n6 it follows that such a construction would exclude the preferred embodiment that incorporates microcontroller 412. A claim construction that excludes a preferred embodiment, however, "is rarely, if ever, correct and would require highly persuasive evidentiary support... ." Vitronics, 90 F.3d at 1583 (citations omitted). In this case, of course, no extrinsic evidence of any kind was submitted in connection with the meaning of the claim term "circuitry."

n6 At the hearing, Defendants suggested that their proposed construction of the claim term "circuitry" applies to every use of that term in the claims of the '771 Patent. In addition, this Court notes that it is not clear whether Defendants' proposed construction would, if adopted, exclude so-called "software based implementations." As noted above, Defendants contend that "call progress detector circuitry for detecting a call waiting signal" should be construed as "a collection of electrical hardware components configured to detect a conventional call waiting system.". One could reasonably view this proposed construction, however, as exchanging one term ("circuitry") that is arguably ambiguous with respect to software based implementations for a set of terms ("electrical hardware components" that have been "configured") that are equally ambiguous with respect to software based implementations.

Finally, this Court notes that there is no confusion about the meaning of the claim language "call progress detector circuitry for detecting a call waiting signal" other than the dispute regarding "circuitry." The parties acknowledge that the limitation
at issue calls for circuitry for performing the task of detecting a call waiting signal. (See Pl.’s Cl. Constr. Br. p. 11; Def.’s Handout p. 18.) Defendants do not argue, and did not submit expert testimony to suggest, that one of ordinary skill in the art would have a difficult time understanding the meaning or scope of this limitation. There is no suggestion, moreover, that the relevant claim language is governed by 35 U.S.C. § 112 P 6. Finally, the parties recognize that the "call progress detector" of the preferred embodiment is the commercially available Teletone M-981 tone detector. (See Pl.’s Cl. Constr. Br. p. 11; Def.’s Handout p. 21); see also ’771 Patent, Col. 10, ll. 6-10 ("Isolation and protection circuitry 430 output is connected to a commercial call progress tone detector circuit 413, such as a Teletone M-981, comprising of, but not limited to, a differential amplifier, reference generator, bandpass filter, and a level sensor.").

In sum, the sole dispute with respect to the claim language "call progress detector circuitry for detecting a call waiting signal" involves the claim term "circuitry." (See Def.’s Handout p. 18.) For reasons explained above, this Court rejects Defendants’ argument that claim limitations involving the term "circuitry" necessarily exclude so-called "software based implementations." n7 Therefore, this Court concludes that no further construction of the claim language "call progress detector circuitry for detecting a call waiting signal" is necessary. This language is found in claims 1, 6 and 9 of the ’771 Patent.

--- Footnotes ---

n7 This Court notes that the specification of the ’771 Patent contains language suggesting that the claim term "circuitry" encompasses software based implementations. See ’771 Patent, Col. 14, ll. 1-6 ("[W]hile the disclosed embodiments of the present invention utilize programmed processors, and special-purpose integrated circuits, and digital processors these devices can be implemented using discrete devices, or any analog or hybrid counterpart of any of these devices."); cf. Abacus Software, 462 F.3d at 1357 (interpreting similar language as suggesting that certain computations can be accomplished by software based implementations that involve hardware).

--- End Footnotes ---

6. Signal interface including "circuitry for limiting transmission of the internal signal in the high frequency band from the telephone wiring network to the telephone exchange"; Signal interface including "circuitry for limiting transmission of signals in the high frequency band from the telephone wiring network to the telephone exchange": the signal interface includes circuitry that prevents high frequency signals (i.e., frequencies above the telephone voice band between 0.25 MHZ and an undetermined upper limit) from traveling upstream from the signal interface to the telephone exchange.

Defendants propose this claim term means the signal interface must include "circuitry that prevents high frequency signals (i.e., signals of 250 kHz and higher) from traveling upstream on the telephone wiring network to the telephone exchange." n27 Inline argues that this phrase "requires that the high frequency analog signals encoded by the signal interface for transmission downstream to the transceiver, including but not limited to, frequencies in a range above 250 kHz, are limited from transmitting upstream to the telephone exchange." n28

--- Footnotes ---

n27 D.I. 470 at 23.
n28 D.I. 452 at 2.

--- End Footnotes ---

The court construes this phrase based on its prior rulings. The court has already determined that the signal interface is designed to prevent high frequency signals from passing onto the public trunk line and back to the telephone exchange. n29 The court construed "high frequency band" as "frequencies above the telephone voice band between 0.25 MHZ and an undetermined upper limit." n30 The court, and defendants, n31 do not disagree that the "comprising" transitional phrase may mean that signals other than those in the high frequency band may be prevented from transmitting to the telephone exchange.
exchange. At a minimum, however, the signal interface must have circuitry for preventing transmission of high frequency band signals (as previously construed by the court) to the telephone exchange. \footnote{29}{2004 Markman Opinion, 302 F. Supp. 2d at 323-24 (citing the '596 patent, 48:37-39; Figure 2; and the prosecution history of the '596 patent).}

After the court construed "high frequency band" in its October 19, 2004 Memorandum Opinion, the parties represented that they did not wish to present arguments concerning the upper limit of the "high frequency band." \footnote{30}{Inline Connection Corp. v. AOL Time Warner Inc., 347 F. Supp. 2d 56, 80 (D. Del. 2004).}

Consistent with the court's prior construction of that phrase, therefore, the court construes the phrase at issue as requiring the signal interface to have "circuitry that prevents high frequency signals (i.e., frequencies above the telephone voice band between 0.25 MHZ and an undetermined upper limit) from traveling upstream from the signal interface to the telephone exchange."

\footnote{31}{See D.I. 470 at 27-28.}

\footnote{32}{See Amgen Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1345-46 (Fed. Cir. 2003) ("Comprising is a term of *1345 art used in claim language which means that the named elements are essential, but other elements may be added and still form a construct within the scope of the claim." (quoting Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997)).)

The parties' dispute appears to focus on the last portion of Defendants' proposed construction, i.e., whether "circuitry for performing a mute . . . and transferring" performs the relevant operations "without placing an on-going modem connection on hold." \footnote{10}{(Def.'s Handout p. 48.)

n9 It is difficult to identify the claim language that is disputed. (Compare Def.'s Cl. Constr. Br. p. 21 (requesting that this Court construe the claim phrase "line seizure circuitry for . . . muting . . . and . . . transferring") with Def.'s Handout p. 48 (requesting that this Court construe the claim phrase "circuitry for performing a mute . . . and transferring").) This difference might be meaningful as one phrase occurs in claim 6 while the other is found in claim 9. Compare '771 Patent, Col. 16, ll. 56-59 (claiming "first line seizure circuitry for performing the flash operation, muting the telephonic device connected to the data port and transferring from the data port to the voice/Fax port. . . .") with '771 Patent, Col. 15, ll. 8-11 ("first line seizure circuitry for performing a mute and disconnect of the telephonic device connected to the data port and transferring from the data port to the voice/Fax port. . . ."). Relying on Defendants' representation that the handout submitted at the Markman hearing contains its final proposed claim constructions, this Court assumes that Defendants only seek to construe the language "circuitry for performing a mute . . . and transferring" set forth in claim 6 of the '771 Patent.

n10 This proposed construction differs from the one set forth in Defendants' claim construction brief (See Def.'s Cl. Constr. Br. p. 21 (proposing that the relevant claim language be construed as requiring circuitry for "muting a telephonic device attached a [sic] data port and switching the connection from the telephone to another port").)
on hold." In support of their proposed construction, Defendants emphasize that the specification "teaches that transferring the line without putting the modem line on hold was an important feature of the invention." (Def.'s Handout p. 50 (emphasis in original).) Defendants also take the position that this limitation requires that the claimed invention disconnect the modem line instead of placing it on hold. (Id. ("Inventors specifically distinguished systems that placed the modem line on hold rather than simply disconnecting it.").) Plaintiffs respond that the phrase "without placing an on-going modem connection on hold" inserts a new, unnecessary limitation into the claim that is irrelevant to the disclosed invention.

Defendants proposed construction fails for two reasons. First, it lacks support in the intrinsic record. The written description distinguishes prior art schemes that adapt modems for use with call waiting. See generally '771 Patent, Col. 2. The specification notes that one disadvantage of these systems is that they are "not independent" of the modem connected to the internet because they "must pass information or signals to a modem or modem interface." Id. at Col. 2, ll. 31-34. Specifically, they "adapt[] a modem interface" for purposes of "maintain[ing] the data session on hold while responding to a third party call." Id. at Col. 2, ll. 27-29. Such systems are contrasted to the claimed invention, which does not require a particular modem or modem interface and is therefore "independent of the type of telephone devices connected to the internet." Id. at Col. 2, ll. 52-53. This context is important because it shows that the additional limitation sought by Defendants--"without placing an on-going modem connection on hold"--is relevant to understanding how the claimed invention differs from prior art schemes, but not the meaning of the claim language itself.

Second, Defendants' contention that the limitation "circuitry for performing a mute . . . and transferring" requires that the modem line be disconnected is contradicted by the specification:

Another aspect of the present invention is to provide a signal detection, alerting and switching management device of the general character described which permits a single telephone line subscriber utilizing the telephone network for a data transmission, to employ a telephone feature such as distinctive call-waiting to answer a distinctive incoming caller, or the option not to answer, without terminating the data session.

'771 Patent, Col. 4, ll. 33-41 (emphasis added). The intrinsic record acknowledges that the device claimed by the '771 Patent may terminate the data session by disconnecting the modem line. Id. at Col. 11, ll. 27-28 ("[D]isconnect operations are performed by the line seizure and control switch circuitry 416."); (Dec. 12, 2002 Amendment p. 10 ("[T]here is no concern that the connection is lost (we state that it is acceptable to reconnect using a mouse click).".). However, disconnecting the modem line does not appear to be required by the claim language at issue. Therefore, this Court concludes that no further construction of the claim language "circuitry for performing a mute . . . and transferring" is necessary. This phrase is found in claim 6 of the '771 Patent.

Buffers are electrical devices having sectors divided into tracks for the storage of data. Blocks of data can be stored in consecutive tracks or disparately throughout the storage device, as long as data can be correlated logically. Thus, data written onto a track can have both a "physical address" and a "logical address." The "physical address" identifies the sector
the "logical address" explains how data with one physical address is related to data with a different physical address. "Look-up tables" are used to correlate the logical and physical addresses. (Decl. of Hellman at 3-8.)

The district court construed the "circular storage buffer" limitation to mean:

- a physical memory device that contains digital signal values and that is circular in the sense that when the last address is reached, the next address accessed is the first address location. While the digital input signal values are always stored in the same repeating physical addresses, these addresses do not have to be physically contiguous. The "circular buffer limitation" requires that the circular buffer store the digital input signal values in continually advancing physical addresses.

Summary Judgment Opinion at 17. The district court explained that the claim requires that "digital signal input values representing an incoming audio or video program signal" be written into memory, and that when the circular buffer "writes over the oldest of said input signal values," it must write over the oldest actual signal values and not just the logical address. Id. at 16-17. The district court went on to reason that the extrinsic evidence proffered by Pause conflicted with the claim language, and that nothing in the intrinsic record defined the buffer as "logically" circular. Id. at 14-16. The district court concluded that "this claim limitation precludes a logical circular buffer which would only store pointers or references that wrap around." Id. at 17.

Pause asserts that the claimed "circular storage buffer" can be a buffer system that stores data at "continually advancing" logical addresses. In such a system, when the write address circles back to the oldest logical address, that address is overwritten by a new logical address, which is correlated to the physical address of the newest input signal values. According to Pause, the claimed buffer need not immediately circle back and write over the actual signal values, which may remain stored at the oldest physical address.

To support its construction, Pause quotes from the Encyclopedia of Computer Science 143 (3d ed. 1993), which says that "circular buffering . . . typically uses a single buffer, usually one that is larger than a single physical record and which is managed as a queue. The basic strategy is to give the appearance that the buffer is organized in a circle with data 'wrapping around' . . . ." Id. Pause argues that this description reflects the ordinary meaning of "circular storage buffer." Pause notes that the claim recites, inter alia, a "circular storage buffer" comprising "an addressable digital memory," "a programmed processor," and "memory access means." '801 reissue patent, col. 6, ll. 23-25. Pause argues that the inclusion of a "programmed processor" indicates the use of a logical addressing scheme. Pause asserts that the "writing addresses established by said processor" at which data is stored, id., ll. 28-29, need not be physical addresses. Pause also argues that the written description does not disclose a "fully physical addressing scheme" and that the written description is only consistent with logical addressing. In Pause's view, physical addressing would read out an embodiment. Pause adds that the Examiner reviewing the reissue application did not think that "circular storage buffer" was limited to physical addressing.

TiVo responds that regardless whether a circular buffer could employ logical addressing, the claimed buffer must write to "continually advancing" physical addresses. According to TiVo, the phrase "circular storage buffer" as used in the context of the claim requires that the system "write over" signal values stored at the oldest physical address with the newly input signal values, which are then stored at the same physical address. TiVo argues that Pause's construction ignores the surrounding words in the claim. TiVo asserts that the written description and prosecution history are consistent with its proposed construction. We agree with TiVo.

We begin with the language of the claim. The claimed "circular storage buffer" comprises, inter alia, a "memory access means [that] continuously writes said sequence of digital input signal values in to said addressable digital memory." Id., ll. 23-27. The writing occurs "at a sequence of continually advancing writing addresses established by said processor to write over the oldest of said input signal values recorded in said digital memory as said sequence of writing addresses are advanced." Id., ll. 27-32. In this way, "said digital input signal values received during said immediately preceding time interval of predetermined duration are stored in said addressable memory." Id., ll. 27-35. The antecedent for "said digital input signal values" is the "digital input signal values representing an incoming audio or video program signal." Id., ll. 9-10. Thus, as "writing addresses" advance, new signal values "write over" the "oldest of [the] input signal values recorded in [the] digital memory." Id., ll. 30-32.

Pause urges us to ignore the "write over" clause and other language appearing later in the claim in construing "circular
storage buffer." Specifically, Pause argues that "regardless of what claim language appears in a later portion of the claim, that language should not be read into the interpretation of a separate claim element." However, "proper claim construction . . . demands interpretation of the entire claim in context, not a single element in isolation." Hockerson-Halberstadt, Inc. v. Converse Inc., 183 F.3d 1369, 1374 (Fed. Cir. 1999); accord Philips, 2005 U.S. App. LEXIS 13954, at *27 ("The context in which a term is used is the asserted claim can be highly instructive."); ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1088-90 (Fed. Cir. 2003) ("While certain terms may be at the center of the claim construction debate, the context of the surrounding words of the claim also must be considered . . . ."); Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1299 (Fed. Cir. 2003) (same). The parties dispute how the claimed "circular storage buffer" must operate to store digital signal values in memory and, specifically, whether the claim is broad enough to cover a buffer implemented through purely logical addressing. The "write over" clause and other language appearing later in the claim detail how the buffer employs addressing to store digital signal values in memory. There is no basis for us to ignore that language in properly construing the claim language in dispute.

Because the claim recites that the "circular storage buffer" must function to "write over" the oldest digital signal values in memory as the sequence of writing addresses advances so that the new digital signal values are stored in memory, '801 reissue patent, col. 6, ll. 23-35, a logical implementation in which the oldest digital signals remain in memory for some period impermissibly conflicts with the plain meaning of the claim. See Philips, 2005 U.S. App. LEXIS 13954, at *39 ([A] court should discount any expert testimony that is clearly at odds with the claim construction mandated by the claims themselves, the written description, and the prosecution history, in other words with the written record of the patent." (internal quotations omitted) (emphasis added)); Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1584 (Fed. Cir. 1996) (noting that expert testimony may not be used "to vary or contradict the claim language"). The context of the claims makes clear that the term "write over" means that new signal values replace the oldest signal values in memory.

Pause argues that the digital signal values need not be stored in the same repeating physical addresses. Pause adds that the buffer need not be circular in the sense that when the last address is reached, the next address accessed is the first address location. However, because the claim specifies that the new digital signal values replace the oldest digital signal values in memory, the new signal values must be written to the physical address of the oldest signal values. Because the new signal values must be written to the physical address of the oldest signal values, and because the writing addresses are continually advancing, when the last physical address is reached in the buffer, the next address accessed will be the address at which the oldest digital signal values are stored, i.e., the first physical address location. In this manner, digital signal values are stored in the same repeating physical addresses. We also reject Pause's argument that an implementation of the buffer through physical addressing is inconsistent with the written description and would read out an embodiment. The written description says that "the memory subsystem 5 continually stores the incoming data, writing over the oldest data stored on the hard disk 7," '801 reissue patent, col. 3, ll. 11-15, and, thus, is not inconsistent.

The prosecution history also confirms that the claimed "buffer" must employ physical addressing. In a June 27, 1997 Office Action ("Office Action"), the Examiner said that "circular buffer" was "a term well-known in the art and used to describe a memory controlled so as to continuously record-ultimately over the oldest-recorded material." Office Action at 3. The Examiner concluded that it would have been obvious to modify the memory-management algorithm in Goldwasser et al., U.S. Patent No. 5,241,428 ("Goldwasser"), to implement a circular buffer, and entered a final rejection. Id. at 2 & 8. In a January 9, 1998 Preliminary Amendment ("Amendment"), the applicant added language "to more clearly distinguish [his] invention" and asserted that:

claim 1 as amended requires the presence of a circular storage buffer for storing those digital input values representing audio or video programming which was received during the immediately preceding time interval of predetermined duration. The circular storage buffer as claimed includes an addressable digital memory and memory access means for continuously writing into the addressable digital memory at a sequence of continually advancing writing addresses to write over the oldest of said input signal values recorded in said digital memory as said sequence of writing addresses are advanced so that said digital input signal values received during said immediately preceding time interval of predetermined duration are stored in said addressable memory.

Amendment at 5. The applicant then distinguished Goldwasser:

Goldwasser et al. teach both analog tape memory and digital random-access memory embodiments of their invention, neither of which operates as claimed in applicants' claim 1. The reel-to-reel tape embodiment shown in Goldwasser et al.

- 1101 -
Figs. 1 and 2 is physically incapable of operation as a circular buffer since the recording head cannot physically write over the oldest of the signal values which are located on the tape wound at the interior of the take-up reel. The digital random access mechanism seen in Fig. 3, as noted by the Examiner, employs an address control mechanism which operates in accordance with the algorithm shown in Fig. 4, is not a circular buffer, and has no mechanism for writing over the oldest recorded signal values as claimed.

... It is submitted that nothing in the cited art would suggest to one of ordinary skill in the art that the function of the Goldwasser et al. recorder should be altered by substituting a circular storage buffer which, as claimed, writes over the oldest of said input values recorded.

Applicants' invention works in a way not taught by Goldwasser et al. Applicants' circular buffer is fully loaded during viewing and the oldest recorded programming is being continuously overwritten. ... The buffer memory is fully loaded with prior programming at time viewing begins. Nothing in any of the cited references suggests or discloses this unique mode of operation in which the oldest material is being continually overwritten.

Id. at 5-7.

Thus, Pause made clear to the Examiner that the buffer "as claimed" is "unique" in that it must write over the oldest signal values recorded in the digital memory as the writing addresses advance. Id. at 5. In other words, the "oldest material" stored at the oldest physical address must be "continuously overwritten" with newly inputted signal values, which are stored at the same repeating physical addresses. Because this construction is driven by the use of "circular storage buffer" in the context of the claim and is supported by the written description, a broader construction that lacks support in the intrinsic record must yield. See Phillips, 2005 U.S. App. LEXIS 13954, at *40-* 42; see also Vitronics, 90 F.3d at 1584-85 ("Regardless of how those skilled in the art would interpret a term in other situations, where those of ordinary skill ... would conclude that the [patent] documents preclude the term being given the meaning propounded by the expert witnesses, we must give it the meaning indicated by the patentee in the patent claim, specification, and file history.").

Pause's final argument as to this limitation is that the "physical address," "same repeating," and "last address/next address" language employed in the district court's construction does not appear verbatim as claim language, and that an interpretation employing this language impermissibly narrows claim scope. Pause correctly notes that courts cannot "rewrite" claims. However, in clarifying the meaning of claim terms, courts are free to use words that do not appear in the claim so long as "the resulting claim interpretation ... accords with the words chosen by the patentee to stake out the boundary of the claimed property." Cf. Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998) (noting that "without any claim term susceptible to clarification ... there is no legitimate way to narrow the property right").

In this case, we agree that the district court's claim construction stayed true to the claim language as it is used in the context of the claim itself. Moreover, the district court's interpretation is consistent with the written description and prosecution history. Accordingly, we affirm the district court's construction of the "circular storage buffer" limitation.
4. "Claim level:" 4 "Structured set of information about an insurance claim." For the above reason, the court rejects plaintiffs' proposed construction of "any insurance claim." In all other respects, the parties agree with this construction, which is consistent with col. 84:37-63.

b. Connection to an External Power Source

UI asserts that the definition of "clamping" should include the requirement that it be "accomplished via an electrical connection to a fixed bias (e.g., power supply or ground)." UI Claim Construction Brief at 31. In other words, UI's definition limits clamping to instances involving an external power supply. Fujitsu, on the other hand, takes the position that the common and ordinary meaning of the word "clamping" refers to the act of adding "any voltage reference, whether 'externally' or 'internally' generated." Fujitsu Claim Construction Brief at 39. The Court concludes that "clamping" need not be accomplished through a connection to an external power supply but rather, can be accomplished by adding any voltage reference, whether internally or externally generated.

The starting point for the Court's analysis is the definition of "clamping" found in the IEEE Dictionary, which is instructive in determining the common and ordinary meaning of the term. The IEEE Dictionary defines "clamping" as "[a] function by which the extreme amplitude of a waveform is maintained at a given level." IEEE Dictionary (3d Ed. 1984) at 146, Exh. K to Nui Decl. The IEEE dictionary definition is silent as to whether clamping requires a connection to an external power supply or rather, may also be accomplished through connection to an internally generated reference voltage. Thus, this definition supports Fujitsu's position that one of ordinary skill in the art in 1986 would not have understood the term "clamping" to include the limitation contained in UI's definition of the term. 12

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

12 Fujitsu also cites to a number of patents, including a patent issued to Dr. Weber, in which the term "clamping" refers to fixing to an internally generated reference voltage. See Silzars Decl. at PP221-222. Although the Court places less weight on this extrinsic evidence than it does on the words of the patent and the IEEE dictionary definition, this evidence also offers some support for Fujitsu's argument that the definition of "clamping" does not include a requirement that there be a connection to an external power supply. Nor is the Court persuaded by UI's argument that all of this prior art is inapposite because the referenced patents do not involve plasma display panels. As discussed below, the '349 and '400 patents explicitly state in the Abstract that the invention is not limited to plasma panels but also can be used with electroluminescent panels and with liquid crystal panels. Because the invention is not limited to plasma panels but rather covers a variety of types of panels, the prior art cited by Fujitsu is relevant to the construction of the word "clamping" in the '349 and '400 patents.

The Court does not place a great deal of weight on the deposition testimony cited by Fujitsu of inventors Dr. Weber and Mr. Wood. See Silzars Decl. at P222. In the cited testimony, neither Dr. Weber nor Mr. Wood addresses directly the question of whether "clamping" requires a connection to an external power source. Although their failure to mention such a requirement might support Fujitsu's position, that evidence is of very limited probative value. Nor does the Court find the decision of the European Patent Office revoking the European counterparts of the '349 and '400 patents to be helpful. See Exh. 66 (September 26, 2000 Decision revoking patent); Exh. 67 to Silzars Decl. (September 26, 2002 decision on appeal affirming revocation of patent); Silzars Decl. at P223. Neither the original decision revoking the patent nor the decision affirming the revocation explicitly addresses the question of whether "clamping" requires a connection to an external power source.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -
UI suggests, however, that even if the term "clamping" is not generally understood to require a connection to an external power supply, the term is defined differently when it is used in the context of plasma display panels. In particular, UI asserts that:

Clamping the voltage across a plasma display panel is not comparable to clamping the voltage in other contexts -- even to clamping in the context of other display technologies. Unlike in other display technologies, a source of significant current is required to clamp the voltage of a plasma display panel because of the large and abrupt gas discharge current that is drawn when pixels are illuminated.

UI Reply Claim Construction Brief at 21. UI does not, however, present any evidence that one of ordinary skill in the art in 1986 would have understood that the word "clamping" carried a different meaning when used in the context of plasma display panels than when used with reference to other types of display panels. Moreover, UI's argument is unpersuasive to the extent that the '349 and '400 patents explicitly state in the Abstract that the invention is not limited to plasma panels but also can be used with electroluminescent panels and with liquid crystal panels.

Finally, the Court rejects the assertion by Dr. Inan that a "special definition" is given to the word "clamping" in the Patents. Inan Report at 44. Dr. Inan relies exclusively on the fact that in all of the preferred embodiments in the Patents, clamping is accomplished through a connection to an external power source, namely, Vcc or ground. See id. The presumption that words in a patent carry their common and ordinary meaning may be overcome when a special definition is "clearly stated" in the patent, that is, when the specification "expressly defines terms used in the claims or when it defines terms by implication." See Vitronics, 90 F.3d at 1582. On the other hand, it is well-established that the scope of an invention disclosed in a patent is not limited to the preferred embodiments but rather, is defined by the claim terms. See Autogiro Co. of America v. United States, 181 Ct. Cl. 55, 384 F.2d 391, 398 (Fed. Cir. 1967). The latter rule would be rendered meaningless if the Court were to accept UI's argument and hold that the term "clamping" has a special definition that is more limited than the common and ordinary understanding of the word simply because only a certain type of clamping is used in the preferred embodiments. Therefore, the Court concludes that even though the preferred embodiments in the Patents involve clamping to an external power source, this fact alone does not provide a sufficient basis to find that the word "clamping" has a special definition in the '349 and '400 patents.

c. Clamping as Maintaining vs. Clamping as Adding a Voltage Reference Level

UI argues that "clamping" is a type of "maintaining" rather than a type of switching. UI Claim Construction Brief at 31. Because clamping is simply a type of maintaining the panel capacitance in a charged or discharged state, UI asserts, it does not refer to the switching that may occur prior to clamping, which is at most a "possible condition precedent" to clamping. Nor, for example, does clamping refer to the short period shown in Figure 8 between the time when switch S3 is closed and the point when the panel capacitance reaches Vcc, according to UI. Fujitsu, on the other hand, argues that "clamping" includes the act of switching to add a voltage reference, as well as maintaining the voltage reference once the panel capacitance reaches the level of the reference voltage. The Court finds Fujitsu's position more persuasive.

The IEEE Dictionary defines a "clamping circuit" as one that "adds" a reference voltage, suggesting that "clamping" includes the act that adds the reference voltage as well as the maintenance of that voltage level. IEEE Dictionary at 146, Exh. K to Nui Decl. This construction is supported by the claims and written description of the '349 and '400 patents. In particular, switching is repeatedly equated with "clamping." See, e.g., '400 patent, col. 22, ll. 47-48 ("third switch means . . . for clamping"), 55-56 ("fourth switch means . . . for clamping"). It is inconsistent with the usage in the patent to exclude the very act that "clamps" the voltage level from the definition of clamping.

Accordingly, the Court defines "clamping" as "the act of adding a specific reference voltage level, which results in holding the panel capacitance at such reference voltage level." Further, as noted above, "clamping" need not be accomplished through connection to an external power supply but rather, can be accomplished by adding any voltage reference, whether internally or externally generated.
Claims 1 and 20 of the 651 patent require that "said product relationships comprising an includes classification." Trilogy contends that the court should define "includes classification" as "a classification in which a second set of one or more elements is included when all members of a first set of one or more elements exist in a configuration." Selectica contends that the court should define the term to mean "a designation identifying elements that are included automatically in the configuration when a set of one or more elements are selected." After reviewing the briefs and the arguments of counsel, the court is persuaded that Trilogy's construction is correct.

The term "includes classification" means "a classification in which a second set of one or more elements is included when all members of a first set of one or more elements exist in a configuration."

1. "sorting" and "classifying"

ADE argues that the words "sorting" and "classifying" as used in the '525 patent have an ordinary meaning in the art. ADE further asserts that one of ordinary skill in the art would recognize that the '525 patent teaches "sorting" and "classifying" of defects on the surface of silicon wafers according to pre-selected criteria or "recipe[s]." D.I. 318 at 24. KLA contours this construction by arguing that the '525 patent does not disclose any preselected criteria or "recipe" for "sorting" and "classifying" defects, therefore, the claims are invalid under 35 U.S.C. § 112, P1 because the inventors were not in possession of the invention claimed at the time of filing. D.I. 414 at 33-34. At the very least, KLA asserts, the two words should be construed to mean that defect organization is conducted by the operator based upon certain criteria. Id.

This court agrees with KLA that the written description of the '525 patent does not contain a "recipe" for "sorting" and "classifying" defects, but this court cannot extend such reasoning to a holding that dependent claims 19 and 20 are invalid under 35 U.S.C. § 112, P1 because the inventors lacked possession of the invention at the time of filing. Dependent claims 19 and 20 do not contain the word "recipe." An inventor need not be in possession of something that is unclaimed.

Dependent claims 19 and 20 use the word "sorting" and "classifying." These words have a common meaning in everyday language. Nothing in the specification or prosecution history indicates that the inventors intended any other meaning to apply. According to Webster's II New Riverside University Dictionary, 1988, "classifying" means "to organize or arrange according to class or category." Id. at 268. In this same dictionary, "sorting" means to "arrange according to class, kind, or size." Id. at 1110. Consistent with these definitions and the teachings of the '525 patent, this court holds that "classifying" means to "organize or arrange" pit and particle defects according to "class or category." Similarly, "sorting" as used in the '525 patent means to arrange pit and particle defects "according to class, kind, or size."

1. "Classifying the specimen" (claims 11 and 16)

The parties agree as to plain meanings of "classifying" and "specimen." The dispute focuses on whether "classifying" includes the steps enumerated in claims 11(b)(i) and (ii) and 16(b)(i) and (ii). Specifically, the parties disagree on whether these steps include tertiary classification conducted by a human.

Tripath argues that the language "said classifying including" at the end of claims 11(b) and 16(b) necessarily incorporates each of the steps in claims 11(b)(i) and (ii) and 16(b)(i) and (ii), respectively. Steps 11(b)(ii) and 16(b)(ii) are actions that provide for "viewing and further classification by a human." Thus, classification is not complete until a person has reviewed the suspect specimens. In contrast, Cytyc contends that the device itself classifies the specimen so that further review by a human could take place, if needed. The machine, therefore, completes the classification.

A careful reading of the claim terms and the specification leads to the conclusion that the claimed invention does not include human review. Beginning with the claims themselves, the preamble to claim 11 reads "a method . . . comprising the steps of . . . ". The word "comprising" indicates a closed grouping. In other words, the steps that follow constitute the entirety of
the claim. See Manual of Patent Examining Procedure, § 608.01(i)(e)(2005) ("any independent claim should contain . . . a preamble comprising a general description of all the elements or steps of the claimed combination which are conventional or known") (emphasis added). "Obtaining the specimen" and "classifying the specimen" are thus the only two steps claimed in claim 11.

The question remains whether "classifying the specimen" includes final, tertiary classification by a human. Claim 11(b) states that the goal of classifying the specimen is "to determine the likelihood that individual objects in the specimen have attributes of cell abnormality justifying further evaluation." (emphasis added). "Justifying further evaluation" indicates that the classification is complete when cells have been identified for further review. In contrast, a final diagnosis would not require further evaluation.

Similarly, claim 11(b)(ii) defines "classifying" as "selecting location coordinates of one or more of the objects to provide for viewing and further classification by a human." In light of the specification, the language "to provide for" means to prepare incompletely diagnosed cells for further review. Neither the specification nor the claim suggest that the secondary classifier makes or is capable of making a final diagnosis. Rather, the patent contemplates a tertiary classifier to make the final diagnosis:

Electronic image representations of cells which are classified by the primary and secondary classifiers as being suspect are stored in the computer memory . . . for further (tertiary) classification by a person trained to detect the truly abnormal cells.

'n377 patent at col. 8, 11. 48-53. See also id. at col. 8, 11. 57-59 ("the technician can make a final determination as to whether each of the suspect cells is truly abnormal."). Thus, claim 11 does not include the tertiary classifier, which the specification tells us, makes the final diagnosis.

TriPath argues that the 377 patent is a semi-automated method, or a method that is partly performed by humans and partly performed by machines. n4 To read the tertiary classification by a human out of the claims, it contends, is to disregard the semi-automatic nature of the invention. This argument fails for two reasons. First, although the specification refers repeatedly to a human as the tertiary classifier, it need not be so. The specification states that in a preferred embodiment, this classifier is a human, but it specifically reserves the possibility that it could be a machine. Id. at col. 5, 11. 5-9. Second, even if the tertiary classifier is a machine, the process still requires human involvement. For example, the automated microscope contains a coarse focus adjustment feature that can be operated manually. Id. at col. 6, 11. 53-55.

n4 Cytyc and TriPath agree to this definition of "semi-automated."

--- Footnotes ---

n5 The term "classifying the specimen" is also at issue in claim 16. Claim 16(b)(i) and (ii) are identical to claim 11, except that the word "for" is omitted in claim(b)(ii). Without the word "for", the step of "identifying locations of . . . the objects" in and of itself appears to provide viewing and further classification by a human. While this literal reading tends to support the inclusion of "further classification by a human" in the definition of "classifying", it neither comports with the specification nor makes logical sense.

It is clear from the specification that identifying the location of the cells on the slides alone does not provide viewing or further classification by a human. The locations of the suspect cells are stored in the computer until they can later be inspected or examined by a human "on a video monitor." 377 patent at col. 8, 11. 48-57. Thus, it is the video monitor that provides viewing, not "identifying locations." "Identifying locations" provides for viewing and further classification in that...
it identifies suspect cells for tertiary review. Consequently, the same analysis of "classifying the specimen" applies to claims 11 and 16.

--- End Footnotes ---

A. Patent Infringement

Given some additional claim construction I provide in this section, I cannot find noninfringement as a matter of law with respect to independent claims 11 and 16 of the '377 patent. 11, 12 In order for a technology to infringe a patent, it must infringe every limitation embodied in the patented claim. See Section IIB, supra. Because accepting Cytyc's sole argument would exclude the preferred embodiment of the patented technology from the patent, I deny Cytyc's motion for summary judgment.

--- Footnotes ---

11 The text of claim 11 (with my emphasis added to highlight the major difference between Claims 11 and 16) is:

A method for providing interactive review of objects in a specimen indicative of the highest likelihood of abnormality in the specimen, comprising the steps of:

a) obtaining the specimen; and

b) classifying the specimen to determine the likelihood that individual objects in the specimen have attributes of cell abnormality justifying further evaluation, said classifying including

I) assigning individual objects in the specimen a value according to the likelihood that an object has attributes of cell abnormality, and

ii) selecting location coordinates of one or more of the objects to provide for viewing and further classification by a human.

The text of Claim 16 (with my emphasis added) is:

A method of providing location-guided screening of a specimen for objects in the specimen having a likelihood of cell abnormality, comprising the steps of:

a) obtaining the specimen;

b) classifying the specimen to determine the likelihood that individual objects in the specimen have attributes of cell abnormality justifying further evaluation, said classifying including

I) ranking objects in the specimen in an order according to the likelihood that an object has attributes of cell abnormality, and

ii) identifying locations of one or more of the objects to provide viewing and further classification by a human.

12 Because infringement of a dependent claim cannot occur without infringement of the underlying independent claim, I first address the independent claims. See Wahpeton Canvas Co., Inc. v. Frontier, Inc., 870 F.2d 1546, 1552 n.9 (Fed. Cir. 1989) ("One who does not infringe an independent claim cannot infringe a claim dependent on (and thus containing all the limitations of) that claim."). Claims 13 through 15 depend on claim 11, and include limitations on the types of cells to be screened and the system for assigning values to cells. Claims 17-20 and 22-26 depend on claim 16 and add limitations concerning the selection and presentation of objects of interest to a human, mapping the objects, and ranking them according to likelihood of abnormality and morphological features.
The single disputed issue for infringement regarding both claims 11 and 16 is whether Cytyc's technology "classifies the specimen," as opposed to "objects within the specimen." There is no dispute that Cytyc's TIS meets the other limitations of the claims. Cytyc argues, however, that the TIS does not "classify specimens" because the TIS never places specimens into one of two or more groups. See Markman Order at 66 (defining classifying as placing something into "one of two or more groups."). Instead, the TIS, Cytyc argues, merely facilitates human classification of the specimen by placing objects within the specimen into one of two or more groups. Docket No. 160 at 10. It is the human, not the machine, that Cytyc claims classifies the slide or entire specimen as normal or abnormal. Cytyc points to the following testimony by TriPath's technical expert:

Q: And so it is accurate to say that the TIS machine may classify objects within a specimen but does not classify the specimen itself?
A: Yes, that's correct.
Q: And only the human being classifies the specimen?
A: Yes.

Russ Dep. at 91 (Shannon Decl., Ex. 15).

Because the parties seem essentially to agree on the definition of "specimen," I will assume that it refers only to an entire sample of biological material and not the objects within the sample. This assumption should not be fatal to either side. The legal result is the same with respect to these claims regardless of whether I construe "specimen" as including "objects within the specimen" or construe the phrase "classifying the specimen" as including "classifying objects within the specimen." At the same time, counsel argued that the patented technology classifies the specimen "by going through the entire specimen and screening out 99 percent of the objects," but without assigning the specimen to a group. See Tr. at 132; TriPath Slide titled "Rutenberg Classifiers: Primary, Secondary, Tertiary." Thus, it seems TriPath is arguing that I find that classifying the specimen includes classifying a subpart of or objects within the specimen.

Because the parties seem essentially to agree on the definition of "specimen," I will assume that it refers only to an entire sample of biological material and not the objects within the sample. This assumption should not be fatal to either side. The legal result is the same with respect to these claims regardless of whether I construe "specimen" as including "objects within the specimen" or construe the phrase "classifying the specimen" as including "classifying objects within the specimen."
specimen. Cytyc suggests that classifying the specimen involves assigning the entire specimen to one of two or more
groups, whatever the specimen consists of. That reading would exclude Cytyc's technology because the TIS primary and
secondary screens do not assign the entire specimen into one of two or more groups "for further classification," but rather,
do so only for objects or cells within a specimen.

--- Footnotes ---
15 TriPath contends that I have construed the term "classifying the specimen" incorrectly because I misconstrued the term
"comprising" in Claims 11 and 16. In the Markman Order, I interpreted "comprising" as denoting a closed grouping. See
Markman Order at 10-11. TriPath argues that the terms "comprising" and "including" are "open-ended," i.e., that they both
mean "including, but not limited to." I must agree that under governing Federal Circuit law -- as opposed to classical
grammatical usage convention -- "comprising" and "including" are open-ended. Cytyc does not dispute this contention. As
the Federal Circuit has stated, "comprising" is "inclusive or open-ended and does not exclude additional, unrecited
elements or method steps." See CollegeNet, Inc. v. ApplyYourself, Inc., 418 F.3d 1225, 1235 (Fed. Cir. 2005) ("A drafter
uses the term 'comprising' to mean 'I claim at least what follows and potentially more.'") (quoting Vehicular Tech. Corp. v.
Titan Wheel Int'l, Inc., 212 F.3d 1377, 1383 (Fed. Cir. 2000)); see also Georgia-Pacific Corp. v. U.S. Gypsum Co., 195 F.3d
1322, 1327 (Fed. Cir. 1999) (stating that "consisting of," on the other hand, indicates a closed grouping); Moleculon
Thus, insofar as I have previously construed "comprising" as describing a closed set or a whole, TriPath has convinced me that I
was incorrect and I will correct this aspect of the Markman order.

This correction, however, does not change my definition of "classifying the specimen" as used in claims 11 and 16. I will
continue to construe "classifying the specimen" in those claims to exclude final classification. The resulting construction
may be the result of an inartful draft in the patent claim, but it is the only way to make sense of language claiming a method
"classifying the specimen to determine the likelihood that individual objects in the specimen have attributes of cell
abnormality justifying further evaluation."

Because the change in the definition of "comprising" does not change my definition of "classifying the specimen," it is also
immaterial to the dispute of whether Cytyc's TIS classifies the specimen as stated within claims 11 and 16. Cytyc's argument
is that its technology does not perform one of the explicit steps within the claim, that is, "classifying the entire specimen for
further evaluation." Thus, whether "comprising" is open-ended or not, the dispute is whether Cytyc's TIS performs that
particular element.

Having corrected my claim construction to coincide with Federal Circuit case law, I am compelled to note in this connection
that the Federal Circuit has chosen to become its own lexicographer for the word "comprise" by abandoning an ordinary,
customary, and distinctive -- if frequently misunderstood -- meaning defended by usage experts.

The distinction is concisely stated in Gowers. "The difference between comprise and include is that comprise is correct
when all the components are enumerated and include when only some of them are." Sir Ernest Gowers, The Complete Plain

Jacques Barzun has urged writers "to make the effort of coming to terms with include, compose and comprise." Jacques
Barzun, Simple & Direct: A Rhetoric for Writers 128 (rev. ed. 1994). Barbara Wallraff explains that "[t]he reason comprise
is confusing to many people is the same reason that it's useful: It doesn't work the same way as similar words." Barbara

Among those concerned with maintaining meaningful linguistic distinctions, the difference between "comprise" and
"include" continues to be observed.

The preeminent Twentieth Century newspaper copy editor explained that "[c]omprise has the meaning of contain, embrace,
include and comprehend . . . The whole comprises the parts, not the reverse." Theodore M. Bernstein, The Careful Writer: A
Modern Guide to English Usage 113 (1965). He further observed that "[t]he word include, however, usually suggests that
the component items are not being mentioned in their entirety. If all are being mentioned it would be better to write 'The
seven were . . . '; or, if there is an irresistible urge for a fancy word, to use comprised." Id. at 228.

Similarly, a journeyman book of American usage cautions writers to "be careful to use include only of incomplete lists: A
baseball team is made up of nine players. It includes a pitcher, a catcher, and four infielders. It is composed of these, plus three outfielders. (And the team comprises these nine players; they compose the team.)" Kenneth G. Wilson, The Columbia Guide to Standard American Usage 106 (1993).

Of course the distinctiveness of words in common and ordinary meaning can be eroded when those bodies charged with superintending language, such as the Federal Circuit, neglect the distinctions. Thus the former editor of the Oxford English dictionaries has reported from the field that "[c]omprise is . . competing with include". The New Fowler's Modern English Usage 387 (3d ed. 1996). Nevertheless in this competition he finds that the differences still remain: "[w]hen two words such as include and comprise have roughly the same meaning, examination will generally reveal a distinction; and the distinction between the present two seems to be that comprise is appropriate when the content of the whole is in question, and include only when the admission or presence of an item is in question." Id.

But under Cytyc's reading, the preferred embodiment of the patented technology would also not "infringe" the asserted claims. In the preferred embodiment, as TriPath points out, the first two screenings identify only objects within the specimen as normal or abnormal without classifying the specimen as a whole. The '377 specification seems to use "classifying the specimen" interchangeably with "classifying portions of the specimen." See, e.g., column 2, lines 31 - 37 ("[T]he invention includes an initial classifier . . . to classify a cytological specimen and a subsequent classifier . . . to classify those portions of the cytological specimen selected by the initial classifier for subsequent classification."). It seems clear, as well, that the primary and secondary classifiers that Rutenberg describes classify only objects within one biological sample. See, e.g., column 17, lines 34-52:

Fig. 5 shows the screening of a typical Pap smear which contains approximately 100,000 benign cells and other objects. Through erosion/dilation and IDO filters, the primary classifier 400 will filter out 99% of these objects, passing approximately 1,000 objects to the secondary classifier 420. Classifier 420 . . . in turn filters out 80% of these 1,000 objects, passing the images of approximately 200 residual objects deemed to be the most suspect of pathology to the output monitor for tertiary human inspection.

If a Pap smear is the same as a "specimen," then the '377 specification clearly calls for a method of screening out objects within that specimen. In other words, because "classifying the specimen," according to my construction, must refer to the classification by only the primary and secondary classifiers, "classifying the entire specimen" is something that neither Cytyc's TIS nor '377's methods 11 and 16 perform.

To avoid the untenable result that the patent claim excludes the preferred embodiment of the patented technology, I must construe "classifying the specimen" to include classifying objects within a specimen in an overall process falling short of classifying the entire specimen. 16 Under this construction, Cytyc's TIS "classifies the specimen . . . for further review by a human" insofar as it screens objects within the specimen and assigns them to groups. Cytyc does not dispute that its technology classifies objects within a specimen. Thus, Cytyc's current motion for summary judgment 17 is denied with respect to the asserted claims. 18
iii. "cleaning of semiconductor wafers"

The phrase "cleaning of semiconductor wafers" appears in the preamble of Claims 1 and 57 of the '532 patent. The parties agree, as does the court, that "cleaning of semiconductor wafers" refers to the removal of contaminants from the surface of the wafers.

iv. "treatment of semiconductor wafers"

The phrase "treatment of semiconductor wafers," appears in the preamble of Claims 54, 55 and 58. CFMT asserts that the phrase "treatment of semiconductor wafers" means all aspects of wafer processing, including but not limited to cleaning. Apparently, YieldUP agrees with CFMT's construction of the phrase because YieldUP requests an instruction that "treatment of semiconductor wafers" includes cleaning. Therefore, the court finds that the phrase "treatment of semiconductor wafers" refers to all aspects of wafer processing, including cleaning.

The district court construed the term "clear" of independent claim 1 to mean "transparent" or "having the property of transmitting light without appreciable scattering so that bodies lying beyond are seen clearly." Order I at 7. Terlep challenges the district court's interpretation arguing that the term should be construed to also cover translucent holders.

Brinkmann responds that the district court's construction is correctly informed by the written description, which states that the purpose of the holder is to maximize light output, and that any other interpretation would be inconsistent with the '433 patent. Brinkmann adds that the "translucent" argument was not made to the district court and, thus, was waived.

Claim 1 recites an omni-directional LED lamp that has three elements: an LED; a semi-spherical reflector; and a clear plastic tubular holder. The claim sets forth the positional relation between these elements such that the light emitted from the LED is rendered omni-directional after reflecting off the semi-spherical reflector. See '433 patent, col. 6, ll. 26-27. The reflected light passes through the holder, which holds the semi-spherical reflector. See id. at ll. 24-28. The text of claim 1 and the other claims provide little guidance on the meaning of the term "clear."

The written description discloses a preferred embodiment in which the LED is surrounded by "tubular canopies" or holders that are made of "clear and pliable plastic material." Id. at col. 3, ll. 58-59. Another embodiment describes a colored lens cover that is made "from clear colored plastic." Id. at col. 5, l. 1. While these passages are not particularly helpful in discerning the meaning of the term "clear," other portions of the written description provide greater guidance. The Background and Prior Art sections state that various techniques for applying diffusion directly to the LED surfaces had been attempted in the past and were unsuccessful in rendering the light emitted from the LED omni-directional. Id. at col. 1, ll. 37-45. The Summary of the Invention section describes the invention as an omni-directional LED lamp that does not use a diffusion lens over the LEDs. Id. at col. 2, ll. 5-7. Implicit in these passages is the distinction between lenses or holders that diffuse or scatter light and those that transmit light without obstruction. The written description is thus consistent with and supports the district court's construction of the term "clear" to refer to holders that are "transparent or [have] the property of transmitting light without appreciable scattering so that bodies lying beyond are seen clearly." Order I at 7.

Terlep argues that the written description also is consistent with a "translucent" holder because it refers to an embodiment in which "the lens cover ... can include a phosphorescent coating which glows when the LED ... is on so as to diffuse light evenly over a wide viewing angle and amplify visibility." See '433 patent, col. 5, ll. 54-57. However, the text quoted by Terlep relates to the embodiment of Figures 4A-4C, which does not include a "clear plastic tubular holder" as recited in claim 1, at issue in this case. Because the "lens cover" described supra is not the same structure as the "clear plastic tubular holder," compare id., Figures 4A-4C & col. 5, ll. 54-57, with id., Figure 2A & col. 3, ll. 57-65, Terlep's argument is misplaced. Moreover, there is nothing in the description of the phosphorescent coating embodiment to warrant construction of the term "clear" as it relates to the "clear plastic tubular holder" of claim 1 to include translucent holders.
The prosecution history further supports the district court's construction. On August 9, 1995, the application that issued as the '433 patent was filed. In a February 7, 1996 Office Action, the Examiner, inter alia, rejected claim 1 under 35 U.S.C. § 103(a) as being unpatentable over U.S. Patent No. 5,469,157 to Carpenter et al. in view of U.S. Patent No. 1,198,734 to Ludescher. In a May 6, 1996 Response ("Response"), Terlep amended claim 1 to add, inter alia, "a clear plastic tubular holder." Response at 1. Terlep distinguished the claimed invention from the prior art stating that the prior art disclosed rotating LEDs and LEDs having a top "flattened and ... side surface(s) ... sandblasted or otherwise roughened to diffuse the light output," whereas the "subject invention did not use any 'flattened' tops and/or 'sandblasted or roughened' sides." Response at 5. Because the "clear plastic tubular holder" limitation helped distinguish the prior art from the claimed invention, the prosecution history supports construing the term "clear" to exclude plastic holders that are translucent or otherwise diffuse the light emitted from the LED. See Seachange Int'l, Inc. v. C-Cor Inc., 413 F.3d 1361, 2005 WL 1523382, at *8 (Fed. Cir. 2005) ("Where an applicant argues that a claim possesses a feature that the prior art does not possess in order to overcome a prior art rejection, the argument may serve to narrow the scope of otherwise broad claim language.").

In construing the claims, the parties have cited several dictionaries. District courts are authorized "to rely on extrinsic evidence, which consists of all evidence external to the patent and prosecution history, including ... dictionaries" as one of many claim construction tools. Phillips, 2005 U.S. App. LEXIS 13954, at *37 (internal citations omitted). The dictionary defines "clear" as "giving free passage to light or to the sight: easily seen through: not cloudy, turbid, or opaque." Webster's Third Int'l Dictionary 419 (1993). This definition lists "transparent" and "translucent" as synonyms. The definition also sets forth an express distinction between transparent and translucent: "transparent stresses complete absence of obstruction to vision" and "translucent applies to that which permits passage of light but bars clear and complete vision." Id. The distinction between these synonyms cannot be ignored. See Int'l Rectifier Corp. v. IXY Corp., 361 F.3d 1363, 1374 (2004) (holding that it was improper for the district court to adopt a definition that was attributed to a synonym of the disputed term while disregarding the distinction set forth in the usage note). Moreover, the distinction mirrors the distinction reflected in the written description and prosecution history between the unobstructed passage of light of the holder of the patented invention and the prior art structures that diffuse light. Here, the district court "attached appropriate weight" to the dictionary definitions in the context of the intrinsic evidence in reaching its construction of the claim term "clear." Phillips, 2005 U.S. App. LEXIS 13954, at *58.

Finally, Terlep argues that to define "clear" so as to exclude "translucent" is to import a functional limitation into the claim. Terlep asserts that "clear plastic tubular holder" is merely a structural limitation and that the district court erred in importing a functional limitation into a structural term. However, Terlep fails to recognize that the construction properly adopted by the district court merely assigned meaning to the claim term "clear" and did not impermissibly import a functional limitation. Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so.").

We conclude that the district court correctly construed the term "clear" to mean "transparent or having the property of transmitting light without appreciable scattering so that bodies lying beyond are seen clearly," and that nothing in the claims or the written description warranted giving the term "clear" an expansive meaning that would cover "translucent" holders. Because Terlep's "translucent" argument is without merit, we need not consider Brinkmann's additional argument of waiver.

630

N. "Clearinghouse Means" in Claim 24

The parties disagree about the applicability of 35 U.S.C. § 112, P 6 to "clearinghouse means" as used in Claim 24. Defendants contend that the patentee's use of the word "means" clearly signals that the patentee intended this to be a means-plus-function clause. Under this theory, the word "means" gives rise to the presumption that Section 112, P 6 applies to the claim element. Defendants further contend that Plaintiff cannot overcome this presumption, because the claim does not recite a function that corresponds with the clearinghouse means or a sufficiently definite structure for performing the function. Therefore, Defendants contend, Section 112, P 6 applies to the claim element. Plaintiff contends that Claim 24 is a step-plus-function claim, not a means-plus-function claim, and under step-plus-function construction rules, Section 112, P 6 is not presumed to apply.
The first question the Court must answer is whether Claim 24 invokes a means-plus-function limitation or a step-plus-function limitation, or neither. When interpreting section 112, P 6, "structure" and "material" are associated with means-plus-function claims, whereas "acts" or "steps" are associated with step-plus-function claim elements. Seal-Flex, 172 F.3d at 843 (Fed. Cir. 1999)(citing O.I. Corp. v. Tekmar Co. Inc., 115 F.3d 1576, 1583 (Fed. Cir. 1997)).

Because Claim 24 claims "[a] method of controlling access . . . comprising the steps of [the claimed elements, including clearinghouse means]," n5 the Court is not persuaded by Defendants' argument that the mere presence of the word "means" makes this claim element a means-plus-function element. Instead, the Court agrees with Plaintiff that Claim 24 is a method claim, and considers the term "clearinghouse means" in Claim 24 to be little more than an "overzealous use" of the word means. See Genzyme, 212 F. Supp. 2d at n. 10 (D. Del. 2002). In light of this determination, Section 112, P 6 could apply to this claim term only under the step-plus-function analysis.

The second question the Court must answer is whether Claim 24 is written in step-plus-function format so as to invoke Section 112, P 6. Generally, if a claim element includes the words "step for," it is presumed to be a step-plus-function limitation, and Section 112, P 6 is presumed to apply. However, when the claim uses the word "step" alone, or "steps of," then Section 112, P 6 is presumed not to apply to that element. St. Clair Intellectual Prop. Consultants, Inc. v. Canon Inc., 2004 U.S. Dist. LEXIS 17489 at *78 (citing Seal-Flex, 172 F.3d at 849 (Fed. Cir. 1999)).

The first limitation of Claim 24 describes the step of "registering identity data . . . in a clearinghouse means[.]") ('416 Patent at col. 38, ll. 42-46). The second limitation of Claim 24 describes the step of "requiring a subscriber client computer to forward its identity data to said clearinghouse means[.]" (Id. at ll. 47-50). The fourth and fifth limitations of Claim 24 describe the steps of "attempting to authenticate the identity data [of a subscriber client computer and first server computer . . . from said clearinghouse means[.]]" (Id. at ll. 56-63). The Court concludes that none of these elements are written in step-plus-function format, because, (1) the language "step for" is not used, and (2) the limitations individually describe the precise acts required to control access to selected computer resources. Thus, Section 112, P 6 does not apply to the term "clearinghouse means" as used in Claim 24.

Having concluded that the use of the term "clearinghouse means" in Claim 24 invokes neither a means-plus-function limitation or step-plus function limitation, and therefore, concluding that Section 112, P 6 does not apply, the Court adopts Plaintiff's proposed construction of "clearinghouse means" in Claim 24. Accordingly, "clearinghouse means" is construed to mean "any clearinghouse server(s) with software capable of storing and authenticating identity data."

--- Footnotes ---

n5 Contrast this language with that of Claim 1, which claims "[a] system for controlling the operation of and access . . . comprising [the claimed elements.]" (416 Patent at Col. 35 ll. 25-30)

--- End Footnotes ---

2. "clerk system"

Claim 1 recites a "clerk system operable to process auction bids." The parties dispute the meaning of the term "clerk system."

The claim term "clerk system" does not have a plain meaning to one of ordinary skill in the art. Therefore, the Court must look to other sources to ascertain its meaning. In the Court's view, the specification provides the guidance needed. As all parties acknowledge, the specification makes clear that the clerk system is software. It further defines the "clerk system" by the functions that it carries out. In the "Summary of Invention," the '612 Patent states that "[t]he Clerk System controls the sequencing of items to be sold through the auction and controls the bidding process . . . for each item to be sold." ('612 patent col. 3, 11. 10-13.) This statement serves to define the claimed "clerk system," and the Court therefore incorporates these functions into its construction of that term. Accordingly, the term "clerk system" shall mean "software to control the sequencing of items to be sold and control the bidding process for each item to be sold."
client computer

Claims 1, 4-8, 10, 11, 13, 17, and 18 contain the term "client computer." Accolade contends that "client computer" does not require construction and is defined by the limitations in the claim and alternatively argues that the term means "computer used to interact with the host computer." Citrix contends that "client computer" means "the computer accessing the host computer." The parties dispute whether construction is necessary, whether the client computer accesses or more broadly interacts with the host computer, and whether the claim language allows for a plurality of client computers.

A construction is appropriate to clarify to the jury which computer in the claimed invention is performing the accessing and which is being accessed, and the Court construes "client computer" as "a computer accessing the host computer." 5 Claim 1 refers to the client computer as accessing the host computer: "a host computer coupled to said TCP/IP protocol network and being capable of being accessed by said client computer . . . wherein said host computer is initially accessed by said client computer." Col. 13:59-14:8 (emphasis added). Also, the Abstract and Disclosure of the Invention state, "The computer 'posted' on the web page is referred to as the 'host' or 'advertiser' computer, and computers accessing the host computer are referred to as 'client' or 'user' computers." Abstract; Col. 3:28-31. Thus, the intrinsic record shows that a client computer accesses the host computer.

In regards to the parties' dispute on whether the claim language allows for a plurality of client computers, the Court modifies its earlier preliminary construction of "client computer" and construes this term using the indefinite article "a" when referring to "computer" to allow for a plurality of client computers. The Federal Circuit has stated, "[a]n indefinite article 'a' or 'an' in patent parlance carries the meaning of 'one or more' in open-ended claims containing the transitional phrase 'comprising.'" That "a" or "an" can mean "one or more" is best described as a rule, rather than merely as a presumption or even a convention. The exceptions to [the "indefinite article"] rule are extremely limited: a patentee must "evince [ ] a clear intent" to limit "a" or "an" to "one." The subsequent use of definite articles "the" or "said" in a claim to refer back to the same claim term does not change the general plural rule, but simply reinvokes that non-singular meaning. An exception to the general rule that "a" or "an" means more than one only arises where the language of the claims themselves, the specification, or the prosecution history necessitate a departure from the rule.

Baldwin Graphic Sys., Inc. v. Siebert, Inc., 512 F.3d 1338, 1342-43 (Fed. Cir. 2008) (citations omitted). Claim 1 uses the open claim term "comprising" and initially refers to "client computer" as "a client computer" and subsequently refers to "said client computer." Col. 13:44-Col. 14:14. The "indefinite article" rule treats the use of "comprising" combined with the initial use of "a" to mean "one or more." Also, the subsequent use of "said" to refer to "client computer" only reinvokes the "one or more" meaning of "client computer." Thus, under the "indefinite article" rule, "client computer" allows for a plurality of client computers.

Citrix argues that an exception to the "indefinite article" rule applies, proposing that "client computer" should be construed as "the client computer" because claim 18 expressly requires a plurality of client computers and claim 1 does not. Citrix is apparently referring to the principle of claim differentiation--"when a dependent claim adds a limitation to an independent claim, it is presumed that the independent claim does not include the limitation. See Phillips, 415 F.3d at 1314-15. First, claim differentiation is merely a presumption; it is not a hard and fast rule. Second, claim 1 and claim 18 are sufficiently different in scope. Claim 18 requires more than one client computer coupled to the host computer. Claim 1 requires one or more client computers coupled to the TCP/IP protocol network. Thus, claim differentiation does not support limiting "client computer" to a single client computer. Accordingly, the Court construes "client computer" as "a computer accessing the host computer."
G. Subscriber Client Computer

Plaintiff contends that the inventors never intended the "Subscriber Client Computer" to be limited to just a personal computer. Rather, Plaintiff contends, the subscriber client computer encompasses "any programmable electronic device that is capable of running the client software means." (D.I. 207 pg. 21). Plaintiff further contends that the patent covers devices which have been invented since 1997 and that can perform the functions and steps defined in the asserted claims.

Defendants contend that because the specification consistently describes the subscriber's computer as a "desktop" or personal computer, Plaintiff's proposed construction is inconsistent with the intrinsic evidence.

After reviewing the term "subscriber client computer" in the context of the specification and other claims, the Court agrees with Defendants, that the "subscriber client computer" described in the '416 Patent is not as broad as Plaintiff now proposes. Though nothing in the claim language requires the subscriber client computer to be a desktop computer, every description of the subscriber client computer suggests that it is a desktop personal computer or Macintosh. ('416 Patent col. 4, ll. 39-40, col. 5, ll. 35-40, col. 9, ll. 1-3, col. 14, ll. 57-58, 63-66, and Figs. 1 and 2). The repeated disclosure of using a personal computer, and corresponding figures, limit the "subscriber client computer" to "a computer that a subscriber uses to access selected computer resources of the first server computer." n3

--- Footnotes ---

n3 To the extent that Defendants may seek further clarification on the phrase "resources of the first server computer," as used in this construction, the Court would direct the parties to this Memorandum Opinion's earlier construction of "first server computer" and "selected resources of said [at least a] first server computer." The Court's construction of those terms applies here as well, and use of the phrase "resources of the first server computer" in no way suggests that the resources must be stored on the first server computer.

--- End Footnotes ---

L. Client Computers

The only occurrence of this term in the patent is in claim thirteen. The Defendants propose the construction "a computer coupled to the wide-area-network and adapted with a graphical user interface, such as a browser, configured to receive test data for and properties of the pavement material mixture." The Defendants arrive at their construction first by including the surrounding words of the claim. Such inclusion is redundant and unnecessary.

The Defendants also argue that the collection of information required by the claim is defined by browser box 201 in FIG. 2. The Defendants argue that the specification directs that client workstations can be computers running browsers in col. 3:8-11.

The Plaintiff proposes that the term not be construed, but offers the construction "a computer that receives services from another computer." The Plaintiff bases its definition on extrinsic evidence in the form of technical dictionaries.

The Defendants' proposed construction, stripped of the portions already in claim thirteen, is "a computer adapted with a graphical user interface, such as a browser." The Plaintiff's definition is largely the same as this revised version of the Defendants'. The patent does not require that the client workstation have a browser as the Defendants suggest, but it does require that the client workstations communicate with the network. Col. 3:5 - 67.

- 1115 -
The extrinsic evidence cited by the Plaintiff proves a commonly understood meaning of the disputed phrase for networks using client-server architecture like the patent. "Clients are PCs or workstations on which users run applications. Clients rely on servers for resources, such as files, devices, and even processing power." RANDOM HOUSE WEBSTER'S COMPUTER & INTERNET DICTIONARY 94 (3rd ed. 1999). "Client" is also described as "a hardware or software entity that requests shared services from a server," while the definition for a client-server system is "a computing system composed of two logical parts: a server, which provides information or services, and a client, which requests them. On a network, for example, users can access server resources from their personal computers using client software." MCGRAW-HILL DICTIONARY OF SCIENTIFIC AND TECHNICAL TERMS 406 (6th ed. 2003).

Construction: A computer that requests information or services from a server.

2. Client database

The term "client database" appears in several of the claims of the patents-in-suit. Seven proposes that this term means "a collection of data stored electronically on a device." Visto seeks to construe the term to mean "a full local database on the portable client that serves as a temporary representation of a host database." Given Seven's concession at the hearing that the client database must be located physically on the client device, the court construes the term to mean "a collection of data stored electronically on the client device."

GO BACK

636

client program

Claims 1, 3, and 4 contain the term "client program." Accolade contends that "client program" means "a set of instructions for execution by a client computer by, for example, a browser program or the operating system." Citrix contends that the term means "a script for execution by a browser program on, or the operating system of, the client computer," or alternatively, "a script for execution by a client computer by, for example, a browser program or the operating system." The parties dispute the scope of "client program" as the term relates to "script."

The Court construes "client program" as "a set of instructions for execution by a client computer." The specification provides guidance on the relationship between "script" and "client program," stating that "the script . . . will be referred to generically as a 'client program.'" Col. 7:63-64 (emphasis added). Given the language "generically," the specification describes "script" as a species of the genus "client program." Accordingly, "client program" presumably encompasses more than "script" and thus cannot be limited to "script."

The prosecution history also refers to "client program" generically:

It is well known in the art that scripts may be executed on browsers capable of running a script language, such as Java. An advantage to having the browser run the client program is that the client program can be platform independent. Running a client program on an operating system requires platform specific code. In contrast, client programs run in browsers no longer must communicate with the operating system directly, and thus may run on any system capable of running a script enabled browser.

Defs.' Br., Ex. 7 (08-6-99 Amendment), 3-4 (emphasis added). The prosecution history establishes that a client program structured as a script is not compiled to code executable on a particular operating system platform. Instead, a client program structured as a script is executed at run time using an interpreter program. A client program structured as a script can be run on a script-enabled browser, but a client program can also be code that is specifically compiled to be executable on a particular operating system platform. Accordingly, the full scope of the generic term "client program" extends to a set of instructions for execution on a client computer.
Citrix's proposed construction is overly limiting because it restricts "client program" to a particular implementation of "client program" disclosed in the specification--"script." Accolade's construction, on the other hand, is consistent with the description in the specification and the prosecution history that "client program" is generic to a script executed by an interpreter (script engine) and to a set of instructions that is compiled to code specifically executable on an operating system platform. Thus, the Court modifies its preliminary construction and construes "client program" as "a set of instructions for execution by a client computer."

7. Client program

The Court's Construction: A computer program that is executed by the client computer. Markman Tr. 51:24-25; 53:25-54:1; 55:4-6.

Both parties objected to the Court's construction. Ethos argued that the construction of this term should include an explanation that "the client program includes a process that monitors the download." Id. 52:2-7; see also Pl. Br. at 10. In support, Ethos cited the specification of the '892 patent which, in describing an embodiment of the invention, states: "[t]he executed client program also includes a process for monitoring the download operation." Pl. Rep. at 10 (quoting '892 patent col.6 ll.27-28); see also '709 patent col.6 ll.35-36. This language, however, refers to the client program as executed. Turning again to Figure 1, the diagram shows the "client program and other files" on the side of the server computer and an "executed client program" on the side of the client computer. '892 patent fig.1; '709 patent fig.1. Within the square labeled "executed client program" is a smaller square labeled "download monitoring process." '892 patent fig.1; '709 patent fig.1. This diagram establishes that the download monitoring process is associated with the "executed client program," as the specifications state, and not with the dormant "client program." The Court thus properly excluded Ethos' proposed addition from its definition.

RealNetworks wished to add that the computer program can also be compiled and then executed on the client computer. See Markman Tr. 54:6-10. In support of this construction, RealNetworks relied on language in the specification of the '892 patent stating that the client program may be "compiled for execution on the desired platform, such as a machine with a Windows95 operating system." Def. Br. at 14 (quoting '892 patent col.8 ll.10-14); see also '709 patent col.8 ll.18-22. The Court found this language ambiguous and unable to support RealNetworks' construction.

The remaining two terms are found only in the '709 patent. Both terms relate to the sending of a second request for a data file to the server computer after the termination of the initial download. '709 patent, claim 1, col.12 ll.17-21.

1. clock

an electronic circuit that generates accurately timed pulses used for synchronization in a digital computer

The support for this definition lies in the description of the operation of the clock in the claims and in the following specification language.

Slow speed system board B will normally include a continuously operational crystal clock that generates the clock signal SCLK intended to clock the ghost microprocessor originally present on board B. Many systems use a higher speed crystal clock and divide by 2 to generate SCLK, while some use a divide by K, where K might be normally 2 but is increased to 3 to slow the system clock for data transfers on an I/O expansion bus forming a part of the slow speed system board. This causes SCLK to be synchronously switched between two rates. The Sub-Harmonic generator 3, produces S-HCLK 23 which is a synchronized to SCLK as a low sub-harmonic of SCLK. This permits many different SCLK frequencies to be synchronized as different harmonics of S-HCLK. As an example a slow speed system board may use a 48 Mhz crystal clock and normally divide the clock by 2 to produce a 24 Mhz SCLK signal, but synchronously change SCLK to 16 Mgz for
certain I/O operations by changing the divider to 3.

('981 Patent, Col 4:58 - 5:8)

This definition is also consistent with the definition provided by the following technical dictionaries.

Clock circuit

The Court agrees with MediaTek and construes the term according to its ordinary meaning as "a collection of electrical elements for producing clock signals." See IEEE 100 AUTH. DICT. OF IEEE STANDARD TERMS, 168 (7th ed. 2000).

Sanyo argues that the term should be construed as "a circuit using a single voltage controlled oscillator ("VCO"), that reacts to a program clock reference ("PCR") of the input video signal to generate both the system clock and the raster clock."

Sanyo's construction adds three limitations: 1) the use of a single VCO, 2) generation of both the system and raster clocks, and 3) generation in reaction to a PCR. The second and third limitations are unnecessary because they are already limitations in claim 1: '486 Patent col. 14:25-30. Construing "clock circuit" to require these limitations would only add redundancy to the claim.

Sanyo argues that the specification only teaches--and therefore requires--the use a single VCO. Sanyo's interpretation attempts to improperly import a limitation from the specification into the claim. See Phillips, 415 F.3d at 1323. While the specification illustrates the use of a VCO, it does not limit the invention to any particular type of clock source. See '486 Patent col. 4:36-39; 13:1-4 (stating that the invention allows the use of a single clock source "such as a voltage controlled crystal oscillator") (emphasis added).

Clock Pulse Interval

The parties agree that a "clock pulse interval" is the time interval during which the signal on the clock bus is high (logic "1"), including the rising and falling edges. However, Defendants seek to add an additional limitation--that clock pulse intervals be "periodic," i.e., that all clock pulse intervals occur at regular intervals. 8

8 The dictionary definition for "periodic" is: "occurring or recurring at regular intervals." (Webster's at 875, Exhibits in Support of U.S. Philips Corp.'s Reply Memorandum of Law on the Interpretation of the Asserted Claims of U.S. Patent No. 4,689,740 ("Reply Br. Ex."), Ex. C)
bus returns to the 'free' condition after the formation of the stop condition, block 62 on FIG. 3." (740 patent, Col. 5, lines 46-48.) The claims reflect this basic truth. When a clock pulse interval is meant to be periodic, the claims recite "periodic clock pulse interval." At other times, it is referred to only as a "clock pulse interval," or a "fraction of a clock pulse interval." Thus, the patent expressly provides that the clock pulse interval is periodic at some times and not periodic at others, and there is no basis to construe "clock pulse interval" as always being periodic. Accordingly, I find Philips' construction to be correct.

GO BACK

641

External clock signal

The Court construes "external clock signal" as "a single timing signal from outside of a device." MEI argues that the term should be construed as "a clock signal from outside of a device." Samsung argues that the construction should be "a single external timing signal provided to a single input pin." MEI acknowledged in its brief that a clock signal provides timing information. MEI Claim Const. Br. at 7 (Docket No. 112). Samsung's argument that the external clock signal is limited to a single input pin is presumably based only on an amendment to claim 1. See Response to Examiner at 113-14 (Exh. 5, Docket No. 120). This statement is not sufficient to establish a waiver of claim scope.

Samsung also argues that the term is limited to a single clock signal. The Court agrees. The specification of the patents-at-issue consistently emphasize and disclose the use of a single clock signal on the random port. See '921 Patent col. 2:17-19 (distinguishing the invention on the basis that it uses a single clock signal); col. 2:25-29 ("Under the teachings of the present invention, a single clock pulse drives an internal state machine to provide the control pulses thereby minimizing the number of signal paths to and from the chip . . . .") (emphasis added); col. 3:31-34 (stating that a single clock pulse is used); col. 7:36-40; col. 8:13-15; col. 9:57-58; col. 14:14-18; col. 15:38-40. Furthermore, the patentees responded to the examiner's rejection by distinguishing their claimed invention from the Target Specification because the Target Specification did not operate on a single random port clock input: "the Target Specification does not operate in response to a single clock as claimed in claim 1. . . . The Target Spec [sic] . . . requires more than one clock to perform this function." Response to Examiner at 115 (Exh. 5, Docket No. 120). A construction limiting clock signal to a single timing signal is consistent with the express purpose of the invention, the specification, and the prosecution history.

Clock signal

For the reasons discussed above in the construction of "external clock signal," the Court construes "clock signal" as "a single timing signal."

GO BACK

642

22. clocking circuitry for a generating time related signal, said repository device for storing time related data associated with picture image data

This phrase only appears in claim 20 of the '927 patent. The defendants contend that the phrase is indefinite because it is incomprehensible and the specification fails to provide meaning for to this phrase. The court disagrees and finds that one of ordinary skill in the art would understand the phrase to refer to clocks and time related signals associated with picture image data. Accordingly, the defendants' indefiniteness argument is rejected and the phrase means "clocking circuitry for generating a time related signal, said repository device for storing time related data associated with picture image data."

3. Term 4 ('645 Patent, Claim 1) 6

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - - - - -
The parties reached an agreement as to the construction of several contested terms prior to the Markman hearing and agreed that one other did not require immediate construction. Therefore, Terms 3, 8 and 20 are not addressed by the court here.

<table>
<thead>
<tr>
<th>Term</th>
<th>Court's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>... the given name server that receives the DNS query being close to the client local name server as determined by given location information ...</td>
<td>... the particular name server that receives the DNS query is selected by the alternative domain name system and is close in Internet terms to the client</td>
</tr>
</tbody>
</table>

The parties' first disagreement concerns whether "close" refers to geographic distance or Internet distance. 7 While Limelight argues that the specification only intends to specify Internet distance where explicitly stated, the language of the specification supports the concept of Internet distance generally where it refers to distance. 8 For example, the Brief Summary of the Invention describes an object of the invention as "to serve Web content efficiently, effectively, and reliably to end users" by "provide[ing] a network architecture that moves content close to the user" to avoid having to "build[] a massive infrastructure to handle the associated traffic." (Id. col.2 ll.41-42, 49-53 (emphasis added).) "Close," read in this context, refers to Internet distance. In addition, the description of the preferred embodiment generally references the network or network delays in its measure of distance:

"Several factors may determine where the hosting servers are placed in the network . . . . By studying [network] traffic patterns, the ISP may optimize the server locations for the given traffic profiles." (Id. col.611.28-34 (emphasis added).)

"[A]ppropriate control routines [] are used to determine where in the network the user is located, and then to direct the user to a . . . server that is close-by." (Id. col.9 ll.51-54 (emphasis added).)

"Thus, a given top-level DNS server directs the user to a region of the Internet . . . ." (Id. col.9 ll.57-59 (emphasis added).)

After determining where in the network the request originated, the top level DNS server redirects the DNS request to a low level DNS server close to the user in the network. (Id. col.10 ll.28-30 (emphasis added).)

In general, the clients are directed to regions in a way that minimizes the overall latency experienced by clients subject to the constraint that no region becomes overloaded. 9 (Id. col.10 ll.64-67 (emphasis added).)

A particular DNS or content server may be closer to a user in geographic terms, but delays in routing or high-traffic conditions along a particular route may mean that information can be obtained in less time from a server that is physically located farther away.

The exception to the general reference to Internet distance in the specification occurs in the Brief Summary of the Invention which asserts "[a]n additional feature [of the inventive framework], the actual content that is replicated at any one geographic location is specifically tailored to viewers in that location." (645 Patent, col.311.7-9.) However, it does not appear that this particular benefit of the invention is claimed in the '645 Patent. (See also id. col.10 ll.11-16 ("Alternatively, the user's location or IP address could be directly encoded into the request sent to the top level DNS.").)

9 Latency refers to the time delay between making a request for Internet content and receiving the requested content.

While Limelight is correct that none of these descriptions explicitly states that closeness refers to Internet distance, it is implied by the emphasized text. (Cf. id. col.10 ll.9-11 ("[T]he routines make the assumption that the user is located near (in

- 1120 -
the Internet sense) this server.

The second issue concerns whether there is any limitation on how this closeness is determined. Akamai argues that the words of the claim do not limit the determination of closeness, while Limelight asserts that it must be determined by the alternative domain name system. For the reason discussed supra, Term 1, I believe Limelight has the better argument. The specification describes "the present invention" as "manipulat[ing] the DNS system so the name is resolved to one of the ghosts that is near the client." (Id. col.9 ll.42-44 (emphasis added); see also id. col.3 ll.42-44 (Brief Summary of the Invention) ("[T]he top-level DNS server determines the user's location in the network . . . .").) As discussed supra, Term 2, the purpose of establishing "an alternative domain name system (DNS), distinct from the Internet domain name system" is to run "appropriate control routines" to "determine where in the network a user is located." (Id. Claim 1; id. col.9 ll.52-53.) Read in light of the specification, the invention claims an alternate DNS system that selects a DNS server in response to a user request based on the location of the user.

3. Opened/Closed

Artesyn seeks a claim construction with respect to the phrases "said auxiliary switch is opened prior [to] the ON period of said primary switch," and "said auxiliary switch is closed after the ON period." It argues that the words "is opened" and "is closed" do not refer to the actual status of the switch and its ability to conduct current, but instead to the sending of a signal from a central control or processor mechanism. Artesyn relies on terms in the specification which indicate action performed by the switch control circuit. See e.g. Col. 6, 11. 63-65. ("The flow of positive currents is controlled by the switch control circuit 22 which applies a suitable voltage to the gate of the MOSFET.")

Vicor responds that these words should be defined by reference to the status of the switch because only that definition is consistent with the requirement of "dead time" which means the absence of current flowing through the switches. See Col. 7, 11. 3-8 ("[A] delay between the opening of the auxiliary switch and the closing of the primary switch 10 represents dead time."); (Hearing Tr. 51. Bassett: "I think we've defined here and we could live with the concept that dead time means there's no current that could otherwise be blocked.").

The dictionary definitions of "closed" and "open" in the context of an electrical circuit are also helpful because they use those terms to describe the status of the circuit, not the act of opening the circuit. "Closed circuit" is defined as "Elect. a circuit without interruption, providing a continuous path through which a current can flow. Random House at 389. "Open circuit" is defined as "Elect. a discontinuous circuit through which on current can flow." Id. at 1356. While the matter is not open and shut, Vicor's argument is more persuasive, and I adopt it.

*   *   *

ORDER

The Court orders as follows:

1. Claims 1 and 5 of the '098 patent are not invalid as indefinite;

2. "Closed" means that a switch is enabled to conduct current that it could otherwise block;

3. "Open" means that a switch is not enabled to conduct current that it could otherwise block;

(4) "generating a clothes twist signal"
The parties also dispute the term "generating a clothes twist signal," which appears in Claims 1, 3, and 4. LG proposes construing the term to mean "generating a signal indicative of the bundling [i.e., uneven distribution] of clothes." (Id.) Whirlpool proposes instead that the term be construed to mean "generating a signal indicative of clothes that are entwined together." (Id.) For reasons already discussed, the Court will adopt Whirlpool's proposed construction. The term "generating a clothes twist signal" is therefore construed as "generating a signal indicative of clothes that are entwined together."

A. "Coaxial Cable"

The term "coaxial cable" is found in independent claim 2 of the 416 Patent, as well as in dependent claims 3 through 5. Claim 2 describes "[a] biased cable apparatus for communicating a voltage varying electrical signal from an output of a first electrical device to an input of a second electrical device on a coaxial cable having a center conductor and a conductive shield." 416 Patent, col. 9, lines 27-29; col. 10, lines 1-2.

Plaintiff contends that "coaxial cable," as the term is used in the 416 Patent, means an "electrical cable that has two or more conductors that share an axis." Quest proposes a construction of the term as a "transmission cable consisting of two concentric conductors -- a center conductor and an outer conductive shield' -- with the space between them being filled with dielectric." The crux of the parties' disagreement thus turns on whether the apparatus includes "two" or "two or more" conductors, whether the conductors must be concentric, or simply "share an axis," and whether the added specification regarding the space between them is necessary.

1. Two, or two or more conductors

In construing claims, the court looks first at the language of the claim itself. SmithKline Diagnostics, Inc. v. Helena Lab., Corp., 859 F.2d 878, 882 (Fed. Cir. 1988). Claim 2 specifically references "a coaxial cable having a center conductor and a conductive shield." 416 Patent, col. 10: 1-2 (emphasis added). The claim goes on to describe the apparatus as "comprising" various means and elements, including "the center electrode" (agreed by the parties to mean "center conductor") and "the conductive shield." Monster Cable argues that the intermittent references to "a" center conductor and "a" conductive shield means that there can be one or more conductors, and that any use of "the" merely cross-references the element's antecedent basis as a synonym for "said."

Monster Cable offers the correct general rule for indefinite articles where they follow the open-ended transition word "comprising," namely that "the article a' receives a singular interpretation only in rare circumstances when the patentee evinces a clear intent to so limit the article." KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000). "[T]he claim limitation a,' without more, requires at least one," and "disclosure of a preferred or exemplary embodiment does not disclaim a plural element." Id. Applied to this patent, however, this argument astonishingly belies the fact that "having," rather than "comprising," is the transitional word preceding the disputed elements of a "coaxial cable." 416 Patent, col. 10: 1-2. The Federal Circuit has distinguished the two terms, holding that "'having' does not convey the open-ended meaning as strongly as comprising," and holding that "'having,' for instance, does not create a presumption that the body of the claim is open." Crystal Semiconductor Corp. v. Tritech, 246 F.3d 1336, 1348 (Fed. Cir. 2001). Where the word "having" is used to transition to claim terms, the court should examine the claim in its full context to determine whether "having" limits the claim to its recited elements. Id. Monster Cable is not entitled to a presumption of "one or more" in assessing the claim context. Id.

Throughout the specifications, the patent names two conductors in a coaxial cable: a center conductor or electrode and an outer conductor or conductive shield. Figure 9, which depicts the preferred embodiment of claims 2-5, depicts a coaxial cable with two conductors: one center conductor and one conductive shield. Mirroring the language of claims 2 through 5, the written description of the biased cable apparatus uses the definite article "the" in reference to both "the center conductor" and "the outer conductor," as well as the indefinite article "a." 2 Compare 416 Patent, col. 7, lines 22, 26, 27, 29, 31 with 416 Patent, col. 2, lines 62-63. The patent does not include any references -- directly or indirectly -- to more than two conductors.
2 The parties have agreed that the "outer conductor" and the "conductive shield" are used interchangeably.

The 416 Patent's use of the definite article "the" after the term "comprising" and elsewhere in the patent specifications creates the inference that the patentee intentionally limited the element. See Insituform Technologies, Inc. v. Cat Contracting, Inc., 99 F.3d 1098, 1105 (Fed. Cir. 1996) (holding that repeated references to both "a cup" and "the cup" indicated that only one cup was involved). Though it promulgated a seemingly more strict standard in KCJ, the Federal Circuit expressly did not overrule the basis in Insituform for holding that the inventor intended to limit the claim to "one" where he used both "a" and "the." See KCJ, 223 F.3d at 1357. Rather, the court referred approvingly to Insituform's determination that the claim was restricted to one cup, even though in that case, as here, the patent had referred to "a cup" and "the cup" without ever specifying the number of cups as "one."

Monster Cable's argument that the depiction of the coaxial cable (marked by a free-standing arrow) inclusively refers to the ground reference line as a third conductor is specious. 3 The coaxial cable label in figure 9 cannot include the ground reference line, because that line does not share an axis with the center conductor and the conductive shield. If it does not share an axis, then it cannot be counted as a conductor under Monster Cable's proposed construction of "two or more conductors that share an axis." 4 If its conductors share an axis, which they clearly must, the preferred embodiment of a coaxial cable in the 416 Patent necessarily excludes the ground reference line from the count of conductors. 5

3 The arrow marking element 184 (defined as the "coaxial cable") cannot refer to the entirety of figure 9. Rather, arrow 184 refers to "a coaxial cable illustrated generally," which is specified as follows: "In addition to the center conductor 182, the coaxial cable 184 includes an outer conductor 186 and a dielectric 188." 416 Patent, col. 7, lines 23-28.

4 Monster Cable's own brief concedes this point by acknowledging the contradiction between their proposed definition of coaxial cable and an argument that it might include the ground reference line depicted in the patent specification. "Because coaxial cable 184 can include at least ground reference line 192, the specification discloses an embodiment with more than two conductors and where one or more conductors might not share an axis." Reply at 11, n.4 (emphasis added).

5 At the claim construction hearing, Monster Cable argued off-handedly that the "dielectric" could be construed as a third conductor in the coaxial cable depicted in figure 9. They gave no evidence, however, that "dielectric" is a conductor, and in fact in his tutorial, their own expert described "dielectric" as a property which intensifies electrostatic fields and can degrade signal quality, not an independent conductor.

Prior art, which is also part of the intrinsic record of a patent for the purposes of claim construction, confirms a two-conductor reading of the term "coaxial cable." See Kumar, 351 F.3d at 1368 (holding that "prior art cited in a patent or cited in the prosecution history of the patent constitutes intrinsic evidence"). The prior art references cited in the 416 Patent distinguish between multiple-conductor cables and coaxial cables, and each "coaxial cable" they describe has two conductors. The 416 Patent cited U.S. Patent No. 4,538,023, an audio cable in which "a plurality of outer conductors" surround "at least one inner conductor." See U.S. Patent No. 4,538,023, Behun Decl., Exh. E, col. 4, lines 2-5. The 023 Patent does not refer to this cable as a coaxial cable, but rather calls it a "multi-conductor audio cable." Id., col. 1, lines 11-14.

By contrast, two patents also cited as prior art describe so-called "coaxial cables" that have one center conductor and one conductive shield. See U.S. Patent No. 4,954,787, Masur Decl., Exh. K; U.S. Patent No. 4,622,638, Behun Decl., Exh. F. The first of these, the 787 Patent cited by Monster Cable, does not claim technology specifically involving a coaxial cable, however the embodiments described in the specifications employ a coaxial cable "compris[ing] an inner conductor [] and an outer conductor," which are also repeatedly referred to as "the inner conductor" and "the outer conductor." See U.S. Patent No. 4,954,787, Masur Decl., Exh. K, col. 5, lines 19-29, 49. The latter 638 Patent does not state the elements of a coaxial cable in its claims or specifications, however it depicts two coaxial cables embodied as a center conductor line running
through a conductive shield. See U.S. Patent No. 4,622,638, Behun Decl., Exh. F, figures 1-2. While this second patent could not be limited to two conductors based on its preferred embodiment, the prior art record as a whole lends support to an interpretation of the term "coaxial" as specifically having two conductors.

On the basis of the language of the claims, the specifications, and the prior art, this court is satisfied that the claim for "coaxial cables" in the 416 Patent is limited to two conductors. Technical dictionaries provided by the parties provide little assistance in confirming this reading of the disputed term, because they are clearly weighted towards cable technology in the context of computer networking, television, and radio. See Texas Digital, 308 F.3d at 1202 (holding that technical dictionary definitions can provide important evidence of the ordinary meaning of a term to persons skilled in the art). However in general, these technical dictionary definitions are overwhelmingly consistent with a two-conductor understanding of coaxial cables. Vitronics, 90 F.3d at 1584, n.6. The Illustrated Dictionary of Electronics, the McGraw-Hill Dictionary of Scientific and Technical Terms, the Dictionary of Electronics, and the New IEEE Standard Dictionary of Electrical and Electronics Terms all specify that coaxial cables have two conductors. See Behun Decl., Exhs. B, C, D; Villasenor Decl., Exh. B. The definition provided in the John Douglas-Young Illustrated Encyclopedic Dictionary of Electronics defines a "triaxial cable" to include three conductors, but the fact that this is defined as a species of "coaxial cable" given a distinct name only proves the point that "coaxial" ordinarily refers to two-conductor cables. Masur Decl., Exh. F.

Only one technical dictionary raised before this court, the Penguin Dictionary of Electronics, defines the term to include "two or more" conductors. Masur Decl., Exh. E. If this court were to use dictionaries as the principal mode of construction, this broad definition might prevail. However, given the Federal Circuit's relative clarity about the secondary status of dictionaries in relation to the language of the patent itself, this court errs in favor of the terms of the patent and the intent of the inventor as expressed therein. See Nystrom v. Trex Co., Inc., 374 F.3d 1105, 1112, n.2 (Fed. Cir. 2004) (holding that claim terms encompass all dictionary definitions not inconsistent with the intrinsic record). The term "coaxial cable" as used in the 416 Patent thus incorporates the overwhelming weight of dictionary evidence that is consistent with the claim terms and patent specifications limiting the term "coaxial cable" to encompass one center conductor and one conductive shield.

Extrinsic evidence need not be considered in construing the number of conductors understood to constitute a "coaxial cable." Inventor and expert witness testimony are forms of extrinsic evidence admissible only where the intrinsic evidence proves insufficient to enable the court to construe disputed claims. Vitronics, 90 F.3d at 1584. The ordinary meaning of "coaxial cable" refers to a species of cable with two conductors.

2. "Concentric" or "Share an Axis"

The 416 Patent does not specify whether the two conductors within the coaxial cable described must be concentric, nor does it specify any form of symmetry in their arrangement. However, the patent makes three references to the relative locations of the two conductors: (1) one conductor is referred to alternately as the "inner conductor" and the "center conductor," (2) the second conductor is alternately referred to as the "conductive shield" and the "outer conductor," and (3) figure 9 depicts the coaxial cable to have the center conductor running concentrically through the conductive shield. 416 Patent, figure 9. The dispute between the parties turns on whether these three aspects of the specifications amount to a requirement of concentricity.

The parties do not contest that the inner and outer conductors of a "coaxial" cable "share an axis," and indeed, that this is the ordinary meaning of that term. See, e.g., McGraw-Hill Dictionary of Scientific and Technical Terms, Masur Decl., Exh. D (defining "coaxial" as "sharing the same axes"). A coincident axis is consistent with the preferred embodiment of claim 2, which depicts a conductor running through the center of the conductive shield. See 416 Patent, figure 9; col. 7, lines 19-33.

By definition, concentric conductors would share an axis; however, as Monster Cable articulates, the terms "concentric" and "share an axis" are not synonyms. The 416 Patent never refers to the conductors of the coaxial cable as concentric. It does, however, specifically refer to the inner conductor as the "center conductor" or "center electrode." See, e.g., 416 Patent, col. 10, lines 1, 6. Standing alone, this parlance is inconclusive: the ordinary meaning of the adjective "center" can be read broadly to suggest that the inner conductor is merely in the "middle part" of the outer conductor, or narrowly to mean that the inner conductor is "equidistant" at all points from the outer conductor. See Webster's Third New International Dictionary 362 (1986) (defining "center" as either "$[a]$ point equidistant from all points on a circumference" or "middle part in contrast to sides, boundaries, outskirts, circumference, or peripheral features"). The depiction in figure 9 of the center conductor as
A patent describing an "electronic multi-function card" that would synthesize multiple "credit cards, or the like," and that evidenced in the intrinsic record. A recent case from the Federal Circuit is instructive. The court construed the term "card" in with concentric conductors without grafting the limitation of concentricity onto the patent where such a limitation was not evidenced in the intrinsic record. A recent case from the Federal Circuit is instructive. The court construed the term "card" in a patent describing an "electronic multi-function card" that would synthesize multiple "credit cards, or the like," and that concentric with the conductive shield would support this latter construction, however, this court is obliged to grant the broadest construction of a term which is consistent with the written description. Nystrom, 374 F.3d at 1111, n.1 (noting that "[i]f everything in the specification were required to be read into the claims, or if structural claims were to be limited to devices operated precisely as a specification-described embodiment is operated, there would be no need for claims"). Patent 787, part of the prior history and thus the intrinsic record of Patent 416, provides strong support for a broader reading of the term "coaxial." Its preferred embodiment depicts and describes a "coaxial cable" that includes an "outer conductor" around an "inner" or "center conductor." See U.S. Patent 4,954,787, figure 3; col. 5, lines 19-28. The outer conductor of the coaxial cable depicted in the diagram is helically wrapped rather than forming a cylindrical tube around the inner conductor. Such a spiral conductor is not a circle, cylinder, or sphere. See McGraw-Hill Dictionary, Masur Decl., Exh. D, at 406 (defining "concentric" as "pertaining to the relationship between two different-sized circular, cylindrical, or spherical shapes when the smaller one is exactly centered within the larger one"). In essence, it is not concentric with the inner conductor, because in cross section, a spiral is a point in space rather than a circle. 6 The helical shape does not mean that the outer and inner conductor are not symmetrical. A helical outer conductor sharing an axis with an inner conductor would render the two shapes radially symmetrical.

6 Quest argues in its opposition brief that a "helical conductor as a whole is still concentric with the inner conductor." Opp'n at 32. Yet as discussed, because a helix is not a cylinder, a helical conductor surrounding a center conductor would not fall within the ordinary definition of concentric. Quest has provided no intrinsic or dictionary-based evidence that a helical conductor should be read "as a whole" to be a cylinder, nor that the ordinary meaning of concentricity should include the concept of a helix.

On the basis of the intrinsic record, this court agrees with Monster Cable that adding the requirement of concentricity to the two-conductor cable system would impermissibly limit the claim language. Though most of the technical dictionaries submitted to this court describe coaxial cables as having concentric conductors, 7 the court must "giv[e] a claim term the full range of its ordinary and customary meaning, consistent with the written description and prosecution history." See Nystrom v. Trex Co., Inc., 374 F.3d 1105, 1113 (Fed. Cir. 2004). This court reads dictionary definitions that require concentricity to be more restrictive than the patent terms, perhaps because of their orientation towards other forms of cable technology.

7 The Penguin Dictionary of Electronics defines coaxial cable without the specification of concentricity, defining the terms as "[a] cable formed from two or more coaxial cylindrical conductors insulated from each other ..." Masur Decl., Exh. E at 74. Other definitions provided by the parties, however, specify concentricity. Definitions of coaxial cable included in the New IEEE Standard Dictionary of Electrical and Electronics Terms refer to the two-conductor system of the cable as "concentric" or as a "cable with two conductors where one completely surrounds the other." See Villasenor Decl., Exh. B, at 201. The Illustrated Dictionary of Electronics also specifies the concentricity of the two conductors, defining coaxial cables as consisting of "two concentric conductors." Behun Decl., Exh. C, at 144. The Dictionary of Electronics defines a coaxial cable to have a "transmission line formed between two conductors, one a wire and the other a cylinder concentric with the wire." Behun Decl., Exh. D, at 53. The McGraw-Hill Dictionary of Scientific and Technical Terms defines a coaxial cable as "a transmission line in which one conductor is centered inside and insulated from [the second conductor]," and its lists of synonyms for the term coaxial cable includes "concentric cable; concentric line; concentric transmission line." See Villasenor Decl., Exh. D, at 373.

A construction of the term "coaxial cable" that requires radial symmetry along a shared axis would encompass all cables with concentric conductors without grafting the limitation of concentricity onto the patent where such a limitation was not evidenced in the intrinsic record. A recent case from the Federal Circuit is instructive. The court construed the term "card" in a patent describing an "electronic multi-function card" that would synthesize multiple "credit cards, or the like," and that
had the advantage of "the outer dimensions of a usual credit or check card." See E-Pass Techs., Inc. v. 3COM Corp., 343 F.3d 1364, 1369 (Fed. Cir. 2003). The circuit held the references in the specifications to the "standardized dimensions" of the "card" were not "lexicographic," because the statements about the size of the card "suggest[ed] a preferred aspect of the invention subject to variability rather than a precise definition." Id. Vacating the grant of summary judgment of noninfringement, the circuit remanded to the district court for further proceedings on infringement by the accused device, a palm pilot with 58 times the volume and 25 times the thickness of a credit card. Id. at 1366, 1371. In the case of the 416 Patent, the inventor did not even arguably add limitations regarding concentricity onto the meaning of coaxial cable. The meaning of the term thus must be protected in its broadest form to include conductors that share an axis, whether or not they are concentric.

Therefore, this court determines that the two conductors of a coaxial cable must share an axis, but they need not be concentric.

3. "The Space Between Them Being Filled with a Dielectric"

The claim language of the 416 Patent does not specify what fills in the space between the two conductors of a coaxial cable. In the specifications of the preferred embodiment, however, the patent describes that "[i]n addition to the center conductor 182, the coaxial cable 184 includes an outer conductor 186 and a dielectric 188." 416 Patent, col. 7, lines 26-28. Quest argues that this specification should be imported into the construction of the term coaxial.

This court has no reason to believe that adding the specification "the space between [the conductors] being filled with a dielectric" would limit the term coaxial, but nor is there any reason to believe that such specification is necessary to the construction of the term. While the inventor articulated that a dielectric would lie between the inner and outer conductors in his preferred embodiment of the bias cable apparatus, there is no evidence that he was limiting the term "coaxial" to carry that specification. Only one technical dictionary definition provided by the parties specifically describes the space between the two conductors. See The Dictionary of Electronics, Behun Decl., Exh. D, at 53; Masur Decl., Exh. H at 53 (defining a coaxial cable as two conductors, "the space between them being filled with a dielectric"). Other dictionary definitions of "coaxial cable" are silent on the issue of the space between the conductive shield and the inner conductor, suggesting that such a fact is unnecessary for an ordinary understanding of that term. See Masur Decl., Exhs. D, E, I; Behun Decl., Exh. C., at 144. On the basis that the claim terms themselves do not carry a limitation regarding the dielectric, and the lack of alternate indications that the ordinary meaning of term would include this limitation, the court finds that this information is unnecessary to the term's construction.

Thus, for the reasons stated above, the court construes "coaxial cable" as a "cable with two conductors that share an axis."

647

A. "Code"

The claim term "code" is used throughout independent claims 1 and 5 of the '364 Patent. Lynx argues that "code" as properly construed means "newly received code that is to be stored in a memory location" rather than previously stored codes. Chamberlain, on the other hand, claims this construction is improper and that the term as properly construed means "the identity codes of the transmitters."

Lynx argues, first, that the term "code" was defined by implication in the written description because it is used in a manner consistent with only one meaning, "newly received codes." Although the general rule of claim construction is that "limitations from the specifications are not to be read into the claims," the Federal Circuit has explained that "the written description 'can provide guidance as to the meaning of the claims, thereby dictating the manner in which the claims are to be construed, even if the guidance is not provided in explicit definitional format.'" Bell Atlantic Network Services, 262 F.3d at 1270-71, quoting SciMed Life Systems, Inc. v. Advanced Cardiovascular Systems, Inc., 242 F.3d 1337, 1344 (Fed Cir. 2001). A patentee will be found to have defined a term by implication if the "patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning." Id. at 1270 (citations omitted).

Lynx directs the court to a number of provisions in the specifications to support its proposed claim construction, including:
"wherein the receiver can be placed into a program mode wherein it will receive and store two or more codes corresponding
to two different transmitters," (The '364 Patent, col. 1, lines 47-49); and "in the program mode a code must be received four
times in a row in order to be permanently stored in the receiver." (The '364 Patent, col 1, lines 17-19; col. 4, lines 34-37).
The court recognizes that Lynx's proposed construction is consistent with these portions of the written description, but notes
that it is not consistent with other portions. For instance, the specifications also state, "in the invention, each transmitter . . .
will have a unique code which is determined by the encoder chip contained in the transmitter," (The '364 Patent, col. 3, lines
31-33), and "when the garage door operator is initially installed, the switch . . . is moved to the program mode and the
energize button . . . of the first transmitter . . . is depressed so that the unique code of the first transmitter is transmitted."
(The '364 Patent, col. 3, lines 40-43.) Lynx's proposed claim construction does not comport with these portions of the
written description. Because the court finds that the term "code" is used in a manner consistent with more than one meaning,
the term has not been defined by implication.

Lynx also directs the court to certain statements made by Rhyne during the prosecution of the '703 Patent, which Lynx
claims support its proposed claim construction. Chamberlain argues that statements made during the prosecution of the '703
Patent are not relevant to the claim construction of terms in the '364 Patent. The court notes that Lynx does not address
Chamberlain's relevancy argument. In any event, the court does not need to resolve this dispute because it finds the Federal
Circuit's decision in Overhead Door Corp. dispositive regarding the proper construction of the term "code."

To insure uniformity in the treatment of a patent, the court will rely on the Federal Circuit's claim construction related to
claim terms in the '364 Patent. Markman, 517 U.S. at 390-9 ("the limits of a patent must be known for the protection of the
patentee, the encouragement of the inventive genius of others and the assurance that the subject of the patent will be
dedicated ultimately to the public.") In Overhead Door Corp., 194 F.3d at 1274, the Federal Circuit considered the district
court's construction of the "different codes" claim element in claims 1 and 5 of the '364 Patent. The district court construed
this claim element to mean "factory-defined codes stored within the radio transmitters which uniquely identify each
different transmitter and are not selectable or modifiable by the user of the garage door opener . . . system." Id. The Federal
Circuit stated that the district court's claim construction was supported by both the claims and the written description of the
'364 Patent. Id. ("The claim language requires association of each code with a different transmitter. The written description
notes that each code uniquely identifies a transmitter.") The Federal Circuit stated, further, that "the claim language does not
supply any further constraints on the meaning of 'codes.'" Id.

Lynx proposes a claim construction, "newly received code", that associates the term "codes" with the storing process set
forth in the '364 Patent. In this court's view, Lynx's construction is inconsistent with that of the Federal Circuit. In Overhead
Door Corp., the Federal Circuit indicated that a code is associated with a transmitter, whether it is in the process of being
stored or not. Id. at 1274. Chamberlain's proposed claim construction, in contrast, does correspond with the Federal Circuit's
construction, and associates the term "code" as it relates to each transmitter. In addition, Lynx's proposed construction seeks
to impart additional constraints on the "code" element, counter to the Federal Circuit's direction that no further constraints
were warranted. Because the court finds that Chamberlain's claim construction of "code" is consistent with the Federal
Circuit's construction of the term "different codes," the court construes the term "code" in claim 1 and 5 to mean "the
identity codes of the transmitters."

648

G. "a code directed to"

- Plaintiff's proposed construction: "code or instructions that execute to carry out"

- Defendants' proposed construction: "software or firmware for"

The parties dispute as to this term echoes their dispute concerning the "integrated computer software application" claim
term. This term is found in claims 1, 6, 14, 16, and 17 of the '655 patent and claims 16 and 17 of the '172 patent. Plaintiff's
"code or instructions" construction mirrors the "code or instructions" of its construction of "integrated computer software
application." Defendants' "software or firmware" construction is more ambiguous relative to their proposed construction
above. "Software or firmware" would also allow an "integrated computer software application" to include firmware rather
than software, which is not supported by the intrinsic record. "Firmware" is completely absent from the patents. The
patents describe using "software codes" to implement the disclosed functionality. 12

Plaintiff also seeks to use the term "that execute to carry out" to link its code to the function performed by the code. Defendants seek to use "for." The term "carry out" is used to express the function of code in the specification. 13 In spite of this, "for" is less ambiguous and covers the same scope as Plaintiff's proposed construction of the term.

The Court therefore defines "a code directed to" as "software code or instructions for."

1. "code which includes data indicating whether the player wins or loses"

a. The Parties' Proposed Constructions

The parties' dispute over this claim term centers on the meaning of the term "indicating." (D.I. 113 at 14-16; D.I. 117 at 9-15.) Ingenio asserts that "indicating" should be construed to mean "points to," in accordance with its ordinary meaning. (D.I. 113 at 14.) In support of its proposed construction, Ingenio cites two dictionary definitions of the word "indicating," which define that term as "shows the way to, points to, or makes clear in another way." (Id.) GameLogic, on the other hand, asserts that "indicating" connotes that the data itself states the win/loss outcome. (D.I. 117 at 9.) GameLogic relies heavily on the specification, including the preferred embodiments, and the prosecution history of the patent to support its assertion. (Id. at 10-15.) Specifically, GameLogic asserts preferred embodiments in the patent state that all of the win/loss data is stored in the code itself, without referencing additional information. (Id. at 11-15.) To further support its argument, GameLogic also relies on the inventor's statements during prosecution that the "code determines whether you win or lose the game," and on the fact that a particular prior art reference was distinguished. (Id. at 12-15.)

b. The Court's Construction

No where in its briefing does GameLogic argue that the ordinary meaning of "indicating" does not include "shows the way to, points to, or makes clear in another way," as Ingenio contends. However, GameLogic asserts that in the context of the patent, including the specification and the prosecution history, Ingenio has limited the term "indicating" to mean that the code itself must include or store the relevant win/loss data. (D.I. 117 at 9-15.) In support of its argument, GameLogic points to several preferred embodiments, which state that "the outcome of the game is stored in the Destiny Code," n4 ('082 patent at 6:28-29), or that the "primary function of the Destiny Codes is to store the outcome of the game of chance," (Id. at 2:58-59). However, GameLogic ignores the embodiment of the patent that states that "[t]he outcome may be determined, for example, by comparing the Destiny Code to a lookup table to determine if the number is a loser or a winner and the size of the prize, if any." ('082 patent at 9:63-66.) That embodiment allows for the code to point to something else, e.g., a lookup table, to determine the outcome of the game. Thus, the specification of the '082 patent does not limit the meaning of "indicating" as GameLogic argues.

n4 The "Destiny Code," or access code, is a "symbolic code[] that signifies the outcome of the particular game of chance to
be played by the player." ('082 patent at 2:66-67.)

GameLogic also cites to the prosecution history of the '082 patent to support its argument that "indicating" must mean that the data is stored in the code itself. (D.I. 117 at 12-15.) During the prosecution of the '082 patent, the applicant distinguished the invention in U.S. Patent No. 5,377,975 issued to Clapper, Jr. ("Clapper, Jr.") from the invention of the '082 patent. In a January 31, 1996 office action, the examiner, reviewing the application for the '082 patent, rejected claims 18 and 20-21 as anticipated by Clapper, Jr., and claims 1 and 10, as well as several dependent claims, as obvious over Clapper, Jr. in combination with two other references. (D.I. 114, Ex. C at IN1409-10.) In responding to that office action, the applicant stated:

None of the cited references disclose or suggest a game or method of playing a game in which a code entered by the player prior to game play controls the outcome, win or loss, of the game. The Clapper, Jr. reference discloses the use of a bar code which merely identifies indicia printed on a strip. The bar code is used to display the strip indicia to a game player. The printed indicia on the strip determines whether the player wins or loses the game, and not the code.

(Id. at IN 1406.) GameLogic argues that by this statement, the applicant disclaimed a product where the data containing the win or loss information is not in the code itself, but is located elsewhere.

I do not read the applicant's statements, or the Clapper, Jr. reference, in the way that GameLogic does. In Clapper, Jr., a strip of paper containing indicia, or symbols, such as lemons or cherries, is dispensed to a game player. (Clapper, Jr., D.I. 116, Ex. 5 at GL00334.) A duplicate strip containing the same indicia is stored in the machine. (Id.) On the back of the duplicate strip, a printed bar code is scanned by the machine to display the same indicia printed on the strip on an electronic display. (Id.) Thus, the bar code in Clapper, Jr. is used to display the same indicia that a player has on his or her game piece on the machine. The applicant's statements in distinguishing Clapper, Jr. do not give up a method of playing a game where the code requires a processor to go to a lookup table to determine the win or loss result.

Therefore, I will construe "indicating," in the context of "code which includes data indicating whether the player wins or loses," in accordance with its ordinary meaning to mean that the code "shows the way to, points out, or makes clear in another way."

Although the parties acknowledged for the first time at the Markman hearing that "security measures" and "coded embedding" are not identical, they did not offer the Court any proposed construction for the term "security measures." Consequently, it falls to the Court to determine the meaning of "security measures."

The claimed invention seeks to prevent dishonest persons from misusing the invention by issuing drafts payable to someone other than an authorized payee. The system uses "security measures" to "reduce the likelihood of production of unauthorized drafts." '677 patent, col. 4, lines 31-34. Every time the term "security measures" is referred to in the identified claims, it includes, but is not limited to, "coded embedding." See, e.g., '677 patent, claim 2 ("security measures comprising the coded imbedding of said identification of said payee in said software"); claim 22 (same); claim 37 (same); claim 39 (same). Other security measures that are available in addition to "coded embedding," include password protection and encryption. See, e.g., '249 patent, claim 12 (claiming hard coding and password protection as security measures). Thus, "security measures"
is broader than "coded embedding" and shall be construed as "measures taken to preclude the generation of drafts payable to someone other than the payee, including at least coded embedding of the payee identification information."

With respect to "coded embedding," both parties agree that it is synonymous with "hard coding." Given that, and the fact that the patent examiner explicitly found that the terms are synonymous, 11 this Court agrees. However, in defining "coded embedding/hard coding," both parties err.

--- Footnotes ---

--- End Footnotes ---

AutoScribe suggests that "coded embedding" means "an adjective describing a routine or program that is designed for a specific situation or that uses imbedded constants in place of more general user input." (Joint Chart at 2, emphasis added). The problem with that definition is that it is circular, using "imbedded constants" to define "coded embedding." Intell-A-Check on the other hand originally argued that "coded embedding" means "fixing within a given copy of the program the payee identification information and the secreting thereof into the program code so that it cannot be changed." (Id., emphasis added). In making that argument, Intell-A-Check goes too far by adding the requirement that coding requires secrecy. Coding does not require secrecy, and Intell-A-Check admitted as much at the Markman hearing. (Tr. at 68:7-19).

However, the Court, and AutoScribe based on its representation at the Markman hearing, 12 agree with the first portion of Intell-A-Check's construction -- "fixing within a given copy of the program the payee identification information." The ’677 and ’249 specifications support that construction by disclosing that "the payee is hard-coded into the program and cannot be readily changed even by an authorized user of the system." ’677 patent, col. 13, lines 66-67; ’249 patent, col. 13, lines 54-55. Although Intell-A-Check appears to suggest that the payee identification information should be fixed within a specific file on the system, e.g., an identifiable executable file, this Court finds no such limitation in the patents' disclosures and, therefore, will impose no such limitation. As long as the payee identification information is fixed within the program, regardless of what file it is located in that is associated with the program, the information is properly "coded embedded / hard coded."

--- Footnotes ---

12 (Tr. at 76:4-9).

--- End Footnotes ---

In conclusion, the Court will construe "coded embedding" and "hard coding" to mean "fixing within a given copy of the program the payee identification information."

In conclusion, the Court will construe "coded embedding" and "hard coding" to mean "fixing within a given copy of the program the payee identification information."
Both parties request unsupportable constructions of this term. Plaintiff's construction is exceedingly broad. Defendants' construction imports limitations not found in the claims. The patent specification does not define the term "code," however, the specification does state that a "coder … may be any form of such device utilizing a known algorithm[.]" ('148 patent, col. 3, ll. 37-39) Thus, the term "coding" shall be construed to mean "transforming information by applying a known algorithm."

32. The method in accordance with Claim 1 further comprising coding said contributions at said electronic contribution accepting devices to obtain coded contributions; and decoding said coded contributions at a device other than said electronic contribution accepting devices.

"Coding" means to put the information into computer-readable format, so that the information can be read by the intended recipient, but not readily read by other recipients, whether computers or people. "Decoding" is the reverse of "coding," that is, reading the information by the recipient computer. Beyond that, this claim language does not require further definition.

654

Literal Infringement

The '389 patent contemplates a CVD process sequence that starts with a cold reactor chamber, the chamber having been cooled in order to permit the operator to remove the coated substrates and insert uncoated ones. The '389 claims are directed to the removal of static attraction during the gaseous purge of the cooled chamber within which electrostatic contamination has formed. Although the parties dispute whether this requires treating at a "relatively low" temperature that is high enough to eliminate the static charges, or is accomplished solely by an infrared photon flux at low intensity, claim 1 appears to include both mechanisms, while claim 4 is specific to heating the wafer above about 180 degrees C. The '389 patent describes about 180 degrees C as the temperature above which static electricity does not form or exist.

The ASM Epsilon One reactor process also conducts an initial purge with inert gases as the first step in the deposition cycle. However, this purge is conducted at about 850 degrees C. Since in the Epsilon One reactor the substrates are removed and replaced mechanically, the chamber need not be cooled significantly to perform this step and does not acquire electrostatic contamination during the processing cycle. Thus although the Epsilon One process includes an initial gaseous purge below the deposition temperature, the temperature of this purge is stated to remain above 850 degrees C. ASM argues that this can not reasonably be deemed a "cold purge process." ASM states that the problem solved by the '389 invention does not exist at the Epsilon One operating conditions, and that the '389 specification makes clear that the invention relates to a process wherein the chamber is cooled to ambient temperatures, permitting electrostatic contamination to form, in order to remove it by raising the temperature to above 180 degrees C, but still at relatively low temperatures. ASM points out that the prior art shows the initial cold purging with inert gases, and that the sole "inventive" contribution of the '389 patent is removal of the electrostatic contamination that occurred below about 180 degrees C. ASM states that under its operating conditions, which do not drop below 850 degrees C during or between processing cycles, electrostatic contamination does not occur, and thus that it does not practice the invention of the '389 patent.

Applied Materials states that "cold purge" is a word of art for the initial gas purge step, and that "cold" is understood in this art as a relative term and means a temperature below the processing temperature. Applied Materials states that the claims require only that the initial gaseous purge is conducted below the processing temperature, and that ASM does so, literally. Applied Materials states that it is the claims that define the invention, and that it is incorrect to limit the claims to any specific temperature mentioned in the specification. Thus Applied Materials states that claim 1 reads literally on the Epsilon One process.

The construction of patent claims, as well as the meaning and scope of a disputed technical term or terms of art in a patent
claim, are deemed to be questions of law and are determined de novo on appeal. Markman v. Westview Instruments, Inc., 52 F.3d 967, 34 U.S.P.Q.2d (BNA) 1321 (Fed. Cir. 1995) (en banc), aff'd, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). Although this court requires that no deference be given to the testimony of experts, id. at 983, 34 U.S.P.Q.2d (BNA) at 1333 ("when legal 'experts' offer their conflicting views of how the patent should be construed, or where the legal expert's view of how the patent should be construed conflicts with the patent document itself, such conflict does not create a question of fact nor can the expert opinion bind the court or relieve the court of its obligation to construe the claims according to the tenor of the patent. This opinion testimony also does not change or affect the de novo appellate review standard for ascertaining the meaning of the claim language."), we take note that extensive expert testimony was adduced at trial.

The district court first considered Applied Materials' argument that since the phrase "cold purge" appears only in the preamble of claim 1, it does not limit the claims as applied to the accused process. The district court concluded that "cold purge" is indeed an element of the claims, and "establishes a limitation which the accused device must meet in order to literally infringe the '389 patent." We reach the same conclusion.

Whether a preamble stating the purpose and context of the invention constitutes a limitation of the claimed process is determined on the facts of each case in light of the overall form of the claim, and the invention as described in the specification and illuminated in the prosecution history. See In re Stencel, 828 F.2d 751, 754, 4 U.S.P.Q.2d (BNA) 1071, 1073 (Fed. Cir. 1987) (the preamble is interpreted in light of the invention as a whole); Perkin-Elmer Corp. v. Computervision Corp., 732 F.2d 888, 896, 221 U.S.P.Q. (BNA) 669, 675 (Fed. Cir.), cert. denied, 469 U.S. 857, 83 L. Ed. 2d 120, 105 S. Ct. 187 (1984) (the limitations stated in the preamble give meaning to the claim and can serve to define the invention). It is thus appropriate to determine whether the term in the preamble serves to define the invention that is claimed, or is simply a description of the prior art.

The term "cold purge" has its roots in the specification, which states that in a typical deposition process of the prior art "both the nitrogen prepurge and hydrogen purge are carried out 'cold', that is, without heating." The specification explains that in the '389 process these initial purges are carried out at low radiant energy or low thermal energy. The district court found that "cold purge process" means temperatures below 180 degrees C, and that the '389 invention was directed to the use of heat sufficiently high to remove electrostatic contamination in the initial purge steps, that is, heat above about 180 degrees C, in a reactor whose operating conditions include temperatures below 180 degrees C. "Cold purge" is interpreted in light of the problem the '389 patent solved: the elimination of electrostatic contamination during the initial purge step. The specification states:

During the use of the above outlined process sequence, electrostatic attraction is operative almost exclusively during the cold purging steps (steps 1 and 2). It is substantially non-existent when the susceptor/wafer is at an elevated temperature, such as for example above about 180 degrees C.

'389 patent, column 9, lines 17-22. The specification also states that the purpose of the invention is the removal of contamination caused by this electrostatic attraction. Claims 1 and 4 include this requirement.

The district court correctly placed the term "cold purge process" in the context of the state of the art when the '389 invention was made. This context requires construing the literal meaning of the claims as limited to the process wherein electrostatic contamination is formed and removed. The Epsilon One reactor does not meet this criterion. We affirm the court's ruling that claim 1 is not literally infringed.

655

E. "Collating"
The parties ask the court to construe the term "collating," contained in the second clause of claim 3. The defendants argue that the term "collate" has a well-understood meaning—to compare and to merge two similarly-ordered sets of information into a single set of information. The plaintiffs argue that the inventors used the term "collate" in the context of the patent to refer simply to the act of "comparing" not merging. Although the defendants correctly observe that the term "collate" has a well-understood meaning of "to compare and to merge two similarly-ordered sets of information into a single set of information," the patentee has used the term throughout the specification in a different manner. Throughout the specification, the patentee refers to a device which compares the data received from the disk with a table stored in memory to discern what type of disk was being read. It is true that definition by implication is a tough climb, whether suggested by a patentee or an accused infringer. Nevertheless, the court is bound to construe the claim terms in light of the specification. The claim language itself supports this interpretation when, in the third limitation, the modulation of the servomechanism means depends on the optical disk standard data which corresponds with the processed signal. Use of the term "corresponds" suggests that the signal has been compared to the standard data stored in memory to determine a match. The plaintiff's proposed construction of this term is correct.

2. "Collecting Electronically"

<table>
<thead>
<tr>
<th>Simplification's Construction</th>
<th>Block's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>Gathering by way of devices, circuits, or systems utilizing electron devices.</td>
<td>The act of gathering data automatically without manual intervention from the user.</td>
</tr>
</tbody>
</table>

Other than the dispute over the interpretation of the term "electronically," the parties only disagreement is about whether the term "collecting" should refer to "gathering data" (Block's position) or simply "gathering" (Simplification's position). The Court's review of the claims reveals that the term "collecting electronically" is used exclusively in conjunction with the term "tax data." Accordingly, the Court concludes that the word "data" need not be included in the construction of "collecting electronically." Unlike the claim term "automatic tax reporting," where the Court looked to surrounding claim language to help construe the word "automatic," the Court finds no need to resort to surrounding claim language to clarify the meaning of the disputed term. The Court will thus construe the term "collecting electronically" to mean "gathering without manual intervention from the user."

VI. "collective verify signal" in the 351 patent

<table>
<thead>
<tr>
<th>Lexar's proposed construction:</th>
<th>Toshiba's proposed construction:</th>
</tr>
</thead>
<tbody>
<tr>
<td>a signal output from the input/output buffer that is generated upon the simultaneous verification of the state of a plurality of memory cells</td>
<td>3 a signal that a collective verify operation has taken verification of the state of a plurality of memory cells</td>
</tr>
</tbody>
</table>

--- Footnotes ---

2 At oral argument, Lexar conceded that the word "simultaneous" could be employed in the construction rather than its initially proposed "parallel." (Claim Construction Transcript 31:6-13.)

3 At oral argument, Toshiba conceded that the term "signal" could be employed in the construction rather than its initially proposed "indication." (Claim Construction Transcript 33:8-9.)

--- End Footnotes ---
The disputed claim phrase "collective verify signal" appears in claims 1, 4, and 5 of the 351 patent. Claim 1 of the 351 teaches:

a memory means having a plurality of memory cells . . . for outputting a collective verify signal when all the data of the data group have been written; and . . . said memory means to allow said memory means to latch and write the transferred new data group therein and further to transfer the collective verify signal to said control circuit whenever the new latched data group has been written.

Claim 4 teaches:

a read only memory (ROM), said ROM configured to receive data of a predetermined number of bits as a page of data and to output a collective verify response to the collective verify signal received from said ROM, the control circuit outputs data to be next written to said ROM.

Claim 5 teaches:

A memory system as recited in claim 4, wherein said ROM comprises an electrically erasable ROM (EEPROM) . . . wherein during the write operation for writing m pages of data into the EEPROM, m being an integer greater than or equal to one, the EEPROM outputs the collective verify signal for each page of data written into the EEPROM.

For the most part, the parties agree about the proper construction of this claim phrase. The remaining dispute here lies in whether the construction should explain from where and to where the signal is outputted (i.e. whether the construction should include Lexar's proposed "from the input/output buffer" language). Toshiba argues that Lexar's focus on defining the means for outputting a collective verify signal is redundant because surrounding claim language explains what generates the signal and what receives it. Lexar contends that including such language would be beneficial to the jury to understand exactly what the collective verify signal does. However, at oral argument, Lexar agreed that the Court could "properly construe th[e] term without . . . including an output from the input/output buffer." (Claim Construction Transcript at 31:14-22.) Therefore, the Court declines to incorporate from whence the collective verify signal is output in its construction of the claim phrase. To do so would improperly load up surrounding claim language into the construction of a single phrase.

"Collective verify signal" is construed as a signal generated upon a simultaneous verification of the state of a plurality of memory cells.

b. Displaying in "Color"

The claims require that pixels be displayed in two predetermined colors, a first color for attenuated radiation and a second color for backscattered radiation. The district court construed the phrase "predetermined single color" to require display in a color "other than black and white and shades thereof." AS&E argues that the district court erred by so limiting the term "color." According to AS&E, a display in black and white and another color, such as green, would infringe claims 5 and 8. Vivid responds that such an interpretation would defeat the purpose of the invention, which is to avoid grey scale images.

The specification states that "the present invention is directed to an inspection system having a color display." The specification describes prior art images displayed in black and white and shades of grey, points out that images in grey tones are often difficult for the operator to interpret and may become monotonous to watch, and acknowledges that to solve this grey tone problem in the prior art "it has heretofore been proposed to use color images." The specification states that in one prior art system the range of grey tones "is replaced with a range of different colors." Thus the specification makes clear that the patentee intended to distinguish "color" displays from grey tones including black and white displays.

We conclude, as did the district court, that "color" as used in the '283 patent means colors other than black and white and shades thereof.
Each color in the color image has a corresponding separate and distinct color pattern. The claim is not limited to the particular pattern masks disclosed in the specification, and thus images may contain more than eight colors. The phrase "visual discrimination" means that when the output image is displayed, the pattern masks provide visual discrimination between areas that were originally represented by different colors in the color image.

B. "Information about said different color values"

Claim 1 of the '550 patent claims:

A method for blending images, comprising the steps of selecting a first portion of a first image, said first portion of said first image includes different color values;

storing information about said different color values . . .

Sportsvision contends that the phrase should be construed as: "At least one piece of information corresponding to a color value and at least a second piece of information corresponding to different color value." (Sportsvision's Memo at 14.)

SportsMEDIA proposes that the phrase be construed as: "A set of characteristics that describe a class of pixels." (SportsMEDIA's Memo at 17.)

Claim 1 discloses steps in a method for blending images. The method discloses selecting a portion of a first image, where the selected portion includes different "color values." The written description of the '550 patent refers to "color values" as follows:

The establishment of inclusions and exclusions in embodiments of the present invention provides for making fine distinctions between luminance and color values that are very close, where it is critical to modify pixels with one luminance-color combination and not modify pixels with another combination. Such circumstances arise during the rendering of a first down line, as described above, when the appearance of a player's uniform is very similar to the field. For example, an inclusion may describe the green color of grass while an exclusion might describe a different shade of green used on a player's uniform. A traditional chroma key system lacks the ability to make such distinctions, since it merely provides for replacing a predetermined color.

'550 patent, 20:4-16.

Thus, the Court construes the term "color values" to mean luminance and or chrominance. Color values do not contain position information.

The phrase "different color values" refers to color values within the selected portion, i.e., one color value in the selected portion is different from another color value in the selected portion. Thus, at this step in the patented method, the only information which is stored are the color values, and nothing else.

Accordingly, the Court defines the phrase "information about said different color values" to mean: "Luminance information or chrominance information or both in a selected portion of an image."
VI. "combining" 15

15 The term "combining . . . " is contained in claims 1, 9, 25, and 33. Additionally, Defendant asks the Court to construe the phrase, "combining, from each receiver antenna of the plurality of receiver antennas, each of the first plurality of detected spread-spectrum signals, thereby generating a first combined signal; and combining, from each receiver antenna of the plurality of receiver antennas, each of the second plurality of detected spread-spectrum signals, thereby generating a second combined signal." RESP. at 26-28. Yet Defendant arguments relate to a proper construction of the term "combining." Id. Therefore, the Court declines to construe the "combining . . . " phrase proposed by Defendant, in favor of construing the disputed term.

Plaintiff's Proposed Construction

forming a single aggregated version of
the received signal from the multiple
versions of the transmitted signal
received at the multiple receiver
antennas

Defendant's Proposed Construction

signals are combined using space
diversity and time diversity
employing multiple combiners and
rakes

Plaintiff argues that the patent specification clearly discloses that any appropriate method known in the art may be used to combine the received signals. OPENING at 17-18. Plaintiff contends, therefore, that Defendant's proposed construction improperly limits this term to the preferred embodiment by requiring combining to include both time and space diversity components, Id. Further, Plaintiff objects to Defendant's proposed constructions for phrases which were not previously disclosed as being subject to dispute. REPLY at 7.

Defendant argues that space and time diversity are required elements of this term not only because the specification discloses these two required elements, but also because Plaintiff specifically distinguished two prior art references--Higashi and Ono--on this basis. RESP. at 27. Defendant also argues that Plaintiff's proposed construction is unduly broad because it fails to take into account that the first and second plurality of detected spread-spectrum subchannel signals must be combined from each receiver antenna. Id.

The patent discloses that the received signals are combined using space and time diversity. First, the claims explicitly acknowledge that the signals are transmitted in a multipath environment. '322 patent at 14:15-22 (claim 1); 15:47-54 (claim 9); 18:55-61 (claim 25); 20:26-32 (claim 33). Second, every combiner contained within the figures is labeled a "RAKE and space combiner." Id., Figs. 3, 6, 7. Third, the specification consistently refers to RAKE and space-combiners. See, e.g., id. at 2:53-58; 3:49-52; 4:38-41; 4:66-67, 5:1-4; 6:1-6; 9:42-67; 10:1-67; 11:33-38. Further, the "Detailed Description of the Preferred Embodiments" section notes:

The present invention provides a novel approach for reducing the effect of fading due to shadowing and multipath, through the use of multiple antennas at the terminal and also at the base station, as well as a single RAKE/maximal ratio combiner to combine all time and space signals. Previous solutions have assumed multiple antennas at the base, where space diversity is then applied. Also, each antenna receiver has an individual RAKE. Placing multiple antennas at the terminal, however, can result in a significant improvement in system performance. The use of maximal ratio combining, RAKE and erasure decoding further enhance system performance.

Id. at 4:26-37 (emphasis added). In fact, every time the patent refers to a "combiner" or a "combining" function, the patent also refers to RAKE and space or time and space diversity combiners. See, e.g., id. at 2:53-58("[a] plurality of RAKE and space-diversity combiners combine the plurality of detected spread-spectrum signals"); 3:49-52 ("[a] RAKE and space-diversity combiner combines the detected spread-spectrum signal"); 4:38-41 ("the present invention broadly includes an
antenna system employing time (RAKE) and space (antenna) diversity and coding of spread spectrum signals"); 4:66-67, 5:1-4 ("[t]he RAKE and space-diversity means is coupled to each matched filter means of the plurality of receiver subsystems"); 6:1-6 ("[t]he RAKE and space-diversity means combines the plurality of detected spread-spectrum signals"); 9:42-67 ("[t]he plurality of RAKE and space-diversity combiners combines each plurality of detected spread-spectrum signals"); 10:1-67 ("[a] second RAKE and space-diversity combiner 162 is coupled to the [filters]"); 11:33-38 ("[t]he plurality of RAKE and space-diversity combiners 161, 162, 163, 164 combine the plurality of detected spread spectrum signals").

--- Footnotes ---

16 The Court acknowledges that claims 1 and 9 only use the term "multipath" within the preamble to each respective claim. The Court further recognizes that as a result this term may or may not be a limitation on the claims. See Symantec Corp. v. Computer Associates Int'l, Inc., 522 F.3d 1279, 1288 (Fed. Cir. 2008) ("Because the disputed term appears in the preamble to claim 1, we must first determine whether it is in fact a separate limitation."). However, the Court declines to address the issue, as the dispute is adequately resolved on other grounds, as discussed below.

--- End Footnotes ---

Fourth, the specification also explicitly notes the importance of the order of combining, depending on the data sent by each transmitter. Id. at 11:60-63 (noting that the order of combining is important if each transmitter antenna sends different data, but not if each transmitter antenna sends the same data); 12:26-41 (noting that when the same data is transmitted over each antenna, any order of combining yields the same result and all combining from all receiver antennas can be done simultaneously--time and space diversity).

Here, the patent claims and specification emphasize time and space combining as a key feature in the patented invention. Moreover, the prosecution history also supports this conclusion. As Defendant argues, Plaintiff distinguished its invention over the prior art by arguing that the invention disclosed the use of both space and time diversity. RESP. at 27. In a final amendment before the '322 patent was allowed, Plaintiff represented to the Patent Office that:

The present invention has the advantage of providing space diversity and time diversity, using a plurality of antennas and a plurality of spread-spectrum signals.

Ono does not teach or suggest a system, having space diversity and time diversity, for receiving data which were demultiplexed, spread-spectrum processed and then sent over the communications channel having multipath.

RESP., EXH. C at 188-89. Ono is entitled and teaches a Rake Reception Method For a Spread Spectrum Signal. U.S. Patent No. 5,999,560 ("the '560 patent").

This representation is pertinent to the issue of claim construction because "[t]he prosecution history gives insight into what the applicant originally claimed as the invention, and often what the applicant gave up in order to meet the Examiner's objections." Lemelson v. Gen. Mills, Inc., 968 F.2d 1202, 1206 (Fed. Cir. 1992). Further, the prosecution history is important where there is particular prior art that the patentee was trying to distinguish. Id. Referring to the prosecution history in this way for the purposes of claim construction ensures that the claims are construed during litigation consistently with the intended scope as allowed by the Patent Office. Chimie v. PPG Indus., Inc., 402 F.3d 1371, 1384 (Fed. Cir. 2005). Thus, the doctrine of prosecution history disclaimer applies, narrowing the ordinary meaning of the claim consistent with the disclaimer, when a "patentee has unequivocally disavowed a certain meaning to obtain his patent." Id. (quoting Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003)).

Not only do the claims and specification disclose that both space and time-diversity combining are required limitations, but Plaintiff also made an affirmative representation to the Patent Office during prosecution which limited the claimed invention to this embodiment. Plaintiff disclaimed methods which failed to include both space and time-diversity combining. Plaintiff now seeks a construction for the "combining" term that would expand the claim scope beyond that which was represented to the Patent Office. Plaintiff proposes that "combining" should be construed as "forming a single aggregated version of the received signal from the multiple versions of the transmitted signal received at the multiple receiver antennas." OPENING at 17-18. This construction plainly and adequately describes what is taking place when signals are combined. However,
because the intrinsic evidence supports the conclusion that this construction fails to include the required limitations of both time and space combining, Plaintiff's proposed construction is too broad.

Plaintiff argues that the patent discloses that it is not limited to combining that includes both space and time diverse signals and that "the '322 patent clearly discloses that any appropriate method known in the art may be used to combine the received signals." OPENING at 17-18. In support of this argument, Plaintiff points to the following portion of the specification:

The first RAKE and space-diversity combiner 161 may use any of a number of techniques for combining signals, such as selecting the four strongest signals and adding their strengths, maximal ratio combining, maximal likelihood combining, etc. RAKE and combining techniques are well known in the art.

'322 patent at 9:62-67. However, this portion of the specification does not support Plaintiff's argument. It merely notes that differing time and space-diversity combining techniques are well known in the art and may be used. It does not state that both of these techniques are not required limitations of the claimed invention. In other words, the claimed invention requires both the ability to combine both time and space-diverse signals, but the methods used to combine these signals is left up to the designer.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
17 This statement is repeated three more times throughout the patent. See '322 patent at 10:14-19, 33-38, 52-57.
- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

Defendant's proposed construction is also flawed because it fails to describe what is actually taking place when the signals are being combined. A construction which defines the term "combining" as "signals are combined using space diversity and time diversity employing multiple combiners and rakes" requires time and space-diversity combining, but fails to explain what that means or what is taking place when the received signals are combined. Thus, the Court rejects Defendant's proposed construction. For all the foregoing reasons, the term "combining" is properly construed as "forming a single aggregated version of the received signal from the multiple versions of the transmitted time and space diverse signals received at the multiple receiver antennas."

GO BACK

**662**

d. combining

Fairchild contends that the term "combining" should be construed to mean "adding together from two or more different sources." (D.I. 156 at 37-38). Power Integrations contends that this term does not require construction, and should be subject to its plain English-language interpretation. To the extent construction is required, Power Integrations contends that the term "combining" means "adding together" and that different sources are not required as Fairchild contends. (D.I. 152 at 13).

In light of the Court's construction of the terms "primary voltage" and "secondary voltage" the Court agrees with Power Integrations that the term "combining" should not be construed as requiring different sources. Fairchild contends that the plain meaning of this term necessarily requires different sources, however, even the dictionary does not define the term "combine" by reference to a particular source. See Webster's Ninth New Collegiate Dictionary 262 (9th ed. 1988). Accordingly, the Court will construe the term "combining" consistent with its plain meaning such that the term "combining" means "adding together."

GO BACK

**663**

c. "Combining" (Claims 18 and 66)
The disputed limitation of claims 18 and 66 of the '121 patent is: "supplying user program selection criteria to the data processor, . . . the data processor combining said user selection criteria." Re'121 patent, claims 18, 66 (emphasis added). The parties raise two issues, addressed in turn below.

(1) Logical Combining of the User Selection Criteria

Relying on the intrinsic evidence, the ITC held that "combining" required logical AND combination of the user selection criterion, specifically the "theme, prime time, and channel" criteria. FID Opinion 2002 ITC LEXIS 812 at *78. The ITC noted further that because the theme and channel criteria could be "comprised of lists of multiple themes or channels," the themes or channels composed in such lists are "combined in a logical 'OR' manner." Id. The ITC based its construction on alleged waivers made by Gemstar in the prosecution history to distinguish the claimed invention from the Kram prior art reference. Id. 2002 ITC LEXIS 812 at *90.

Gemstar argues that neither the ordinary meaning nor prosecution history limits "combining" to the particular sequence of logical AND/OR combinations enumerated in the ITC's construction. Scientific-Atlanta defends the ITC's construction, arguing that Gemstar disclaimed other methods of "combining" by describing this particular sequence of logical AND/OR combinations to distinguish its invention over the prior art.

The ordinary meaning of "combining," which is a present participle of "combine," is "to cause (as two or more things or ideas) to mix together: MINGLE: BLEND." Webster's Third New International Dictionary 452 (1993). This broad definition of "combining" as mixing or blending is not constrained to the specific logical AND/OR combinations required by the ITC's construction. Instead, "combining" may encompass any logical combination of the user selection criteria.

The ITC's claim construction is not warranted by alleged disavowals or disclaimers in the prosecution history relied upon by Scientific-Atlanta. The ITC referred to the following passage from the prosecution history:

Furthermore, even if the system of Kram could be used as a television guide controller for Kruger, the present system would not result. . . . The examiner cited a "weather" then "city" operation in Kram. . . . If the user selects a keyword topic "weather", the system constructs an index menu including each page having the keyword "weather". Each such page will also have a particular supplemental keyword which will be displayed on the index menu. The user then chooses one of the index entries to retrieve either a single or a series (one at a time) of relational pages. The system of Kram cannot automatically combine two selection criteria such as "weather" and "channels 2, 5, and 11" to provide the user a custom assembled list of programs meeting the combined criteria. The system of Kram could only provide a first index in response to "weather", from which the user would have to select "channel 2" to receive that screen, and then select "channel 5" to receive that screen, and then select "channel 11" to receive that screen.

Amendment, Aug. 2, 1992, at 43-44 (emphasis added). Gemstar's statements in the prosecution history do not indicate a disavowal or disclaimer of claim scope, see ACTV, 346 F.3d at 1091, but merely provide an example to illustrate differences between the invention and the prior art. In essence, Gemstar stated only that the Kram reference was incapable of performing a certain type of search, not that the scope of the claimed invention was limited to that particular type of search. Contrary to the ITC's holding, the prosecution history did not limit the '121 patent to that particular sequence of logical searching.

(2) Combining the User Selection Criteria Prior to Search

The second issue disputed by the parties is the ITC's requirement that the user selection criteria "must be combined prior to any search." FID Opinion 2002 ITC LEXIS 812 at *106. The ITC found that the parties agreed that Gemstar disclaimed "dependent, hierarchal" searching during prosecution and dismissed Gemstar's arguments that hierarchal searching with independent user selection criteria was preserved. 2002 ITC LEXIS 812 at *103. Hierarchal searching involves sequential searching where the data input to the current search is the output from the prior search.

Gemstar argues that statements in the prosecution history cannot reasonably be read to disclaim the sequential entry and combination of user selection criteria. Specifically, Gemstar contends that the statements in the prosecution history relate specifically to unasserted claim 65, and there are numerous examples of sequential searching in the prosecution history.
Scientific-Atlanta responds that Gemstar's disclaimer of "dependent, hierarchal" searching applies equally to all asserted claims because it appeared in a section entitled "Combining User Selection Criteria and Selecting Programs," which was not specific to unasserted claim 65.

We must consider statements made in the prosecution history "because it may demonstrate that . . . the patentee disclaimed or disavowed subject matter, narrowing the scope of the claim terms." ACTV, 346 F.3d at 1091. The disputed statement in the prosecution history states in pertinent part:

Combining User Selection Criteria and Selecting Programs

Several of the present claims recite a process in which the user enters user program selection criteria, and the data processor combines the program selection criteria, searches through the stored schedule information, and creates and stores a display list of program listings that meet the combined criteria. . . . The user may then make program selection choices (which the Examiner has characterized as further program selection criteria) from this display. The data processor then stores information for these program selections, including information identifying program titles, in a reminder calendar list.

Several claims recite the data processor combining a plurality of user selection criteria other than the program choices. This is different from the scenario that the Examiner has proposed would be inherent in Levine and similar art, namely that the user could enter a date as a first selection criteria, then be presented with a page of program listings, and then enter a program choice as a second criteria to be 'combined' with the data selection criteria. As amended, several claims (such as claim 1) require the data processor combine a plurality of selection criteria in addition to the program choice. The Examiner's proposed date entry does not meet the requirement of combined selection criteria even if entered as a series of page commands. Each page command simply establishes a new requirement that supersedes and replaces the previous requirement rather than being combined with it . . .

The user selection criteria may be entered and activated independently under different categories (theme, channel, prime time) and are maintained by the data processor whether currently activated or not. This is disclosed, for example from column 12 line 12 to column 15 line 17 (wherein it is stated that buttons can be pressed to independently activate the THEME, PRIME-TIME, and CHANNEL selection criteria) and from column 18 line 11 to column 20 line 38. Furthermore, the selection criteria can be combined as alternatives (in a logical OR fashion), such as a list of acceptable channels or a list of acceptable themes. This is far different from even the cited teletext art, where search criteria are entered and combined in a dependent, hierarchal fashion. At each stage in the cited teletext art, the available search choices are determined by and dependent upon the previous choices made. Furthermore, they are only combined in a logical AND fashion. Also, the prior art does not allow complex entries (such as theme or channel lists) to be deactivated yet saved in memory.

Supplemental Amendment After Final, Feb. 25, 1993, at 22-24 (emphases added; emphasis in original omitted).

Gemstar's comments in the prosecution history constitute a disclaimer of claim scope to distinguish the prior art. To avoid a rejection based on teletext prior art cited by the examiner, Gemstar explained the operation of its claimed invention as follows:

The user enters user program selection criteria, and the data processor combines the program selection criteria, searches through the stored schedule information, and creates and stores a display list of program listings that meet the combined criteria. . . . The user may then make program selection choices (which the Examiner has characterized as further program selection criteria) from this display . . .

Id. at 22. Gemstar then distinguished this "independent[]" method of combining search criteria, id. at 23, as "far different" from the teletext prior art where new search criteria were continuously entered and combined with prior search results in a "dependent, hierarchal fashion," id. at 24.

Based on Gemstar's statements in the prosecution history disclaiming dependent searching to distinguish the prior art, the "combining" limitation must be read consistently in the claim. See Tegal Corp. v. Tokyo Electron Am., Inc., 257 F.3d 1331, 1343 (Fed. Cir. 2001). Thus, the ITC's requirement that "combining" must be combined prior to any search is correct.

In conclusion, "combining" within claims 18 and 66 of the '121 patent encompasses any logical combination of the user
selection criteria. However, the logical combination of the user selection criteria must occur prior to any search and does not include dependent, hierarchical searching where new user selection criteria are combined with prior search results.

2. The word "COMBINING" (claim 29) requires no construction.

3. "Command" means a reconfiguration command. A reconfiguration command is a command that rearranges the previous configuration of the gaming device so that the gaming device pays out extra money it would not have paid in its previous configuration. There are virtually no commands described in the patents that are not related to reconfiguration which is, ultimately, the crux of the invention.

(1) "Command"

EMC contends that the term "command" means an instruction to initiate an action. HP responds that a command is an instruction issued by the user through the host computer and, specifically, that the '497 Patent requires at least three commands which accomplish the steps described therein. EMC does not appear to dispute that contention but rather claims that a command can consist of more than a single instruction or a single word.

To the extent that there is a separate dispute with respect to whether Claim 1 of the '497 Patent requires at least three commands, the language of the claim is dispositive. Unquestionably, the plain language of Claim 1 requires three commands which accomplish the steps described therein. Although the term "command" is preceded by the indefinite article "a", it still requires that the disclosed invention contain at least one "first command", at least one "second command" and at least one "third command" each of which accomplishes the successive functions described in the claim.

That issue notwithstanding, there appear to be two substantive disputes with respect to the term "command":

(1) whether a command can include more than one instruction, and

(2) whether a command must be issued by the host computer. The plain and ordinary meaning of the term "command" is "an order given". Webster's Third International Dictionary, 455 (1981). Nothing in that definition nor in the claim language limits the term "command" to a single instruction or a single word. In fact, the claim language contemplates that each command may involve more than one word or instruction. The second command (also called the split command), for example, produces two distinct results, namely, it detaches the second data storage facility from the first and subsequently attaches it to be addressed by the second application. That more than one result is contemplated by virtue of the split command supports the notion that, when the host adaptor, as depicted in Figures 12 and 14 of the '497 Patent, receives the split command, such command may be comprised of more than one single instruction or word. Indeed, the command-initiating device may issue a number of words or instructions each of which form a part of the first, second or third commands. Nothing in the Specification or prosecution history either implicitly or explicitly limits the term "command" to a single word or instruction.

Likewise, nothing in the claim language, Specification or prosecution history limits the term "command" to an instruction issued by the host computer. While the Specification and the relevant figures therein often describe a "command" as issued by the host computer, it is well-established that such a limitation cannot be imported into the claim terms unless EMC has acted as its own lexicographer. There is no implicit or explicit evidence of that here.

The described evidence notwithstanding, the Specification of the '497 Patent clearly contemplates that a user can initiate the
subject commands through something other than a host computer when it states that, "[i]n accordance with one embodiment of this invention . . . the host 220 in FIG. 9 can issue a number of commands . . .." '497 Patent, Col. 16, ll. 64-67. More specifically, the Specification contemplates that a user may initiate commands through a device called a "system manager" (which is depicted, in Figure 1, as separate from the host computer). See '497 Patent, Col. 11, ll. 24-55 (discussing, albeit not explicitly, the functions of the split command); Col. 12, ll. 34-41 (discussing, albeit not explicitly, the functions of the re-establish command).

Consequently, based on the claim language, the Specification and the prosecution history, the term "command" will be construed to mean one or more words or instructions to initiate, terminate or otherwise control the execution of an operation. A "command" may be issued by a host computer, a service manager or other initiating device.

5. to the extent data responsive to said query is not available at said client computer, combining said query with at least one additional query associated with said application program, for simultaneous transmission from said client computer across said network

The parties' proposed constructions are similar, but not identical, to those proposed above. Hyperion seeks to add a negative limitation while OutlookSoft does not. Further, OutlookSoft attempts to limit the construction to spreadsheet programs, and the parties disagree on the construction of "simultaneous." For the vast majority of the phrase, the Court again applies a plain meaning construction. For the "simultaneous transmission" term, the Court construes the phrase to mean "sending to the server in a single request or package."

Accordingly, the phrase "to the extent data responsive to said query is not available at said client computer, combining said query with at least one additional query associated with said application program, for simultaneous transmission from said client computer across said network" is construed to mean "when data needed to respond to the data request of the application program is not stored in the client computer, combining that data request with at least one other data request of the application program, for sending to the server in a single request or package."

3. "combining the associate value and the additional parameter to determine motion control commands" (claims 9 and 23)

Omax proposes to construe this phrase to mean "a computerized, mathematical combination of the associated value and the additional parameter to determine motion control commands provided to the machine tool to automatically adjust velocity or acceleration to achieve the desired quality of result." Flow argues that the phrase should be construed to mean "the mathematical combination of the associated value and the additional parameter to calculate the velocity (U) for a segment. It is insolubly ambiguous as to how the patented system utilizes the resultant velocity (U) for the segment to determine the incremental instructions to be sent directly to the machine tool."

Flow's proposed construction of this claim term has many shortcomings. First, by describing the claim as "insolubly ambiguous," the construction renders the claim invalid, despite the existence of a valid, equally plausible interpretation of the claim term. Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1557 (Fed. Cir. 1996) ("When claims are amenable to more than one construction, they should when reasonably possible be interpreted so as to preserve their validity."). abrogated on other grounds, Festo Corp. v. Shoketsu Kinzoku Kogyo Kabushiki Co., Ltd., 234 F.3d 558 (Fed. Cir. 2000) (en banc). Second, Flow arrives at its construction improperly by importing an embodiment described in the specification, the formula at col. 15, l. 9, to limit the terms of the claim to only providing for velocity along a straight line. Phillips, 415 F.3d at 1323. Finally, Flow's proposed construction contradicts other claim terms, which claim a method that adjusts velocity and acceleration, for the purpose of; among other things, improving dimensional accuracy around corners and curves. See, e.g., '596 Patent, claim 13; see also, Phillips, 415 F.3d at 1316 (requiring clear, intentional disclaimer to limit claim term). The Court adopts Omax's proposed construction of this claim, which is consistent with its ordinary
OPTi contends that "command information" is "information relating to one or more commands for controlling a bus transfer, rather than to address or data." nVidia contends that the proper construction for "command information" is "bits that define one or more commands for controlling the bus transfer, including the bits defining M/IO #, W/R #, and SBHE # rather than address or data bits."

nVidia again seeks to limit the construction of a term to the preferred embodiment. This methodology has been rejected by the Court. While it is clear that M/IO #, W/R #, and SBHE # are commands used in the preferred embodiment, the patentee makes clear that these commands are merely examples of commands and not the universe of commands that can be used. See 141 patent, Col. 8:44-45 "command information (e.g., M/IO #, W/R #, SBHE #)" (emphasis added); see also Col. 6:64-65 (same). Accordingly, the Court rejects nVidia's construction and adopts OPTi's proposed construction for "command information."

6. "address set," "command set," "data set"

The dispute with regard to these terms is whether a "set" can contain a single bit, as Power-One proposes, or, as Artesyn suggests, whether it must contain two or more bits. Power-One concedes that the examples of sets given in the specification are multi-bit sets. See, e.g., '916 patent, col. 4:19-25. However, the '916 specification provides that "communication cycles containing more or less information and/or bits is within the spirit and scope of the present invention." Id. at col. 4:30-33.

Although the '916 specification provides examples of multi-bit sets, this does not mean that a "set" referred to in the claims must contain more than one bit. See, e.g., Varco, L.P. v. Pason Systems USA, Corp., 436 F.3d 1368, 1373 (Fed. Cir. 2006) ("In examining the specification for proper context . . . this court will not at any time import limitations from the specification into the claims."). Accordingly, the Court declines to narrow the definition of set and construes these terms as follows:

**Address set:** A set of one or more bits in a message specifying the address of one or more devices connected to a bus.

**Command set:** A set of one or more bits in a message specifying a given command operation.

**Data set:** A set of one or more bits in a message reflecting data that is read from or written to a device.
at a minimum "specifying" means "identifying, naming, or stating explicitly or in detail." Joint Claim Construction and Prehearing Statement ("JCCPS"), Ex. B. This is consistent with the plain language of the claim and is sufficient for purposes of claim construction. There is no ambiguity that requires reference to a particular method or embodiment for identifying explicitly or in detail. Nor is there any apparent reason for exchanging the word "transferred" for "transmitted" and "order" for "command" as proposed by HP.

Accordingly, the appropriate construction of "command specifying data to be transferred" as used in claim 1 is "a command sent from a host processor that identifies, names, or states explicitly or in detail which data is transferred from a first storage medium to a second storage medium."

1. "commercial access provider . . . of INTERNET" or "of digitized packet based network"

Claim 1 (and its dependent claims) use the phrase "commercial access provider node of INTERNET," while the remainder of the asserted claims use the phrase "commercial access provider node of a digitized packet based network." The phrases "commercial access provider node" (and similar phrases), "node," and "digitized packet based network," however, are separately disputed. Accordingly, the parties have here focused on "commercial access provider." The parties agree that the phrase should receive the same construction, whether in claim 1 or the remainder of the asserted claims.

The phrase appears in claim 1 as follows:

1. A method of forming a long distance communication channel between two telephone devices each of which are connected to a PSTN, said method comprising

   a user of one of said telephone devices initiating and establishing a telephone communication with a first commercial access provider node of INTERNET and providing thereto a telephone address,

   using INTERNET to establish a communication channel between said first commercial access provider node and a second commercial access provider node of INTERNET and providing said telephone address to said second commercial access provider node,

   said second commercial access provider node using said telephone address and a telephone dial out capability of said second commercial access provider node to establish a communication with a telephone device at the telephone address using a PSTN, and

   using the INTERNET communication channel to link said telephone devices and form a real time voice communication between said telephone devices. (emphasis added)

a) The Parties' Proposed Constructions

The parties propose the following constructions:

IDT
A service provider that provides subscription-based computer system commercially available to telephone users that acts to provide an interface to or from the Internet.

A computer system commercially available to
telephone users that acts to provide an interface to or from a digitized packet based network.

A service provider that provides subscription-based services and uses a computer system commercially available to telephone users that acts to provide an interface to or from a digitized packet based network.

*2*See Doc. No. 99 at 13 (JCCC, Exhibit 1 at 11).

In its opening brief, eBay urged that a "commercial access provider" is (1) a computer system, (2) that is commercially available to telephone users, and (3) provides an interface to or from the Internet or a digitized packet based network. (Doc. No. 82 at 16-20). eBay criticized IDT's then-proposed construction as (1) having no basis in the claim language, and (2) being inconsistent." Id. at 16-19. IDT thereafter revised its proposed construction adopting that portion of eBay's proposed construction calling for "commercially available to telephone users that acts to provide an interface to or from the Internet" (or a digitized packet based network). Thus, the core of the dispute is whether "commercial access provider" in the context of the claims and the '350 patent would mean to one of ordinary skill in the art (1) a "computer system" as eBay contends, or (2) a "service provider that provides subscription-based services and uses a computer system" as IDT contends. IDT contends that a "commercial service provider" (1) uses a computer system to provide access to the Internet or a digitized packet based network, and (2) provides a subscription-based service. (Doc. No. 86 at 9-11).

b) Discussion

(1) The Claims

Beginning as always with the words of the claim -- and using claim 1 as representative -- the claim language per se offers some, but not much, assistance in resolving the current dispute. Beginning with the preamble, which the parties agree is limiting, claim 1 is drawn to a method "of forming a long distance communication channel between two telephone devices each of which are connected to a PSTN." The first step provides:

a user of one of said telephone devices initiating and establishing a telephone communication with a first commercial access provider node of INTERNET and providing thereto a telephone address.

Quite simply, a "user" initiates and establishes a telephone communication with a "first commercial access provider node" and provides a "telephone address" which the parties agree means a telephone number. The term "user" per se does not on its face require a subscription, or a contractual or similar relationship between the "user" and the "first commercial access provider." The term "node" (which again is a separately disputed term) may suggest a computer network type of connection, but that does not necessarily mean that the "commercial access provider" (1) is a computer system, or, on the other hand, (2) means a service provider that "uses a computer system." Either could provide a "node."

The second step:

using INTERNET to establish a communication channel between said first commercial access provider node and a second commercial access provider node of INTERNET and providing said telephone address to said second commercial access provider node,

similarly may suggest a computer network type of connection, but again does not necessarily mean that the "commercial access provider" (1) is a computer system, or (2) means a service provider that "uses a computer system."

The third step:

said second commercial access provider node using said telephone address and a telephone dial out capability of said
second commercial access provider node to establish a communication with a telephone device at the telephone address using a PSTN, and

likewise may suggest a computer network type of connection, but yet again does not require that the "commercial access provider" (1) is a computer system, or (2) means a service provider that "uses a computer system."

The fourth step:

using the INTERNET communication channel to link said telephone devices and form a real time voice communication between said telephone devices.

also does not resolve the dispute. The claim does call for "a real time voice communication between said telephone devices," and the preamble, once again, calls for "forming a long distance communication channel between two telephone devices each of which are connected to a PSTN." That suggests claim 1 is drawn to "a real time voice communication" between two telephones. 8 Independent claims 8, 10 and 12 contain similar language (claim 8 "causing a real time voice communication channel to be formed between said telephone devices," claim 10 "forming a real time voice communication between said telephone devices," claim 12 "to form a real time voice communication channel therebetween."). But once again, that does not require that the "commercial access provider" (1) is a computer system, or (2) means a service provider that "uses a computer system."

--- Footnotes ---

8 The term "telephone device" is not a disputed term and both parties appear to regard the term as meaning a conventional "telephone" capable of connecting to a PSTN.

--- End Footnotes ---

(2) The Specification

(a) Generic Internet Commercial Access Provider

Turning then to the specification, as noted briefly above, the specification under the heading "Background of the Invention" explains:

INTERNET TM now provides a network where a subscriber typically contracts with a commercial access provider (CAP) and obtains an Internet address as well as the capability to send and receive E-Mail on Internet and perform other functions which Internet supports. The subscriber typically uses his personal computer and modem to contact the commercial access provider using the public switched telephone network (PSTN), and once connected to Internet, performs the desired functions. The CAP provides an E-Mail box for the subscriber and the subscriber, when connected to the CAP, can review the contents of this electronic mailbox.

'350 patent, col. 1, lines 21-32. Thus, the patentee explains by way of background that typically a "subscriber" would "contract" with a "commercial access provider (CAP)" and obtain an Internet address and the capability to send and receive e-mail. 9 The patentee notably does not say in that typical scenario that a "subscriber" is assigned a "telephone address" or "telephone number."

--- Footnotes ---

9 Although not addressed by the parties, an "Internet address" typically refers to an identification of a particular computer on the Internet, see e.g., http://en.wikipedia.org/wiki/Internet_address, http://browsers.about.com/od/webbrowsglossary/g/internetaddress.htm, while an e-mail address typically consists of a unique identifier for a person (e.g., a name), followed by "@" and a domain name, see e.g., http://www.webopedia.com/TERM/E/e_mail_address.html, although sometimes "Internet address" can refer to the e-mail address as well. See e.g., http://www.webopedia.com/TERM/I/Internet_address.html.
Drawing Figs. 1-3 of the '350 patent also illustrates a computer 22 connected through PSTN 10 and a "Generic Internet Access Provider" 8 to the Internet 4:

GET DRAWING SHEET 1 OF 5

The specification explains that the "Internet has a number of Internet commercial access providers (CAPs) 8 which each have a host of subscribers who then have access to the various services of [the] Internet typically using their personal computers. The conventional Internet access provider would provide each subscriber with an Internet address and password number for retrieval of E-Mail." '350 patent, col. 5, lines 19-25. The specification goes on to explain that one using computer 22 may, for example, therefore send an e-mail message to "subscriber 'gordon@toronto.UniPost.com" at 12.

The specification's explanation by way of background that a "subscriber typically contracts with a commercial access provider (CAP)" suggests that a "commercial access provider" in that context refers to an entity that may use computers and computer systems to provide access to the Internet and e-mail services, but is not a "computer system" per se -- one does not typically "contract" with a computer (although computers may be "used" in forming contracts, e.g., clicking "I Agree" to an agreement specifying terms of service/access). Also, that explanation suggests "commercial access providers" provide a subscription service. But, of course, the patentee's foregoing explanation relates to background and the prior art -- not necessarily the invention of the '350 patent.

(b) Parties Arguments and Remainder of Specification

Turning then to the parties' arguments and the remainder of the specification, eBay argues that the specification expressly describes a "commercial access provider" as "computer system" pointing to the following first line from the "Summary of the Invention":

A messaging system according to the present invention having a bank of direct-in-dial (DID) telephone lines associated with a public switched telephone network and a computer system which also acts as a commercial access provider for the Internet or other data communication networks through which digital messages can be delivered. (emphasis by eBay)

'350 patent, col. 2, lines 6-12, 10 (Doc. No. 82 at 17). But, "a computer system" that "acts as a commercial access provider" does not necessarily mean that a "commercial access provider" in the context of the invention of the '350 patent is a computer system -- as opposed to a service provider that "uses a computer system."

The next sentence in the specification, for example (which also has a bearing on the second question, i.e., the "subscription" question), which eBay does not quote, explains that "[t]he computer system provides each subscriber with an E-mail address and account for the data communication network, as well as a fax telephone address and a voice mail telephone address, where a communication addressed to any of the addresses results in the computer system receiving and storing the particular message in an electronic messaging mailbox for retrieval by the respective subscriber." '350 patent, col. 2, lines 12-19 (emphasis added). Although a "computer system" may be used to automate the process by providing (1) an e-mail account, (2) an account, (3) fax telephone address (telephone number), and (4) voice mail telephone address (telephone number), the term "subscriber" suggests something more than simply a "computer system" per se.

IDT also notes that the Summary of the Invention "later clarifies that a [sic.] the commercial access provider is not a computer system, but uses a computer system," (Doc. No. 86 at 9), pointing to col. 3, lines 44-49, which explain: "The invention is also directed to a method of transmitting of voice, E-Mail and facsimile messages destined for a particular identified subscriber, which messages are received by a computer system of a commercial access provider connected to a data communication network through which E-Mail is transported" (emphasis by IDT).
eBay urges that further support for its argument that a "commercial access provider" is a "computer system" appears in the specification at col. 2, lines 19, 26, and col. 3, lines 49 and 59. (Doc. No. 82 at 17). Although eBay cites only to lines 19 and 26, the portion of the specification in column 2 that eBay relies on explains in context as follows:

The computer system is accessible to any subscriber using the public switched telephone network and/or the data network for retrieval of communications stored on behalf of the subscriber or a summary of the communications whereby the subscribers may contact a single automated source for retrieval of voice mail, E-mail, data files, or facsimile transmissions received on its behalf by the computer system.

'350 patent, col. 2, lines 19-26. eBay relies on the reference to "computer system." However, the specification also explains that the "computer system" is "accessible to any subscriber." In context, the specification is also referring to "retrieval of communications." The specification does not say that the "computer system" is accessible to "anyone" -- i.e., to someone who is not a "subscriber" -- for retrieval of communications.

According to the specification, the "system" is, however, available to "anyone" wishing to leave messages "for the subscriber." For example, the very next two sentences in the specification explain:

Similarly, the system is accessible to anyone wishing to leave a voice, facsimile, or other message for the subscriber by dialing the telephone number associated with the subscriber's electronic message mailbox. As a result, data networks, such as Internet, are accessible by devices other than computers, namely by telephones and facsimile terminals.

'350 patent, col. 2, lines 26-33 (emphasis added). That is, one wishing to leave messages "for the subscriber" need not themselves be "subscribers," but rather need only use "the telephone number associated with the subscriber's electronic message mailbox." Again, in the preceding portion of the same paragraph, the specification explains that "[t]he computer system provides each subscriber with an E-mail address and account for the data communication network, as well as a fax telephone address and a voice mail telephone address, where a communication addressed to any of the addresses results in the computer system receiving and storing the particular message in an electronic messaging mailbox for retrieval by the respective subscriber." '350 patent, col. 2, lines 12-19 (emphasis added). The specification does not say that the system provides "anyone" with an e-mail address, account etc. -- that is reserved for "subscribers."

The portion of the specification in column 3 that eBay points to, although again eBay cites only to lines 49 and 59 (the portions eBay cites to are highlighted below), explains in context:

The invention is also directed to a method of transmitting of voice, E-Mail and facsimile messages destined for a particular identified subscriber, which messages are received by a computer system of a commercial access provider connected to a data communication network through which E-Mail is transported. The computer system is also connected to a public switched telephone network by means of which facsimile transmissions and voice transmissions are received and transmitted, and wherein a subscriber may access the computer for retrieval of messages stored in his electronic message mailbox or, his behalf. The retrieval of messages can use the public switched telephone network and the data communication network directly connected to access the subscriber's electronic message mailbox or retrieval can use the public switched telephone network to form a direct connection with the computer system for retrieval of messages. This method provides the subscriber with a number of alternatives for accessing his particular electronic message mailbox including using the data communication network to access his mailbox when this is the most desirable or cost effective manner to retrieve the communications. (emphasis added)

'350 patent, col. 3, lines 44-65. That is, the "computer system" is connected to the PSTN which allows a "subscriber" to retrieve voice, e-mail and fax messages using several alternatives. But again, that does not mean that the "commercial access provider" is a "computer system," as opposed to a service provider that "uses a computer system." And, once again, the specification refers to the fact that "a subscriber may access the computer" which suggests the "commercial access provider" is more than a "computer system" per se.

eBay further argues that the disclosure of "UniPost Access Nodes," which eBay says are "specialized access computers," (Doc. No. 82 at 17)(citing col. 4, lines 30-34), and that the specification "repeatedly refers to this system as including 'commercial access providing computers,'" (eBay's emphasis), id., (citing col. 2, lines 6-11, 44-51, 54 and 65, and col. 3,
lines 3-4, 11, 17-38, 40 and 49), support construing "commercial access provider" as a "computer system." In particular, eBay relies on the following quote from the specification:

According to yet a further aspect of the invention the communication system includes at least two commercial access providing computers, each interconnected to the Internet, and wherein the subscribers to the system can access either of the two commercial access providing computers for retrieval of communications stored on behalf of the subscriber. Information is effectively exchanged between the two commercial access providing computers when necessary to allow retrieval of the information by the subscriber by accessing either of the computers. This effective communication between the computers using the Internet, allows a fast, reliable and cost-effective transfer of information. Such a system has the benefit of providing the subscriber with access to the closest commercial access providing computer and can reduce long distance charges as well as improve the quality of the communication channel, as typically a local or shorter long distance call is required to connect with the particular commercial access providing computer.

(Doc. No. 82 at 17-18) (citing '350 patent, col. 3, lines 17-38) (emphasis by eBay). eBay argues that the "fact that a 'commercial access provider' includes 'commercial access providing computers' further underscores the fact that a 'commercial access provider' is a computer system." (Doc. No. 82 at 18). But "commercial access providing computers" in the context of the foregoing simply means that "computers" are providing "commercial access" to the Internet for "subscribers" such that "subscribers" can retrieve communications. That does not mean that a "commercial access provider" is a "computer system" per se, as opposed to a service provider that uses a computer system.

Indeed, the specification uses "UniPost" to refer to a "new type of commercial access provider of the type associated with the Internet." The specification explains:

The term "UniPost" will be used to describe a new type of commercial access provider of the type associated with Internet. UNIPOST TM provides dial-in access to its subscribers through specialized access computers called UniPost Access Nodes (UANs) located in different geographical regions (see FIG. 1). Each UniPost Access Node provides a subscriber with an E-Mail address and account, preferably an Internet address, for example:

jsmith@acmefireworks.com

This address provides access to the subscriber for other Internet subscribers, and for subscribers to services that have gateways into Internet. In addition, the subscriber is provided with a Personal Mailbox Telephone Number, for example: 1-416-555-1234, and Personal ID Number (PIN): 63265. Therefore, a UniPost subscriber may be provided with the following:

Internet Address: gordon@toronto.unipost.com

Personal Mailbox Number: 1-416-555-1234

Personal ID Number or password: 63265

The UniPost Access Node provides the subscriber with access to all normal facilities of Internet, including E-Mail, databases, conferences, and forums. The UniPost Personal Mailbox Number provides the subscriber with an access point which can receive messages from terminals other than computers, specifically from telephones and facsimile machines. Thus, his Personal Mailbox Number allows for receipt of voice and facsimile messages.

'350 patent, col. 4, lines 30-58. As noted above, the patentee explained by way of background that prior to the invention of the '350 patent, "a subscriber typically contracts with a commercial access provider (CAP) and obtains an Internet address as well as the capability to send and receive E-Mail on Internet" and the "CAP provides an E-Mail box for the subscriber and the subscriber, when connected to the CAP, can review the contents of this electronic mailbox." '350 patent, col. 1, lines 21-32. The "new type of commercial access provider" described in the specification, like the "typical" commercial access provider, provides a "subscriber" with an e-mail address and an account. However, the "new type of commercial access provider" also provides the "subscriber" with a "Personal Mailbox Telephone Number." Thus others can not only send e-mails to the "subscriber" in the same way as in the prior art, but can additionally send the "subscriber" voice and facsimile messages.
Recall, as the Court noted earlier in briefly summarizing the disclosure of the '350 patent, that the patentee explained "E-Mail systems have been available for many years and although they provide a very cost effective alternative to facsimile transmissions, the popularity of E-Mail does not nearly approach the popularity of voice and facsimile messaging and the number of users is many times lower." '350 patent, col. 1, lines 38-42. The invention of the '350 patent, by providing "subscribers" with a "Personal Mailbox Telephone Number" addressed the problem the patentee perceived -- i.e., now, in addition to e-mails, others could use telephones and fax machines to leave voice mail and fax messages for a "subscriber" by using the subscriber's "Personal Mailbox Telephone Number."

The specification, for example, further explains that with an e-mail address and a "Personal Mailbox Telephone Number" subscribers may be contacted, not only by e-mail users, but "the hundreds of millions of telephone and facsimile devices now in use":

With this arrangement, the subscriber can be contacted by the millions of PC users in the world familiar with E-mail, as well as the hundreds of millions of telephone and facsimile devices now in use. Furthermore, the various received communications are received by a centralized system and can be retrieved by the subscriber his or her convenience.

Also, the specification explains that message retrieval is facilitated because it was contemplated that UniPost Access Nodes would be distributed throughout the world:

The fact that the various UniPost Access Nodes are distributed throughout various countries and the world and connected by the Internet or another commonly available data communication network makes retrieval of messages more effective.

'350 patent, col. 4, line 64-col. 5, line 1.

The specification also explains that the UniPost Access Nodes can include provisions for converting e-mail to facsimile transmissions (or vice versa) or to speech, thus further facilitating retrieval by "subscribers":

Furthermore, each UniPost Access Node can include arrangements for converting of various communications from one form to another making retrieval easier and more flexible. For example, a subscriber may not wish to actually receive E-Mail as E-Mail, but may wish to have an E-Mail address. When a communication is address[ed] to him using the E-Mail address, the UniPost Access Node may convert it to a facsimile transmission and send it out to the subscriber as a facsimile transmission. In this way, the subscriber need not have the capability of receiving all transmissions and can use certain features of the UniPost Access Nodes for conversion of communications received in one form to another form. The UniPost access mode can also provide conversion of facsimile transmissions to E-mail, or E-Mail to speech. In this way, subscribers need not have their own conversion hardware and/or software.

'350 patent, col. 5, lines 2-16 (emphasis added). The context suggests those services are offered through the use of a "computer system," but it is equally clear those features are offered to "subscribers."

(3) E-Mail, Voice and Facsimile Messages

From the foregoing -- as well as the specification and drawings as a whole, and eBay's arguments -- a fundamental feature of the '350 patent is using the Internet (or a digitized packet based network) to allow sending and retrieval of not only e-mail messages, but voice and facsimile messages as well. In each of those instances, there is (1) an originator of a message or communication, and (2) a recipient.

(a) E-Mail Messages

Turning first to e-mail communications, it seems clear that both the originator and recipient must have (1) access to the Internet (or a digitized packet based network), and (2) an e-mail address. In the prior art described in the specification, both were provided when "a subscriber typically contracts with a commercial access provider (CAP)." As noted above, the UniPost commercial access provider does the same ("The term 'UniPost' will be used to describe a new type of commercial access provider of the type associated with Internet," "UNIPOST TM provides dial-in access to its subscribers . . .," "Each
UniPost Access Node provides a subscriber with an E-Mail address and account . . .," "The UniPost Access Node provides the subscriber with access to all normal facilities of Internet, including E-Mail, databases, conferences, and forums.").

In the case of e-mail communications, the specification draws a distinction between "UniPost," used "to describe a new type of commercial access provider" and "Internet commercial access providers (CAPs) 8," '350 patent, col. 5, lines 19-20, which are labeled on the drawings as "Generic Internet Access Providers." In connection with Fig. 1, the specification explains that the "Internet 4" "has a number of Internet commercial access providers (CAPs) 8 which each have a host of subscribers who then have access to the various services of Internet typically using their personal computers. The conventional Internet access provider would provide each subscriber with an Internet address and password number for retrieval of E-Mail":

GET DRAWING SHEET 1 OF 5

According to the specification, "[o]ne such subscriber 22 is shown using the local public switched telephone network 10 to gain access to the generic Internet CAP for transferring a file to E-Mail subscriber 'gordon@toronto.UniPost.com' indicated as 12. This is via the Toronto UniPost Access Node 6, which includes the electronic Mailbox of Gordon." '350 patent, col. 5, lines 17-30. Gordon can then retrieve the e-mail from UniPost Access Node 6 as indicated by line 24: '350 patent, col. 5, lines 30-33. Thus, in the case of e-mail messages, the specification refers to both the originator of the e-mail 22, and the recipient 12, as "subscribers" presumably because both require a "commercial access provider" to provide (1) access to the Internet (or a digitized packet based network), and (2) an e-mail address.

(b) Voice and Facsimile Messages

In the case of voice and facsimile communications, however, the situation is different. Unlike the "generic Internet CAP," the UniPost commercial access provider additionally provides a "subscriber" with a Personal Mailbox Telephone Number which allows at least two functions not available from a "generic Internet CAP," namely the Personal Mailbox Number (1) allows others to send voice and facsimile messages to a subscriber, and (2) "provides the subscriber with an access point which can receive messages from terminals other than computers, specifically from telephones and facsimile machines." '350 patent, col. 4, lines 53-57.

Specifically, in the case of voice and facsimile message, the specification explains in connection with Fig. 1 that "[m]essages to the UniPost Internet subscriber 12 can also be made from a facsimile machine 14, from a telephone set 16, from a computer modem connection indicated as 18, or a message via Binary File transfer (BFT) indicated by the apparatus 20," '350 patent, col. 5, lines 37-41, through a local PSTN 10. The specification explains that "[t]his, to a caller calling a UniPost subscriber from a telephone, the UAN will behave like a voice mail system. For callers calling a UniPost subscriber from a facsimile machine, the UAN will behave like a receiving facsimile machine." '350 patent, col. 6, lines 9-12.

The patent further explains that "the communications can be accessed by the UniPost Internet subscriber 12 making contact with the Toronto UniPost Access Node 6 or any other UAN worldwide and retrieving of communications that have been received for the subscriber." '350 patent, col. 5, lines 51-55. In particular, in Fig. 2 "each subscriber with a separate electronic message mailbox, generally shown as 30," is provided with "a facsimile in-box 32, a voice in-box 34, an E-Mail box 36 and a facsimile out-box 38." '350 patent, col. 6, lines 41-44. According to the specification, a "subscriber" may retrieve e-mail, voice and fax messages using a computer and modem 12. '350 patent, col. 6, lines 51-63:

GET DRAWING SHEET 2 OF 5

Alternatively, the specification explains, a "subscriber" may use a facsimile machine 25 or telephone 27 to retrieve messages. The specification further describes the steps for doing so: "if the subscriber is at the facsimile machine 25 and wishes to retrieve messages, he can contact the Toronto UniPost Access Node 6, key in his particular password, and direct the UniPost Access Node to send the facsimile message to the machine preferably directly without forming a further communication. On the other hand, the subscriber could use the telephone set 27 to get a summary of messages received as well as any voice messages, and then direct the Toronto UniPost Access Node 6 to send E-Mail or facsimile messages to the facsimile machine 25." '350 patent, col. 6, line 64 --col. 7, line 8.

In the embodiments of Figs. 1 and 2, it therefore seems clear that anyone having a telephone or facsimile machine is able to leave voice and fax messages for a "subscriber." In that instance, the originator of the message need not be a "subscriber."
However, it also seems clear from the specification of the '350 patent that the recipient of such messages must be a "subscriber."

That conclusion is further supported by the claims of the parent '786 patent which similarly provide that the recipient is a "subscriber." For example, claim 1 of the parent '786 patent provides:

1. A communication system comprising a plurality of commercial access providing computers where each commercial access providing computer is associated with INTERNET to allow subscribers to use the services offered by INTERNET, said communication system having many registered subscribers who are collectively unrelated and each subscriber is associated with one of said commercial access providing computers, providing each subscriber with an E-mail address for INTERNET, a fax address telephone address and a voice mail telephone address, where a message addressed to any of the addresses results in said associated commercial access providing computer receiving and storing the addressed message for retrieval by the respective subscriber, said commercial access providing computers allowing each subscriber to access and retrieve messages stored on his behalf or a summary of messages stored on his behalf by using either a telephone set which forms a telephone communication with said associated commercial access providing computer or using a computer and modem which forms a telephone communication with one of said commercial access providing computers, and wherein said plurality of commercial access providing computers use INTERNET to exchange information therebetween, and wherein subscribers of the system can access any of said commercial access providing computers for retrieval of messages stored on behalf of a subscriber, said commercial access providing computers cooperating such that messages stored for a subscriber in said associated computer are transferred using INTERNET from said associated access providing computer to one of the other commercial access providing computers which has been contacted by the subscriber for retrieval of communications stored on his behalf. (emphasis added)

(Doc. No. 82-5 at 13) ('786 patent, col. 11, lines 26-57).

Claim 9 of the '786 patent similarly provides:

9. A method of receiving voice, E-mail, and facsimile messages addressed to a subscriber which messages are received by a computer system connected to a data communication network through which E-mail is received and transmitted and wherein the computer system has a plurality of commercial access providing computers interconnected by said high speed data communication network, each commercial access providing computer including many direct in dial telephone lines connected to a public switched telephone network by means of which facsimile messages and voice messages are received and transmitted, and wherein any of the subscribers may retrieve messages stored on his behalf using said public switched telephone network and said date communication network directly associated with said computer system or using said public switched telephone network to form a direct connection with any of said commercial access providing computers of said computer system for retrieval of messages with said computers communicating the messages therebetwen through said data communication network. (emphasis added)

Id. ('786 patent, col. 12, lines 29-48).

Claim 11 of the '786 patent likewise provides:

11. A unified messaging system comprising a computer system having a plurality of commercial access providing computers interconnected by a high speed data communication network for digital data transmission, each commercial access providing computer including a bank of direct in dial telephone lines associated with a public switched telephone network and acting as a commercial access provider for said high speed data communication network through which E-mail is delivered, said computer system providing each subscriber with an E-mail address for data communication access, a fax telephone address and a voice mail telephone address, where a message addressed to any of the addresses results in the computer system receiving and storing the addressed message for retrieval by the respective subscriber, said computer system being accessible to any subscriber using said public switched telephone network and/or said high speed data network for retrieval of messages stored on behalf of said subscriber or a summary of said messages whereby said subscribers may contact any of said commercial access providing computers for of voice mail. E-mail or facsimile messages received on its behalf by said computer system which messages, if necessary, are exchanged between any of said commercial access providing computers over the data communication network. (emphasis added)
In addition, there is no disclosed embodiment in which a "non-subscriber" may leave voice mail or facsimile messages for another "non-subscriber." Although that is not necessarily dispositive, it is a factor to consider.

eBay argues that "[t]he fact that the patentee expressly included a 'subscriber' limitation in the claims of the '786 patent but did not include such a limitation in the claims of the child '350 patent provides additional compelling support against importing a 'subscriber' limitation into the claims of the '350 patent." (Doc. No. 82 at 22) (emphasis by eBay). Perhaps. The point, though, is not "importing a 'subscriber' limitation into the claims," but rather attempting to get a sense for how one of ordinary skill in the art would construe "commercial access provider." "The inquiry into how a person of ordinary skill in the art understands a claim term provides an objective baseline from which to begin claim interpretation." Phillips, 415 F.3d at 1313. However, "[i]mportantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Id. "[T]he line between construing terms and importing limitations can be discerned with reasonable certainty and predictability if the court's focus remains on understanding how a person of ordinary skill in the art would understand the claim terms." Id. at 1323. After all, "[u]ltimately, the interpretation to be given a term can only be determined and confirmed with a full understanding of what the inventors actually invented and intended to envelop with the claim. The construction that stays true to the claim language and most naturally aligns with the patent's description of the invention will be, in the end, the correct construction." Id. at 1316, quoting Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998) (citations omitted). The claims of the parent '786 patent are certainly not dispositive, and not necessarily all that persuasive, but remain a factor that may be taken into account.
