The parties agree that an element "comprising aluminum" includes some amount of aluminum but may additionally include other materials. Genentech, Inc. v. Chiron Corp., 112 F.3d 495, 501 (Fed. Cir. 1997). APT argues further that the aluminum must be in electrical contact with the layer of polysilicon. However, despite noting one section of the specifications that describe an embodiment of the invention that involves electrical contact between the first metallization layer and the polysilicon, APT cites to no language within the claim itself that could reasonably be understood to require such contact. 3 The Federal Circuit has "cautioned against limiting the claimed invention to preferred embodiments or specific examples in the specification." Teleflex, Inc. v. Ficosa North America Corp., 299 F.3d 1313, 1328 (Fed. Cir. 2002).

2. Whether the aluminum must overly the entirety of the polysilicon layer, and whether the entirety of aluminum may overly polysilicon

The parties disagree on two issues relating to Ixys' use of the word "portion" in two places within this claim language. The first question is whether, in the context of the language found in claim 1 of the '715 patent (the first phrase listed under "E." above), the aluminum layer must completely cover the polysilicon layer, or whether it may only overlay a portion of that layer. APT constructs a compelling linguistic argument that this court must read a meaningful difference into the fact that Ixys used the phrase "overlying said polysilicon layer" in claim 1 of the '715 patent and the phrase "overlying a portion of said polysilicon layer" in claim 23 of that patent and claim 11 of the '419 patent. In the course of construing claims, a court must endeavor to give meaning to every word of the claim language. See, e.g., Apple Computer, Inc. v. Articulate Systems, Inc., 234 F.3d 14, 25 (Fed. Cir. 2000); Harris Corp. v. Ixys Corp., 114 F.3d 1149, 1152 (Fed. Cir. 1997) (holding that a construction that effectively rendered certain terms of a claim irrelevant "would contribute nothing but meaningless verbiage to the definition of the claimed invention" and is therefore disfavored). APT therefore urges this court to construe the "overlying said polysilicon layer" to mean that the metallization must overly the entire layer, in order to give meaning to the phrase "overlying a portion" that appears in later claim language.

Ixys counters by pointing to Figure 2B of its patent, which it says describes a preferred embodiment of the invention, and which distinctly shows a metallization layer that covers some, but not all, of the polysilicon. '715 patent, Fig. 2B. A claim construction that would not cover a preferred embodiment in the specification "is rarely, if ever, correct and would require highly persuasive evidentiary support." Vitronics, 90 F.3d at 1583. APT argues that Claim 1 does not reference Figure 2B, but only Figure 2A, and that Figure 2B must be therefore linked to some other claim language, such as Claim 23. Yet this argument is belied by the language of the specifications: "FIG. 2B is a top view showing an interconnections [sic] 120 for the improved device of FIG. 2A." '715 patent, 5:66-6:2. Although this court is extremely reluctant to adopt a construction that effectively renders the second "portion" meaningless, APT's showing does not constitute the necessary "highly persuasive evidentiary support" required by Vitronics to overcome the presumption created by the preferred embodiment.

A similar pattern of argument repeats itself over the question of whether the language requiring a metallization layer "having [a] portion overlying" the polysilicon demands that only a portion of the metallization overly the polysilicon (in other words, that there be some of the metallization layer that does not overly the polysilicon) or whether all of the metallization layer may overly the polysilicon (in other words, at least a portion of the metallization layer must overly the polysilicon). APT points out that Ixys was well aware of how to use the phrase "at least" in this type of context; Claim 1 of the '715 patent itself contains the phrase "a source bus overlying at least said insulating layer." '715 patent, 8:8-9. This time, however, APT must contend with both Figure 2A and Figure 2B of the '715 patent, which appear to show the entirety of the metallization layer overlying a polysilicon layer, which is to say that there is not one portion of the metallization layer that does not overly the polysilicon.
In an attempt to adduce the "highly persuasive evidentiary support" demanded by Vitronics as a necessary predicate to construing claim language away from a preferred embodiment, APT points also to Ixys' argument before the patent examiner. Under established law, there exists a "heavy presumption that claim terms carry their full ordinary and customary meaning" unless the patentee has "expressly relinquished claim scope during prosecution." Omega Eng'g., Inc. v. Raytek Corp., 334 F.3d 1314, 1323 (Fed. Cir. 2003) (emphasis added). APT claims that Ixys did precisely this before the patent examiner in the course of distinguishing its own invention from the prior art of Korman et al. APT argues that the patentability of Ixys' device over Korman's prior art rests upon the fact that Korman used a "selective process" to deposit metal on polysilicon, while Ixys employed a mask-patterned method in which metal was deposited "often over portions of silicon oxide [not just polysilicon], and then masked and etched to form the desired patterns." Catalano Dec. Exh. 11, at 4.

The language of Ixys' letter to the patent examiner (from which the above-quoted line is drawn) is rather convoluted, and its interpretation bears upon several related questions involved in the construction of this claim term. It is worth reproducing the passage referenced by APT in its entirety:

Specifically, Korman et al. advocate the use of "selectively forming silicide layers only on the exposed surfaces of the polysilicon gate electrode and the source/body regions." (emphasis added) Korman et al., col. 3, lines 40-45. As previously noted, Applicant asserts such selective formation of silicide suggests away from the claimed combination with the first metallization layer comprising aluminum having a portion overlying the polysilicon layer portion, often not a selective process.

In addition, when a metal layer other than metal silicide layer is used, Korman et al. emphasize that such metal is "deposited using a process which deposits the metal on the single crystalline or polycrystalline silicon, but not on silicon oxide," that is, a selective process. (emphasis added). Korman et al., col. 3, lines 50-55. Applicant asserts such metal layer other than metal silicide as taught by Korman et al. cannot be aluminum because the claimed metallization layer comprising aluminum is typically deposited overlying a top surface of a semiconductor often over portions of silicon oxide, and then masked and etched to form the desired patterns. Accordingly, Applicant asserts Korman et al. suggest away from the claimed aluminum having a portion overlying the polysilicon layer portion, which may often be formed over silicon oxide."

Feeman Decl. Exh. 6, at 4 (In re Application of Nathan Zommer) (italics added) (all other emphases and alterations in original). APT argues that the presence of aluminum over other parts of the substrate in addition to the polysilicon was precisely the "improvement" that allowed Ixys to patent its invention over Korman's prior art; an interpretation of claim language that allowed Ixys to recapture devices in which the aluminum overlies only polysilicon would effectively return to Ixys that which it was forced to relinquish in the course of putting forth a patentable device.

What APT has put forth is a potentially persuasive case regarding invalidity, not a winning argument of claim construction. Under the Omega Engineering standard, the court may properly narrow claim scope only when a patentee "expressly relinquished claim scope during prosecution," and Ixys, whatever else the above language might appear to indicate, has not done that. Omega Eng'g., 334 F.3d at 1323. Only "definitive statements" of claim scope abandonment are judicially cognizable at this stage of the proceedings, as the Federal Circuit has "declined to apply the doctrine of prosecution disclaimer where the alleged disavowal of claim scope is ambiguous." Id. at 1324.

APT's case for claim scope relinquishment is felled by the ambiguity permeating the patent amendment excerpted above. Several times within the quoted paragraphs, Nathan Zommer, the inventor of the '715 and '419 patents, suggests that the claimed invention is distinct from the prior art of Korman et al. by virtue of the fact that the first metal aluminum is deposited not just overlying polysilicon, but over silicon oxide (an insulator) as well. See Feeman Decl. Exh. 6, at 4. APT argues that these references lead ineluctably to the conclusion that the inventor had disclaimed inventions in which the first metallization layer overlay only polysilicon, and not other materials. However, each instance in which this potential limitation is described is preceded by the word "often." See id. ("Accordingly, Applicant asserts Korman et al. suggest away from the claimed aluminum having a portion overlying the polysilicon layer portion, which may often be formed over silicon oxide."). This language simply does not constitute an "ambiguous" and "express" relinquishing of claim scope; the presence of the hedging term "often" lodges it firmly within a realm of ambiguity. The prosecution history lacks the definite and unmistakable abandonment of claim scope necessary to limit the full ordinary and customary meaning that claim terms would otherwise carry.
3. Mask-patterning

Much in line with the previous discussion, APT next asserts that APT's claims must be limited to cover only metallization layers that have been deposited using mask-patterning. There is no particular language within the claim itself that would indicate that mask-patterning is necessary. Rather, APT again argues that Ixys specifically relied upon a mask-patterning process to distinguish its invention from that of Korman et al. The process used to deposit the first metallization layer is discussed twice within the portion of the amended application quoted above: "... Applicant asserts such selective formation of silicide suggests away from the claimed combination with the first metallization layer comprising aluminum having a portion overlying the polysilicon layer portion, often not a selective process."; "... the claimed metallization layer comprising aluminum is typically deposited overlying a top surface of a semiconductor often over portions of silicon oxide, and then masked and etched to form the desired patterns." Feeman Dec. Exh. 6, at 4 (underlining in original) (italics added).

APT claims that this represents an "explicit relinquishment" of the claim scope at issue; Ixys argues in response that the distinction being drawn in that discussion regards aluminum vs. metal silicides as a metallization material.

The court believes that neither party is fully correct. While Ixys is certainly attempting to distinguish between Korman's use of metal silicide and its own invention's employment of aluminum, the distinction rests in part on the question of how the material was deposited; the quoted language ties the type of metal used (aluminum) to the method by which it is deposited ("masked and etched"). However, although it is certainly possible to read into this language an implied disclaimer of "selective processes" and a limitation based on mask-patterning, that disclaimer is far from explicit. See Invitrogen Corp. v. Biocrest Mfg., L.P., 327 F.3d 1364, 1367 (Fed. Cir. 2003). As with the sections referring to the placement of metal over silicon oxide in addition to polysilicon (discussed above), each mention of mask-patterning is accompanied by a linguistic hedge: "often not a selective process;" "typically deposited... and then masked and etched." Feeman Dec. Exh. 6, at 4. (emphasis added).

4 A moderate amount of discussion took place during oral argument regarding whether the word "typically" in the sentence at issue here ("Applicant asserts such metal layer other than metal silicide as taught by Korman et al. cannot be aluminum because the claimed metallization layer comprising aluminum is typically deposited overlying a top surface of a semiconductor often over portions of silicon oxide, and then masked and etched to form the desired patterns.") is meant to refer only to the clause that immediately succeeds it ("deposited overlying a top surface of a semiconductor...") or to the entire phrase, including the reference to masking and etching. This is a linguistic dilemma without a clear answer, but that fact is itself dispositive--the line in question does not represent an unambiguous disclaimer of claim scope.

Regardless of whether or not the Ixys patents are novel over prior art only to the extent that they require mask-patterning, the prosecution history APT cites simply does not contain a sufficiently definite and express statement of relinquished claim scope to legitimate a narrowing of those claims at this stage of the proceedings. APT has, in essence, asked this court to peek ahead and adjudicate the invalidity of these claims in the course of construing them. Although in close cases it is preferable to construe claims in such a manner as to sustain their validity, a court must not depart from a claim's otherwise appropriate meaning in an attempt to preserve it. Rhine v. Casio, Inc., 183 F.3d 1342, 1345 (Fed. Cir. 1999) ("We have admonished against judicial rewriting of claims to preserve validity."). This court declines APT's invitation to save Ixys' claim term by such round-about means.

The court construes the claim language found in claims 1 and 23 of the '715 patent and in claim 11 of the '419 patent to mean: "A metallization layer that contains aluminum at least a portion of which is overlying at least a portion of the polysilicon layer.

D. "first state of circuit operation" and "second state of circuit operation"

We now reach the parties' dispute concerning the claim limitations "first state of circuit operation" and "second state of
circuit operation," which are required by claims 2, 3, 34, and 35. The Commission construed these terms to mean "that the first state of operation can be linked to high load currents, and the second state can be linked to low load currents, although the states of operation do not necessarily have to be linked to a high or low load current." Final Determination, 2007 ITC LEXIS 1108 at *35. AATI contends that the "first state" should "occur[] at high load currents," while the "second state" should "occur[] only at low load currents." AATI argues that its construction is supported by the '258 patent's specification and by statements Linear made in prosecuting similar claims in the parent '178 patent. Linear and the Commission contend that the current constructions of these terms are correct, arguing that neither the specification of the '258 patent nor the prosecution history of the parent '178 patent clearly disavow any claim scope.

We decline to disturb the Commission's constructions of "first state of circuit operation" and "second state of circuit operation." While the '258 patent specification provides examples and embodiments where the "first state of circuit operation" may occur at high load currents and the "second state of circuit operation" may occur at low load currents, there is no "clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction,'" which is necessary to further narrow the claim language. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) (quoting Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002)); see also Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1301 (Fed. Cir. 2003) ("Absent a clear disclaimer of particular subject matter, the fact that the inventor anticipated that the invention may be used in a particular manner does not limit the scope to that narrow context."). We have repeatedly held that, even in situations when only one embodiment is disclosed, the claims generally should not be narrowed to cover only the disclosed embodiments or examples in the specification. See, e.g., Liebel-Flarsheim, 358 F.3d at 906 ("Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope . . . ."); Brookhill-Wilk 1, 334 F.3d at 1301 ("The statements from the description of the preferred embodiment are simply that--descriptions of a preferred embodiment . . . [which] do not indicate that the invention can only be used in such a manner."). In fact, the '258 patent specification discloses situations contrary to AATI's suggested construction--operating in the "first state of circuit operation" at low load currents. For example, at low load current levels when the output capacitor has fully discharged--thus being incapable of maintaining the regulated voltage--the "first mode of circuit operation" is initiated to "vary the duty cycle of the switching transistors" in order to turn the top transistor 16 ON long enough to "recharge" the output capacitor. See, e.g., '258 patent col.9 1.63-col.10 1.10.

Nor do the statements made during prosecution of the parent '178 patent evince a "clear and unmistakable" disavowal of claim scope that would compel a result different than the claim language. ResQNet.com, Inc. v. Lansa, Inc., 346 F.3d 1374, 1383 (Fed. Cir. 2003). As an initial matter, the statements made in the prosecution of the parent '178 patent do not remotely relate to the "first state of circuit operation" and, as such, do not narrow this limitation, as urged by AATI. See, e.g., id. (finding no "clear and unmistakable" disavowal of claim scope where the prosecution history of the parent patent did not address the same claim limitations); Advanced Cardiovascular Sys., Inc. v. Medtronic, Inc., 265 F.3d 1294, 1305-06 (Fed. Cir. 2001) (declining to construe a term more narrowly based on the parent patent's prosecution history because common claim terms were not in dispute). Moreover, while the prosecution history of the '178 patent does mention "low output current levels," it neither "clearly and unmistakably" addresses the "second state of circuit operation" nor limits that state to occurring only at low output load current. See, e.g., ResQNet.com, 346 F.3d at 1383; Advanced Cardiovascular Sys., 265 F.3d at 1305-06. Indeed, the claim amendments do not "clearly and unmistakably" modify "the second state of circuit operation," but instead more directly address claim language not disputed in this case. In addition, the amendments do not "clearly and unmistakably" limit the second mode to operating at only low load currents. Rather, the amendments address when the second mode is activated--specifically, when the current to the load falls lower than a predetermined threshold. In other words, the amendments specify entering the second state when the load current drops below some value in comparison to a threshold value--a value that could be relatively high or low. Thus, the amendments and statements in the parent '178 patent are plainly different than the limitations in AATI's proposed construction.

In any event, the remainder of the claim language that modifies the "first state" and "second state" of circuit operations clearly describes the terms. See, e.g., Linear Tech., 379 F.3d at 1324 (looking to the other portions of the claim language in finding that further narrowing of a limitation was unnecessary). In particular, the claim language states with specificity that the "first state of circuit operation" corresponds to when the duty cycle of the switching transistors is varying "to maintain the output at the regulated voltage." '258 patent col.16 ll.50-52. Similarly, the claim language clarifies that the "second state of circuit operation" corresponds to when the "output capacitor maintains the output substantially at the regulated voltage." Id. col.16 ll.55-57; see id. col.2 ll.42-46; id. col.6 ll.4-8 ("when the voltage at output is capable of being maintained substantially at the regulated voltage by the charge on the output capacitor"). We therefore affirm the Commission's claim.
construction of the "first state" and "second state" of circuit operation.

1756

6. "With the first terminal of the battery"

Claim 9 includes "a contactor having a spring . . . and at least one contact for electrical connection with the first terminal of the battery." '900 Patent col.11 1.36-41 (emphasis added). Invisible Fence proposes that the "first terminal of the battery" is "one of the two terminals of the battery," while Perimeter argues that a proper reading should be that the "first terminal of the battery is "the anode terminal of the battery that is positioned adjacent to the base, i.e., opposite the open end of the cup-shaped battery holder through which the battery is inserted." 18 (Joint Statement 5.)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
18 Perimeter's inclusion of "oppose the open end of the cup-shaped battery holder through which the battery is inserted" was rejected supra, Part III.B.1, and therefore will not be considered here.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Perimeter provides no scientific or technical reason for why the first terminal must be the anode terminal, and instead relies on the Description. 19 See, e.g., '900 Patent col.7 1.14-18 ("The battery . . . is orientated inside the battery holder . . . so that the anode terminal faces the battery base . . . and the cathode terminal faces the opening of the battery holder . . . "). Because the language of claim 9 does not require that the first terminal be the anode terminal, the Court declines to read that limitation into claim 9. See Ekchian, 104 F.3d at 1303.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
19 Indeed, Perimeter does not refute Invisible Fence's argument that the orientation of the anode and cathode terminals of the battery can easily be reversed by switching the mating terminals in the receptacle of the electronic housing device.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Although the first terminal is not limited to the anode terminal, the patent does limit the orientation of the first terminal, specifically positioning it at the closed base. Although claim 9 does not explicitly furnish this limitation, the Summary provides that "the retaining ring includes a central aperture through which the second terminal of the battery is exposed at the opening . . . ". ‘900 Patent col.2 1.22-24. With the second terminal exposed at the opening, the first terminal must necessarily be positioned at the closed base. Unlike purported limitations made in the Description, statements found in the Summary can be used to limit claim language. See C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004) ("Statements that describe the invention as a whole [such as the Summary], rather than statements that describe only preferred embodiments, are more likely to support a limiting definition of a claim term."); Microsoft Corp. v. Multi-Tech Sys., Inc., 357 F.3d 1340, 1348 (Fed. Cir. 2004) ("Those statements, some of which are found in the 'Summary of the Invention' portion of the specification, are not limited to describing a preferred embodiment, but more broadly describe the overall inventions. . . ").

The proposition that the cited language in the Summary limits the entire patent is supported by the numerous claims which describe the second terminal as exposed either at the opening or the central aperture. See ‘900 Patent col. 10 1.13-14 (claim 1), col. 10 1.24-25 (claim 2), col. 11 1.7-8 (claim 7), col.11 1.52-54 (claim 10), col.13 1.27-29 (claim 21). Moreover, the claims that specifically provide for the spring to make electrical connection at the base of the battery holder via a resilient center portion provide that this connection is made with the first terminal of the battery. See ‘900 Patent col.10 1.33-36 (claim 4), col.10 1.59-60 (claim 7), col.12 1.61-64 (claim 10), col.13 1.5-12 (claim 21). Accordingly, the patent read as a whole suggests that the "very character of the invention" requires the first terminal to be positioned at the base. 20 See Alloc, Inc., 342 F.3d at 1370.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
20 Although one could argue that the doctrine of claim differentiation creates a presumption that the cited claims are narrower than claim 9, this presumption is easily overcome. Claim differentiation "can not broaden claims beyond their correct scope, determined in light of the specification and the prosecution history and any relevant extrinsic evidence . . . Claims that are written in different words may ultimately cover substantially the same subject matter." Seachange Int'l, 413 F.3d at 1369 (quoting Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1480 (Fed. Cir. 1998)). Given that the Summary and the cited claims above all describe the orientation of the second terminal of the battery as exposed at the opening, and since the specification states nothing to the contrary, it is apparent that the very nature of the invention requires this limitation.

For the foregoing reasons, the Court construes the "first terminal of the battery" as "the terminal positioned at the closed base of the battery holder."

Chamberlain encourages us to further define "fixed code" to include the clause "regardless of how it is later encrypted before or during the RF (radio frequency) transmission." Defendants disagree, arguing that not only must the make-up of the fixed code remain unchanging, but the representation of the make-up must remain also fixed, up until and through the transmission of the radio frequency signal. So, under defendants' construction, if the fixed code is 123, it must remain 123, and cannot ever be encrypted - for example, mirrored to read 321. Defendants state that because, "[i]n the only embodiment shown, the same fixed code signal is generated and transmitted with each transmitter activation," the "fixed code" must remain the same in each transmission (Lear's Markman position slides, p. 20). First, we note that both parties' arguments anticipate an infringement dispute and should not necessarily be part of the claim construction. Therefore, we decline, at this stage, to define "fixed code" beyond "a coded signal representing a fixed code generated by the processor."
In fact, the specification connects the "fixed" nature of the "fixed code" to the "actuation of the transmitter." Lear failed to point out any instance in the claims, specifications, or prosecution history, wherein the patentee clearly disclaimed encryption of the fixed code signal before or during the radio frequency transmission.

--- End Footnotes ---

1758

o. "fixed frequency"

The plaintiffs contend that no construction is necessary, but if the court determines that a construction is needed, then they propose "a non-variable frequency." The defendants propose "having a speed that is tightly controlled and varies minimally." This term is not a technical term and can be understood according to its plain and ordinary meaning. Accordingly, the Court declines to construe this term.

1759

a. "Fixed Level Control Signal"

The limitation "fixed level control signal" is found in Claim 1 of the '290 patent. '290 patent, col.6, 1.17. With little discussion, the parties agreed that "fixed" means "constant." Markman Hr'g Tr. at 8:20 to 9:16. In addition, there was no real dispute that "signal" refers to an electrical characteristic that carries information. Delta then argued that "level" pertains to a specific amplitude, such as four volts. Id. at 9:22-24. The Court was unwilling, however, to read the word "amplitude" into the claim and declined to adopt Delta's proffered definition. Id. at 10:9-11. Instead, the Court construed "fixed level" as a complete phrase meaning "a constant level which means does not vary according to external temperature." Id. at 10:14-20. Delta offered no basis for its "simplification" from the intrinsic record and the Court was unpersuaded. Indeed, reading "level" in light of the written description, the Court explained, "the reason you have a fixed level control signal [in this patent] is so that it will not vary in accordance with external temperature." Id. at 10:24-25. Ultimately, the Court presented the following definition: "Fixed level control signal [means] a constant level, that is, one which does not vary according to external temperature; and a signal simply means an electrical characteristic that carries information." Id. at 11:10-14.

1760

5. Flat-Panel Display Device/ LCD Device

a. The Parties' Constructions

LPL argues that the "flat panel display device" is simply an apparatus with at least a flat display panel and supporting frames. Defendants assert that in the context of the invention, a "flat panel display device" includes a sandwich of layers or stack of components, including the flat display panel, held together or assembled by the first and second frames. ViewSonic further asserts that the stack of components are assembled along the edges. Defendants argue that the intrinsic record mandates such a construction and specifically point to the description in the common specification of an LCD device for support. n19 ViewSonic also submits that under LPL's construction, a portable computer would be a flat-panel display device, thereby rendering superfluous the non-asserted claims' term "portable computer."

--- Footnotes ---

n19 For example, Defendants cite to the '641 patent, 1:42-45: "The LCD device 130 has an LCD panel 132, a backlight device 134 fixed to the back of the LCD panel 132, and a supporting frame 136 for assembling the LCD panel 132 and the backlight device 134 along the edge."
b. The Special Master's Constructions

Based on the express language of the claims, the Special Master does not adopt that portion of Defendants' constructions requiring multiple layers assembled or held together, along the edge or otherwise. The Special Master does agree with the Defendants, however, that the flat-panel display device includes the first and second frames.

The language of claims 55 and 56 provides a definition of flat-panel display device. '641 patent, 12:1-18. Tellingly, both claims recite that the flat-panel display device includes only three main elements, namely a first frame, a second frame, and a flat display panel disposed there between. Thus, to limit the flat-panel display device to one that includes multiple layers would be contrary to the claim language and would, in the Special Master's view, improperly read in the preferred embodiment of an LCD device. Mindful that other claims recite multiple layers, such as the backlight unit of claim 35 of the '641 patent, the Special Master adopts a construction that includes at least a flat display panel.

Additionally, the claim language further specifies that the flat display panel of the device is located between, or sandwiched by, the first and second frames. Claim 35 of the '641 patent recites, for example, that the "flat display panel is between the first and second frames." The claim term "between" does not require, however, that the panel and frames be assembled as Defendants argue. Instead the claim merely defines the location of the flat-display panel relative to the frames. The Special Master therefore concludes that requiring the frames and panel to be assembled, whether along the edges or not, improperly reads in the preferred embodiment from the common specification.

The term "LCD device," on the other hand, is specifically called out in claim 40 of the '718 patent. Because the language of claim 40 itself does not expressly define an LCD device, the common specification provides the best definition for that term. Phillips v. AWH Corp., 415 F.3d at 1315 ("The specification 'is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.'") (internal citation omitted). Referring to Figures 4A-4C, the common specification defines the LCD device as an LCD panel, a backlight unit, and a supporting frame. '718 patent, 4:17-21. Also, Figure 4C shows that the backlight unit 14 and the panel 12 are disposed between the frames 14g and 16.

Accordingly, the Special Master's constructions are as follows:

<table>
<thead>
<tr>
<th>CLAIM TERM</th>
<th>SPECIAL MASTER CONSTRUCTION</th>
</tr>
</thead>
<tbody>
<tr>
<td>flat panel display device</td>
<td>A display device having at least a flat display panel sandwiched by the first and second frames</td>
</tr>
<tr>
<td>liquid crystal display (LCD)</td>
<td>A display device including a LCD panel and a device backlight unit both of which are sandwiched by the first and second frames</td>
</tr>
</tbody>
</table>

1761

a. The '159 Patent

The '159 patent recites a system and method for updating flight management files and providing a retrievable record of the flight performance of an aircraft. Each independent claim of the '159 patent recites a "flight management computer." Therefore, in order to infringe the '159 patent, the System must consist of a "flight management computer" or its equivalent. FedEx maintains that the System does not include a flight management computer. In response, Harris argues that summary judgment as to noninfringement is inappropriate because there are disputed issues of material fact regarding whether or not the System meets the "flight management computer" limitation under the doctrine of equivalents. 8
1. A system for updating flight management files and providing a retrievable record of the flight performance of an aircraft comprising:

   a flight management computer positioned on board the aircraft that interfaces and provides flight critical data received from flight navigation database files to a plurality of aircraft navigation and operational components located throughout the aircraft, wherein the aircraft has a unique tail number identifier;

   a ground data link unit that obtains flight performance data representative of aircraft flight performance data during flight of the aircraft and updates flight navigation database files to the flight management computer . . . .

8 Harris also argues that summary judgment is inappropriate because "there is a significant difference between counsel's strategic decision that certain claims are not worth pursuing and the absence of disputed facts." (Doc. No. 87 at 15.) While the Court notes this distinction, the Court also notes that where counsel's strategic decision not to pursue claims results in an absence of disputed facts, summary judgment is appropriate. The mere possibility that such facts could have been discovered had counsel chosen to pursue the claims is insufficient to establish a genuine factual dispute.

When a court engages in claim construction, "the claims themselves provide substantial guidance as to the meaning of particular claim terms." Phillips, 415 F.3d at 1314 (citing Vitronics, 90 F.3d at 1582); see also ACTV, Inc. v. Walt Disney Co., 346 F.3d 1082, 1088 (Fed. Cir. 2003) ("The context of the surrounding words of the claim must be considered in determining the ordinary and customary meaning of those terms."). Independent claims 1 and 12 recite a "flight management computer positioned onboard the aircraft that interfaces and provides flight critical data received from flight navigation database files to a plurality of aircraft navigation and operational components located throughout the aircraft . . . ." U.S. Patent No. 6, 173, 159 B1 col.32 1.57-61; col.341.4-7 (filed Jun. 25, 1999). Independent claim 24 recites "a method for updating flight management files and providing a retrievable record of flight performance of an aircraft . . . comprising . . . updating a flight management computer located on board the aircraft by transferring files from ground data link unit to the flight management computer." Id. col.35-36 1.16-6.

In addition to the insight provided by the claim language, "it is fundamental that the claims are to be construed in light of the specification." Phillips. 415 F.3d at 1316 (quoting United States v. Adams. 383 U.S. 39. 49, 86 S. Ct. 708, 15 L. Ed. 2d 572, 174 Ct. Cl. 1293 (1966)). Here, the specification states that "[a] flight management computer is positioned onboard the aircraft and interfaces and provides flight critical data received from flight navigation database files to a plurality of aircraft navigation and operational components located throughout the aircraft." Id. col.2 1.36-40. The specification further recites an "aircraft data communications system that downloads flight performance data and uploads flight critical data of flight navigation database files to a flight management computer." Id. col.1 1.10-14. In light of this intrinsic evidence, the term "flight management computer" refers to a computer capable of receiving flight critical data from navigation databases files.

1762

1. "floppy diskette controller"

Defendants agree with the Special Master's construction of the term "floppy diskette controller" for the '414 patent, as limited to controlling the transfer of data to or from a floppy diskette, but disagree with his additional findings that, for the '002 and '222 patents, a "floppy diskette controller" can also control "other types of spinning storage media" and for the '858 patent that a "floppy diskette controller" can also control "some type of non-volatile memory storage medium." 46 In his Part A, the Special Master found that "where the term 'floppy diskette' 47 is used alone, it has a narrower meaning; but when it is used as a modifier, it may have a broader meaning." 48
47 It is used as a stand-alone term in claim 1 of the '414 patent. Defendants do not object to the Special Magistrate's construction of the term "floppy diskette."

48 R & R at 22.

--- End Footnotes ---

Defendants argue that the Special Master's construction of the meaning of "floppy diskette controller" is improper because it gives no meaning to the modifier "floppy diskette" in the term and, therefore, reads "floppy diskette" out of the claim. In support, Defendants cite Mangosoft v. Oracle Corp., 49 Merck & Co., Inc. v. Teva Pharmaceuticals USA, Inc., 50 and Apple Computer, Inc. v. Articulate Systems, Inc. 51

--- Footnotes ---

49 525 F.3d 1327, 1330-31 (Fed. Cir. 2008) (affirming trial court's claim construction because the requested claim construction would render superfluous the claim term "local" in "local persistent memory devices").

50 395 F.3d 1364, 1372 (Fed. Cir. 2005) (reversing the district court's construction of the term "about" as meaning "exactly" because it rendered "other parts of the claim superfluous").

51 234 F.3d 14, 24 (Fed. Cir. 2000) (reversing because "the district court's interpretation of 'help access window' was so broad as to read the 'help' limitation out of the claim").

--- End Footnotes ---

Those cases are distinguishable. In Mangosoft, there was "nothing in the intrinsic record [that] describe[d] or supporte[d] [the requested] expansive meaning." 52 In Teva Pharmaceuticals, the patentee did not clearly redefine "about" in the specification, 53 and therefore, the Federal Circuit held that it "should be given its ordinary and accepted meaning of 'approximately.'" 54 In Apple Computer, the term "help access window" was defined broadly, but "interpreting the claim in light of the teachings of the written description and purpose of the invention described therein" 55 revealed that it could not be given the broad interpretation adopted by the trial court.

--- End Footnotes ---

In the present case, as discussed by the Special Master, the '222, '002 and '858 patents add disclosures and must be independently evaluated. 56 The Special Master supported his finding with examples from the '002 and '222 patents. His first example, the schematic found at Figure 1 of the '002 and '222 patents, perfectly illustrates his point. In those schematics, the "floppy diskette controller (FDC)" is shown as connected to a "Media Drive (e.g. Floppy Diskette drive) designated by reference numeral 16." 57 Because a "floppy diskette drive" is used in '002 and '222 patents as only an example of the broader category of "media drives" controlled by the FDC, the '002 and '222 patents "clearly contemplated--and, indeed, claimed--portable storage media that were not limited only to traditional floppy diskettes." 58 As noted by the Special Master, this disclosure was added by the '002 and '222 patents, 59 and distinguished the meaning as used in the earlier '414 patent. The Special Master also noted the addition in the '222 patent at C13L50-59.

--- End Footnotes ---
The Court is not persuaded by Defendants' argument that because the '222 patent uses the term "controller" in claim 13 and the term "floppy diskette controllers" in the other claims that Dr. Adams must have used "controller" when he meant "media controllers." Such a construction is not supported by reading the '222 patent as a whole. Further, as pointed out by Plaintiff, Defendants did not seek to have the term "controller" in claim 13 in the '222 patent construed, despite having submitted a total number of terms "far beyond anything" that the Special Master had previously encountered.

Nor is the Court persuaded by Defendants' citation to matters in the prosecution history of an unasserted patent, U.S. Patent No. 7,409,601 (the '601 patent), issued as continuation of the '858 patent. While there are circumstances "in which statements a patentee makes in a later-filed case can impact the interpretation of the claims in an earlier-filed patent," Defendants have not shown that the present case presents such circumstances.

Defendants cite two pages of the '601 patent's prosecution history, but not the exact language they rely on, for the proposition that the "patentee expressly represented that a 'defective I/O controller' has a different scope than 'defective floppy diskette controller' to overcome an obviousness-type double patenting rejection." Plaintiff argues that the citation does not make that statement.

Reviewing the cited pages, it appears that Defendants are referring to the applicant's statements at the third and fourth paragraphs of page DEF 005704. However, as shown on those pages by the applicant's underlined emphasis of the words...
"correcting" and "detecting" in those paragraphs, the applicant's statement was focused on that difference in the patents. Thus, the Court is unable to locate any such express representation as is alleged by Defendants.

Defendants also argue that in the patent prosecution of '601, the cancellation of claims including the term "floppy diskette controller" and adding claims with the new term "I/O controller" shows the claims did not have the same meaning. However, that is far from the type of "clear disavowal or disclaimer made during prosecution" of the subsequent patent as would inform construction of the earlier patents. 64 In this case, as in TIP Systems, "the meaning of the term [floppy diskette controller in the '002, '222, and '858 patents] can be discerned from the language of the claims themselves, and is fully supported by the specification, drawings, and prosecution histories" of those patents. Further, a finding by the patent examiner that the claims of the subsequent patent application were obvious in view of the claim of the earlier '002 patent has bearing on the construction of the term in the earlier patent.

64 See e.g. TIP Sys., LLC v. Phillips & Brooks/Gladwin, Inc., 529 F.3d 1364, 1371 (Fed. Cir. 2008) (treating an amendment eliminating a term entirely from the claims of the subsequent patent as different from a clear disavowal or definition of the term in the subsequent patent).

The parties disagree on whether the Court should consider a statement by the Special Master regarding the meaning that the electronics industry has settled on the term "floppy diskette controller." That statement was part of a larger examination of the following statement in the '414 patent: "Specifically, data loss and/or data corruption can occur during data transfers to diskettes (or even tape drives and other media which employ the FDC)." 65

65 Id. at 24 (quoting '414 patent C1L54-57).

The Special Master, reading the '414 patent as a whole, found that the above quoted "statement tends to establish two things: the inventor considered diskettes as distinct from 'tape drive and other media' and he also contemplated that an FDC might be used to control memory other than diskettes." 66 As the Special Master further explained in a footnote:

This is an extremely important concept. Despite the name, a "floppy diskette controller" apparently can control data transfer to and from various types of storage media in addition to traditional "floppy diskettes." A better term might have been "storage media controller" but once the electronics industry settles on a name for a device it is difficult to pry them loose from it, even when it becomes misdescription. 67

66 Id. at 24 (footnote omitted).

67 Id. at n.47.

Plaintiff relies on the statement to support the position that not only did the terms "floppy diskette" and "floppy diskette controller" evolve during the prosecutions of the patents in suit, but also in the "relevant art during this twelve year period to the point where a 'floppy diskette' is now a metaphor for storage media." 68

68 Pl.'s Response at 2.
Tellingly, Defendants do not argue that the Special Master is incorrect on his understanding of how the term has evolved in the electronics industry to mean something more. Rather, they argue that his understanding should not be relied upon because he did not cite any evidence in support of this finding.

The Court need not decide the dispute over whether the statement should be considered because it finds that the Special Master's analysis of the added disclosures that claim portable storage media that are not limited to only traditional floppy diskettes is correct without the need to consider the additional support offered by the statement.

The Court adopts the Special Master's claim construction as follows: "The claims of the '002 and '222 patents are not limited to a system or method in which the FDC is controlling a 'floppy diskette' as that term was defined for '414 patent; other types of spinning storage media may be employed." 69 

69 R & R at 26.

70 Id. at 29.

"flowing process fluids sequentially and continuously" appears in Claim 1 of the '532 patent. The related phrase, "flowing process fluids in sequential steps continuously past said wafers," appears in Claims 54, 55, 57 and 58. CFMT asserts that "flowing process fluids sequentially and continuously" means that process fluids flow past the wafers one after another and contact the wafers in a uniform, spatially uninterrupted manner. YieldUP counters that the term "continuously" requires an uninterrupted flow of process fluids. According to YieldUP, CFMT's construction of the phrase would cover a process where the wafers are dipped in fluids that are stagnant as opposed to flowing.

In the prosecution of the '532 patent, McConnell and Walter asserted that their "full flow" invention differed from the open sink methods used in the prior art because in their invention, "fluids flow sequentially and continuously past the wafers." In the open sink method used in the prior art, wafers are immersed in a sink containing a fluid and then moved to a second sink containing a second fluid. Therefore, the court's construction of the phrase "flowing process fluids sequentially and continuously" should not cover a process where the wafers are dipped in fluids that are stagnant as opposed to flowing. As advocated by YieldUP, the court finds that the phrase "flowing process fluids sequentially and continuously" means that process fluids flow past the wafers one after another and that the term "continuously" requires an uninterrupted flow of the process fluids.

"following a previously computed form line having been defined using positioning information derived from earlier received GPS data and a swathing offset" (Claims 3, 6, 11)

This phrase appears in claims 3, 6, and 11, although the phrase appears in differently worded fashion in each claim. See Tang Decl., Ex. A at 12:53-63; 13:6-15; 14:4-14. The parties agree, however, that the phrases all have the same meaning despite this, and that the wording of claim 3 is representative. Trimble contends that this disputed phrase should be
construed to mean "controlling a vehicle based on steering guidance derived from previously computed terrestrial locations on the field and a swathing offset." Defendants, by contrast, contend that the phrase should be construed to mean "following a previously computed path across the area to be treated, where the path was computed using geographical positions computed from earlier received GPS satellite data transmissions and a distance determined by the effective width of a towed implement." As is the case with the majority of the terms before the court, defendants' proposed construction offers the best interpretation of the claim language.

Beginning with the claim language, and using claim 3 as representative, claim 3 covers a "form line following apparatus" that is comprised of a vehicle fitted with a GPS receiver, and a processor capable of defining updated form lines. See Tang Decl., Ex. A at 12:53-63. According to claim 3, the processor will define an updated form line according to position information computed while the vehicle was doing two things: (1) following a prior form line; and (2) deviating from the prior form line. See Tang Decl., Ex. A at 12:57-63. The disputed phrase can be found in claim 3's description of the processor, and specifically, in the description of the updated form line that the processor defines. Id. The disputed term modifies the first step in this two-step process. Specifically, it describes the prior form line that the vehicle was following, from which the vehicle deviated. In other words, the phrase describes the original expected path across the area to be treated, that the vehicle was attempting to follow. Seen from this perspective, the disputed phrase simply clarifies that this original form line was itself computed using "earlier received GPS data and a swathing offset."

With this understanding of the disputed phrase and its surrounding context in mind, and in view of the court's prior construction of "form line," it is defendants' proposed construction, as opposed to plaintiffs, that most accurately interprets the meaning of the disputed phrase. Defendants' construction describes -- as the disputed phrase is meant to do -- that "following" the original form line simply means following a previously computed path, which was in turn computed (i.e., defined) based on the geographical positions computed from earlier GPS data and a swathing offset.

The court therefore construes the term "following a previously computed form line having been defined using positioning information derived from earlier received GPS data and a swathing offset" as: "following a previously computed path across the area to be treated, where the path was computed using geographical positions computed from earlier received GPS satellite data transmissions and a distance determined by the effective width of a towed implement."

1. The Claims

a. The '462 Patent:

1. A method for producing and locating an apparent origin of a selected sound from an electrical signal corresponding to the selected sound in a predetermined and localized position anywhere within the three-dimensional space containing a listener, comprising the steps of:

   separating said electrical signal into respective first and second channel signals;

   altering the amplitude and shifting the phase of the signal in both said first and second channel signals while maintaining said phase and amplitude differential therebetween for successive discrete frequency bands across the audio spectrum and each successive phase shift being different than the preceding phase shift, relative to zero degrees, thereby producing first channel and second channel modified signals and creating a phase differential and an amplitude differential between the two channel signals;

   maintaining the first channel signal separate and apart from the second channel signal following the step of altering the amplitude and shifting the phase; and

   respectively applying said first and second channel modified signals that are maintained separate and apart and that have said phase and amplitude differential therebetween to first and second transducer means located within the three-dimensional space and spaced part [sic: apart] from the listener to produce a sound apparently originating at a predetermined location in the three-dimensional space that may be different from the location of said sound transducer.
means.

7. A system for conditioning a signal for producing and locating, using two transducers located in free space, an auditory sensory illusion of an apparent origin for at least one selected sound at a predetermined localized position located within the three-dimensional space containing a listener from a single electrical signal corresponding to the selected sound, comprising: first and second channel means both receiving the same single electrical signal, said first and signal second channel means including respective first and second sound processor means each for altering the amplitude and shifting the phase angle of the respective electrical signal on a frequency dependent basis for successive discrete frequency intervals across the audio spectrum to produce a respective modified signal wherein the amplitude alteration differential and the phase angle shift differential occurring between the two channels are respective predetermined values for each said successive frequency interval of the audio spectrum, said sound processor means shifting the phase angle such that each successive phase angle shift is different and independent of a preceding phase angle shift relative to zero degrees, and said first and second channels being maintained separate and apart prior to being fed to the two transducers.

b. The '860 Patent:

1. A method for producing and locating an apparent origin of a selected sound from an input monaural signal corresponding to the selected sound in a predetermined and localized position anywhere within the three-dimensional space containing a listener, comprising the steps of:

   separating said input monaural signal into respective first and second channel signals;

   providing a sound position control signal derived independently of the input monaural signal for making amplitude and phase adjustments at each of a number of discrete frequency bands over the audio spectrum and relating to a sound location determined by azimuth, height, and depth;

   altering the amplitude and shifting the phase of the signal in at least one of said first and second channels in response to said sound position control signal, both altering and shifting being done on a predetermined frequency dependent basis for successive discrete frequency bands across the audio spectrum and each successive phase shift being different than the preceding phase shift relative to zero degrees, thereby producing at least a first channel or a second channel modified signal and creating a continuous phase differential and a continuous amplitude differential between the two channel signals that varies for each of said discrete frequency bands;

   maintaining the first channel signal separate and apart from the second channel signal following the step of altering the amplitude and shifting the phase; and

   respectively applying at least first and second channel modified signals that are maintained separate and apart and that have said phase and amplitude differential therebetween to first and second transducer means located with the three-dimensional space and spaced apart from the listener to produce a sound apparently originating at a predetermined location in the three dimensional space that may be different from the location of said sound transducer means.

5. A system for conditioning a signal for producing and locating, using two transducers located in free space, an auditory sensory illusion of an apparent origin for at least one selected sound at a predetermined localized position located within the three-dimensional space containing a listener from a single monaural input signal corresponding to be selected sound, comprising: first and second channel means both receiving the same single monaural input signal, one of said first and signal channel means including sound processor means connected to receive a sound position control signal derived independently of the input monaural signal for controlling amplitude and phase adjustments at each of a number of selected frequency intervals of the audio spectrum and relating to a sound location determined by azimuth, height, and depth for altering the amplitude and shifting the phase angle of the respective signal on a frequency dependent basis for successive discrete frequency intervals across the audio spectrum to produce a respective modified signal therefrom in response to said sound position control signal, wherein the amplitude alterations and the phase shifts form a continuous differential between the two channels that varies for each said successive frequency interval of the audio spectrum, said sound processor means shifting the phase angle such that each phase angle shift is different relative to zero degrees, and said first and second channels being maintained separate and apart prior to being fed to the two transducers.
2. The Claim Construction

The first claim at issue of each of the patents is a method claim, while the second claim at issue of each of the patents is a claim to a "system." After examining the prosecution history, the special master gave the phrase "being maintained separate and apart" its ordinary, literal meaning. He distinguished, however, between the term "following" that appears in claim 1 of the '462 and the '860 patents and the phrase "prior to" that appears in claim 7 of the '462 patent and claim 5 of the '860 patent.

The special master interpreted "prior to" as simply requiring that the two signals be kept separate and apart "merely immediately before the loudspeakers [i.e., the 'transducers'] where the signals are clearly separate and apart." "Following," however, was deemed more restrictive. The special master interpreted that term to require the two signals to be kept "separate and apart" from each other immediately after the two signals are initially altered.

Because the two channel signals in the accused Spatializer device are combined after their phase and amplitudes are altered, but are separated immediately before they are fed to the speakers, the special master recommended that the Spatializer does not infringe the "following" claims but potentially could infringe the "prior to" claims. As indicated above, the district court adopted the special master's recommendations as to the "following" claims but not the "prior to" claims. The district court held that Desper was entitled to summary judgment of non-infringement on the "prior to" claims as well as the "following" claims. On appeal, QSound challenges the district court's interpretation of both "following" and "prior to." 2

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 

2 QSound also challenges the interpretation of "discrete" and "independent," as it must to ultimately prevail. Given our interpretation of "maintained separate and apart," "following," and "prior to," however, we need not reach these issues.

DISCUSSION

"The law governing summary judgment is well established." C.R. Bard, Inc. v. Advanced Cardiovascular, Inc., 911 F.2d 670, 672, 15 U.S.P.Q.2D (BNA) 1540, 1542 (Fed. Cir. 1990), "Summary judgment is as appropriate in a patent case as it is in any other case." Id. Under the Federal Rules of Civil Procedure, a motion for summary judgment should properly be granted when "there is no genuine issue as to any material fact and . . . the moving party is entitled to a judgment as a matter of law." Fed. R. Civ. P. 56(c).

The determination of whether an accused product or process infringes a claim of a patent is universally understood to involve two steps. First, we construe the asserted claim to determine its meaning and scope. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 976, 34 U.S.P.Q.2D (BNA) 1321, 1326 (Fed. Cir. 1995) (in banc), aff'd, 517 U.S. 370, 38 U.S.P.Q.2D (BNA) 1461, 134 L. Ed. 2d 577, 116 S. Ct. 1384 (1996). In the second step, we compare the accused product or process to the properly construed claim. See id.

Whether a product or process infringes the properly construed claims of a patent, literally or under the doctrine of equivalents, is a question of fact. See Tanabe Seiyaku Co. v. United States Int'l Trade Comm'n, 109 F.3d 726, 731, 41 U.S.P.Q.2D (BNA) 1976, 1981 (Fed. Cir. 1997). Often, as in this case, the composition of the allegedly infringing process or product is undisputed. In such a case, literal infringement collapses into claim construction--a matter of law--amenable to summary judgment. See Athletic Alternatives, Inc. v. Prince Mfg., Inc., 73 F.3d 1573, 1578, 37 U.S.P.Q.2D (BNA) 1365, 1370 (Fed. Cir. 1996).

To determine the meaning and scope of a claim, we first examine the claim language, the specification, and, if in evidence, the prosecution history. See Vitrionics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1581, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996). Extrinsic evidence, that is, evidence outside the record before the United States Patent and Trademark Office ("PTO"), such as expert testimony about how those skilled in the art would interpret certain language in the claim, may also be considered when appropriate as an inherent part of the process of claim construction and as an aid in arriving at the proper construction of the claim, but may not be used to vary or contradict the otherwise unambiguous meaning of the claim. See id. at 1582, 39 U.S.P.Q.2D (BNA) at 1577. The proper interpretation of a claim is a legal conclusion, over which
we exercise plenary review. See Cybor Corp. v. FAS Tech., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (in banc) ("We review claim construction de novo on appeal including any allegedly fact-based questions relating to claim construction.").

I. "Following"

We start first with the claim language itself. See Thermalloy, Inc. v. Aavid Eng'g, Inc., 121 F.3d 691, 692, 43 U.S.P.Q.2D (BNA) 1846, 1848 (Fed. Cir. 1997) ("Throughout the interpretation process, the focus remains on the meaning of claim language."). The first claims of both the '462 patent and the '860 patent require that the system "maintain[] the first channel signal separate and apart from the second channel signal following the step of altering the amplitude and shifting the phase" (emphasis added). The plain meaning of "following" is "subsequent to, after in time" or "next after," depending on the context. Webster's Third New International Dictionary 883 (1986). The problem in this case is that this definition does not tell us how close in time to the "altering" step the signals must be maintained separate and apart. To answer that question we consult the specifications.

Though not definitive, the specifications support an interpretation that requires the two signals to be maintained separate and apart beginning immediately after the amplitude is initially altered and the phase is initially shifted. The word "following" appears only twice in each of the written descriptions and is not used with reference to the channel signals. (The same is true of the phrase "prior to," discussed infra.) The drawings, Fig. 16 and Fig. 18a (pictured supra), however, graphically demonstrate that once the two channel signals are separated they are thereafter kept separate. Thus, the drawings support the interpretation that, immediately after the amplitude and phase of the channels signals are initially altered by the filter, they thereafter must be maintained separate and apart.

QSound points to an isolated passage in the written description to support its proposed claim construction that it is only after the alteration of the amplitude and the shifting of the phase by filters and summers are complete that the signals are required to be maintained separate and apart. The passage upon which QSound relies simply indicates that the sound processor "may include some or all of the following circuit elements: filters, delays, [inverters], summers, amplifiers, and phase shifters." '462 patent, col. 11, ll. 11-12. The passage sheds no light as to when the signals must be maintained separate and apart.

In contrast, the prosecution history confirms our claim construction. The limitation that the channel signals be maintained separate and apart was not in the original claim language. The original claims of what is now the '462 patent were rejected as obvious under § 103 in light of British patent No. 942,459. The original application (Ser. No. 07/398,988) was then abandoned in favor of a File Wrapper Continuation ("FWC") (Ser. No. 07/696,989). See 37 C.F.R. § 1.62 (1997). The limitation that the channel signals be maintained separate and apart was then added in a preliminary amendment dated June 12, 1991. In the remarks accompanying that amendment, the patent applicants' attorney stated:

In fact, according to the present invention, once the monaural signal is split into the two channel signals, those signals are forever after isolated one from another and are never combined or commingled. Various operations may take place in each channel provided by the present invention, yet the signals being operated upon are never recombined or mixed. This is in direct distinction to the teaching of the British patent. . . .

(Emphasis added.) In his closing remarks, the attorney further stressed in urging reconsideration:

In view of the amendments to the claims hereby, as well as the above remarks, it is respectfully submitted that a method and apparatus for producing two sound signals derived from a single monaural input signal in which an amplitude and phase shift is provided with such signals being maintained separate and apart up until the actual production of the sounds at the speakers, as taught by the present invention and as recited in the amended claims, is neither shown nor suggested in any of the cited references, alone or in combination.

(Emphasis added). Rather than wait for a formal, written response, the applicants conducted a personal examiner interview. In the resulting "Examiner Interview Summary Record," the examiner indicated that the amended claims "appear to distinguish over art of record in prior case (FR 1,512,059 & B 942,459)." However, the examiner did come up with a new reference on which to base another prior art rejection. Despite this new reference, the examiner indicated that two dependent claims would be allowable if they were to be rewritten in independent form. In response, the applicants abandoned the original independent claims and took what the examiner allowed. The rewritten claims were subsequently allowed and
issued as part of the '462 patent.

The prosecution history of the '860 patents tells much the same story. The '860 patent was originally filed as a Rule 60 divisional of the FWC (Ser. No. 07/696,989). See 37 C.F.R. § 1.60 (1997). In a preliminary amendment dated October 31, 1991, after the parent application had been rejected in view of the British patent, the applicants amended all the independent claims to include the limitation that the channel signals be maintained separate and apart. In an office action dated February 5, 1992, the examiner rejected the amended claims as obvious in light of another reference. The applicants' attorney responded with further amendments to the claims, and accompanying remarks in which the attorney distinguished the claimed invention from the cited reference. This amendment was sufficient to overcome the rejection, and the amended claims were issued as part of the '860 patent. Thus, in the file history of both patents, the limitation that the channel signals be maintained separate and apart was added to overcome the prior art rejection based on the British reference, and in both cases it succeeded.

QSound does not argue on appeal that its attorney's comments do not, on their face, limit the scope of the asserted claims. Rather, QSound argues that the prosecuting attorney's remarks should not be used to interpret the disputed claim language because the remarks, according to QSound, were both erroneous and extraneous -- erroneous because they are contrary to the express teaching of the patent itself and extraneous because they did not become part of the claim. We disagree on both accounts.

Fig. 18a (pictured supra), according to QSound, "proves . . . that counsel's statement was erroneous." Brief for Appellant at 33. In particular, QSound argues that "after the signals pass through the points labeled 1657 and 1658, figure 18[a] shows that the signals cross, and are commingled, at the point labeled 1659." Brief for Appellant at 34. This post-hoc argument flies in the face of the entirety of the written description and the operation of a switch as well understood in the art. The symbol for 1659 shows a broken, diagonal line with a continuous, diagonal line passing through the opening therein. This notation is used, as is well known in the art, to indicate that the two conductors within the switch are not connected. The switch, according to the written description, "allows the filter signals to be fed directly or interchanged, to first inputs of summing elements 1660 and 1670." '462 patent, col. 13, lines 12-14. Thus, reversible switch 1659 does not, as QSound alleges, "commingle" the two channel signals, but, instead, re-routes the respective signals to either summing element 1660 or 1670 depending on the switch setting. Switch 1659 therefore gives the operator the ability to create a mirror image of the sound illusion by simply flipping the switch. This reading is consistent with the normal operation of a reversible switch. Counsel's argument to the contrary is disingenuous at best and blatantly false at worst.

Following oral argument, during which counsel's characterization of the switch was challenged, QSound attempted to bolster its untenable position with a submission of testimony from its expert, ostensibly pursuant to Fed. R. App. P. 28(j). Rule 28(j), however, permits a party to bring supplemental authorities to the court's attention, not supplemental argument. Accordingly, QSound's submission was improper. Even were we to consider the proffered testimony, it does not prove QSound's point. None of the cited testimony establishes that reversible switch 1659 commingles the two channel signals. QSound's attempt to sacrifice the prosecuting attorney who wrote and prosecuted the application before the PTO, and who presumably was in the best position at the time to understand the true nature of the invention -- for the sake of its case here -- is unavailing.

QSound also argues that the prosecuting attorney's remarks were "extraneous" in that "they did not become part of the claim." In essence, QSound argues our interpretation would import into the claim the attorney's "erroneous" remarks. In support of this proposition QSound relies primarily on Intervet America, Inc. v. Kee-Vet Labs., Inc., 887 F.2d 1050, 12 U.S.P.Q.2d (BNA) 1474 (Fed. Cir. 1989). Intervet provides no such support. In Intervet, the trial court read two limitations into the claims ("single administration" and "attenuation") based on the remarks of the prosecuting attorney. The "single administration" limitation was, in fact, an express limitation in one of the independent claims but not the others. During prosecution, "the attorney made the unqualified and now admittedly untrue statement that 'the claims are restricted to a single vaccination scheme.'" Id. at 1054, 12 U.S.P.Q.2d (BNA) at 1477. This court, not surprisingly, held that the independent claims in which the "single administration" limitation did not appear were not limited to a "single administration," the attorney's remarks notwithstanding. Id. This court also reversed the trial court's construction that required the claims to include an "attenuation" limitation based on the attorney's remarks, even though that word did not appear in any of the claims. Id. at 1055, 12 U.S.P.Q.2d (BNA) at 1478 ("We have set forth the asserted claims in full above and it is clear that they make no reference whatever to attenuation.").
The differences between Intervet and this case are apparent. First, the dispute in this case involves the proper interpretation of language that is in the claims, in particular, the words "following" and "prior to." We are interpreting explicit claim language, not importing limitations into the claim. Second, the attorney's remarks in this case were not "erroneous." As we have discussed above, the attorney accurately described the claimed invention and the cited prior art. There is no "admittedly untrue statement" in this case as in Intervet. Thus, QSound's reliance upon Intervet is misplaced.

QSound further argues that the attorney's remarks should not be used to interpret the claim language because the amendment that precipitated the remarks did not end the prosecution. In effect, QSound argues that the remarks were inconsequential because they did not result in allowance of the claims. Again, QSound relies on Intervet. What QSound fails to acknowledge, however, is that the amendment and accompanying remarks were made for the purpose of overcoming the outstanding rejection based on the British patent. That the prosecution shifted to a different focus does not blunt the impact of those remarks made to overcome the prior rejection. The significance of the remarks in this case is no different than in a case in which the claims are allowed in response to an amendment.

We conclude that the claim construction for claim 1 of the '462 patent and of the '860 patent adopted by the district court is correct.

C. "for the first type network node" (Claim 1) & "for the second type network node" (Claim 2)

Plaintiff: Claim construction of "for the first type network node" and "for the second type network node" is unnecessary. The plain and ordinary meaning controls.

If the court concludes that "for the first/second type network node" requires construction, then the Court should construe "for the first/second type network node" within the context of the claims to mean "on behalf of one or more computer devices on a computer network."

Defendant: "for the first type network node": Designed for a participating Internet Service Provider (ISP) or organization from which a service request is received.

"for the second type network node": Designed for an Internet Content Provider (ICP).

The significant additional term in these phrases is "for." The Court agrees with Plaintiff here -- the term needs no construction. "Claim construction is a matter of resolution of disputed meanings and technical scope, to clarify and when necessary to explain what the patentee covered by the claims, for use in the determination of infringement." United States Surgical Corp. v. Ethicon, Inc., 103 F.3d 1554, 1568 (Fed. Cir. 1997). Here, the term "for" is non-technical, is in plain English, and derives no special meaning from the Patent. The ordinary meaning of the term speaks for itself, and the Court will avoid paraphrasing the language. The Court finds very little risk that the ultimate factfinder will be unable to understand this term.

Defendant's proposal is rejected as importing limitations into the specification. The Patent, read as a whole, does not support adding the word "designed" in front of "for" in construing the term. The specification states both that an ICP forms customized web pages "for its participating web sites" and that web page files may be "designed for" a network node. '577 Patent at Abstract; 7:45-55; 8:55-67. Defendant claims that forming a web page "for" a network node "is so amorphous as to require guidance from the specification," but the Court is not convinced. There is no need to inject verbiage into a such a straightforward and ordinary term.
The plaintiff contends that the terms do not need to be construed. To the extent that a construction is needed, the plaintiff proposes that "coupling" be construed as "connecting" and "connectable" be construed as "capable of being connected." The defendants propose that both terms be construed as "capable of being placed in data communication." The court has consistently construed the term "coupled" to mean "directly or indirectly connected." Accordingly, "for coupling" means "for directly or indirectly connecting." Furthermore, the court agrees with the plaintiff that "connectable" means "capable of being connected."

With respect to the next 3 elements of claim 10, the parties dispute whether they are written in means-plus-function format such that they invoke the requirements of § 112, P 6. Specifically the parties dispute the meaning of the following three claim elements:

1. "a statistical decoder coupled to said I/O port for decoding variable-length-encoded compressed video signals"
2. "I/O circuitry coupled to said I/O port, for providing processed video signal to said I/O port, and for accepting a processed video signal from said I/O port"
3. "a pixel interpolator for generating values representing pixels interstitial to pixel values represented by said processed video signal"

Because the parties argue whether each of these claims are claimed in mean-plus-function format, the court will address that threshold issue before turning to the construction of the claim language for each of the three elements.

Broadcom argues that the elements "statistical decoder," "I/O circuitry," and "pixel interpolator" are means-plus-function elements, which must be construed according to § 112, P 6. Despite acknowledging that these elements do not contain the word "means," Broadcom nevertheless argues that these claim elements must be construed as means-plus-function elements because each of the elements simply recites a function but fails to recite any definite structure. See MAS Hamilton Group v. LaGard, Inc., 156 F.3d 1206, 1213 (Fed. Cir. 1998) (the phrase "lever moving element for moving the lever" is a means-plus-function element governed by 112, P 6); C.R. Bard v. United States Surgical Corp., 102 F. Supp. 2d 199, 215-16 (D. Del. 2000) (the phrase "surface of said hollow plug . . . being extremely pliable, allowing localized portions of the hollow plug to adapt to irregularities" is a means-plus-function element governed by 112, P 6). According to the cases cited by Broadcom, when it is apparent that an element invokes purely functional terms without the additional recital of a specific structure for performing the function, the claim element may be a means-plus-function element despite the lack of express means-plus-function language. Broadcom argues that this is the case with respect to the three elements at issue here.

Intel argues that these elements are not means-plus-function elements. Intel first points out that when the term "means" is not used in a claim element, a presumption arises that 112, P 6 does not apply. See Personalized Media Comm. LLC v. Int'l Trade Comm'n, 161 F.3d 696, 703-04 (Fed. Cir. 1998); see also Al-Site Corp. v. VSI Int'l Inc., 174 F.3d 1308, 1318 (Fed. Cir. 1999) ("When an element of a claim does not use the term 'means,' treatment as a means-plus-function claim element is generally not appropriate."); Greenberg v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580, 1584 (Fed. Cir. 1996) ("The use of the term 'means' has come to be so closely associated with 'means-plus-function' claiming that it is fair to say that the use of the term 'means' . . . generally invokes 112(6) and that the use of a different formulation generally does not").

Intel next argues that the functional language used in the claims does not equate to means-plus-function. See Greenberg, 91 F.3d at 1583 ("The fact that a particular mechanism . . . is defined in functional terms is not sufficient to convert a claim element containing that term into a 'means for performing a specified function' within the meaning of 112(6)"). Rather, because each of the three terms at issue "has a reasonably well understood meaning in the art" as the name for a structure, 112, P 6 should not apply. Id.; see also Personalized Media, 161 F.3d at 705 (holding that "detector" is a sufficiently definite structural term to preclude the application of 112, P 6, even though the detector was defined in terms of its function, because the term "detector" refers to a well-known structure for those knowledgeable in the art). Last, Intel contends that when a claim recites "means" language for some elements, but not others, the drafters presumably knew the difference and deliberately drafted the claim to reflect their intention that some elements should be construed as means-plus-function but that others should not be construed as means-plus-function.
As stated above, there is a rebuttable presumption in patent law that when a claim drafter fails to use "means" in a claim element that the claim element is not a means-plus-function element. See Personalized Media, 161 F.3d at 703-04; Greenberg, 91 F.3d at 1580. That presumption may be overcome if the claim element only provides functional terms without the recitation of structure for performing that function.

In determining whether the claims language recites a structural term or merely recites functional terms, the court should read the claim language in light of both the specification and prosecution history. See C.R. Bard, 102 F. Supp. 2d at 216 (stating that review of prosecution history demonstrates that the examiner would not have allowed the claim but for examiners finding that claim limitation at issue was a "means" element). Moreover, a court should examine whether the claim element at issue has a well-understood structural meaning in the art. See MAS Hamilton Group, 156 F.3d at 1213 (holding that district court correctly held that "movable link member for holding the lever . . ." was a means-plus-function element because there was no evidence that a "movable link member" had a well-understood structural meaning in the art). In this case, the court finds no reason to overcome the presumption that the three elements at issue are not means-plus-function elements. First, it is undisputed that the terms "statistical decoder," "I/O circuitry," and "pixel interpolator" had reasonably well-known structural meanings to persons skilled in the art at the time of the 201 invention was filed. Von Herzen Decl. PP 11-27. Second, there is nothing in the specification or prosecution history that precludes these three terms from being defined by referring to their well-known general structures. Therefore, the claim elements convey sufficient structure such that they are not defined purely in terms of their stated function.

Additionally, it should be noted that the claim drafters here used both means-plus-function language and non-means-plus-function language in the claims. Claim 1 recites "statistical decoding means," while claim 10 recites "statistical decoder." Claim 1 recites "input means" and "output means," while claim 10 recites "I/O circuitry." Claim 1 recites "pixel interpolating means," while claim 10 recites "pixel interpolator." In such instances, where there are no reasons for construing the latter terms as means-plus-function elements, a court should give effect to the intentional language used by the claim drafter.

The court finds that the "statistical decoder," "I/O circuitry," and "pixel interpolator" of claim 10 are not means-plus-function elements. Therefore, the court has no need to construe the function or the corresponding structure disclosed in the specification. The task for the court is merely to define those terms using ordinary claim construction rules.

5. "For electrical connection"

Claim 9 includes "a contactor having a spring . . . and at least one contact for electrical connection with the first terminal of the battery. . . ." '900 Patent col.11 1.36-44. Invisible fence says that the term "for electrical connections" means "allows for electrical connection," and Perimeter argues that it means "the spring and the elongated contact arms make electrical connection to only one terminal of the battery (i.e., the first terminal)." 16 (Joint Statement 5.)

16 Both parties ostensibly agree that Claim 9 clearly reads that the electrical connection is made with the first terminal of the battery.

The parties disagree as to what components of the contactor are required to make the electrical connection. Invisible Fence argues that any combination of contact arm(s) and/or the spring can make the electrical connection, while Perimeter argues that the pair of contact arms and the spring are all required to make the electrical connection. 17

17 Perimeter's claim that there must be a pair of contact arms was rejected supra, Part III.B.3.
As a threshold matter, the Court construes the term "for electrical connection" as modifying "a contactor" and not "at least one contact." If the term were read to modify "at least one contact," then claim 9 would curiously exclude the possibility that the spring might also make an electrical connection with the first terminal of the battery, a position neither party advocates and one clearly not supported by the Summary. See '900 Patent col.2 1.1-6 ("The flexion spring may be positioned within the battery holder so that . . . a resiliently bowed center portion is positioned for electrically contacting the first terminal of the battery. . . ").

While claim 9 provides that the contactor makes electrical connection with the first terminal of the battery, it does not specify which component makes the connection. The Summary, however, contemplates that any combination of contact arm(s) and/or the spring can make this connection:

The flexion spring may be positioned within the battery holder so that the respective ends of the spring are in contact with the base of the battery holder and a resiliently bowed center portion is positioned for electrically contacting the first terminal of the battery when the battery is inserted into the battery holder. The electrical contact may be connected with one end of the spring for electrical connection with the first terminal of the battery.

'900 Patent col.2 1.1-8 (emphasis added).

In addition, the doctrine of claim differentiation supports the proposition that the spring is not always required to make an electrical connection. Claim 20, which is ultimately dependent on claim 9, provides that the spring has a "resilient center portion for electrically contacting the first terminal of the battery." '900 Patent col.12 1.61-64. In sum, a presumption is created whereby claim 20 specifically recites that the spring must make the electrical connection, while broader claim 9 merely provides that the spring may make the electrical connection. See Seachange Int'l, Inc., 413 F.3d at 1368-69.

In light of the foregoing, the Court interprets the term "for electrical connection" to mean "any combination of contact arm(s) and/or the spring makes the electrical connection with the first terminal of the battery."

The disputed term in the '415 patent appears in claim 1, which discloses:

1. A method for color-coded imaging of blood flow velocities in a field onto a display, comprising the steps of:

   scanning an ultrasonic beam pulsed at a pulse repetition frequency across the field to provide a Dopplershifted backscattered signal from a discrete set of range cells in the field;

   sampling the backscattered signal from the range cells along the beam;

   estimating predetermined parameters from the backscattered signal from each range cell, said parameters comprising the mean frequency, the power and the bandwidth of the backscattered signal;

   assigning, on the basis of said parameters, predetermined colors for imaging the blood flow velocities on the display, such that for low bandwidth, the mean frequency is assigned to a range of selected first colors which are predeterminately varied as the mean frequency varies, in both the positive and negative sense, from zero frequency to the pulse repetition frequency of the beam, and for increasing bandwidth said first colors are gradually replaced with a single second color until, at large bandwidths, only said single second color is assigned to the display, said single second color being selected to strongly contrast with said first colors; and

   mapping the assigned colors for both positive and negative mean frequencies onto the display, whereby the displayed image presents the full range of blood flow velocities in the field such that different flow conditions may be readily distinguished.
1. "for increasing bandwidth said first colors are gradually replaced with a single second color until, at large bandwidths, only said single second color is assigned to the display"

Plaintiffs' construction: as bandwidth increases continuously or in regular steps, said first colors are replaced continuously or in regular steps, with a single second color until, at large bandwidths, only said single second color is assigned to the display.

Defendant's construction: as bandwidth increases, the first colors (e.g., blue, red, and yellow) displayed are gradually replaced with a single second color (e.g., green), until, when bandwidth meets a minimum threshold, only the second color (e.g., green) is displayed, regardless of the mean frequency.

The parties' debate about this term boils down to whether the changeover from the first to the second color occurs at "high bandwidths" or when the bandwidth reaches a "minimum threshold." The parties do not dispute that the change occurs at "high bandwidth," but defendant argues that more specific language is required as well. The term "threshold" does not appear anywhere in the claim language or the patent specification. Rather, defendant suggests that Figures 5a and 5b of the '415 patent indicate that the invention includes the limitation that there is a "minimum threshold" above which only the second color is displayed. Plaintiffs agree that Figures 5a and 5b are instructive, but disagree that either indicates that the patent discloses a specific "minimum threshold" for the display of the second color. Because much of the parties' arguments relate to these figures, I have included them below.

In Figure 5a, areas of high bandwidth appear at the center of the circle. The frequency of blood flow is represented by the angle of the arrow. In Figure 5b, the x-axis represents increasing bandwidth. The y-axis represents frequency. Defendant argues that there is a point on both figures, which it calls a "minimum threshold," at which the bandwidth is sufficiently high so that the second color is displayed for all mean frequencies. This is true. It is possible to draw a small circle inside area 502 in Figure 5a; it is possible also to draw a vertical line at a certain bandwidth on Figure 5b. Inside this circle and to the right of the line are areas of sufficiently high bandwidth that only the second color, in this case green, is displayed. However, the fact that it is possible to draw a circle or a vertical line at some point on each chart does not suggest that a reference to this "minimum threshold" line should be imported into the claim language. The term "minimum threshold" is no more definite than the term "at high bandwidths." Therefore, I conclude that it would be improper to read this limitation into claim 1 of '415 patent.

Court's construction: as bandwidth increases continuously or in regular steps, said first colors are replaced continuously or in regular steps, with a single second color until, at large bandwidths, only said single second color is assigned to the display.

The court agrees with 01 Communique that Citrix seeks to narrowly construe the term "includes" as "stored in the locator server's dynamic directory." As previously discussed, one may not import limitations from the specifications into the claims. Furthermore, the prosecution history can be distinguished because the cited paragraphs from the June 9, 2004 Request for Continued Examination (Doc. No. 39-3) describe how the claims as had been formulated up to that point distinguish themselves from a particular prior art reference. Therefore, the court rejects Citrix's proposed construction and instead adopts that of 01 Communique.
4. "For providing a generator torque command signal for commanding maneuvers"

To understand the parties' arguments about the construction of this phrase, the phrase must be read in context:

a variable speed wind turbine controller, responsive to the sensed signals indicative of generator speed and generator electrical power output, for providing a generator torque command signal for commanding maneuvers of the generator speed according to a mathematical rule defining the relationship between generator speed and generator electrical power output which maneuvers tend to cause the wind turbine to operate substantially on the wind turbine power coefficient versus velocity ratio optimum performance curve substantially at the peak thereof;

The dispute is whether the phrase "for providing a generator torque command signal for commanding maneuvers" defines the purpose for which the turbine controller is responsive to signals indicative of generator speed and power output, as defendant suggests, or whether plaintiff is correct in asserting that the phrase defines the purpose of the controller. Under plaintiff's construction, the controller need only be responsive to these sensed signals in some fashion, not necessarily for producing torque command signals. Plaintiff contends that "responsive to the sensed signals indicative of generator speed and generator electrical power output" is a non-restrictive clause because it is set off with commas. As a general rule, plaintiff is correct that non-restrictive clauses are parenthetic and should be enclosed between commas. William Strunk Jr. and E. B. White, The Elements of Style 3 (3d ed. 1979)).

However, for the reasons just explained, the variable speed controller must calculate torque command signals using a mathematical rule defining the relationship between generator speed and generator electrical power output. It would be inconsistent with this limitation to adopt plaintiff's construction, under which a controller need not be responsive to sensed signals of generator electrical power output and generator speed in any particular manner or for any particular purpose. As defendant notes, the claim specification makes clear that the figures of generator speed and power the controller uses in defining the torque command signals are provided by the sensed signals:

The variable speed wind turbine controller, by means of a signal processor, determines what the generator air gap torque should be according to a function defining sensed power versus generator speed to obtain maximum efficiency.

'S736 Pat., col. 5, Ins. 5-10. In addition, the preferred embodiments depict a system in which the sensed signals of generator speed and power are used to calculate torque command signals. E.g., Id., Figs. 2 and 5. Plaintiff has not identified any portion of the claim specification suggesting any other purpose that the patentee may have intended or even anticipated.

Furthermore, defendant's construction is consistent with the numerous pairings of "responsive to [something]" followed by "for [doing something]" found throughout the other claims of the '736 patent. In each instance, the "for [doing something]" defines the purpose for which the relevant device is "responsive [to something]." E.g., '736 Pat., col. 9, line 68 - col. 10, lines 1-2 ("frequency converter responsive to the generator torque command signal for controlling the magnitude of power flow . . ."); col. 10, lines 6-7 ("a high pass filter, responsive to the sensed generator speed signal for providing a damping signal"); col. 10, lines 8-9 ("summing junction, responsive to the generator torque command signal and the damping signal for providing an augmented generator torque command signal"); col. 10, lines 16-18 (generator speed reference schedule, responsive to the sensed generator electrical power signal for providing a generator speed reference signal"); col. 10, lines 21-25 ("integral control, responsive to a difference signal having a magnitude indicative of the difference in magnitudes between the generator speed reference signal and the generator sensed speed signal for providing the generator torque command signal"); col. 10, lines 47-49 ("integral control, responsive to a difference signal having a magnitude indicative of the difference in magnitudes between the generator speed reference signal and the generator sensed speed signal for providing the generator torque command signal"); col. 10, lines 57-59 ("electro-hydraulic aerodynamic torque control, responsive to the aerodynamic torque command signal for changing the aerodynamic torque of the turbine rotor"); col. 11, lines 3-9 ("integral control, responsive to a difference signal . . . for providing the aerodynamic torque command signal").

As noted above, it is presumed that language is to be given consistent meaning throughout different portions of the claim. Fin Control Systems, 265 F.3d at 1318. The claim specification provides no reason to deviate from this principle here. In fact, both the specification language and drawings suggest that providing torque command signals is the only purpose for
which the controller uses sensed signals of generator speed and electrical power output. Accordingly, I conclude that the variable speed controller must be responsive to sensed signals of generator velocity and electrical power output for the purpose of providing torque command signals.

1773

3. Category for Providing Information

The parties' proposed constructions are as follows:

Plaintiff
Category for pages that contain articles, journals, publications, or other non-commercial materials.

Defendant
A category for network pages that have as a primary purpose the provision of information, for example, network pages that contain articles, journals, or publications. In the alternative, this term is indefinite.

Plaintiff's proposed construction closely mirrors the preferred embodiment set out in the specification of the '459 patent, which states that: "Web pages involved in providing information include pages that contain articles, journals, publications, or other non-commercial materials." (5:4-6.) As discussed above, the use of the word "include" in the preferred embodiment, and the example of the fictional website www.abcde.com, which had "as its purpose" the teaching of the alphabet, as providing information (8:31-32), indicate that the preferred embodiment is not the only embodiment of the "category for providing information." Plaintiff's proposed construction, therefore, improperly limits the claim to the preferred embodiment.

As also discussed above, defendant's importation of the term "primary purpose" likewise poses the problem of not aligning with the preferred embodiment that allows for network pages to be categorized as both providing information and transacting business. Thus, the court proposes a modified construction: A category for network pages that have as a purpose the provision of information, for example, network pages that contain articles, journals, or publications. This construction encompasses the preferred embodiment and allows for other embodiments of the invention, while eliminating the potentially troublesome commercial/non-commercial distinction present in the plaintiff's proposed construction.

Defendants argue that any network page provides some form of information, and that the term "category for providing information" is indefinite so to render the patent invalid. Because every network page theoretically "provides information," defendant argues that this category could include every network page every made. Patents enjoy a presumption of validity because they have gone through the prosecution process with the Patent Office, and defendants offer no expert testimony or evidence that a person with ordinary skill in the art would not be able to determine the scope of the patents claims. This argument is therefore rejected.

Therefore, the term "category for providing information" means "A category for network pages that have as a purpose the provision of information, for example, network pages that contain articles, journals, or publications."

1774

C. a plurality of first signal conditioning units coupled to the workstations for receiving electronic signals produced by the keyboard and mouse and for creating a serial data packet that includes the electronic signals. a plurality of second signal conditioning units coupled to the remote computer systems, for receiving the serial data packets transmitted on one of the plurality of second communication links switch and for supplying the data packets to a keyboard and mouse input of the remote computer, the plurality of second signal conditioning units receiving video signals produced by the remote computer systems and transmitting the video signals to the central switch on one of the plurality of second communication links.
Raritan asserts that the term "signal conditioning units" does not connote structure. Raritan asserts that it has overcome the presumption against the application of § 112, P6 that arises from the absence of "means plus function language." The term "units" in the phrase "signal conditioning units" is used with the parenthetical term "pod" thereby giving it further definition as structure. (’076 Patent at Column 2, line 20.) Counsel for Raritan acknowledges that it is appropriate to consider the term "pod" in deciding whether the word "units" connotes structure. (Tr. 164.) The adjectival phrase "signal conditioning" also gives it further definition. I conclude that there is sufficient structure so as to avoid the application of § 112, P6. To a person of ordinary skill in the art it means a stand-alone entity or box that receives a signal input and translates (i.e. conditions) the signal into an output in a different format.

6. "For storing the received programs, and for subsequently playing the video programs."

USVO proposes "establishing an order of events (storing, playing) in which playing does not commence until the storing commences." Time Warner suggests "for storing the entire program within the receiver and for playing the stored program after downloading and storage of the program is complete." The key dispute between the parties over this term is in what order the storage and playing of the video program occurs: USVO's position is that the video program can be played after storage commences but before it is complete, while Time Warner argues that the video program can only be played after storage is complete.

The claim term describes two steps: (1) the program is stored ("storing the received program"), then (2) the program is played ("subsequently playing the video programs"). This plain language compels the conclusion that the program is played after it is stored. Accordingly, the court must construe "program" and decide whether it means portions of the program or the entire program.

Time Warner argues that the claims, specification, and prosecution history consistently use "program" to mean the entire program, rather than just portions of it. See, e.g., Claim 1, col. 7, ll. 46-48 ("wherein said request interface receives requests for video programs made over the telephone network"); col. 1, ll. 14-17 ("video programs include motion pictures, entertainment programs for television"); col. 5, ll. 29-31 ("[in a preferred embodiment] data is stored onto mass storage device 78 until the entire requested program has been down loaded from the central data facility 10"). Applicants also stated in the prosecution history that "the remote unit stores the program for later playback," and that the distribution interface allows for "downloading a compressed video program for later decompression and playback." Amendment of 5/22/91, Def. Claim Const. Br., Ex. 1-A at 8-9 [Doc. # 152, pp. 9-10 of 12]. Like "subsequent" in Claim 1, "later" means that the program is decompressed and played after it is downloaded and stored. There is nothing in the claims, specification, or prosecution history that would indicate that when the word "program" is used, it means something other than the entire program. There is no distinction made between a program that is remotely requested (which the court does not think can logically mean anything other than the entire program) and the program that is downloaded or stored.

USVO argues that when the patentees were referring to an embodiment where the entire program was stored before playback began, as in the preferred embodiment and in Claim 6, they clearly stated that they were doing so. See, e.g., col. 5, ll. 29-31; Claim 6, col. 8, ll. 55-58. They also take the position that Time Warner is improperly importing a limitation from the specification into the claim language, by reading the requirement of the preferred embodiment that the program be fully stored before playing into Claim 1. However, the statements made by the applicants during prosecution clearly indicate that, in order to overcome the prior art, the limitation of "subsequent" or "later" decompression and playback was added, with no hint that the program could be only partially downloaded before said decompression and playback would occur. "Program" is used consistently throughout the specification and claims in a manner that strongly suggests it refers to the entire program. The court will define this term as follows:

"For storing the received programs, and for subsequently playing the video programs" means: "For storing the entire received program and for playing the video program after storage is complete."
2. Category for Transacting Business

The parties' proposed constructions are as follows:

**Plaintiff**

Category for (1) e-commerce pages, which provide users with the ability to conduct online purchases, sales, leases, or other financial transactions, (2) pages that may be involved in transacting business, but do not enable the user to conduct the transaction on-line, and (3) other pages that contain commercial information.

**Defendant**

A category for network pages that have as a primary purpose transacting business. In the alternative, this term is indefinite.

Plaintiff's proposed construction closely mirrors the preferred embodiment set out in the specification of the '459 patent, which states that:

Web pages involved in transacting business include e-commerce pages, which provide users with the ability to conduct online purchases, sales, leases, or other financial transactions, pages that may be involved in transacting business, but do not enable the user to conduct the transaction on-line, and other pages that contain commercial information.

(4:62-5:4). The defendant argues that the plaintiff is impermissibly attempting to turn the description of the preferred embodiment into a definition, and that the term "commercial information" is ambiguous.

As to the former claim, criteria outlined in the preferred embodiment do not ordinarily serve to limit the claims of the patent to those criteria. See Anchor Wall Sys., 340 F.3d at 1306. Yet the claim terms can be defined by what is set forth in the preferred embodiment as long as that limitation properly describes the whole invention. See Honeywell Intern., Inc. v. ITT Indus., Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006); Vitronics, 90 F.3d at 1582 ("Although words in a claim are generally given their ordinary and customary meaning, a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history.

The specification "acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication"); Irdeto Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004) ("Even when guidance is not provided in explicit definitional format, the specification may define claim terms by implication such that the meaning may be found in or ascertained by a reading of the patent documents.") (citations omitted); see also Phillips v. AWH Corp., 415 F.3d 1303, 1316 (Fed Cir. 2005) ("[T]he specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor . . . In that instance [, the inventor has dictated the correct claim scope, and the inventor's intention, as expressed in the specification, is regarded as dispositive."). Often, it will be clear upon reading the specification in the context of its purpose--which is to teach and enable those of skill in the art to make and use the invention and to provide a best mode for so doing--whether the patentee is setting out specific examples of how to practice the invention or "whether the patentee intends for the claims and the embodiments in the specification to be strictly coextensive." Phillips, 415 F.3d at 1323.

In Honeywell International, the Federal Circuit found that the preferred embodiment of a fuel filter was the only embodiment of the invention because it referred to the fuel filter as "this invention" on multiple occasions in the specification. Id. ("The public is entitled to take the patentee at his word and the word was that the invention is a fuel filter."). The preferred embodiment of "category for transacting business" in this case does not expressly define the invention by its terms. Here, the preferred embodiment states that "web pages involved in transacting business include [the
three types of pages listed by the plaintiff as its proposed construction.]

" (4:62-5:4) (emphasis added). Generally, this use of the word "include" is meant to convey a minimum rather than a maximum. See Black's Law Dictionary 831 (9th ed. 2009) ("To contain as a part of something. The participle including typically indicates a partial list."). By the preferred embodiment's own language, it does not purport to limit categories for transacting business to the list of three types of web pages offered by the plaintiff as its proposed construction.

There is further support in the specification that the use of the word "include" was meant to be illustrative rather than definitional of the term "category for transacting business." The word "include" is used similarly in the preferred embodiment of another disputed term, "category for providing information." (5:4-6; see infra.) Immediately after the purported definition of "category for transacting business," the specification goes on to state: "Web pages involved in providing information include pages that contain articles, journals, publications, or other non-commercial materials." (5:4-6) (emphasis added).

The specification later, however, provides an example of how one would categorize the fictional website www.abcede.com, which had "as its purpose" the teaching of the alphabet, as providing information. (8:31-32.) This purposeful metric for categorizing pages as providing information is lacking from the alleged definition of the term "category of providing information," indicating that the preferred embodiment is not the only embodiment of that category. Nor do other uses of the word "include" in the specification imply that what follows is exclusive. (See '459 patent 4-5.) The preferred embodiment, therefore, does not clearly define the term "category for transacting business" as exclusive to the examples listed and accordingly the court will not limit the scope of the patent claim to those examples.

The defendant's proposed construction imports the term "primary purpose," which the plaintiff argues limits the term to categories with one "primary purpose" when the specification is clear that a web page can be assigned to both the transacting business and providing information categories. (5:7-9.) Such pages, asserts plaintiff, would therefore have two "primary purposes" according to the defendant's logic. The dictionary definition of the adjective "primary" applicable here is the secondary definition, "something that stands first in rank, importance, or value." Mirriam-Webster's Collegiate Dictionary 986 (11th ed. 2003). This definition of "primary" appears to exclude the possibility of multiple "primary purposes," and would exclude the preferred embodiment of the invention which has network pages categorized as both for transacting business and for providing information.

Plaintiff further asserts that defendant's proposed construction excludes the preferred embodiments of e-commerce pages and pages that contain commercial information. Concerns regarding the first embodiment are without merit, as "transacting business" would be thought to include web pages that allow users to complete online commercial and financial transactions. The second embodiment of pages that merely "contain commercial information" might be excluded if defendant's "primary purpose" construction is adopted. While the other two preferred embodiments would be included in the "primary purpose" language proposed by the defendant, the defendant's proposal would seem to exclude pages that merely "contain" commercial information but whose "primary purpose" remained the providing non-commercial information. Therefore, the defendant's proposed construction must be rejected.

Since the plaintiff and defendant both have proposed constructions that do not perfectly align with the claims and specifications of the patent, the court construes the term as: A category for network pages that have as a purpose transacting business. At oral argument both parties indicated that, while they each preferred their own proposed construction, this construction could be satisfactory. This definition is broad enough to encompass the preferred embodiment and also takes into account the purposeful analysis that the patent specification has indicated is also appropriate. Furthermore, this construction recognizes that for the patent to function the term "category for transacting business" must both be sufficiently definite to be meaningful to network page creators seeking to categorize their network pages, and be flexible enough to allow them to categorize their network pages as they best see fit. This construction also avoids the term "commercial information" proposed by plaintiff and challenged by defendant as impermissibly indefinite.

Therefore, the term "category for transacting business" means "A category for network pages that have as a purpose transacting business."
6. for use in transferring data between a flash memory module and a user's computer n2

n2 The corresponding phrases are "For use in transferring data between a removable flash memory module and a user's computer;" "to transfer said image data between a removable flash memory module of a digital camera and a user's computer;" and "For use in transferring data between a digital camera flash memory module and a user's computer."

This phrase appears in the preamble of several claims in both patents. The parties agree that this phrase should be considered a limitation of the claims. The plaintiff, however, contends that this phrase requires no construction. To the extent it does need construction, the plaintiff proposes that the phrase means "the claimed device must be able to transfer data between a flash memory module and a user's computer." The defendants propose "the principal functionality of the claimed device is to transfer data between a flash memory module and a computer." The main dispute is whether this phrase limits the claim to a "principal functionality." The defendants cite to the prosecution history where the patentee added this phrase to distinguish prior art. Although the phrase was added during prosecution, nothing in the prosecution history states that a "principal functionality" limitation was also added. Accordingly, the court concludes that this phrase requires no construction and rejects the defendants' proposed limitations.

---

1. "form line"

This phrase appears in claims 1-6, and claim 11. See Tang Decl., Ex. A at 12:35-14:14; Ex. D at 2 (amended Claims 1, 3). Trimble contends that "form line" should be construed to mean "two or more computed terrestrial locations which when linked by a line approximation define a direction of travel across a field to provide steering guidance." Defendants, by contrast, contend that "form line" should be construed to mean "path across the area to be treated." Both parties agree that the term "form line" has no accepted meaning in the relevant art, and that the term must therefore be construed in a manner consistent with that provided for by the '383 patent itself, even as they disagree with the construction that the '383 patent purportedly dictates.

Preliminarily, the court notes that the construction of "form line" proves to be the single most important construction at issue before the court, as it underlies nearly every term that follows. For that reason, it follows that the majority of the constructions before the court will also be determined, at least in part, by virtue of the court's construction here.

To begin its analysis, the court first turns to the claims themselves. The term "form line" is first introduced in claim 1, which sets forth the general contour guidance method claimed by the patent. Claim 1 states that the claimed method consists of defining a "first form line," defining a "second form line," and then "updating Ethel second form line" to account for any deviations made while defining the "second form line." See Tang Decl., Ex. A at 12:35-49. The overall method claimed is generally described as a "form line following" method. Id. The claims subsequent to claim 1 generally either define the method further, or define the "form line following apparatus" that enables the form line following method to take place. Nearly all claims employ repeated reference to the phrase "form line," as it was initially set forth in claim 1.

Based on the court's review of the claim language, two things become apparent. First, the phrase "form line" is meant to have the same meaning in each claim, since there is no indication that the phrase is to be given a specific definition in any one claim versus another, and no indication that the phrase has been particularly defined, or referred to differently, in any specific claim. Second, the claim language does not actually shed light on the construction to be given the phrase "form line," since the language does not ever indicate what a form line is, merely stating at most how such "form lines" are to be defined. See Tang Decl., Ex. A at 12:35-40; Ex. D at 2 (amended Claims 1)(a first form line is to be defined "using two or more terrestrial locations," and a second form line is to be defined "using positioning data derived from GPS data and a swathing offset").

Accordingly, the court must turn to the specification for added insight. It is here that defendants' proposed construction
begins to make sense. For at various points, the specification generally refers to form lines as "paths" and "computed paths" that are defined by the operator and/or by application of GPS data and a swathing offset, and which the operator is to follow across an area. See, e.g., Tang Decl., Ex. A at 6:21-32 ("During spraying operations, LED 74 will be lit when sprayer rig 30 is following a computed form line path..."); 7:23-32 ("[GPS] positions (when linked together, e.g., by a straight or curved line approximation) will define the first form line -- that is, the path followed by sprayer rig 30 as it maneuvered across field 32"); 2:31-33 ("The display device may include a moving map display and/or a light bar display which allow an operator to follow a computed form line path") (emphasis added). These descriptions of a form line as a path that is followed by the vehicle across the field, or as having a computed path that the operator is to follow, support the construction that "form line" means a path across the area to be treated. For in order for there to be a path that has first been computed, and which an operator must then follow, it stands to reason that the path must first extend across a given area. Else, there is nothing for the operator to follow.

A further critical factor supports this construction. That is the fact that a central element of plaintiff's claimed method is the ability to update a second "form line" to account for deviations that occur in order to accommodate terrain features. See generally Tang Decl., claims 1, 3, 6, 11. If a form line were not construed, as defendants propose, as a path extending across an area to be treated, it is not wholly clear how a vehicle could deviate from it, such that an updated "form line" could be computed to take the deviations into account. In other words, a vehicle cannot deviate from any form line if the form line is not, in fact, first a path extending across an area to be treated, which the vehicle then fails to follow. Indeed, several references to the deviation process in the specification indicate that a form line is a path across an area to be treated, from which the operator may choose to deviate. See, e.g., Tang Decl., Ex. A at 1:61-2:2 ("A second form line is then computed using positioning data obtained while following the first form line and a swathing offset..."). The second form line is updated according to one or more deviations from its computed path.

The patent's figure drawings, and the specification's description of the figure drawings, also support this construction. Figure 3, for example, illustrates the "spraying rig operating in the open field crop environment in accordance with the present invention." See Tang Decl., Ex. A at 2:47-49. The specification's description of the drawing refers to "form lines" 52, 54, and 56. Turning to figure 3 to identify form lines 52, 54, and 56, each form line is portrayed as a line representing a path across the field that is treated by the vehicle. Figure 5 confirms this. It is not an illustrative drawing, but rather a chart depiction of the contour guidance method that is patented. It depicts the various steps that an operator undertakes when following the guidance method described in the '383 patent. It is significant, however, that in depicting the process for defining a "form line," figure 5 depicts the operator -- in steps 104, 106 and 110 -- as defining the first form line by beginning "contour following," at which point "GPS position data collection begins" as well. It is only when the GPS position data collection ends, that the operator is described as having "finished" the first form line. See Tang Decl., Ex. A at fig. 5. All subsequent "form lines" are then depicted as being computed based on the immediately preceding form line, which the operator then selects and "follows" until he "finishes." See id. (at steps 116, 118, 120, 122). The common sense interpretation of this chart is that a "form line" is not actually complete -- or defined -- until an operator has finished moving along his intended path, thereby defining the "form line" as a path across the area that the operator has treated. Lastly, figure 6, similar to figure 3, is an illustrative drawing that depicts different lines or paths across a field, which the specification states are "intended form lines." This language, too, supports construing the phrase "form line" as a path across an area to be treated.
Not only is defendants' proposed construction therefore supported by the language of the patent itself, as described above, but plaintiff's proposed construction also proves problematic. First, it is difficult to ascertain from it precisely what is meant, as the language employed is confusing and ambiguous. Second, and more importantly, however, plaintiff's construction does not find support in the patent's language. As plaintiff acknowledges, its proposed construction differs from defendants' in that it defines a "form line" as one that can be comprised of only a "segment" of the territory covered by a vehicle traveling across an area being treated. But the patent's figure drawings and specification point away from such a construction.

To illustrate this point, review of figure 3 is once again helpful. Figure 3 depicts "form line 52," which as noted previously, is one path that extends across the treated field as illustrated in the drawing. Form line 52, in turn, depicts several intervals that are numbered 200, 204, 206, 208, and 210. The specification states that these numbers represent "points" at which "GPS data is collected." Tang Decl., Ex. A at 7:18-21. According to the specification, "the GPS data collected at each point is processed along with the differential GPS information (or RTK corrections) and a series of terrestrial positions are computed. These positions (when linked together, e.g., by a straight or curved line approximation) will define the first form line..." Id. at 7:23-28. In other words, the points numbered 200, 204, 206, and 208 on figure 3 are the examples of points at which GPS data is collected to compute a "terrestrial position" for the points, all of which will be linked together to create a single "form line 52." The "form line" is therefore really comprised of numerous points that are not form lines in and of themselves, but are simply linked together to create a single form line. Under plaintiff's proposed construction, however, the "form line" in figure 3 could be defined as the distance between points 200 and 204 only; since its proposed construction essentially states that a form line may be "two or more computed terrestrial locations" that are "linked by a line approximation" that merely "define a direction of travel across a field." Yet, looking at figure 3, it is inconsistent, at best, to construe the distance between any of the lesser points as a form line, when the specification specifically states that the "form line" in, the drawing is the completed "form line 52."

In sum, and for all the reasons set forth above, the court adopts defendants' proposed construction of "form line," and construes the term "form line" as: a "path across the area to be treated."

8. "form line following information corresponding to the updated form line" (Claim 4)

This phrase appears in claim 4. See Tang Decl., Ex. A at 12:64-67. Trimble contends that phrase no. 8 should be construed to mean "steering guidance provided to the operator based upon terrestrial locations representing the direction or path of travel actually taken by the vehicle on the previous pass," while defendants urge that the-court construe the phrase to mean "the recomputed path across the area to be treated that is to be followed."

The language at issue appears in claim 4. Both parties agree that claim 4 is targeted at the display device that will actually provide "steering guidance" to the operator of the vehicle. They simply dispute the meaning of "updated form line." In essence, plaintiff contends that the updated form line information that will be conveyed via the display device corresponds to a form line that does not extend across the field, and defendants assert that by updated form line, the patent refers to a form line that does extend across the field.

Once again, this rehashes arguments as to "form line" that have been already resolved. Consistent with the court's prior resolution that "form line" means a path across the area to be treated, "updated" form line means a recomputed path across the area to be treated, and "form line following information corresponding to the updated form line" is therefore construed as: "the recomputed path across the area to be treated that is to be followed."

2. "form line having been defined" (Claim 11)

This phrase appears in claim 11. See Tang Decl., Ex. A at 14:4-14. Trimble contends that the phrase should be construed to mean "a form line for steering guidance based upon the computed terrestrial locations of the previous form line and a
distance determined by an effective width of a towed implement." Defendants contend that it should be construed to mean "path across the area to be treated that has been computed."

There is no dispute between the parties that the form line referred to in claim 11 -- i.e., the "form line having been defined" -- is based on "computed" locations. Plaintiff expressly acknowledged this, both in its reply, and when questioned at the hearing on the instant matter. Accordingly, there is no dispute that the phrase at issue should be construed to mean "path across the area to be treated that has been computed."

Furthermore, and as noted in the previous discussion of "form line," defendants are correct that the '383 patent specification refers in numerous places to form lines -- including subsequent form lines that take into account operator-controlled deviations from prior form lines -- that are "computed." See, e.g., Tang Decl., Ex. A at 8:6-10 ("the subsequent form line is computed based on the actual path traveled by sprayer rig 30 and not just the expected path computed after the first form line was completed."); 8:32-36 (only significant deviations from a computed form line guidance path (e.g., the second form line discussed above) will be used as decision points for displaying guidance…). This supports the conclusion that a form line that has been "defined" is a form line that has been "computed," based on prior positioning information and a swathing offset.

Moreover, as defendants point out, the prosecution history also supports this conclusion. During reexamination of the '383 patent, Trimble represented to the PTO that "defining" a form line mean's "computing" a form line. See Tang Decl., Ex. D at 4-5. Specifically, Trimble distinguished the claims of the '383 patent from the prior Korvel patent, with the statement that Korvel did not disclose or suggest "defining an updated second form line (that is, recomputing the previously computed form line) according to one or more deviations from the second form line…". See id. at 4 (emphasis added). With this statement, Trimble expressly acknowledged that "defining" a "form line" is equivalent to "computing" a "form line" -- as defendants urge here. As such, Trimble will not now be allowed to circumvent this prior definition. See Hemphill v. McNeil-PPC, Inc., 25 Fed. Appx. 915, 917-18 (Fed. Cir. 2001)(prosecution history can act like a dictionary and statements made during reexamination proceedings "are relevant prosecution history when interpreting claims")(unpub. disp.).

The court therefore adopts defendants' proposed construction, finding that it is most consistent with both the '383 patent's language, and the prosecution history. The phrase "form line having been defined" is therefore construed as: "path across the area to be treated that has been computed."

GO BACK

II.

A.

The first critical issue is the correct construction of the term "form set." According to the trial court's construction, "form set" includes "single-ply" form sets, Paymaster Techs., Inc. v. United States, 54 Fed. Cl. 579, 590 (2002) ("Paymaster I"). The government argues that "form set" must be interpreted to exclude "single-ply" form sets because, it says, the claim language itself recites and the specification discloses more than one "sheet" in every form set described. Paymaster responds that, while claims 1 and 5 recite a form set including three specific "sheets," the plain language of claim 10 allows a form set that includes only one such specific "sheet." Furthermore, it asserts, the written description discloses a form set having only one specific "sheet." We agree with the trial court.

We start with the claim language. Independent claim 10 recites in relevant part:

[a] form set . . . comprising . . . at least one negotiable instrument sheet . . .

'283 patent, col. 18, ll. 5-12. In contrast, claim 1 recites in relevant part:

[a] form set . . . comprising . . . an upper negotiable instrument sheet . . , a lower customer receipt sheet, an intermediate voucher sheet. . . , a first transfer medium positioned between said upper negotiable instrument sheet and said intermediate voucher sheet, and a second transfer medium positioned between said lower customer receipt sheet and said intermediate
voucher sheet. . . .

Id. at col. 16, ll. 25-37. Claim 5 uses the exact same relevant language. Id. at col. 16, l. 60 - col. 17, l. 5.

According to its plain language, claim 10 reads on a form set that includes a negotiable instrument sheet. Under conventional construction of "comprising," a form set as recited in claim 10 may include only one negotiable instrument sheet, so long as it includes another form. See Vehicular Techs. Corp. v. Titan Wheel Int'l, Inc., 212 F.3d 1377, 1383 (Fed. Cir. 2000).

Claims 1 and 5 add the limitation that their form sets must include two specific additional sheets, a lower, customer receipt sheet and an intermediate, voucher sheet. But this limitation cannot mean that the form set of claim 10 must have these same two specific additional sheets. It merely recites that the form set of these two claims will also include these two other specified sheets.

The issue, then, is whether a form set with "at least one negotiable instrument sheet" may be "single-ply." We hold that a form set as recited by all three claims and disclosed in the specification may be single-ply. A "form set" is simply a set of forms, i.e., more than one form. For example, a negotiable instrument sheet may constitute one form, a customer receipt sheet may constitute another form, and a voucher sheet may constitute another form. Together, these forms constitute a form set. Yet each form in a form set does not have to occupy a separate layer, or ply. Rather, multiple forms in a form set may be in a single ply, as perforated, detachable forms. But there must be at least two different forms to constitute a form set.

Every relevant part of the specification accords with this meaning of the term "form set." Indeed, the key to understanding the correct construction of the term "form set" is to apprehend that the summary of the invention describes two different types of form sets: (1) a set of forms with at least one negotiable instrument sheet, and (2) a set of forms with specifically an upper negotiable instrument sheet, a lower customer receipt sheet, an intermediate voucher sheet, and transfer medium sheets positioned between.

The first two paragraphs of the Summary of the Invention describe a form set as recited in claims 1 and 5, a form set with five specific sheets - including the "upper" negotiable sheet, the "lower" customer receipt sheet, the "intermediate" voucher sheet, and the two transfer medium sheets "positioned between" these sheets. '283 patent, col. 2, ll. 10-44. Because the five specific sheets are disclosed as "upper," "lower," and "intermediate," and because the transfer medium sheets are "positioned between" the forms or sheets, id. at col. 16, ll. 40, 43, col. 17, ll. 8, 11, this type of form set has to be multi-ply. This type of form set is the type later disclosed as the preferred embodiment. Id. at col. 4, ll. 15-17.

The third paragraph of the summary of the invention, however, describes a form set as recited in claim 10 - a form set only specifying a negotiable instrument sheet. Id. at col. 2, ll. 52-53. This "negotiable instrument sheet" is not described as an "upper" negotiable instrument sheet. No transfer medium sheets are "positioned between" the negotiable instrument sheet and any other sheet. The additional form in this second type of form set may be part of a single ply. This reading of all three paragraphs of the summary of the invention - and the two different types of form sets that they describe, multi-ply and single-ply - is the key to understanding the meaning of "form set."

It is true that also disclosed in the summary of the invention are form sets with the specific three sheets as described above and their interlayered transfer medium sheets. Id. at col. 2, ll. 12-17. A "multicopy form set" comprised of a "plurality of sheets" is further disclosed in detail in the written description, id. at col. 7, ll. 17-18, but only under the heading "Description of a Preferred Embodiment." It is axiomatic that claims are only rarely, if ever, construed as limited to the preferred embodiment. See, e.g., Johnson Worldwide Assocs., Inc. v. Zebco Corp., 175 F.3d 985, 992 (Fed. Cir. 1999).
user to select among different "image file formats."

After considering the claim language, patent specification, and hearing the attorneys' arguments, the Court concludes that the patents-in-suit teach the selection of different image file formats. (D.I. 52, Ex. A, B, C, D). The Court believes that two paragraphs of the common specification support its conclusion:

(1) The compressed digital frame is then formatted into either an IBM PC/Clone (such as GIFF) or Apple Macintosh such as PICT II) image file format depending on the setting selected by the operator for a user switch 17 (Fig. 6) position on the control panel 2. After formatting, the file is written into the temporary memory buffer within the disk input/output (I/O) interface circuit 13 which, under the command of the digital control unit 9, controls the high density (1.4 Mbyte storage capacity) disk drive unit 5.

(D.I. 52, Ex. D, col. 4, ln. 61-col. 5, ln. 2) (emphasis added).

(2) As shown in FIG. 7, the output of the image compression processor 12 is routed to the RAM memory 24 where the compressed image is formatted for either the PICT II or GIFF format depending on the setting of format switch 17 (FIG. 6). It should be noted that a large number of image formats for PCs exist, PICT and GIFF are the most common for the Apple and IBM PC's and therefore the preferred formats for the present invention although other formats can be easily incorporated into the design by changing the software format routines.

From the paragraphs quoted above, as well as the claim language and remaining patent specification, the Court concludes that Switch 17 allows the user to select a particular image file format, such as PICT, GIFF, or JPEG, compatible with operating systems, such as Apple and IBM, and their required memory formats. (D.I. 52, Ex. D, col. 4, ln. 61-col. 5, ln. 2, col. 11, ln. 1-10). After the image file is formatted, per the user's selection, the image file is then written onto the memory device. In sum, the Court concludes that the term "format" relates to the image signal, and not the computer hardware. An appropriate Order will be entered.

The parties dispute the meaning of the term "format." Intel argues that the term "format," as defined in the claims and specification, is a form in which data is transmitted between nodes according to its encoding, protocol, encryption, and compression. Therefore, Intel submits that one format is different from another format if it uses different encoding, protocol, encryption, or compression, or any different combination thereof. However, one format is not different from another format if they both use the same encoding, protocol, encryption, and compression, but differ only in transmission rates.

While agreeing that the asserted claims expressly limit the format to a format "defined in terms of data architecture," Broadcom argues that Intel's construction the term "format" combines additional claim limitations that appear only in the asserted claims. Specifically, Broadcom argues that the Intel's construction combines the term "format" with two separate claim elements - "wherein said formats are defined in terms of data architecture" and "wherein said data architecture is defined in terms of at least one member of a group consisting of encoding, encryption, compression, and protocol."

According to Broadcom, the term "format," standing alone, must have a broader meaning, because it cannot include limitations that are recited only in some of the claims.

The court finds that the specification defines each of the terms relating to the definition of format. The term "format" is a data transmission characteristic that is defined in terms of "data architecture" and/or the "rate of data transmission." The "rate of data transmission" is defined in the specification as "the rate at which data bits are transmitted from source node to destination node." "Data architecture" is defined in the specification "by one or more of the following data transmission characteristics: encoding, encryption, compression, and protocol."

The phrase "wherein said formats are defined in terms of data architecture" qualifies the term format, as used in claim 1, and limits it to formats that are defined in terms of "data architecture." This means that the formats referred to in claim 1 are not defined in terms of the "rate of data transmission," but are limited to being defined in terms of "data architecture."
The phrase "wherein said data architecture is defined in terms of at least one member of a group consisting of encoding, encryption, compression, and protocol," limits the "data architecture," as used in the "format" of claim 1, to a one or more members of this group of four specific types of data architecture. Each term is defined in the specification, and each term is well-known to persons of ordinary skill in the art. The court adopts each of the meanings of the four types of data architecture, as they are set forth in the specification. "Encoding" is the waveform pattern or other waveform representation of data bits used for transmission of data on the communication medium. "Encryption" is the organization and arrangement of data into a nonintelligible form for transmission. "Compression" is the representation of data in a shorter form which requires fewer bits to represent the data. "Protocol" is the convention used for data transmission which defines frame organization and content including command codes for the protocol handler of the destination node.

1784

i. "format set"

The parties dispute the meaning of the term "format set." Intel claims that a format set is the collection of individual formats for a node, represented by a string of bits, where each individual bit represents a single format. Broadcom agrees that the term "format set," as used in the phrase in claim 1, "wherein each of the said nodes has a format set comprised of one or more formats," means that every node coupled to the network must have a "format set" and that the format set is a collection of individual formats for a node that contains at least "one format." Broadcom disagrees, however, that a "format set" must be represented by a string of bits, where each individual bit represents a single format.

The claims of a patent must be read as a whole. Reviewing the claims, the court finds that a format set need not be represented by a string of bits. Claims 6 and 17, which depend, respectively from claims 1 and 15, add the limitation "wherein said format sets are represented by bit strings." The term "format set" must have the same meaning in each claim. Southwall Tech., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995) ("claim terms must be interpreted consistently"). If the stand alone term "format set" were required to be represented by a bit string, the scope of this term as used in claims 6 and 17 would be superfluous. Beachcombers, 31 F.3d at 1162. Therefore, the court finds that the term "format sets" means a collection of individual formats for a node consisting of at least one format.

1785

A.

In the main appeal, CollegeNet contends that, in granting JMOL of noninfringement of the '042 patent, the district court misconstrued the "in a format specified by the institution" limitation. The context of the term's usage is shown above in representative claim 16. The district court instructed the jury as follows:

User information provided to the institution by the servicer is available in an unlimited number of formats and is processed wholly by the third party forms servicer and not the institution. That is, the function is one of providing limitless formats for the transfer of user information from the servicer to the institution with no additional formatting or mapping performed by the institution.

This construction does not preclude formatting, mapping, or other manipulation of the user information data by the institution once it is received by the institution in a format specified by the institution.

Any reference to "unlimited number of formats" and "limitless formats" should be interpreted to mean that the third party forms servicer provides the user information to the institution in any format specified by the institution.

"In a format specified by the institution" means in any file format, and it may include any other type of format, specified by the institution.
The '042 patent does not expressly define these disputed claim terms. Thus, this court, like the district court, must derive the meaning of these disputed claim terms from their usage and context. This court seeks a term's usage in the ordinary and accustomed meaning of the words amongst artisans of ordinary skill in the relevant art at the time of invention. See Phillips v. AWH Corp., 415 F.3d 1303, 2005 U.S. App. LEXIS 13954, 2005 WL 1620331 at *5 (Fed. Cir. 2005) (en banc) (citing Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1116 (Fed. Cir. 2004)); Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001). Indeed, "the inquiry into how a person of ordinary skill in the art understands a claim term provides an objective baseline from which to begin claim interpretation." Phillips, 2005 U.S. App. LEXIS 13954, 2005 WL 1620331 *5. "Importantly, the person of ordinary skill in the art is deemed to read the claim term not only in the context of the particular claim in which the disputed term appears, but in the context of the entire patent, including the specification." Id. Thus, a patent applicant may use the words in the specification, prosecution history, or both "in a manner inconsistent with its ordinary meaning." Boehringer Ingelheim Vetmedica, Inc. v. Schering-Plough Corp., 320 F.3d 1339, 1347 (Fed. Cir. 2003) (citing Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325-26 (Fed. Cir. 2002)). In other words, a patent applicant may consistently and clearly use a term in a manner either more or less expansive than its general usage in the relevant community, and thus expand or limit the scope of the term in the context of the patent claims. See Ballard Med. Prods. v. Allegiance Healthcare Corp., 268 F.3d 1352, 1361 (Fed. Cir. 2001) (noting that an applicant may disclaim claim scope during prosecution); Middleton, Inc. v. Minn. Mining & Mfg. Co., 311 F.3d 1384, 1388 (Fed. Cir. 2002) (explaining that in order to disavow claim scope, a patent applicant must clearly and unambiguously express surrender of subject matter during prosecution). In examining the specification for proper context, however, this court will not at any time import limitations from the specification into the claims. Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1326 (Fed. Cir. 2002).

In this case, this court agrees with CollegeNet that the district court erred in construing the claim limitation "a format specified by the institution" to require an unlimited number of formats. First, the district court improperly read the term "format" to mean "any file format." The specification and claims use the word "format" in its customary sense to mean the arrangement of data for storage or display. See Phillips, 2005 U.S. App. LEXIS 13954, 2005 WL 1620331 at *9 ("'customary meaning' refers to the 'customary meaning in [the] art field'") (citing Home Diagnostics, Inc. v. LifeScan, Inc., 381 F.3d 1352, 1358 (Fed. Cir. 2004)). For example, in describing data formatting, the '042 patent states:

Not only are the individual data elements tailored to the specifications of a particular institution, the entire data set is formatted to conform to that [institution's] needs. The data formats may include 1) comma separated values, 2) tab delimited values, 3) fixed length formats, 4) name/value pairs, and 5) EDI 189. For all of these methods, of course, the data is ordered as required (e.g., Social Security number first, last name second, high school name 33rd, etc.).

'042 patent, col. 20, l. 66 to col. 21, l. 6. By listing five exemplary data formats, this passage suggests that an institution may tailor the arrangement of data to its needs within reasonable parameters, namely within one of the supported data formats. While the particular set of supported formats may indeed be broader than those specifically listed in the specification, at no point, however, does the patent require support for an "unlimited" number of formats. Id., col. 3, ll. 52-54 ("The invention is not limited, however, to the processing of any particular type of form or to the use of any particular network or database."). Thus, the district court's definition of "format" was unnecessarily narrow.

The district court also overlooked this court's precedent on the meaning of "a." "It is well settled that the term 'a' or 'an' ordinarily means 'one or' more." Tate Access Floors, Inc. v. Interface Architectural Res., Inc., 279 F.3d 1357, 1370 (Fed. Cir. 2002). The district court replaced "a" with "any." For this proposition, the trial court relied on passages from the specification, which state that the invention "allows the information submitted by the applicant to be transmitted to each institution in any data format that the institution requests so the institution is not required to convert the data to a usable format." '042 patent, col. 8, ll. 22-26 (emphasis added). The specification also states:

The completed application is transmitted to the institution with the data in any format that the institution prefers. The institution can therefore upload the data directly into its applicant or student information system database, merging the information seamlessly into their existing work flow, thereby avoiding the additional expense and errors of re-keyboarding the information. The forms engine thus has the capability of outputting application information universally across platforms.
Id. at col. 9, ll. 4-13 (emphasis added). Based on these passages, the district court reasoned that the claim language requires an unlimited number of formats because it contains no express numeric limitation. CollegeNet, Inc., v. ApplyYourself, Inc., 2003 U.S. Dist. LEXIS 25918, Nos. CV-02-484-HU, CV-02-1359-HU, slip. op. at 8 (D. Or. Sept. 3, 2003) (Claim Construction Reconsideration).

Contrary to the district court's conclusion, the claim language's use of "a" contains the limitation of one or more. In context, the specification notes that the institution may choose any format that is "requested" and "usable." See '042 patent, col. 8, ll. 22-26. n1 In other words, the '042 patent merely requires the institution to specify an acceptable format so it does not have to convert the data to another format. The patent does not require an infinite number of format choices in advance. Instead, the patent accommodates a system that allows the institutions to choose amongst a finite set of supported format choices. This choice qualifies as "a format specified by the institution" in the words of the claim.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -n1 As quoted above, the invention "allows the information submitted by the applicant to be transmitted to each institution in any data format that the institution requests so the institution is not required to convert the data to a usable format." (Emphases added.)

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - -

ApplyYourself points to the prosecution history to further advance its position that the district court correctly required an unlimited number of formats. During prosecution of the parent '278 application, co-inventor and CollegeNet CEO James Wolfston distinguished his invention over ApplyWeb I by stating "ApplyWeb I could not process the applicant information to put it into a form specified by the college." [A5905] Mr. Wolfston further explained that the ApplyWeb I program was "too inflexible to provide the customized application format and customized data processing uploads required by the participating institutions." Contrary to ApplyYourself's contentions, Mr. Wolfston's statements do not require his invention to offer an infinite selection of formats. Rather, Mr. Wolfston's statements merely distinguish his invention from an inflexible, non-customizable item of prior art that provides data in a single, vendor-determined format without any input, selection or other specification from the institution.

In sum, in its determination that "a format specified by the institution" requires an unlimited number of formats, the district court defined "format" too narrowly by limiting it to any "file format" and erroneously imported the term "any" into the claim language, ignoring the ordinary meaning of the term "a."

1786

(3) The words "type of formatting" in "receiving format identifiers identifying the type of formatting required" mean a layout or presentation of text and/or graphics on a page. 5 In ordinary English usage, "formatting" refers to the appearance of text or graphics on a page. A "type of formatting," then, is the layout or presentation of text and/or graphics on a page. The use of this construction in the '737 patent is supported by the specification and the prosecution history. The specification teaches that the format identifier directs the server to find and execute "particular function strings," '737 Patent, Col. 15, ll. 65-66, each of which "generate[s] a particular line of HTML code." '737 Patent, Col 13, ll. 3-4, 16-17. HTML code, the specification explains, consists of text and graphics along with "tags" that instruct the browser how to format the text or display the graphics such that "it is possible to generate a wide range of page layouts from a modest set of (HTML) tags." Id. at Col. 3, ll. 4-11. The prosecution history further clarifies the relationship between the format identifier and the "look" of the page. The applicants describe their claim as "an arrangement whereby two different clients requesting the same content data from the same server may receive differently formatted versions of the same content data depending upon a particular format identifier..." Decl. of Brian Rosenbloom, Ex. M, Amendment, Dec. 16, 2003, at 13. 6

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

5 Dow Jones proposes that "receiving" not read "looking up in a database" or "reading from a database," because, in the preferred embodiment, the format identifier is received from the request. As discussed above, however, the claim language, specification, and prosecution history leave open the possibility that the server could receive a format identifier from a
source other than the request, such as a database.

6 Dow Jones proposed an additional limitation: that the identifier "was included in the request for specified content data." This proposal stems from Dow's position that the format identifier must be included in the request, which has been rejected previously.

--- End Footnotes ---

The construction proposed by Dow Jones - "indexed string for formatting functions" or "indexed function string" - would define "type of formatting" by the mechanism by which a particular type of formatting is created on a web page in the preferred embodiment. As described in the specification, the format identifier directs the server to a particular set of stored functions, which, when executed, creates HTML code "on the fly." The format identifier has two purposes in the claim: it is used for "identifying the type of formatting required" and for "selecting a set of stored functions." 7 Dow Jones, however, proposes to give essentially the same construction to both "type of formatting" and "set of stored functions." Dow construes the former as "indexed function string" and the latter as "a particular indexed function string." Dow Opening Br. at 13. Under Dow's construction, those purposes would be redundant.

--- Footnotes ---

7 Dow Jones admits as much in its Markman presentation, which states that the format identifier "specifies the page format because [it] informs the web server which formatting function should be selected to generate the page on the fly." Dow Jones Markman Presentation, June 6, 2007, at 34 (emphasis added).

--- End Footnotes ---

1787

(5) The term "formatting data" in the phrase "executing said set of functions to generate viewable content comprising said selected content data and formatting data" means HTML tags, which specify the location of text and/or graphics on a page. As explained above, a "type of formatting" is a layout or presentation of text and/or graphics on a page. Within the context of the claim, the plain and ordinary meaning of "formatting data" is data used to create a type of formatting. The specification teaches that this refers specifically to HTML tags. See '737 Patent, Col. 3, ll. 10-11 ("[I]t is possible to generate a wide range of page layouts from a modest set of (HTML) tags."); Col. 3, ll. 66 - Col. 4, ll. 1 ("HTML allows sophisticated formatting structures to be added to the viewable data so as to present a substantially more appealing image to client users.").

--- Footnotes ---

9 Because there are no indications in the claim language, specification, or file history that the applicants considered a markup language other than HTML, Ablaise's proposed construction that "formatting data" means "markup language, such as HTML tags" is rejected.

--- End Footnotes ---

Furthermore, although HTML tags can be used to control both location and presentation (font, color, bold, etc.), the claim language and prosecution history teach that the claim is limited to formatting data that specifies location. The preamble to claim 1 states that a page served by the method of claim 1 includes "formatting data which specifies location of said text and/or graphics within a page." Id. at Col. 20, ll. 1-2. This claim language indicates that the claim does not cover formatting data (HTML tags) that does not specify location. The file history confirms this limitation. In an amendment filed December 16, 2004, the applicants added the same limiting language after the term "formatting data" in several other claims. In the amendment, the applicants state: "The content data, itself, comprises text and/or graphics and these are located within the page as specified by the formatting data. Independent claims 2, 14, 15, and 20 have been amended to make this even more clear." Decl. of Brian Rosenbloom, Ex. M, Amendment, Dec. 16, 2003, at 14.
1788

(1) In the phrase "identifying requests from browsing devices that define a request for specified viewable data, said request including formatting type identification data," the term "formatting type identification data" means data identifying a type of formatting. As in the '737 patent, a "type of formatting" is a layout or presentation of text and/or graphics on a page. The rest of the claim language is clear and requires no additional construction. Dow Jones proposes two limitations similar to those it proposed for the '737 patent. Dow argues that the request must include "an identifier identifying certain viewable data and an identifier identifying a certain file structure" but not a "request to retrieve and execute a file identified in the request." As with the '737 patent, those limitations are rejected.

1789

(2) In the term "maintaining a plurality of formatting types of data," the phrase "formatting types of data" means "sets of HTML tags. The plain meaning of "formatting types of data" is clear when read within the context of the claim. As in the '737 patent, formatting data refers to HTML tags, which are used to specify the location of text and/or graphics on the page. The claim states that "formatting types of data" define "corresponding predetermined formats" - in other words, a particular set of HTML tags that corresponds to a particular format.

Footnotes

10 Dow Jones further argues that "maintaining" means "storing, in a table." Because claim 1 is a method claim, rather than an apparatus claim, a construction that limits the claim to a particular structure is only appropriate if other structures were disavowed by the applicants. Dow Jones points to language in the specification and file history which indicates that formatting data, at least in the preferred embodiment, would be maintained in "string list store 1103," a table within a database. '530 Patent, Col. 15, ll. 9-12; Decl. of Brian Rosenbloom, Ex. R., Amendment, Aug 20, 1999, at 5. Although the applicants did not disclose any other possible method for maintaining this data, none of the references cited by Dow Jones indicate that the applicants "ma[de] clear the invention does not include a particular feature," SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001) or limited the scope of their claim by disclaiming a particular interpretation during prosecution. Biodex Corp. v. Loredan Biomed., Inc., 946 F.2d 850, 862 (Fed. Cir. 1991).

End Footnotes

1790

d. Claim 38

[1] A method for processing digital signals, [2] where the digital signals have first values, second values and other values, [3] where the processing reduces the amount of data utilized to represent the digital signals and [4] where the processing forms statistically coded signals such that the more frequently occurring values of digital signals are represented by shorter code lengths and the less frequently occurring values of digital signals are represented by longer code lengths, where

[5] a first code value is formed representing a set of said first values followed by said second value,

[6] a second code value is formed representing a set of said first values followed by one ore more of said other values comprising,

decoding said first code value to form a set of said first values followed by said second value,

decoding said second code value to form a set of said first values followed by one or more of said other values.

For the reasons stated above with respect to the preamble of claim 1, which is substantially similar to the first four phrases
of claim 38, the Court concludes that the first four phrases of claim 38 are limiting. Additionally, the parties dispute whether phrases [5] and [6] limit claim 38 such that it requires both encoding and decoding. The Court concludes these phrases do limit claim 38 in such a manner.

Because phrases [5] and [6] are not merely descriptions of the purpose of the claim and instead provide specific limitations and antecedents to further claim limitations, the Court concludes that these phrases are limiting. Plaintiff argues that it would be illogical to construe claim 38 such that it would require encoding and decoding in the same device. Defendants' proposed construction, however, does not require such an (arguably illogical) interpretation. Defendants argue merely that the claim requires that both steps be performed, not that the same device perform them. The plain language of the claim requires that the step of encoding is performed, not simply that the values have the characteristic of having been encoded—phrase [5] requires that "a first code value is formed" and phrase [6] requires that "a second code value is formed." Accordingly, the Court concludes that phrases [5] and [6] are limiting and, thus, that claim 38 requires both encoding and decoding.

5. "a plurality of memory cell transistors and a plurality of select transistors formed in said plurality of element regions"

This phrase appears in claims 1 and 16 of the '715 patent. Toshiba does not believe that the phrase requires construction but alternatively proposes replacing "a plurality of" and "said plurality of" with "more than one" throughout the term, changing "formed" with "are made," and changing "transistors" and "regions" to their singular forms. Jt Cl Const, Ex C at 20. Hynix argues that the phrase means "a plurality of memory cell transistors and a plurality of select transistors, each of which resides within one of the plurality of element regions." Id.

Hynix's construction requires each transistor reside "within one of the plurality of element regions." But the claim language requires only that the transistors be "formed in" these regions. Hynix appears to use "formed in" and "within" interchangeably but Toshiba correctly notes that "within" imports an additional limitation requiring a transistor to be wholly contained inside an element region, whereas a transistor might be "formed in" an element region but include components extending outside the region. Indeed, Hynix's proposed construction would impermissibly exclude the many "T-shaped floating gate" embodiments that have transistors extending laterally beyond the element regions. See '715 patent at FIGS 9G, 9H, 13B, 15A, 15B, 35, 40, 42A, 42B. Hence, Hynix's use of "within" is inappropriate because it imports a limitation supported by neither the specification nor the claim language.

Hynix also argues that each memory cell transistor or select transistor can exist only in a single element region rather than being spread over multiple regions. The language of claims 1 and 16 supports this construction. Those claims specify that "each of said plurality of memory cell transistors" is comprised of different elements stacked atop one another, the bottommost of which is "a first gate insulating film formed on a corresponding one of said plurality of first element regions." Id at 34:54-57, 37:28-31 (emphasis added). Similarly, those claims specify that "each of said plurality of select transistors" is comprised of multiple stacked elements beginning with "a third gate insulating film formed on a corresponding one of said plurality of element regions." Id at 34:67-35:2, 37:42-44 (emphasis added). Hence, while a memory cell transistor or select transistor might extend outside an element region, each transistor is formed in one, and only one, element region.

Accordingly, the court adopts a hybrid construction for this term: "a plurality of memory cell transistors and a plurality of select transistors, each transistor of which is formed in one of said plurality of element regions."

2. "formed of"

Mascon alleges the term "formed of" is indefinite. However, the court cannot conclude the term is "insolubly ambiguous," particularly as the parties have articulated several possible constructions. Pulse offers the term should be given its customary
and ordinary meaning, making construction by the court unnecessary, or, in the alternative, the term should be construed to mean "made up of the essential or basic elements of." 4 Mascon suggests "formed of" is the equivalent of "consisting of," which the court recognizes as a term of art signifying restriction and exclusion of any other components or elements. In a second recommendation, Mascon construes "formed of" to mean "including only the named elements and no others," basically synonymous with "consisting of."

--- Footnotes ---

4 This proposed construction comes from Pulse's dictionary reference, a form of extrinsic evidence.

--- End Footnotes ---

Mascon relies in part on a 1913 district court case from Illinois in which the court construed "formed of" to mean "consisting of." Hoskins Mfg. Co. v. General Electric Co., 212 F. 422, 428 (N.D. Ill. 1913), aff'd 224 F. 464 (7th Cir. 1915). However, in Hoskins, the court construed the term in light of narrowing amendments in the prosecution history which precluded a broader interpretation. Mascon also looks to In re Bertsch, 132 F.2d 1014, 1019-20, 30 C.C.P.A. 813, 1943 Dec. Comm'r Pat. 224 (CCPA 1942), which quotes Hoskins for the proposition that "composed of" and "formed of" both mean "consisting of." However, the Bertsch court also acknowledged that "the words 'composed of' may under certain circumstances be given, in patent law, a broader meaning than 'consisting of'…." Id. at 820. The case law does not foreclose a partially open construction of this term. Mascon also offered extrinsic evidence in the form of testimony by its expert, Dr. Acampora, in support of its proposed constructions. However, in light of the intrinsic evidence, the court gives the expert testimony limited weight.

Pulse emphasizes that Mascon's constructions are overly restrictive, as any alarm filter circuit "would include not only the named inductors and capacitor[s], but also a variety of complementary and/or supplementary components such as wire, solder, leads, encapsulant, PCB, etc." (Doc. No. 34 at 12.) The court agrees one skilled in the art would understand materials beyond the expressly listed core elements would be required to make a filter section function as such. Indeed, one skilled in the art would recognize this fact from a straight-forward reading of the term "formed of" in the context of the specification and claims. The intrinsic evidence supports this conclusion; the specification refers, in detail, to the intended functionality of the alarm circuit as a whole and the preamble to claim 1 in each patent defines the intended use of the alarm filter circuit. One skilled in the art would understand these other materials would be necessary to build an operative device. The court agrees that Mascon's construction is too narrow because it would rule out the use of these necessary materials.

On the other hand, the nomenclature used for each section (e.g., first-order low-pass filter section) have specific functional meanings to one skilled in the art, and would limit the components to those listed for each type of section or their equivalents. 5 Mascon alleges that "connecting an additional reactive element to those that form a particular filter can, and often does, change" the function of the filter. 6 (Doc. No. 33 at 12.) From that standpoint, then, Pulse's proposed construction may be overly expansive. A more restrictive approach is supported by the choice of transitional phrases in the claims. Claim 1 in each patent defines an alarm circuit "comprising" three filter sections. "Comprising" is an "open" signal, indicating the claim encompasses all elements listed, but may also include additional, unnamed elements. The claim language then uses the transition "formed of" to describe the particular components for each section. If the inventor intended to maintain an "open" claim form for the filter sections themselves, he could have continued using "comprising" rather than changing to a more "closed" signal.

--- Footnotes ---

5 The specifications contemplate embodiments beyond the preferred ones described in detail. For example, the '347 patent states, "it will be understood by those skilled in the art that various changes and modifications may be made, and equivalents may be substituted for elements thereof without departing from the true scope of the invention." ('347 Patent, Col. 6, ll. 56-59.)

6 The court notes inductors and capacitors are generally considered "passive" components rather than "reactive" ones, so Mascon's characterization may be somewhat imprecise. Nevertheless, the court understands adding additional components to a circuit could change its functionality.
In light of the intrinsic evidence, the ordinary and customary meaning of a claim term is, in fact, "the meaning that the term would have to a person of ordinary skill in the art at the time of the invention." Phillips, 415 F.3d at 1313. This conclusion is especially appropriate given the court's construction of the term, "connected to," below.

Accordingly, the court gives the term "formed of" its plain and ordinary meaning and finds no specific construction of this term is required.

III. Whether the Claim In the '285 Patent Is Limited to a "First Strip" Formed Only of Carbon

SPI's motion for partial summary judgment essentially states that Stowe cannot meet its burden of demonstrating literal infringement because the first sensor in the '285 Patent is limited to one composed exclusively of carbon, and SPI's E-Nip sensor has a strip composed of other material, in addition to carbon, or graphite. SPI contends that the language used in the claim and the specification should be construed to require the first strip to be formed only of carbon. SPI also contends that amendments made to the claims during the prosecution of the '285 Patent limit the strip to a carbon-only strip. Stowe responds that neither the claim, the specification, nor the prosecution history of the '285 Patent dictate a construction requiring the material of the first strip to be 100% carbon.

A. The Claims and Specification

SPI contends that the claims in the '285 Patent contain a common limitation. Both Claim 1 and Claim 6, the only independent claims in the patent, include a description of the material of the first strip as follows: "a first strip formed of a first electrically conductive material having a resistance, . . ., the first material being carbon." SPI argues that the only proper interpretation of this language is that the strip must be formed of carbon and nothing else. Stowe concedes that the claims should be construed to require the conductive material in the first strip to be carbon. However, Stowe contends that nothing in the claims or specification requires that the entire first strip be formed only of carbon.

In addition to the language in the claims themselves noted above, SPI points to language in the specification in support of its suggested construction. The specification describes the first strip as "preferably formed of a homogeneous, constant property material" and states "preferably, the strip is formed of carbon." SPI concludes that this language must mean that the strip is formed of carbon, and no other material.

Stowe responds that SPI is attempting to import the term "formed entirely of" into this claim and its specification. As Stowe points out, it did use the term "formed entirely of" in other portions of the specification which described embodiments of the invention that were not pursued with the patent office. For example, in describing an embodiment in Fig. 11 and Fig. 12 of the '285 Patent, the specification states: "The ink traces 43 and 45 are formed entirely of highly conductive material such as silver." Ex. A 22:17-18. The specification goes on to state: "According to one embodiment, the ink traces 47 and 49 may be formed entirely of force sensitive resistive material having a low saturation value relative to the anticipated nip load." Ex. A 22:37-40. Thus, the term "formed entirely of" was used in other portions of the specification, while only the term "formed of" was used in the specification for the pursued embodiment. Based on this distinction, it would be understood that there was no intent for the claim to include such a limitation.

With regard to its use of the term homogenous in the specification, Stowe asserts that it used that term to describe the conductive material alone, rather than the material of the entire strip. More importantly, however, Stowe contends that one of ordinary skill in the art would know that carbon inks, and thus carbon strips, must contain more than just carbon. First, Stowe attempts to introduce several excerpts from the book Polymer Thick Film, published in 1996 by Ken Gilleo in an attempt to help "the court understand the technology and how one of ordinary skill uses terms." The court finds, however, that these excerpts are inadmissible hearsay evidence in that Stowe has failed to present a witness to testify that a person skilled in the art would consider the text to be authoritative. See Fed. R. Evid. 803(18).

Stowe next points to the use of the term "carbon" by Constantin Trantzas, an employee of CIR Systems, Inc., the supplier of
the accused E-Nip device for SPI. Stowe notes that in certain pre-litigation documents, Trantzas, who invented certain of the components of the E-Nip system, referred to one of the strips used in the E-Nip device as the "carbon" strip and the material used on the strip as the "carbon mixture." SPI responds that Stowe is improperly attempting to refer to the alleged infringing product to define what Stowe meant in its claims. See SRI Int'l v. Matsushita Elec. Corp. of Am., 775 F.2d 1107, 1118 (Fed. Cir. 1985) (en banc). The court disagrees. The reference to "carbon" by Trantzas simply indicates how someone skilled in the art, as Trantzas presumably is, would describe such a strip made of carbon as well as other materials. Though Trantzas does refer to the material as a "carbon mixture," he also describes it as only "carbon," though the strip in the E-Nip device is composed primarily of other materials in addition to a smaller percentage of carbon. Such a reference supports Stowe's argument that a person of ordinary skill in the art would understand that the first strip described in the '285 Patent would include carbon as the key conductive material, but that it could contain other materials as well.

With regard to the claim and specification, Stowe finally contends that SPI's proposed claim construction would not cover the preferred embodiments in the '285 Patent. The Federal Circuit has stated that a "claim construction that does not encompass a disclosed embodiment is . . . rarely, if ever, correct." Medrad, Inc. v. MRI Devices Corp., 401 F.3d 1313, 1320 (Fed. Cir. 2005) (quoting Johns Hopkins Univ. v. CellPro, 152 F.3d 1342, 1355 (Fed. Cir. 1998)). Stowe asserts that carbon itself is not an ink and is not able to adhere to a plastic surface. Thus, because it must have some adhesive to stick to the strips of the invention, carbon in its pure form could not be used. In addition, carbon itself is not flexible and would break if used on the sensor alone, even if it could adhere to the plastic. Therefore, Stowe concludes that a claim construction that required a sensor made only of carbon would not cover the preferred embodiment.

SPI contends that, even if Stowe's assertions are true, the patent would be invalid for failure to disclose the best mode, that is, the use of carbon plus an adhesive. See 35 U.S.C. § 112, P1 ("The specification . . . shall set forth the best mode contemplated by the inventor of carrying out his invention."). In the '285 Patent, however, the claims appear to be identifying only the crucial conductive material and those skilled in the art would understand that an adhesive is needed to get that material, carbon, to stick to the strip. Thus, the adhesive would not necessarily be key to the invention or part of the best mode of its application, rather the key would be the use of carbon as the crucial conductive material.

B. Prosecution History

Along with the claims and the specification, a court may also properly consider the prosecution history of a patent in construing a claim. As previously described, Stowe's original patent application included a broader description of the first and second strips and failed to specify the materials of which the sensors would be composed. After the patent examiner rejected Stowe's patent claims based on the prior art, including the Goldman patent, Stowe amended its claims to specify the material for both strips. SPI contends that this amendment was made solely to distinguish Stowe's claims from the Goldman patent, which disclosed a mixed carbon material sensor that combined carbon with other materials. Though SPI acknowledges that Stowe was compelled to make an additional amendment related to the sensor width to obtain final approval, it points to the earlier amendment as well as Stowe's response in regard to the patent office's later action based on double patentability to support its contention that Stowe had narrowed its claims to include a sensor material for the first strip composed entirely of carbon.

Specifically, SPI points to the language of the amendment itself: "the first material being carbon." Ex. B at 220 (emphasis added). This language remains in the final claims of the '285 Patent. SPI also notes Stowe's attorney's statement during prosecution that "applicants submit that neither of these references can fairly suggest strips of the materials recited in amended Claim 1, i.e. that the first electrically conductive material is carbon and the second electrically conductive material is selected from the group consisting of silver and gold." Ex. B at 217 (emphasis added). Finally, SPI cites Stowe's attorney's defense to the issue of double patentability: "All of the pending claims recite, inter alia, 'a first strip formed of a first electrically conductive material . . . , the first material being carbon.'" Ex. B at 258 (emphasis added). SPI contends that, throughout the prosecution history, Stowe took pains to describe the material as carbon and nothing else, both to distinguish its claims from those in the Goldman patent and from its own claims in the previous patent. 1 Thus, SPI concludes that this history supports its proposed construction of the claims in the '285 Patent to include a first strip with a material of 100% carbon and forecloses any of Stowe's present assertions to the contrary.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

1 The court recognizes that, even if the narrowing amendments were not actually necessary to overcome the prior art,
plaintiff would nevertheless remain bound by the narrower scope. See Springs Window Fashions LP v. Novo Indus., LP, 323 F.3d 989, 995 (Fed. Cir. 2003).

Stowe first responds that SPI has incorrectly read the prosecution history. Stowe admits that it added the specific materials to its claims to distinguish them from those of the Goldman patent. Stowe contends, however, that the distinction is not between pure carbon and a carbon-based material but between two strips composed of the same material, as in Goldman, and two strips composed of different materials with different conductivity, as in the '285 Patent. In Goldman, the specification describes two thin, flexible backing sheets or substrates, each of which is provided with a suitable conductive electrode pattern. U.S. Patent 5,821,433 at 2:44-48. That conductive pattern "may be silver deposited from a silver-based ink that may be screen-printed, for example, on the substrates." U.S. Patent 5,821,433 at 2:48-51. Then,

A layer of pressure sensitive resistive material 309, 409 is deposited over each of the conductive patterns 302, 402. The pressure sensitive resistive material may be a carbon molybdenum disulfide material in a polyester binder. Other pressure sensitive resistive materials and high temperature thermoplastic binders may be used as well.

U.S. Patent 5,821,433 at 2:56-61. Thus, Stowe contends that it amended its claims to state that the first material was composed of carbon and the second of silver or gold to distinguish from Goldman which described two conductive patterns where both are composed of silver and the layer of pressure sensitive resistive material in between is composed of a carbon-based material.

Stowe also asserts that its comments to the patent office in regard to the issue of double patentability did not state that the material at issue was entirely carbon. Instead, Stowe contends that it was noting that Moore's prior patent had failed to mention any materials, whereas the current claims did include a description of the materials.

The court finds Stowe's arguments compelling. First, the attorney's statement during prosecution, "the first electrically conductive material is carbon," simply seems to indicate that the conductive material in the first strip is carbon, not necessarily that the entire strip must be made of 100% carbon. Moreover, the patent examiner stated the following in comparing the proposed claims to the Goldman patent:

Also, since layers 302, 402 may be silver deposited from a silver-based ink and layers 309, 409 may be a carbon based material, the measuring area may be silver, carbon or any suitable conductive pattern of material thus the reference still stands.

With this language, the patent examiner rejected the application. The patent examiner may have failed to see the distinction raised by Stowe between the two strips formed of the same material in the Goldman patent and the two strips in the proposed invention which were formed of different conductive materials, i.e. carbon and either silver or gold. Regardless, the court believes that this language indicates that the patent examiner also failed to see a distinction between a material described as carbon based and one described simply as carbon.

In conclusion, the court finds that, as a matter of law, it cannot hold that SPI's proposed construction of the '285 Patent is supported by the intrinsic evidence. Instead, the intrinsic evidence, as well as the extrinsic evidence of Trantzas's use of the term "carbon," supports a construction of the '285 Patent wherein the conductive material in the first sensor is carbon. The language of the claims states the following: "a first strip formed of a first electrically conductive material having a resistance . . ., the first material being carbon." The "first material" refers to the first electrically conductive material, not to the entire first strip which may also include adhesives, fillers, or other materials, so long as they are not the primary conductive material.

GO BACK

1794

Formed on said layer insulating film

This phrase does not require construction. Samsung's proposed construction--"formed on a thin layer of material that is a
poor conductor of electricity"--adds additional limitations that are not supported by the claims and may themselves require construction (i.e., "thin," and "poor conductor"). MEI argues that the phrase should be construed as "arranged on the uppermost surface of the layer insulating film." However, MEI does not explain how "arranged on the uppermost layer" is more helpful to a jury than "formed on." Accordingly, the Court does not construe the term.

D. The Dixit Patent: "Contact Plug"

As noted above, the parties ask the Court to construe two phrases in the patent. The second phrase, "forming a contact plug comprising a conductive material which substantially fills said contact holes and which is in contact with said barrier layer," also comes from Claim 1 of the Dixit patent. 732 Patent col.7 ls.54-56. The parties agree that the plug substantially fills the contact holes. Oki's Response to AMD's Opening Markman Brief at 9; AMD's Markman Reply Brief at 6. The parties further agree that the plug is made of a conductive material. Oki's Response to AMD's Opening Markman Brief at 9; AMD's Markman Reply Brief at 6.

The Court must resolve one issue. The parties disagree over whether AMD disclaimed a plug that forms one, continuous structure with a metal interconnect that lies over the hole. Thus, the Court must decide whether an ambiguous reference to a prior art patent during the prosecution history disclaims subject matter that unambiguously falls within the scope of the claims and specification. It does not.

1. The Claims of the Dixit Patent as They Relate to the "Contact Plug"

The doctrine of claim differentiation indicates that Claim 1 contemplates a plug that forms a continuous unit with the interconnect that lies above it. The plain language of Claim 1 itself does not require the plug to be separate from the interconnect above. Claim 1 merely requires that the plug (1) substantially fill a contact hole and (2) contact the barrier layer that lies directly beneath it. 732 Patent col.7 ls.55-56. Claim 11 of the Dixit patent ultimately depends from Claim 1. Id. at col.8 ls.14,18. In Claim 11, the "conductive material [that formed the plug of Claim 1] is etched back to expose [the] barrier layer on [the] insulating layer but leaving [the] conductive layer substantially filling [the] contact hole, thereby preserving [the] contact plug." Id. at ls. 19-22. Claim 11 then goes on to recite laying down the interconnect directly above the contact plug. Id. at ls.23-29. This claim language shows that within the scope of Claim 1 lies a plug that forms one continuous piece with the interconnect above. The process of Claim 11 then etches back the portion of the plug that sticks out above the top of the contact hole. Then, the interconnect is laid down on top of the etched back plug. Thus, the presence of the limitation in dependent Claim 11 that the plug be formed separately from the metal interconnected over the hole implies that this limitation is not present in the Claim 1.

Claim 13, which also ultimately depends from Claim 1, expressly describes a plug that forms one continuous unit with the interconnect above. Id. at ls. 14, 33-24. Claim 13 recites a process in which the

conductive material [that forms the plug] and [the] underlying barrier layer and adhesion and contacting layer are patterned and etched to expose portions of [the] insulating layer, leaving defined patterns of [the] conductive material and [the] barrier layer and [the] adhesion and contacting layer forming interconnect regions, with [the] interconnect regions at least partially overlying [the] contact holes.

Id. at col.8 ls.33-41. Claim 13 envisions a process in which a continuous plug and interconnect (and the barrier and adhesion and contacting layers below it) are etched back to expose part of the insulating layer. However, the etching stops before the entire portion of the plug that juts out of the top of the contact hole is etched away. This leaves a plug that forms one continuous unit with the interconnect above. Because Claim 13 depends from Claim 1, it is presumed to fall within the scope of Claim 1. Thus, Claim 1 includes a plug that may be formed continuously with the metal interconnect over the hole.

2. The Specification of the Dixit Patent as It Relates to the "Contact Plug"

The specification of the Dixit patent also describes plugs that extend outside of the contact holes to form part of the overlying interconnect. In fact, the very first figure in the patent depicts such a plug. Id. at fig.1A. Describing this picture,
the specification indicates that "[s]ince the resistivity of tungsten is low enough that it could be used as an interconnect, one could pattern the as-deposited tungsten layer . . . to form the interconnect." Id. at col.5 ls.53-56. Other parts of the specification also envision a plug that forms one piece with the interconnect. Id. at fig.2; col.2 ls.57-59. Thus, the claims and the specification unambiguously include within their scope a plug that forms one piece with the interconnect.

3. The Prosecution History of the Dixit Patent as It Relates to the "Contact Plug"

Oki attempts to squeeze a disclaimer of claim scope from the prosecution history. This attempt fails because the alleged avowal of the claim scope during prosecution is too ambiguous to amount to a disclaimer. During the prosecution of the Dixit patent, the Examiner described the Mori patent as "relevant prior art." Oki's Response to AMD's Opening Markman Brief, Ex. 6 ("References Cited by Examiner") at 4. The Examiner did not reject the Dixit patent over the Mori patent. Instead, the Examiner explained that the Mori reference was relevant because "it shows a first Ti layer then a barrier layer deposited before connecting with aluminum." Id. The Examiner then went on to state that "there is no plug" in the Mori patent. Id. In response, Dixit stated that "[t]he Examiner correctly notes that there is no plug present." Based on this exchange, Oki argues that the plug in the Dixit patent cannot form one piece with the metal interconnect above. Oki asks for too much. Nothing in the text of this exchange indicates that the Examiner or the patentee believed that it was distinguishing the Dixit patent over the Mori patent based on the lack of a unitary plug-interconnect structure in the Dixit patent.

Because the prosecution history admits multiple interpretations of what the patentee intended the claim language to mean, the prosecution history does not limit the scope of the claims. The prosecution history does not reveal why the patentee and the Examiner thought that Mori did not contain a plug. If fact, the prosecution history does not even indicate whether the patentee and the Examiner agreed on the reason the Mori patent did not contain a plug. Oki submits expert testimony claiming that the reason there was no plug is that the Mori reference depicts a one-piece metal interconnect and plug (for lack of a better word) n1. Oki's Response to AMD's Opening Markman Brief, Ex. 9 ("Fonash Decl.") at P 16. AMD submits expert testimony that supports its argument that the contact holes in the Mori patent were too wide and shallow to have been considered plugged by one skilled in the art n2. See AMD's Markman Reply Brief at 7 (citing AMD's Opening Markman Brief, Ex. 4 ("Fonash Deposition") at 87-88). Both interpretations of the prosecution history are plausible. Neither of them appear in the prosecution history itself. The Court will not knit a prosecution history disclaimer from the yarn provided by experts.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n1 In rebuttal, AMD submits expert testimony claiming that a plug can form one piece with the overlying interconnect. AMD's Opening Markman Brief, Ex. 3 ("Neikirk Decl.").

n2 In rebuttal, Oki points to expert testimony suggesting that AMD's expert could not tell how wide and shallow the contact hole in Mori was. Oki's Response to AMD's Opening Markman Brief at 11 (citing Ex. 10 ("Neikirk Deposition") at 114).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

4. Construction of Disputed Terms in the Dixit Patent

Because the prosecution history does not reveal an unambiguous disclaimer of the scope of the claims, the Court construes the phrase "forming a contact plug comprising a conductive material which substantially fills said contact holes and which is in contact with said barrier layer" of Claim 1 of the Dixit patent as follows: The hole is plugged and thereby substantially filled with a conductive material. This plug is in contact with the barrier layer.

1796

We agree with the district court's claim construction. Claim 1 of the '674 patent recites a process sequence requiring formation of the insulation layer over the first gate electrodes prior to implantation of the barrier regions. The relevant part of the claim language states:

[3] forming a first insulation layer over said plurality of first gate electrodes;
forming implanted barrier regions in said semiconductor substrate in the intervals between said plurality of spaced-apart first gate electrodes, the edges of said implanted barrier regions being aligned with the vertical edges of the insulation layer on the respective first gate electrodes;

(Emphasis added.) By the literal language of the claim, the edges of the implantation barrier regions are aligned with the edges of the insulation layer; hence, the insulation layer must already be in place in order to align the barrier regions with it during ion implantation. The specification supports this construction. The specification teaches that the "ion-implanted barrier regions . . . are vertically aligned with the respective outer edges of the thermally-grown thin oxide layer." The reference to the thermally-grown oxide layer is the insulation layer. Nowhere does the specification suggest implanting the barrier regions prior to growing the insulation layer.

The prosecution history also supports this interpretation. During prosecution, the patent applicant limited his claim to the sequence of steps enumerated:

The Examiner has rejected claims 17-24 and 26 under 35 U.S.C. § 112 as vague and indefinite. In particular, the Examiner points out that in the original claim the implanted regions are not, in fact, aligned with the first gate electrode but are aligned with the oxide surface covering the first gate electrodes. The cancellation of claim 18 and the addition of a new step to claim 17 as well as additional language in claim 17 results in the correct recitation that the implanted barriers are aligned with the vertical edges of the first insulation layer over the respective first gate electrodes.

This language clarifies what the applicant saw as his invention, namely, that the ion implanted regions are aligned with the oxide covering of the gate, not the gate itself, thereby limiting the claim to insulated gate masking - the performance of step three prior to step four. In response to a rejection under 35 U.S.C. § 102 that the claims were unpatentable over Walden, U.S. Patent No. 3,852,799, in view of Boleky, U.S. Patent No. 3,745,647, the applicant also argued that "the present invention is directed to a process sequence . . . . This sequence of steps goes far beyond the teaching of Boleky and, therefore, is not rendered obvious by it." (Emphasis added.) This language in the prosecution history supports the construction of claim 1 as limited to performance of the sequence of process steps in chronological order.

Although not every process claim is limited to the performance of its steps in the order written, the language of the claim, the specification and the prosecution history support a limiting construction in this case. Accordingly the claim was properly construed as only covering a fabrication process where insulation is formed prior to ion implantation. It is not disputed that the Sony process implants barrier regions prior to forming insulation, and we therefore affirm the district court's grant of summary judgment of no literal infringement of the '674 patent.
hydrogen into a semiconductor crystal after it is grown, but merely complied with the restriction requirement by cancelling all the product claims, which would have covered the semiconductor whether the hydrogen was introduced into the substrate during its growth or thereafter. By not refiling these claims, plaintiff effectively abandoned such coverage.

In her motion for reconsideration, plaintiff ignores the Court's primary reliance on the ordinary meaning of the words and attacks only the implications of the requirement for restriction and plaintiff's response thereto. Plaintiff argues that because the Examiner's statement referred to the introduction of hydrogen, "it was directed only to the first embodiment concerning the introduction of atomic hydrogen, not the embodiment directed to the introduction of atomic hydrogen and another dopant." (Pl. Mem. at 3.) The Court cannot agree with this strained misreading of the Examiner's statement. The Examiner did not distinguish between method claims calling for the introduction of atomic hydrogen alone and method claims calling for the introduction of atomic hydrogen together with another dopant. Instead he required restriction of the application to either the product claims or the method claims, meaning all of the method claims, including those, such as patent claims 1-9 and 22, calling merely for the introduction of atomic hydrogen and those, such as patent claims 10-21, calling for the introduction of atomic hydrogen together with another dopant. His statement referred only to the introduction of hydrogen for the obvious reason that the introduction of hydrogen was common to all of the method claims.

Plaintiff also argues (Pl. Mem. at 4-5) that because the Examiner rejected claim 20 over the Fan reference, which discloses "growing the ZnSe layer in an environment that includes hydrogen," the Examiner must have understood claim 20 to cover incorporation of hydrogen during growth of the crystal. However the rejection was based alternatively on either anticipation (35 U.S.C. § 102) or obviousness (35 U.S.C. § 103). It therefore carried no implication that the Examiner understood claim 20 to cover incorporation of hydrogen during crystal growth.

Plaintiff further argues (Pl. Mem. at 6) that the "plain meaning" of the verb "to form" is to "make or produce." That argument would have force if we were construing the word "forming" and not the phrase "forming . . . from." Plaintiff's studied disregard of the important word "from" is unpersuasive, to say the least.

There is other intrinsic evidence, not previously discussed, further reinforcing the Court's construction of the claim term in question. Claim 10 itself calls for "selectively doping the semiconductor substrate" (emphasis added). The specification of the '499 patent (at 3:48-51 and 4:33-36) teaches that such selective doping may be achieved by shielding from the hydrogen the side of the substrate that has good conductivity so that there will be "no or minimal diffusion of hydrogen into that side." Obviously such shielding can be accomplished only on a pre-existing solid crystal and not during growth of the crystal from a melt.

In sum, plaintiff has presented no valid reason for the Court to change its construction of this term. Alternatively, plaintiff seeks clarification of that construction. Although plaintiff's explanation of the need for clarification would itself benefit from clarification, plaintiff appears to argue that although the claim term in question has been construed to require doping of a pre-existing substrate, that construction "still covers growing simultaneously with doping" because the low resistivity semiconductor called for in the preamble of claim 10 is not formed until the hydrogen is removed. If that is what plaintiff is trying to say, it is a hopeless non sequitur. The fact that the semiconductor's resistivity remains high until removal of the hydrogen clearly does not mean that the term "forming . . . from . . . a . . . substrate" in the preamble must be construed to cover "forming" during growth of the substrate. The preamble's recited objective of "forming a low resistivity semiconductor from a wide band-gap semiconductor substrate" can obviously be achieved by doping a pre-existing substrate with atomic hydrogen and another dopant, for example by the joint diffusion method, as taught in the specification of the '499 patent (at 5:8-21), and later removing an effective amount of the hydrogen (as taught at 5:45 to 6:04). The range of temperatures recommended for the removal step is 100°C to 500°C. As plaintiff herself points out (Pl. Suppl. Mem. at 2-3), these temperatures are far below the melting point of the substrate material, making it clear that the removal step which completes the claimed process is not performed during growth of the substrate from a melt.

There is no apparent reason for clarification of the Court's construction of this term. It is difficult to imagine a clearer way to say that the claim term requires a pre-existing substrate and that it does not cover doping during growth of the substrate.

**Plaintiff's motion for reconsideration is denied insofar as it relates to this construction.**
1. Forming a Monochromatic Image from a Digital Representation of a Color Image

The phrase "forming a monochromatic image from a digital representation of a color image" means converting, or transforming, a digital representation of a color image into a monochromatic image as described by the steps of the method. 

5. Forming a raster image of each flood map

This limitation is found in claim 5 of the 615 patent. The plaintiff contends that it means "scanning a paper flood map." The defendants contend that the term means "creating a raster map image, defined by X, Y locations, from a paper flood map containing flood zone information." The court rejects both parties' constructions. The patentee knew how to use the term "scanning" and did so in the specification. As such, the court rejects the plaintiffs' limiting construction. The court construes the term to mean "creating a raster image of each flood map.

D. The Dixit Patent: "Adhesion and Contacting Layer"

The parties ask the Court to construe two phrases in the patent. The first phrase, "forming an adhesion and contacting layer of titanium at least in said holes, including along said walls, in contact with the underlying doped region," comes from Claim 1 of the Dixit patent. Joint Statement at 2. Based upon one of the advantages listed in the patent specification, Oki argues that the "adhesion and contacting layer" must cover the "entire insulating wall and the entire bottom of the contact hole without gaps." Oki's Response to AMD's Opening Markman Brief at 14. Oki would also have the Court impose the limitation that the layer be composed of pure elemental Titanium. Id. The Court must resolve two issues: (1) Should the Court construe an advantage the Dixit patent recites as a limitation on the scope of the claim? (2) Does the Dixit patent forbid chemical reactions between the Titanium and the contact hole after the Titanium has been deposited in the holes. The answers to both questions are no.

1. The Claims of the Dixit Patent as They Relate to the "Adhesion and Contacting Layer"

The claims provide no support for either of the limitations Oki wishes to inject into the definition. Claim 1 describes a step-by-step process for manufacturing "contacts in an integrated semiconductor circuit." 732 Patent col.7 1.35. First, doped regions are provided in a semiconductor substrate. Id. at ls.37-38. Second, an insulating layer is laid down over the substrate. Id. at ls.39-40. Third, holes are made in the insulating layer above the doped regions. Id. at ls.41-44. Claim 1 refers to these holes as "contact holes." Id. at 1.41. Fourth, "an adhesion and contacting layer of titanium [is formed] at least in said holes, including along said walls, in contact with the underlying doped region." Id. at ls.45-47. The "adhesion and contacting layer [must be] formed to a thickness insufficient to fill [the] contact holes." Id. at ls.45-47. Fifth, a "barrier layer" is laid down on top of the "adhesion and contacting layer." Id. at ls.50-51. Like the "adhesion and contacting layer," the "barrier layer" cannot be so thick that it fills the hole. Id. at ls.51-52. Finally, a plug is formed in the contact holes. Id. at ls.54-55.

Nothing in the claims requires the adhesion and contacting layer to cover the entire insulating wall and the entire bottom of the contact hole without gaps. In fact, the claim language suggests otherwise. The adhesion and contacting layer only needs to "contact . . . the underlying doped region." Id. at ls.47. The layer can contact the doped regions without covering it entirely. While slightly more ambiguous, the claim language "along said walls" does not necessarily require that the adhesion and contacting layer cover every exposed surface of the walls.

The claims are silent on what happens to the "titanium layer" after it has been formed in the contact holes. Of course, the claims require that the layer initially be formed of Titanium. What may happen after that only becomes clear upon reading the specification.
2. The Specification of the Dixit Patent as It Relates to the "Adhesion and Contacting Layer"

The fact that the Dixit patent asserts that the invention achieves several objectives does not require that Claim 1 be construed as limited to a process that is capable of achieving all of those objectives. The specification lists at least three advantages of a specific embodiment of the invention. The first is that while the material that forms the plug is being deposited into the contact holes, the chemicals "responsible for encroachment and worm hole generation never come into contact with the underlying silicon due to the presence of the adhesion and contacting layer and the barrier layer. Id. at col.5 ls.34-36. Another advantage of the invention is that the plug can be doped with an opposite polarity to the doped regions in the substrate and the barrier layer will prevent the plug and doped regions from interacting. Id. at col.5 ls.39-45. Another advantage is that the barrier layer, since it contacts the interconnect layer, can conduct current if either the plug or the interconnect fails. Id. at col.5 ls.47-52. Oki wishes to convert the first advantage into a claim limitation. According to Oki, the first claim limitation implies that the adhesion and contacting layer can never have any gaps that allow the chemicals responsible for encroachment and wormholes to contact the underlying silicon.

This argument is wrong for two reasons. First, the fact that the Dixit patent asserts preventing these harms as one of several objectives does not require that Claim 1 be construed as limited to a process that is always capable of preventing those harms. Second, even if the Court were to convert the advantage into a claim limitation contrary to Federal Circuit law, the advantage only requires that the combination of the barrier layer and the adhesion and contacting layer prevent the undesired chemical reactions, not that the adhesion and contacting layer do so alone.

The specification also contradicts Oki's suggestion that the layer of Titanium must never react with chemicals in the substrate to form other compounds. The specification refers to a combination of a Titanium (Ti) adhesion and contacting layer and a Titanium Nitride (TiN) barrier layer as "Ti/TiN." Id. at col.6 ls.31-33. The specification then describes the one way to lay down this "titanium/titanium nitride bilayer." Id. at ls.58-59. After describing the process, the specification notes "that in the Ti/TiN process, one substantially obtains TiSi [sub] x contact silicidation where titanium contacts the junction." Id. at ls.58-59. Thus, the specification clearly states that as the Titanium adhesion and contacting layer is formed, the chemical reaction silicidation occurs resulting in the product TiSi [sub] x. The specification also states that if the Titanium adhesion and contacting layer is too thick, it "may consume unacceptable amounts of silicon from the junctions due to titanium silicide formation." Id. at col.4 ls.32-33. Contrary to Oki's argument, this suggests that silicidation always occurs and that its by product reaches unacceptable levels in certain circumstances.

3. Construction of Disputed Terms in the Dixit Patent

Here, the language of the claims and the specification is dispositive. The Court construes the phrase "forming an adhesion and contacting layer of titanium at least in said holes, including along said walls, in contact with the underlying doped region" of Claim 1 to require that Titanium be deposited in the contact holes so as to form an adhesion and contacting layer. This layer runs along the walls of the holes and contacts the underlying doped regions.

G. "controlling said forms"

Plaintiff argues that construction of the term "controlling said forms" can be readily ascertained from the specification. The Court agrees, in part, if the term is considered in the context of the entire claim. Although "controlling said forms" is utilized in a description of the subscriber's "PC type computer electronically connected to said database server," the forms referred to are plainly those "billing and data entry forms" "required" by Plaintiff's "integrated internet billing, data processing, and communication system," or, as the specification describes, "a framework for data entry." In that regard, the Court agrees with Plaintiff's construction and notes that the specification uses this precise phrase in describing how the forms are utilized.

n7 "thus, the forms transferred to each subscribers PC screen provide a framework for data entry of essential data such as the person or company being billed, where the bill is to be sent and charges for services rendered." ('229 patent, col. 3, ll.
"Controlling" the forms is not readily ascertainable from the specifications, however. Plaintiff urges a construction of: "managing" a framework for data entry. (Dkt. 86 at Ex. 1, p. 1). In that regard, Plaintiff relies on the Microsoft Press Computer User's Dictionary 83 (1998) definition of "control." Defendants' suggested construction uses the phrase "develop and customize." n8

n8 Defendants argue that the entire phrase "a PC type computer electronically connected to said database server for controlling said forms as required and responding to queries entered by each browser-based subscriber" should be construed as "[a] PC type computer, as mutually defined by the parties, that: (1) is electronically connected to the database server; (2) is used to develop and customize forms; and (3) submits information requested by a browser-based subscriber in response to a specific set of instructions entered by the subscriber." (Dkt. 86 at Ex. 2, p. 3)(emphasis added). Again, the court disagrees that it is necessary to construe the entire phrase as Defendants urge.

The plain language of the claim provides that the purpose of the PC type computer electronically connected to the database server is twofold, the first being "controlling said forms as required." The referenced "forms" are the billing and data entry forms described in paragraph 3 of Claim 1. The second purpose, responding to queries, is discussed below.

The specification provides that "once into the particular browser-based subscriber area 80 within the system 71, each browser-based subscriber 72 will have access to one of several customized forms that they will complete electronically at their work station and transfer to the database server 90. (emphasis added). Further, the specification expressly provides that "Form development and customization will be done within the system at internal work stations 106 by employees of the system." (Id., col. 5, ll. 12-18)(emphasis added). This particular section references form "development and customization" at 106 in Figure 3, the Billingnetwork PC described in the plain language of Claim 1.

The specification further provides that, "input and query forms are developed within the system 11 by billing network PC work stations 38 which are connected at hub 36, all forms and information input being subject to business rules and logic at 34 before entered into the database server 32." (Id., col 4, ll. 13-18)(emphasis added). Based on these references, the Court finds that Defendants' proposed construction of "development and customization" more accurately defines the term "controlling", as opposed to "managing." Accordingly, the Court finds that a person skilled in the art would understand the term "controlling said forms" to mean "developing and customizing frameworks for data entry" and construes it accordingly.

The Court instead applies a plain language construction. Accordingly, "to the extent data required to render said at least one spreadsheet has not been previously stored by said cache, said cache formulates a single query for transmission from said client across said network to said server" means "when data needed to generate the spreadsheet is not stored in the cache, combining requests for data into one package before sending it to the server."
1803

11. Forward channel protocol; high speed downstream channel protocol

The term "forward channel protocol" is found in claims 35, 36, 37 (by virtue of its dependence on claim 35), and 38 (by virtue of its dependence on claim 36) of the '774 patent. The term "high speed downstream channel protocol" is found in claims 39 and 52 of the '121 patent and claim 119 of the '845 patent. The plaintiff's proposed construction of each of the above terms is "any set of rules for downstream transmission of high speed data which includes standard upper layer protocols." The defendants' counter-construction is "set of rules for transmission of high speed data addressed to a remote link adapter for routing to data terminal equipment in contrast to using the media access layer." The court has considered the parties' arguments and defines the phrase to mean "a set of rules for transmission of high speed data addressed to a remote link adapter."

1804

1. "Fourier transform plane"

The parties appear to agree that the term "Fourier transform plane"--itself a term of art--has a plain and ordinary meaning: The mathematically calculable grouping of points generally corresponding to or substantially near the pupil plane of a projection optical system. The patent discusses a Fourier transform plane in both spatial and functional ways, noting both where such a plane might lie and what purpose such a plane may serve in the photolithographic process. Id.

As Nikon correctly suggests, of course, the relevant specifications discuss more than the Fourier transform plane when delineating the construction of the optical system. "Optical paths," the specifications teach, are placed "substantially equidistant from the optical axis of the projection optical system at or in the vicinity of the Fourier transform plane," see '041 Patent at 3:42-46 (emphasis added); see also id. at 4:45-48 ("... equal distance from the optical axis of the projection optical system at or in the vicinity of the Fourier transform plane"), and "a spatial filter" is "arranged at the Fourier transform plane or the illumination optical system or in the vicinity of the exit end of the integrator element." Id. at 11:3-11 (emphasis added). With these lessons in mind, the court cannot doubt that the specification language contemplates both a Fourier transform plane and a plane conjugate to the pupil plane, adding that planes optically conjugate to particular Fourier transform planes operate analogously to the Fourier transform plane in the photolithographic process. Were the court required to assess the operation of the Fourier transform plane and all of its functional equivalents, then, Nikon would be correct that any definition of the "Fourier transform plane" term should embrace the appendix "or a plane conjugate to the pupil plane."

But it is not for the court to evaluate the photolithographic function of the Fourier transform plane and all of its operational equivalents. Rather, the court's task is to define "Fourier transform plane" as a distinct and independent claim term. 16 See SRI Int'l v. Matsushita Elec. Corp., 775 F.2d 1107, 1121 (Fed. Cir. 1985) (en banc); see also DeMarini Sports, Inc. v. Worth, Inc., 239 F.3d 1314, 1314 (Fed. Cir. 2001). "Fourier transform plane," as noted, has long been understood to denote a mathematically calculable plane generally corresponding to or substantially near the pupil plane of a projection optical system. 17 Nothing in the specification contravenes or expands this plain definition of "Fourier transform plane," see '041 Patent at 14:25-36; 15:23-30, and nothing in the intrinsic record suggests that, as a discrete phrase, "Fourier transform plane" includes distinct planes, whether optically conjugate to the pupil plane or not. Bounded by the scope of the parties' dispute, the court thus construes "Fourier transform plane" to mean "a mathematically calculable plane generally corresponding to or substantially near the pupil plane of a projection optical system." That the plane is so calculable does not require that the finder of fact perform the complex calculation, nor does it mean that such a plane is not measurable optically; it only attaches to the term the standard, widely-accepted definition of "Fourier transform plane."

16 Claim 2 reads in full:
A method according to claim 1, wherein: said optical path is spaced from the optical axis of said projection optical system on the Fourier transform plane in said projection optical system with respect to said pattern.

Id. at 18:27-31.

17 This construction applies to the use of "Fourier transform plane" in claims 3, 4, 5, 7, 9, 12, and 15 as well.

--- End Footnotes ---

Frame means "a spatially complete image with respect to how it is displayed on the display device and an incomplete fractional image of the image to be displayed with respect to the image seen by the viewer."

(3) frame, time frame, slot, time slot, isochronous slot, and non-isochronous slot

These terms relate to aspects of the time-division multiplexed bus. With the exception of National, the parties agree that "frames" are composed of "slots," but disagree as to whether a "slot" is fixed, predetermined, and equal. National asserts that construction is not necessary for these terms. N-Data further proposes the same definition for "frame" and "time frame," as well as "slots" and "time slot." N-Data argues that the patents expressly teach that various frame structures or templates may be used to practice the invention. See N-Data's Brief at 12 (citing '261 Patent, col. 9, l. 56-col. 10, l. 1). The '261 patent explains as follows:

The described frame structure . . . provides data rates for the isochronous and non-isochronous data. . . . Other types of frame structures could be used in connection with other isochronous and/or non-isochronous data sources and sinks such as other types of packet-based systems, . . . in which case a different frame structure or template can be used to provide an allocation of bandwidth suited for the particular purpose. '261 Patent, col. 9, l. 56-col. 10, l. 1 (emphasis added).

In support of its limitations, Dell cites to a different portion of the specification, in which the patent explains the necessity of "frames" comprised of fixed, predetermined, and equal "slots."

Since only predetermined positions of the time slots in each time frame are used for each of the various types of data, it is possible to separate the packet-sourced data from the isochronous-sourced data even though the form of the two types of data, as they travel across the physical medium, appears identical. Id. at col. 4, ll. 4-9 (emphasis added).

Dell contends that in order for a time-division multiplexed system to separate isochronous data from non-isochronous data and utilize its advantageous property of separation based on timing information, the slots of the repeating frames must be fixed, predetermined, and equal. If such is not the case, the system would be required to examine the contents of the data stream, negating any advantages of a time-division multiplexed system over other systems.

The court agrees with Dell. While N-Data's citation seems to support its construction, its reading does not support the purpose of the invention as a whole--the claim language must be read in light of the patent as a whole. Dell's cited specification reference does not imply that a frame structure or template must be flexible, but merely that there can be variable frame structures or templates according to "the particular purpose," so long as each is predetermined, fixed, and equal according to "the particular purpose." Additionally, intrinsic evidence supports giving each term varying constructions. See '261 Patent, col. 2, ll. 44-55; col. 7, ll. 52-61; col. 8, l. 64-col. 9, l. 18; col. 15, l. 66-col. 16 l. 2; Table I, Figs. 10A-10B, 11.

As such, the court defines "frame" as "format for data transmission."
The court defines "time frame" as "fixed period of time for receiving a framed signal."

The court defines "slots" as "predetermined equal length subdivisions of a frame."

The court defines "time slot" as "fixed period of time for receiving a slot signal."

The court defines "isochronous slot" as "predetermined equal length subdivision of a frame containing isochronous data."

The court defines "non-isochronous slot" as "predetermined equal length subdivision of a frame containing non-isochronous data."

The last limitation from claim 31 construed by the Master and challenged by Datapoint is the phrase "achieving a substantially different form of data frame communication over the medium between [nodes]." 2 Initially, the Special Master found that, within the phrase itself: (1) "medium" refers to the compilation of links and hubs which together form the assembly of pathways connecting all of the nodes; (2) "data frame" or "frames containing data" refers to frames formulated at or above the physical layer including both a source and destination address and comprising data communication between the nodes and not other physical layer signals that may exist on the network; and (3) "node" means a device, including an interface to receive and send signals to the network, connected to the network, which serves as a source or destination for frame communication and which includes a unique network address for this purpose. In light of these definitions, the Master concluded that "achieving a substantially different form of data frame communication over the medium between [nodes]" requires that the two different forms of data frame communication occur over the same overall assembly of links comprising the medium interconnecting all of the nodes; it does not merely mean that different modes of communication occur over separate or distinct links, zones, or sections of the system.

2 There appears to us no distinction between the terms "data frame," "frames of data," and "frames containing data." We do not understand the parties to disagree significantly with this assessment.

Datapoint disagrees with the Special Master's construction in two ways. First, it disputes the Master's conclusion that the communication must occur over the entire medium and be heard by all nodes. But based on our discussion above that the invention is limited to LANs wherein the nodes are connected as equal peers through a single logical point, we reject this contention out-of-hand. Second, Datapoint alternatively contends that "frames containing data," when properly construed, means only "a series of signals that are applied by a node to the communication medium," and that the Master allegedly erred by limiting "data frame" to a specific type of frame.

Datapoint's proposed definition is more appropriately assigned to "frames" than "frames containing data." Compare 732 patent, col. 10, lines 49-51 ("A frame is a series of signals applied to the medium."). The written description in the 732 patent facially distinguishes "frames containing data" from simply "frames":

"Link level" again refers to the standard seven layer reference model for networks, and generally relates to the sending and receiving of frames of data over the medium 42 and controlling access to the medium 42. Frames of data, as will be discussed below, relate to groupings of various physical level signals in such a way to achieve the desired network functionality. For example, all the functions involved in sending and receiving frames, including inserting starting delimiters, ending delimiters, and stripping these off once the data is received, are link level functions.

732 patent, col. 7, lines 34-44 (emphasis added). One may readily observe from this passage that "frames containing data"
are groups of frames -- e.g., inquiry frames, response frames, data packet frames, and token frames -- that achieve given certain network functionality. Consequently, it does not appear to us, as Datapoint suggests, that the Special Master's claim construction in any way limits the term "frames containing data" to a specific type of frame. Rather, it properly recognizes the inherent distinction between "frames" and "frames containing data." The Master's in-depth discussion of the prosecution history and the Markman testimony buttresses this conclusion. To be sure, Datapoint must acknowledge that the two have different meanings, as it attempted during prosecution to amend the original language claiming "frames" to further include "containing data." Cf. CAE Screenplates, Inc. v. Heinrich Fiedler GmbH, 224 F.3d 1308, 1317, 55 U.S.P.Q.2D (BNA) 1804, 1810 (Fed. Cir. 2000) ("In the absence of any evidence to the contrary, we must presume that the use of these different terms in the claims connotes different meanings.") (citing Tandon Corp. v. U.S. Int'l Trade Comm'n, 831 F.2d 1017, 1023, 4 U.S.P.Q.2D (BNA) 1283, 1288 (Fed. Cir. 1987). Accordingly, the Special Master's construction of "frames containing data" was correct.

1808

1. "frame segment descriptor"

3Com's proposal of "a descriptor for a frame segment" is of little help, merely reordering the words of the term to be construed. Doc # 81 (05-0098) at 35. Realtek proposes "a descriptor identifying where the corresponding segment is in the host memory." Id.

Upon review of the intrinsic evidence, Realtek's proposal appears to describe the frame segment descriptor accurately. "The segmentation circuit utilizes the descriptor to generate other descriptors that describe each frame segment." '446 patent 2:29-31. This shows that the frame segment descriptors are created from a higher level descriptor. "[D]escriptor queue 206 serves an empty flag along with the stored descriptors to TCP segmentation state machine 208." '446 patent 6:48-50. If the descriptor must be segmented into frames, the "TCP segmentation state machine 208 creates another set of descriptors wherein each descriptor describes a fragment or a segment of the data file." '446 patent 6:59-61. Although not described explicitly as "frame segment descriptors" the "set of descriptors" mentioned above are created from higher level descriptors served to the TCP segmentation state machine and are created only when segmentation into frames is required. Accordingly, this "set of descriptors" must be a set of "frame segment descriptors." Each frame segment descriptor "describes a fragment or segment of the data file." '446 patent 6:60-61. The frame segment descriptors include "pointers to where the data file (payload) is stored within host memory." '446 patent 7:4-5. Because the intrinsic evidence is consistent with Realtek's proposal, the court adopts "a descriptor identifying where the corresponding segment is in the host memory."

1809

1. "Frame Store Means For Storing a Frame"

The second, fourth, sixth, and eighth elements of independent claim 1 recite "frame store means for storing a frame." Adobe contends that a "frame store means for storing a frame" is "a structure that consists of contiguous random-access memory that stores one complete video frame, in which data is stored in the same order that the display is scanned, and which can be addressed fast enough for its contents to be read at the refresh rate of an attached display monitor." By "contiguous," Adobe simply means "logically" contiguous -- that is, capable of supplying pixels in serial order at a sufficient rate to satisfy the refresh rate of a display monitor. Quantel has not challenged Adobe's contention that a "frame store means for storing a frame" is a memory capable of supplying pixels in the order in which they are scanned by the electron gun for display on the monitor. Rather, Quantel appears to dispute only whether a "frame store means for storing a frame" is a store capable of storing a frame of video and whether such a frame store means must be capable of being read at a rate sufficient to refresh the display on the monitor.

The specification of the '286 patent does not define the term "frame store." Thus, the term must be given the ordinary and customary meaning attributed to it by persons of ordinary skill in the art. Vitronics Corp. v. Conceptor, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). At trial, Mr. Taylor testified that a person of ordinary skill in the art at the time of the '286 invention would have understood a "frame store" to be a store capable of storing a picture, image, or frame. See Tr. at 58. As
to what such a person would have understood by the term "frame," Mr. Taylor testified only that such a person would understand that a "frame" could be any size. See Tr. at 78-79. Dr. Phillips, on the other hand, testified that, even though a "frame" may theoretically be of any size, one of ordinary skill in the art at the time of the '286 invention would have understood the term "frame" to be a frame of video. See Tr. at 191-92. He also testified that one of ordinary skill in the art at the time of the invention would have understood the term "frame store" to mean a store with the capability of having data read out "at the appropriate video rate." See Tr. at 189. Dr. Phillips' testimony on these matters was uncontroverted.

For these reasons, the court concludes that the "frame store means for storing a frame" recited in claim 5 is a store that is capable of storing data representing an entire frame of video and supplying pixels in the order in which they are scanned by the electron gun for display on the monitor at a rate sufficient to satisfy the refresh rate of the display monitor.

Bellcore argues that "frame timing information" should be construed to mean frame alignment information. (D.I. 144 at 11; D.I. 142 at 27; D.I. 151 at 8). According to Bellcore, the frame timing information permits a receiver to identify the start of a frame and synchronize to the frame boundaries. (D.I. 142 at 27). In support of its proposed construction, Bellcore cites language from the specification stating: "the overhead field includes, for example, a frame alignment word for frame timing and the empty/full status of the frame" ( '306 Patent, col. 4, lines 52-54 (emphasis added)) and "the following information may be available in the overhead field of every frame, frame alignment word for frame timing . . . ." ( '306 Patent, col. 6, lines 61-64 (emphasis added)).

Fore contends that "frame timing information should be construed to mean one or more bits that indicate the beginning of a frame." (D.I. 144 at 12; D.I. 146 at 11). Fore characterizes the question before the Court as whether "frame timing information" must be more than one bit, as Bellcore contends, or may it be one or more bits, as FORE contends. (D.I. 146 at 11). As for Bellcore's reliance on the specification's use of the phrase "frame alignment word" in discussing "frame timing," FORE contends that a "word" is composed of one or more bits just as a "word" in the English language is composed of one or more letters. (D.I. 146 at 11).

Examining the claim language and specification in light of the parties' arguments, the Court believes it is evident that there is a correlation between frame timing and frame alignment word. Indeed, based on FORE's argument, it appears that FORE agrees that the frame timing information has to do with alignment. Thus, as FORE contends, the question is whether the frame timing information must be more than one bit. The Court is not persuaded by FORE's argument that a "word" contemplates one or more bits just as "word" in the English language contemplates one or more letters. (D.I. 146 at 11). In the IEEE Standard Dictionary of Electrical and Electronic Terms, 6th Edition, there are sixteen different definitions of "word," all of which require more than one bit. (D.I. 152, Exh. M at A143-44). Accordingly, the Court concludes that "frame timing information" means frame alignment information comprised of more than one bit.

Nortel argues that the terms should be construed as “a frame corresponding to the synchronous optical network (SONET) or synchronous digital hierarchy (SDH) standard.” Nortel contends that data frame should be limited such that it only applies to the SONET and SDH standards for transmitting data frames over optical communications networks. Nortel bases its argument on the fact that the SONET standard is mentioned in the title of the patent, the abstract, and the summary of the invention. Furthermore, Nortel argues that the only embodiments of the invention in the patent describe either a SOTEN or an SDH standard. However, the specification states, While the foregoing invention has been described in terms of the embodiments discussed above, numerous variations are
possible. For example, the present invention is also applicable to synchronous digital hierarchy (SDH) formatted signals in addition to SONET signals discussed above. Accordingly, modifications and changes such as those suggested above, but not limited thereto, are considered to be within the scope of the following claims. Col. 6:60-67.

The specification clearly anticipates that other variations of the invention are possible and specifically addresses as an example that alternative formats of signals can be used with the invention.

Furthermore, the claims themselves do not contain such a limitation. Claim 1 of the patent does not mention either SONET or SDH standards. See Col. 7:2-20. Dependent claims 4 and 5 indicate that the inventor did not intend to limit the terms “data frames” and “frames” in claim 1. Claim 4 reads, “A method in accordance with claim 1, wherein each of said first plurality of data frames and each of said second plurality of data frames are in a SONET format.” Col. 7:36-38. Claim 5 reads, “A method in accordance with claim 1, wherein each of said first plurality of data frames and each of said second plurality of data frames are in an SDH format.” Col. 7:39-41. “The presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim.” Phillips, 415 F.3d at 1315. There is a presumption that independent claim 1 does not contain the limitation of either the SONET or the SDH format found in claims 4 and 5 respectively.

A person of ordinary skill in the art would understand the term “data frame” to have its ordinary meaning of “a frame of data” and the term “frames” as more than one frame. Accordingly, and for the reasons discussed above, the Court does not need to construe either term.
have been previously construed and the constructions of these terms are incorporated by reference in the Master's Construction for # 9. As to the remaining terms the plain meaning as understood from the evidence has been used.

REASONS

INTRINSIC EVIDENCE

The Patent Specification sets forth that "When the processor receives a freeze command, it freezes in the still frame buffer an image obtained by the input device, and when the processor receives a save command it saves a frozen image in the memory." (Col. 3, Ls. 36-39).

EXTRINSIC EVIDENCE

Branson's testimony, to the extent it covered this phase, in the Markman Hearing is consistent with the Intrinsic Evidence (Branson Tr. 75:16-21; 79:17-19).

LUMA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

Luma's construction is set forth in the (Luma May 4, 2005, p. 5).

The Master has not used Luma's proposed construction that required: "any device configured"; "response to a freeze command"; and "further configured". The plain meaning of the language of the term does not support adding the proposed words.

STRYKER'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

Stryker's position is set forth in (Stryker May 23, 2005, p. 12).

Stryker argues that Luma is asking for "piecemeal" construction. The Master has addressed this issue in "# 2" above.

KSEA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

KSEA's position is set forth in (KSEA May 23, 2005, Sheet 10).

KSEA argues that Luma has unnecessarily cut words out of the relevant claim term. KSEA's argument with Luma's Construction appears to be the same as Stryker's argument. The Master's comments with respect to Stryker's argument are also applicable to KSEA's argument.

B. STRYKER'S AND KSEA'S REQUESTED TERMS / PHRASES FOR CONSTRUCTION (Stryker/KSEA May 4, 2005)

Stryker and KSEA have submitted a joint request for terms and phrases to be construed. Stryker/KSEA May 4, 2005, p. 1. There is a match of terms that Stryker and KSEA want construed with some exceptions noted by KSEA. (KSEA May 23, 2005, Sheet 1, Paragraph 2.) As to those terms construed, KSEA has indicated where there is agreement with Stryker on the construction of those terms. Where KSEA has disagreed with Stryker, KSEA has given its own construction. (KSEA May 23, 2005, Sheet 1, Paragraph 5.)

1814

h. "processing frequency"

The plaintiffs propose "the speed at which the CPU operates." The defendants propose "fastest safe operating speed." The issue is whether the term refers to the "fastest safe operating speed."
The plaintiffs contend that the specification uses the language "maximum possible frequency" with regard to one embodiment of the CPU. The plaintiffs also point out that "fastest safe operating speed" was mentioned in response to an office action. Response to Office Action, January 8, 1997, at 4. The response to the office action states that the present invention provides

a variable speed clock for the microprocessor, with the clock speed varying in the same way as variations in the operating characteristics of the electronic devices making up the microprocessor. This allows the microprocessor to operate at its fastest safe operating speed, given its manufacturing process or changes in its operating temperature or voltage. Id. at 3-4.

According to the plaintiffs, this does not mean that the CPU must operate at the fastest safe operating speed, but that it is capable of operating at its fastest safe operating speed.

In support of their proposed construction, the defendants point to the specification which states that the "CPU will always execute at the maximum frequency possible, but never too fast." '336 patent, 17:1-2. The defendants also point to a portion of the prosecution history which states that

these claims further state that the plurality of transistors included within the ring oscillator clock have operating characteristics which vary similarly to operating characteristics of transistors included within the microprocessor, thereby enabling the processing frequency of the microprocessor to track the speed of the ring oscillator clock: '...CPU clock 70 executes at the fastest speed possible using the adaptive ring counter clock 430. Speed may vary by a factor of four depending upon temperature, voltage, and process. Response to Office Action, April 11, 1996, at 8-9.

Frequency is not limited to the fastest safe operating speed. The portion of the prosecution history cited by the defendants refers to varying the processing frequency based on operating conditions. In the Court's view, the applicants did not clearly define or limit the term "processing frequency." Accordingly, the Court adopts the plaintiffs' proposed construction.

---

a. frequency jittering

Power Integrations contends that the term "frequency jittering" means "varying the switching frequency of a switch mode power supply about a target frequency in order to reduce electromagnetic interference." (D.I. 152 at 6). Power Integrations also contends that the "jittering" or variation in the frequency signal must be controlled and predetermined. Stated another way, Power Integrations requests the Court to construe the term "frequency jittering" to mean "a controlled and predetermined change or variation in the frequency of a signal." (D.I. 152 at 8).

Fairchild contends that the Court should decline to construe the term "frequency jittering," because it appears in the preamble of the claim and is not a limitation on the claim. (D.I. 166 at 34-35). Rather, Fairchild contends that the term "frequency jittering" in the preamble only states the purpose of the invention, and gives no meaning to the claim. However, if the Court chooses to construe the term "frequency jittering," Fairchild contends that the term means "varying the frequency of operation of the pulse width modulated switch by varying the oscillation frequency of the oscillator." (D.I. 156 at 33). Fairchild contends that the term should not be limited to "controlled and predetermined" changes or variations, because the preferred embodiment should not be used to limit the claim.

Reviewing the disputed term in light of the claim language and the specification n4, the Court concludes that the term "frequency jittering" means "varying the switching frequency of a switch mode power supply about a target frequency in order to reduce electromagnetic interference." The Court further agrees with Power Integrations that changes or variations in the frequency of the signal must be controlled and predetermined to achieve the purpose of the claimed invention. n5

---

n4 The specification of the '851 patent was incorporated by reference into the specification of the '876 patent.

n5 In concluding that the term "frequency jittering" requires construction, the Court further concludes that while the term
"frequency jittering" is found in the preamble, it is a term which gives meaning to the claim and defines the invention. The invention is not just a "circuit" but a "digital frequency jittering circuit." Reading the patent as a whole, the Court is persuaded that this language is not mere introductory language, but language which is meant to define the invention and limit the claim. See In re Pausen, 30 F.3d 1475, 1479 (concluding that term "computer" used in preamble was a claim limitation that gave life and meaning to the claims).

Fairchild's proposed construction for the term "frequency jittering" is derived from the following sentence in the "Background of the Invention" section of the '851 patent:

Varying the frequency of operation of the pulse width modulated switch by varying the oscillation frequency of the oscillator is referred to as frequency jitter.

('851 patent, col. 3, l. 28-30). In the context of the invention as a whole, however, the Court reads this sentence to be a generic description of "frequency jitter" and not a definition of the "frequency jittering" described in the '876 patent. The '876 patent specifically describes the purpose of the invention as "deviating or jittering the switching frequency of the switched mode power supply oscillator within a narrow range to reduce EMI noise by spreading the energy over a wider frequency range than the bandwidth measured by the EMI test equipment." (‘876 patent, Abstract) (emphasis added). As the Court understands the technology, the express purpose of the invention, namely the reduction of EMI noise, cannot be achieved if the jittering is not controlled and predetermined. In this regard, the specification further explains the advantages of the claimed invention in reducing EMI over the prior art are due to the fixed and controlled manner of the frequency jittering:

pulse width modulated switch 262 may also have frequency jitter functionality. That is, the switching frequency of the pulse width modulated switch 262 varies according to an internal frequency variation signal. This has an advantage over the frequency jitter operation of FIG. 1 [the prior art] in that the frequency range of the presently preferred pulse width modulated switch 262 is known and fixed, and is not subject to the line voltage or load magnitude variations.

('851 patent, col. 6, ll. 11-17) (emphasis added). Accordingly, the Court concludes that Fairchild's construction is overly broad and inconsistent with the specification, when it is read in the context of the claimed invention.

Frequency scaling

The Court agrees with MediaTek and construes the term as "multiplying and/or dividing a frequency by a given factor." Sanyo argues that the term should be construed as "doubling and/or dividing a given frequency by easily derived values to obtain a different frequency." Sanyo's argument is not based on the claim language. Instead, Sanyo argues again that the specification and prosecution history require minimal or simple circuitry, and therefore a contextual interpretation of the patent requires frequency scaling accomplished using "easily derived values." Finally, Sanyo argues that specification only discloses examples of frequency scaling that are consistent with using simple circuits, and that the invention "teaches away" from using the standard 74.25 MHz raster frequency, which would require relatively complex circuitry. See '486 Patent col. 8:18-21; 9:21-34; 12:46-52; 13:7-14.

As discussed above in the section construing raster clock signal, the importation of an "easily derived" limitation on this term is not supported. Sanyo's interpretation of "easily derived" as limiting multiplication to a factor of two results in an unsupported, overly-narrow reading of the specification and an improper limitation of the claim.
There are two phrases that use the term "signal." The court agrees with O2 that the patent uses the term signal according to its ordinary meaning. As such, the court defines the term "reference signal" to mean "a signal that provides a reference" and "frequency selection signal" to mean "a signal used to select a frequency."

5. Frequency selector.

The parties dispute whether this term should be construed at all. Samsung argues the court should construe the term and contends that the proper definition is "a circuit that changes the frequency of an output during operation based on a received input." Samsung points to the description, wherein the frequency selector generates a signal for setting the frequency of the PWM signal. Col. 4, ll. 59-61. Notwithstanding the description of the preferred embodiment, the court defines the term to mean "an instrumentality that changes the frequency of an output."

a. frequency variation circuit that provides a frequency variation signal

As a threshold matter, the parties agree that the term "frequency variation circuit" means "a structure that provides the frequency variation signal." (D.I. 152 at 21; D.I. 166 at 20, n.12). Thus, the parties' dispute centers on the meaning of the "frequency variation signal."

Fairchild contends that the term "frequency variation signal" should be construed in accordance with its plain meaning as "a signal that is used to vary the frequency of the oscillation signal." (D.I. 156 at 27). Fairchild contends that its construction is consistent with other claim elements like the oscillator element:

an oscillator that provides an oscillation signal having a frequency range, said frequency of said oscillation signal varying within said frequency range according to said frequency variation signal . . .

(‘851 patent, claims 1, col. 6 ll. 25-28 and claim 11, col. 13, ll. 35-38).

Power Integrations contends that the term "frequency variation signal" means "an internal signal that cyclically varies in magnitude during a fixed period of time and is used to modulate the frequency of the oscillation signal within a predetermined frequency range." (D.I. 152 at 23). Power Integrations' proposed construction is derived from a discussion in the specification of the frequency variation signal which contrasts such a signal from the known prior art.

Reviewing the disputed claim in the context of the claim language and the specification, taken as a whole, the Court concludes that a "frequency variation signal" means "an internal signal that cyclically varies in magnitude during a fixed period of time and is used to modulate the frequency of the oscillation signal within a predetermined frequency range." The Court's construction is supported by the specification which defines the frequency variation signal in terms of a known and fixed frequency range during a fixed period of time. In this regard, the specification teaches:

Alternatively, or in addition to soft start functionality, pulse width modulated switch 262 may also have frequency jitter functionality. That is, the switching frequency of the pulse width modulated switch 262 varies according to an internal frequency variation signal. This has an advantage over the frequency jitter operation of FIG. 1 in that the frequency range of the presently preferred pulse width modulated switch 262 is known and fixed, and is not subject to the line voltage or load magnitude variations.

(‘851 patent, col. 6, ll. 10-17).

Referring to FIG. 3, frequency variation signal 400 is utilized by the pulse width modulated switch 262 to vary its
switching frequency within a frequency range. The frequency variation signal 400 is provided by frequency variation circuit 405, which preferably comprises an oscillator that operates at a lower frequency than main oscillator 465. The frequency variation signal 400 is presently preferred to be a triangular waveform that preferably oscillates between four point five (4.5) volts and one point five (1.5) volts. Although the presently preferred frequency variation signal 400 is triangular waveform, alternate frequency variation signals such as ramp signals, counter output signals or other signals that vary in magnitude during a fixed period of time may be utilized as the frequency variation signal.

('851 patent, col. 6, ll. 25-38).

If the frequency variation signal 400 is a ramp signal, the frequency would linearly rise to a peak and then immediately fall to its lowest value. In this way, the current provided to current source input 485 of PWM oscillator 480 is varied in a known fixed range that allows for easy and accurate frequency spread of the high frequency current generated by the pulse width modulated switch.

('851 patent, col. 7, ll. 43-49).

That is, the switching frequency of the regulation circuit 850 varies according to an internal frequency variation signal. This has an advantage over the frequency jitter operation of FIG. 1 in that the frequency range of the presently regulation circuit 850 is known and fixed, and is not subject to the line voltage or load magnitude variations.

('851 patent, col. 11, ll. 45-50).

Based on the specification taken as a whole, the Court concludes that Fairchild's construction of the term "frequency variation signal" is overly broad. Read in the context of the specification, the Court is persuaded that the definition of the term "frequency variation signal" should include a fixed period of time and a predetermined frequency range. Accordingly, the Court will adopt the construction proposed by Power Integrations for the term "frequency variation signal."

1820

J. "A Signaling Message … From a Narrowband Communication System"

Claim 1 of the ’561 patent recites the phrase "a signaling message . . . from a narrowband communication system." Sprint contends that upon construction of the claimed term "signaling message" (discussed above), this broader phrase does not require further construction and should be afforded its plain and ordinary meaning. Vonage contends that this phrase should be construed to mean a signaling message (as defined above) received in the format sent from a narrowband communication system. Thus, Vonage is essentially arguing that the claimed signaling message "from" a narrowband communication system should be construed to mean a signaling message "received in the format sent from" a narrowband communication system. In support of this argument, Vonage relies on the prosecution history.

The court looks to the prosecution history, when pointed out and placed in evidence, to determine whether it contains statements that narrow the scope of the claims. Phillips, 415 F.3d at 1317. Under the doctrine of prosecution disclaimer, a patentee may limit the meaning of a claim term by making a clear and unmistakable disavowal of scope during prosecution. Purdue Pharma L.P. v. Endo Pharm. Inc., 438 F.3d 1123, 1136 (Fed. Cir. 2006); see also Chimie v. PPG Indus., Inc., 402 F.3d 1371, 1384 (Fed. Cir. 2005) (prosecution disclaimer applies where the patentee unequivocally disavowed a certain meaning to obtain his or her patent). This may occur, for example, if the patentee explicitly characterized an aspect of his or her invention in a specific manner to overcome prior art. Purdue Pharma, 438 F.3d at 1136. Although the prosecution history is relevant to claim construction, "it often lacks the clarity of the specification and thus is less useful for claim construction purposes." Phillips, 415 F.3d at 1317. "It is inappropriate to limit a claim term based on prosecution history that is itself ambiguous." Mars, Inc. v. H.J. Heinz Co., 377 F.3d 1369, 1377 (Fed. Cir. 2004) (quotation omitted).

Thus, the court must determine whether Sprint disclaimed signaling other than that received in a format from a narrowband communication. On February 1, 2001, Sprint submitted a response to the U.S. Patent and Trademark Office (PTO) to an earlier rejection of (among others) claim 1 of the ’561 patent. At that time, the claim recited "receiving signaling formatted for a narrowband system into a processing system." That claim language was not amended in connection with the February
Claims 1 and 21 require "receiving signaling formatted for a narrowband system that is external to any communication switches" and selecting a code or a logical address in the processing system based on the narrowband signaling. La Porta '852 teaches a call processing architecture that operates using a new broadband signaling protocol. La Porta '852 does not teach the processing of signaling from narrowband systems.

(Emphasis in original.) Thus, La Porta '852 teaches the processing of broadband signaling, not narrowband signaling. In this prosecution argument, then, Sprint was making the distinction that claim 1 of the '561 patent did not disclose the processing of broadband signaling because it requires receiving signaling "formatted for" a narrowband system. The remark concluded by reasoning that La Porta '852 does not teach the processing of signaling "from" narrowband systems. In a later response dated August 7, 2002, Sprint explained that Claim 1 requires receiving signaling "from" a narrowband communication system into a processing system. Thus, by that time, the claim had apparently already been amended to the later-issued claim language "from" a narrowband communication system.

The overall thrust of Vonage's argument seems to be that Sprint essentially treated the terms "formatted for" and "from" interchangeably, and therefore the court should construe the claim term "from" to mean "received in a format sent from." The court does not, however, find adequate evidence to invoke such a prosecution disclaimer. The prosecution history is ambiguous concerning the meaning of the distinction between the original claim language signaling "formatted for" a narrowband system and the apparently subsequently amended claim language involving signaling "from" a narrowband communication system. Contrary to Vonage's argument, the prosecution does not contain anything which could be construed as a clear disavowal of claim scope or an explicit characterization of an aspect of the invention to overcome prior art that "from a narrowband system" means "received in a format sent from a narrowband system." To the contrary, Sprint was apparently permitted to amend the claim language "formatted for" to the broader claim language "from." This is simply one of those situations where the prosecution history lacks clarity and, at best, is ambiguous. Accordingly, the court rejects Vonage's argument with respect to this claim element and determines that no further claim construction is required.

2. "read and process data in the identified packets from the buffer"

Only the meaning of "from the buffer" is in dispute. 3Com posits that this term requires no construction because it means precisely what it says, "from the buffer." Doc # 330 (03-2177) at 28. D-Link and Realtek both propose "while the packets are in the buffer." Doc # 81 (05-0098) at 42. The dispute, then, turns on whether data must be processed while in the buffer.

3Com argues that "from the buffer" needs no construction. The word "from" in this claim shows that the buffer is the source of the data to "read and process." 3Com's contends that the term covers "a packet that was once in the buffer." Doc # 340 at 22. D-Link, however, argues that 3Com clearly disclaimed such a broad meaning. D-Link relies upon 3Com's characterization of the invention in the prosecution history that:

The present invention is directed to a network interface which has logic to process packets in the frame buffer that are identified by a packet filter as having a particular format, before the packets are transferred to the host processor to which they are addressed.

Doc # 339 (Gutman decl) (03-2177) ex L at 2 (emphasis added). Notably, this is a characterization of the invention as a whole and not an attempt to distinguish a prior art reference. 3Com identifies this statement as referring "to the packets from
the packet filter claim element." Doc # 88 (05-0098) at 8. 3Com's argument runs counter to the plain meaning of the statement. In this statement, the packet filter merely identifies packets to be processed. The frame buffer, by contrast, is the disclosed location where processing occurs. One of ordinary skill in the art would read the characterization of the invention in the statement above as a clear indication that the disclosed invention will "process packets in the frame buffer."

In light of '884 patent's prosecution history, the court construes "from the buffer" to mean "while the packets are in the buffer."

3. "front"

This term also appears in both the '366 patent and the '408 patent. It appears in the '366 patent claims 1, 2, 4, 6, 7, 8, 41, 44, 45, 46, and 47; and the '408 patent claims 1, 2-6, and 9-15.

Rackable contends that "front" means "the most forward panel that will face toward the user when sliding or moving the computer into or out of a rack. In a standard full depth configuration, the front panel is opposite the side having I/O connectors for connecting to peripheral equipment such as a router. In the patented configuration, the orientation of the main board in the chassis is reversed." Supermicro asserts that "front" is indefinite under 35 U.S.C. § 112(2), or alternatively, means "a panel designed to face toward the user, such as a panel designed to face forward when placed in a rack."

Rackable therefore argues for a narrow definition of "front;" while Supermicro argues that the term is either indefinite or for a broader definition.

Supermicro asserts that "front" is indefinite and ambiguous as used in the patents. It argues that it requires some frame of reference. It contends that normally, computers have a top, bottom, and four vertical sides, and that a member of the public could not determine which side of the computer is the "front" for purposes of determining infringement. Accordingly, Supermicro argues that the term is incapable of construction.

Alternatively, Supermicro argues that the '366 patent provides support for its construction of "front" -- that when a computer is placed in a rack, the "front" side is the side that faces out toward the user. However, Supermicro then argues that there is still ambiguity regarding the '408 patent since that patent does not require a "rack" in its claims, and it is difficult to determine which side of a stand-alone computer is designed to face the user.

Rackable contends that Supermicro has not shown by clear and convincing evidence that the term is indefinite. Rackable further argues that Supermicro's construction ignores the specification, and standard industry practice, which entails I/O access from the rear main board. It contends that Supermicro's "irrelevant prior art" demonstrates as much.

The court adopts in part Supermicro's construction of "front" as a panel designed to face forward when placed in a rack as applied to the '366 patent only. The court rejects both parties' constructions to the extent that they refer to a "user." Reference to a "user" is too ambiguous, as there are multiple user purposes, and the term "front" cannot be defined according to how the computer is being used. See Datamize, 417 F.3d at 1350. Although "a patentee need not define his invention with mathematical precision to satisfy the definiteness requirement," there must be some "objective anchor" by which skilled artisans can identify whether they are practicing the patented invention. Id. (concluding that term "aesthetically pleasing" was indefinite because it was too subjective). Here, as in Datamize, reference to "user" renders the term indefinite because its scope depends "solely on the unrestrained subjective [purpose] of a particular individual purportedly practicing the invention." See id.

As noted above, though, the court's construction of "front" is limited to the '366 patent. That is because the '366 patent, unlike the '408 patent, provides an "objective anchor" in terms of the existence of the "rack." Because the '408 patent lacks such an "objective anchor," the court concludes that "front" is indefinite under 35 U.S.C. § 112 as concerns the '408 patent.

The court recognizes that the finding of indefiniteness with respect to "front" as to the '408 patent only may have some adverse impact with regard to the '366 patent, which contains the same term. However, the court is unclear regarding what,
if any, impact may occur, and expects that the parties will advise the court of any such impact in their briefing on the
dispositive motions.

1823

On appeal, Honeywell argues that the district court erred by limiting the "fuel injection system component" limitation to a
fuel filter and including no other component of a fuel injection system. In doing so, Honeywell contends that the court
imported a limitation from the specification into the claims and thereby improperly limited the scope of the claims to the
specification's preferred embodiment. According to Honeywell, nothing in the specification explicitly limits the claim term
to a "fuel filter." Honeywell relies on a statement contained in the specification referring to "the metallic components used
in prior art systems," '879 Patent, col.1 ll.32-33, to argue that the term "component" was meant to be broad. It also cites the
patent's abstract, which summarized the invention using the term "component," and the title of the patent as amended, to
further argue that the specification did not limit the "fuel injection system component" to a fuel filter.

In addition, Honeywell points to the prosecution history in assigning error to the district court's construction of the "fuel
injection system component" limitation. According to Honeywell, the patentee stated during prosecution that the intended
scope of the claims was to include "all fuel components manufactured of the moldable material disclosed and claimed in the
specification." Honeywell also notes that the patent examiner issued a restriction requirement during prosecution of the '084
application (which also included claims to "fuel filters") because "the fuel system component [claims] do[] not specifically
require that the component be a fuel filter."

Mainly reiterating the points made by the district court in its claim construction decision, ITT/TG responds that the claim
term "fuel injection system component" was correctly limited to a fuel filter. ITT/TG also argues, however, that the court
errd in its construction of the "electrically conductive fibers" limitation. ITT/TG contends that the court should have
construed that term to include only metal fibers with a high aspect ratio, not carbon fibers. According to ITT/TG, the written
description compared the properties of metal and carbon fibers, and "disparaged" the use of the latter as an electrically
conductive fiber. ITT/TG contends that there was a clear disavowal of carbon fibers from the scope of the claims. Moreover,
because the accused quick connects are indisputably made with carbon fibers, ITT/TG asserts that there can be no
infringement either literally or under the doctrine of equivalents.

We agree with the district court that the claim term "fuel injection system component" is limited to a fuel filter. In Phillips
v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 2005) (en banc), this court recognized that "claims 'must be read in view of
the specification, of which they are a part." We further stated that "the specification 'is always highly relevant to the claim
construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.'" Id. (internal
citations omitted). Here, the written description uses language that leads us to the conclusion that a fuel filter is the only
"fuel injection system component" that the claims cover, and that a fuel filter was not merely discussed as a preferred
embodiment. On at least four occasions, the written description refers to the fuel filter as "this invention" or "the present
invention":

- This invention relates to a fuel filter for use in the fuel line that delivers fuel to a motor vehicle engine. '879 Patent, col.1
  ll.8-9.

- According to the present invention, a fuel filter for a motor vehicle is made from a moldable material which may be
  safely used in vehicles equipped with electronic fuel injection system. Id., col.1 ll.40-43.

- This and other advantages of the present invention will become apparent from the following descriptions, with reference
to the accompanying drawing, the sole Figure of which is a cross-sectional view of a fuel filter made pursuant to the
  teachings of the present invention. . . . Id., col.1 ll.43-49.

- According to the present invention, an electrically conductive path is provided between the fuel within the inlet cavity 42
  [of the fuel filter] and the [vehicle] body 38. Id., col.3 ll.41-43.

The public is entitled to take the patentee at his word and the word was that the invention is a fuel filter.
Moreover, the written description does not indicate that a fuel filter is merely a preferred embodiment of the claimed invention. The fuel filter was the only component of an EFI system that the written description disclosed as having a polymer housing with electrically conductive fibers interlaced therein. The only other fuel component specifically mentioned in the written description, the fuel line, was not required by the patentee to be made of an electrically conductive polymer material, as the claims require. See id., col.1 ll.59-60 (stating that the "fuel line may also be made of a non-conductive material"). The written description's detailed discussion of the prior art problem addressed by the patented invention, viz., leakage of non-metal fuel filters in EFI systems, further supports the conclusion that the fuel filter is not a preferred embodiment, but an only embodiment. Id., col.1 ll.10-25. Given the written description's disclosure, we conclude that the patentee has limited the scope of the '879 patent claims to a fuel filter.

Nor are we persuaded by Honeywell's argument that the patentee confirmed a broader scope of his claims during prosecution. Honeywell relies mainly on the patentee's response to the examiner's indefiniteness rejection in which he stated that the claims cover "all fuel components manufactured of the moldable material disclosed and claimed in the specification." Honeywell places too much weight on that statement, as we find it to be ambiguous and possibly inconsistent with the written description. After all, the only fuel component disclosed and claimed in the patent was a fuel filter. In any event, such a broad and vague statement cannot contradict the clear statements in the specification describing the invention more narrowly.

We also do not assign much weight to the patent examiner's restriction requirement with respect to claims for a "fuel filter" and a "fuel system component" during prosecution of the '084 application. In making the restriction requirement, the examiner did not construe the claim term "fuel system component" or determine its meaning in light of the written description. He merely required that the applicant elect one aspect of his invention for prosecution without applying it to the specification.

Nevertheless, even if we were to agree with Honeywell that the patentee clearly expressed his intention during prosecution to have the "fuel injection system component" limitation include components in addition to a fuel filter, it would not change the result in this case. As we determined above, the written description provides only a fuel filter that is made with polymer housing and electrically conductive fibers interlaced therein. No other fuel injection system component with the claimed limitations is disclosed or suggested. Where, as here, the written description clearly identifies what his invention is, an expression by a patentee during prosecution that he intends his claims to cover more than what his specification discloses is entitled to little weight. See Biogen, Inc. v. Berlex Labs., 318 F.3d 1132, 1140 (Fed. Cir. 2003) (stating that "[r]epresentations during prosecution cannot enlarge the content of the specification").

1824

iii. Dependent Claim 13 Is Indefinite

Claim 13 reads as follows:

13. A system as recited in Claim 12 wherein said remotely transmitted signal includes a full band broadcast signal.

Citrix argues that the italicized words in Claim 13 cannot be understood by one of skill in the art and that the claim is therefore indefinite. Citrix argues that the italicized term was coined by Rothschild for use in the patent because it is not a term typically used in the computer field to describe a type of broadcast signal. To support its argument Citrix claims that the term "full band" is not defined in technical dictionary such as the Dictionary of Computer Words, the Microsoft Computer Dictionary, Barron's Dictionary of Computer and Internet Terms or even in ordinary usage dictionaries like the American Heritage of the English Language.

Rothschild proposes that the term "full band broadcast signal" be construed as "an unconstrained transmission. Rothschild cites to the '534 Patent specification in support of this proposed construction, but does not explain how the specification actually supports its construction. In fact, Rothschild has failed to identify a single dictionary or treatise explaining what a "full band broadcast signal" is. In addition, the '534 Patent does not provide any definition of "full band broadcast signal." Instead, the '534 Patent identifies it along with other types of signals -- such as broadband and interlaced -- but fails to identify what the signal is or how it differs from the other identified signals. Col. 3:29-33, Col. 12:30-34, Col. 12:65-13:15.
Although Rothschild proposes that "full band broadcast signal" be construed to mean "an unconstrained transmission," Rothschild fails to identify any such definition in the '534 Patent, or anywhere else.

The Court finds that because the claim term "full band broadcast signal" in Claim 13 has no meaning to one of skill in the art and is not defined in the '534 Patent, Claim 13 cannot be construed and is therefore indefinite. E.g., Honeywell, 341 F.3d at 1338, 1341.

Full-duplex, standing alone, means a "simultaneous two-way independent transmission in both directions." Lewis Decl. Ex. 8 (American National Dictionary for Information Processing Systems 43 (1982)) (emphasis in original). That is, a full-duplex transmission involves communication between the sender and receiver simultaneously, in both directions at once, as opposed to one direction at a time. See id. Ex. 6 (Microsoft Press Computer Dictionary 119 (1991)) (emphasis added). The prosecution history of Multi-Tech's '627 Patent reveals "full-duplex, packetized voice communications as claimed . . . requires simultaneous bi-directional independent asynchronous transmission of voice packets between two modems." Lewis Decl. Ex. 11 at 5 (November 4, 1997, Amendment & Response Under 37 C.F.R. § 1.116). "Through statements made during prosecution . . . an applicant for a patent . . . may commit to a particular meaning for a patent term, which meaning is then binding in litigation." CVI/Beta Ventures, Inc. v. Tura LP, 112 F.3d 1146, 1158 (Fed. Cir. 1997).

Full-duplex digital communication, therefore, is the ability to bi-directionally transmit and receive digital information simultaneously.

The term "full flow" also appears in the preamble of each of the asserted independent claims. CFMT argues that the term refers to the inventors' short hand name for a process that includes the characteristics of flowing process fluids past wafers in a process vessel that is hydraulically full. YieldUP counters that the term "full flow" is a CFMT trademark that is not explicitly defined in any part of the patent documents. If the court construes the term, YieldUP contends that it means requiring turbulent plug flow with a high volume turnover rate.

The court does not find that the term "full flow" is an undefined trademark used by CFMT strictly for its marketing purposes. YieldUP markets its own products as "full flow processors" and YieldUP's co-founder and Chief Technology Officer, Suraj Puri, has filed a patent application covering a "Full Flow Method and Apparatus for Cleaning Objects Using Dilute Ammonium Solutions." Therefore, the court finds that the term "full flow" would be understood by one of ordinary skill in the art.

The specification of the '532 patent does not suggest that "full flow" means "plug flow" as YieldUP argues. On the contrary, the two references to "plug flow" in the specification of the '532 patent suggest that if the inventors had meant to refer to "plug flow" in the patent claims, they knew how to do so, and they would not have used the term "full flow" instead. As advocated by CFMT, the court finds that the term "full flow" is a short-hand name for the method of flowing process fluids past wafers in a vessel that is hydraulically full.
6. **Full-width Data Path**

A data path on the memory module that is at least as wide as the path used by the central processing unit of the computer into which the module is installed.

---

### B. Modes/mode switching means

<table>
<thead>

<td>A mode that allows partial use of the digital data or software</td>
</tr>
</tbody>
</table>
As an initial matter, the Court concludes that the terms "use mode" and "fully enabled mode/full version run" mean the same thing. At the Markman hearing, Microsoft readily agreed that these terms are synonymous. Uniloc, however, was hesitant to agree to synonymous treatment on the spot. But importantly, when pressed by the Court, Uniloc was once again unable to offer an example of a situation when "fully enabled mode" would mean anything other than "use mode." So, although Uniloc has not explicitly agreed that these terms are synonymous, Uniloc has been unable to make an argument, compelling or otherwise, that the terms deserve different treatment. Moreover, the Court observes that Uniloc's proposed constructions for these terms do not vary materially. While Uniloc has included the word "unrestricted" in its construction of the term "fully enabled mode," there is nothing to indicate that "use mode" is restricted in any way other than the scope of the license. Indeed, Uniloc's own expert, David Klausner, stated that use mode is an unrestricted mode:

One of ordinary skill in the art recognizes the patent relates to the use of software or digital data in a restricted or unrestricted mode (use mode/non-use mode). The terms "fully-enabled mode" and "full version run" are used similar to "use mode" to mean allowing unrestricted use in accordance with the license.

Klausner Decl. at P 18. Moreover, the specification discusses these terms in a similar context by explaining that they are the converse of the term "partly enabled or demonstration mode." Compare '216 Patent, col. 2, ll. 44-48 (“The use mode is to be distinguished from what might generally be termed unlicensed modes of operation (which is not to say unauthorized modes of operation) as typified by the demonstration modes later described in this specification”), with id. at col. 15, ll. 1-5 (explaining that the mode switching means switches software between a fully enabled mode on the one hand, and a partly enabled or demonstration mode on the other).

Turning then to the parties' proposed constructions, the main point of disagreement is whether the difference between the full and demonstration modes involves only functional limitations (such as limitations on the ability to save or print a document), or whether the claim terms should be construed broadly enough to encompass temporal limitations as well (such as only being able to use the software for two days). In support of its argument that the demonstration mode only involves functions being disabled, Microsoft cites portions of embodiments 1 and 5. See id. at col. 6, ll. 47-48 (explaining that "a demonstration of the software (which typically has features such as save and/or print disabled)"); id. at col. 11, ll. 14-17 (stating that the "[t]he registration code portion 38 can include a preview or demonstration related to a subset of the balance of the digital data on the CD 54 which can be executed by the platform without license"). But while these embodiments discuss characteristics which a demonstration mode can have, or typically has, the Court declines to read these examples from two embodiments to mandate that in all instances, the demonstration mode only can involve functional limitations. See generally Phillips, 415 F.3d at 1323 (the general rule is that "persons of ordinary skill in the art rarely would confine their definitions of terms to the exact representations depicted in the embodiments."). For these reasons, the words "functionality" and "functions are disabled" will not be part of the Court's construction of these terms.

Instead, the Court determines that the use and fully enabled modes are best described as allowing "full use" of software "in accordance with the license." This language is consistent with the specification's explanation of the term "use mode," see '216 Patent, col. 2, ll. 40-48 (explaining that use mode refers to use of the digital data or software so as to fulfill the licensor's obligations), as well as the specification's general guidance that once the registration routine is complete, "full access to the software is allowed." Id. at col. 8, l. 28.

Accordingly, the terms "use mode" and "fully enabled mode/full version run" shall be construed as: A mode that allows full use of the digital data or software in accordance with the license. n12

--- Footnotes ---

n12 Although Microsoft agreed that the terms "use mode" and "fully enabled mode/full version run" should be treated the same, it did not specify which of its proposed constructions was preferable in that event. Nonetheless, to the extent Microsoft may have intended to press its proposed construction of "use mode," this writer notes that the Court's construction incorporates the limitation expressed therein: that use mode means using the data in accordance with the obligations imposed by the license.

--- End Footnotes ---

GO BACK
1. "fully folded array"

The text of claim 1 is set forth below with the key disputed term highlighted in bold type.

In a storage system having n+1 disks arranged in a RAID array, a plurality of data blocks arranged into a plurality of data chunks, a plurality of parity blocks arranged into a plurality of parity chunks, each parity block associated with n data blocks in n data chunks, said data chunks and said parity chunks distributed over said n+1 disks, one of said parity chunks and all of said data chunks that are associated with said parity chunk forming a strip, a method of reorganizing said data chunks when one of said n+1 disks fails, comprising the steps of:

   - detecting the failure of one of said n+1 disks;
   - determining if said failed disk contains all parity chunks;
   - if said failed disk contains all parity chunks, terminating said method;
   - if said failed disk contains at least some data chunks, then for each strip containing a data chunk located on said failed disk, regenerating the data of said data chunk located on said failed disk and writing said regenerated data onto said parity chunk associated with said data chunk of said failed disk to form a fully folded array.

HP asks the Court to construe this term as: "An organization of a RAID array essentially that of a RAID-0 organized array except that the disk on which a chunk of data is stored may be unconventional." EMC proposes:

A "fully-folded array" is an array of disks that results after the completion of a "folding" process. The folding process begins after a disk in the array fails. The data of the failed disk is reconstructed and stored onto the parity chunks of the active disks in the array. The "folding" is complete when all of the parity chunks of the active disks have been overwritten with the reconstructed data of the failed disk.

The claimed invention enables continuing access to stored data even when a storage disk has failed. It does so by reconstructing the failed data and writing them onto portions containing parity data on other disks. When this occurs, the data are accessible, but the disk storage system no longer has parity data and thus no longer has redundant data storage. Any data that are lost thereafter cannot be reconstructed or regenerated. In this state, the data storage device is a "fully folded array." The user can continue to access the data until a replacement disk is added, at which time the data are "unfolded" and restored to their redundant state.

While the plain language of the claim does not explain the meaning of "fully folded array," the specification provides a sufficient explanation for purposes of claim construction. For example, the summary of the invention clearly defines a fully-folded array as one in which the level of organization of data is non-redundant and which contains regenerated data from a failed disk in the place of previously existing parity data corresponding to that regenerated data. See 453:2/35-49.

HP's proposed construction is accurate in the sense that it restates an explanation from the specification. However, it does not take advantage of the full description provided; the Court's construction seeks to define fully the terms proposed by HP. While the fully-folded array is defined partially by characteristics obtained from the process of folding, EMC improperly attempts to import the process by which the data are fully folded into the construction. At the same time, the fully-folded array contains regenerated data in places that previously contained parity data; the Court will include this property in its construction without importing method or process limitations.

Accordingly, the Court construes this term as "a memory storage array in which the level of organization of data is non-redundant and which contains regenerated data from a failed disk in the place of previously existing parity data corresponding to that regenerated data."
The word "function" in the term "storing executable functions" means an identifiable set of computer instructions. The "ordinary and customary meaning" of the word "function" to someone of "ordinary skill in the art," Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc) (citing Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)), is a set of computer instructions. This construction is supported by the specification. '737 Patent, Col. 12, 11. 46-48 ("A format function…may be considered as the smallest unit of instructions for producing a portion of HTML code."). See also Dow Jones Reply Br., Ex. A, at 2 ("The ordinary meaning of the term "function" is a named set of instructions.").

The parties appear to agree on this point, disagreeing only on whether a function must be "named" or merely "identifiable," and whether a function must include "a set of function steps, at least one of which, when executed, creates a portion of code." The claim itself is unclear on these points. The specification for the '737 patent, however, requires only that each function be identifiable. '737 Patent, Col. 13, lines 41-45 ("At step 905 the functions required to create the particular string…are identified."). 3 Moreover, although certain functions described in the specification create portions of code, others perform different tasks, such as retrieving data from a database. Id. at Col. 15, ll. 54-58.

3 For the proposition that each function must have a name, Dow Jones relies on definitions from standard and computer programming dictionaries. Extrinsic sources such as dictionaries, however, "may not be used to vary, contradict, expand, or limit the claim language from how it is defined, even by implication, in the specification or file history." Bell Atl. Network Servs. v. Covas Commc'ns. Group, Inc., 262 F.3d 1258, 1269 (Fed. Cir. 2001).

Dow Jones argues further that "storing executable functions" requires "storing a universal set of all available functions." In support of this view, Dow points to a passage from the specification in which the preferred embodiment is described, which states "the system as a whole includes a universal family set of all available functions." Id. at Col. 12, ll. 49-50. Dow views the inclusion of the "universal family set" as an essential feature of the preferred embodiment that must be read into the claim. The Federal Circuit, however, has "repeatedly warned against confining the claims" to specific embodiments described in the specification, Phillips, 415 F.3d at 1323 (citing cases), and has "expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment." Id. In order for the specification to be used to limit the claim as Dow Jones would have it, it must "disavow" the claim scope through "words or expressions of manifest exclusion" or "explicit disclaimers." Gillette Co. v. Energizer Holdings, Inc., 405 F.3d 1367, 1374 (Fed. Cir. 2005)(citing Housel Pharms., Inc. v. Astrazeneca UK Ltd., 366 F.3d 1348, 1352 (Fed. Cir. 2004)). The specification of the '737 patent lacks such an indicator of applicant intent.

H. Claim Construction of "function"

In the '072 Patent, the term "function" appears in Claims 1, 2, 3, 4, and 5, but the primary claim language can be found in Claim 1, which states "the specified combination of each scatter pixel and the transmission pixel corresponding to the scatter pixel is a linear combination of a function of the value associated with the scatter pixel and a function of the value associated with the transmission pixel."

Plaintiff argues that this term means a relationship, however derived, that represents a unique association of an output with one or more defined inputs. Defendants argue "function" means a relationship that associates a single input array variable with a unique and determinate output, wherein the relationship does not combine neighboring pixels in the input array. Defendants acknowledge that functions can depend on multiple variables, but argue that the '072 Patent always refers to
functions of a single variable.

The ordinary and customary meaning of "function" is a relationship between inputs and outputs, but beyond that, the claim language does not provide much guidance. While the claim language states that the first function is a function of the scatter value and the second function is a function of the transmission value, the claim language does not specify whether the value input consists of one variable or multiple variables.

The specification indicates that the function may be logarithmic or quadratic. ('072 Patent, Col. 2, lines 36-42.) In the description of preferred embodiments, the specification describes examples of combinations of functions of $T$ (an array of values representing the transmission image) and $S$ (an array of values representing the scatter image), with the general formula consisting of $C = f(S) + g(T)$. ('072 Patent, Col. 4, lines 3-46.)

The Court next turns to the prosecution history. In the December 20, 2001 Amendment Transmittal, the patentee stated that the claims require "forming a value $C$, for each pixel, that is a combination of a function $f(T)$ of the transmission signal $T$ at that pixel and a function $g(S)$ of the scatter signal $S$ at that same pixel." (Defs' Mem. Claim Constr., Ex. 14.) It is clear that the patentee argued that both functions are limited to functions of single entries from their respective transmission and scattering image arrays, and not containing information from other pixels. This basis, the patentee distinguished its patent from the prior art, namely, U.S. Patent No. 5,974,111 issued to Krug et al. The patentee argued that while Krug's method entailed combining and averaging values of neighboring pixels, the patentee's claims "require a method for displaying an image created from pixel-by-pixel combination of actual measured intensity values for detected transmission and scatter x-rays." (Defs' Mem. Claim Constr., Ex. 14.)

Thus, the intrinsic evidence makes clear that Plaintiff intended that "function" be limited to a function of a single variable, a value associated with either a transmission pixel or a scatter pixel. Accordingly, the Court FINDS that "function" as defined in the '072 Patent means a relationship that associates a single input array variable with an output, wherein the relationship does not combine neighboring pixels in the input array.

ix. As a function of priority

Plaintiff contends that this phrase means "using a priority scheme to determine a course of action" and asserts that the priority can be based on either time or level of importance. Apple contends that the phrase means "based on the level of importance assigned to other specific portions' relative to specific portions." Sun's construction is "based on the relative priorities of the defined routines."

The priority language is not limited to the level of importance. A plain reading of the term and a general understanding of the goal of the patented invention would allow for both level of importance and time priority. One of ordinary skill in the art would recognize that if the level of importance of two interrupts was the same, the first in time would be processed before the second.

Further, there is no modifier before "priority" in Claim 11. This is different from other claims (see claims 1, 7, 15, and 20). Because there is no modifier in Claim 11, the court will not read additional limitations into the claim. "As a function of priority" will be given its full breadth of meaning. Accordingly, the Court finds that "as a function of priority" means "based on either time or level of importance."

6. "Function of", "Function of the flight path angle", "Function of … said look ahead distance"
58 This construction applies to the '080, '592, and '570 Patents.

<table>

<td>The boundaries of each alert envelope are determined using the same discrete numerical value for look ahead distance as a variable in their computation.</td>
<td></td>
<td>A mathematical or logical relationship to the look ahead distance.</td>
</tr>
</tbody>
</table>

Again, Honeywell argues that this term has a plain and ordinary meaning in the art, and that Sandel is attempting to restrict that definition. Honeywell alleges that Sandel is attempting to read specific numerical values into the claim language, and urges the court to include logical relationships. Additionally, Honeywell does not object to a construction of "function of" which includes a logical relationship in addition to a mathematical relationship.

Sandel argues that "function of" is commonly used in the avionics industry, and defines, inter alia, a direct mathematical relationship between two variables. In support, it cites various dictionary definitions, and notes that both the specification and prosecution history are consistent with its proposed definition.

"Function of" is commonly known as a mathematical or logical relationship between two or more variables. That is, an unknown variable can be defined as a function of some other variable. Thus, one can determine the unknown variable by reference to another variable. Honeywell's definition includes a mathematical and logical relationship, which is consistent with the common usage. The court rejects Sandel's proposed definition because it is too narrow, and unsupported by the claim language.

1834

(1) A Fundamental Frequency Detector

Square D contends that the term "a fundamental frequency detector" should be construed to mean "a mechanism that
receives an input signal and generates a modified output signal representative of the fundamental frequency." EI contends that the term should be construed to mean "a frequency to square wave converter in which the high frequency components are eliminated by a low-pass filter." At the Markman hearing, Square D offered an alternative construction: "a device that detects the fundamental frequency." Thus, the real dispute here centers on whether the proper construction should require that the fundamental frequency detector must include a low pass filter device.

Based upon the plain language of the specification, the Court finds that it does. The specification states that "[i]n the present invention, the high frequency components in the signal are eliminated through the use of a low pass filter before attempting to measure the signal's fundamental frequency." Id., col. 7, lines 23-30. Square D argues that this language merely requires that a low pass filtering effect be achieved; but that is not what the specification says. Moreover, elsewhere, the patentee used other phrases to make clear that the particular description might apply to one or more embodiments, but should not be read to limit the claim language, see, e.g., col. 4, line 1 ("[i]n the illustrated embodiment"); col. 5, line 43 ("[i]n an exemplary embodiment"); col. 6, line 6 ("[i]n an exemplary embodiment"); and significantly, here, the patentee chose not to use such language, demonstrating that the limiting language requiring the use of a low pass filter would apply to every embodiment of the present invention.

Square D argues that the Court may not construe the claim language in a manner that would preclude a preferred embodiment. And this is certainly true. See, e.g., Oatey Co. v. IPS Corp., 514 F.3d 1271, 1276-77 (Fed. Cir. 2008) (ordinarily, absent a clear disclaimer in the specification or prosecution history, it is inappropriate to interpret claim terms in a way that excludes embodiments disclosed in the specification). See also Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed Cir. 1996). But Square D has not demonstrated that construing "fundamental frequency detector" in this manner does preclude a preferred embodiment. At the Markman hearing, Square D argued that the specification discusses a preferred embodiment which discloses as "a suitable fundamental frequency to square wave converter . . . the LM311D available from National Semiconductor." See U.S. Patent No. 6,185,508 B1, col. 4, lines 46-48. According to counsel for Square D, the LM311D does not use a low pass filter, which necessarily means that a low pass filter is not required. But the language of the specification that identifies the LM311D as an option also says that it should be "configured in a manner known in the art." The Court does not read this language as being inconsistent with the requirement that the device use a low-pass filter to eliminate harmonics. To the extent it is, Square D should have demonstrated as much, and it did not.

The conclusion concerning the necessity of a low pass filter is consistent with the prosecution history, which distinguishes prior art that "does not teach or suggest" that the errors associated with harmonic distortion "can be removed by the low pass filtering effect of a fundamental frequency to square wave converter." See EI's Memorandum in Support of Claim Construction, Exhibit D.

Having said all of this, the Court also rejects EI's proposed construction. EI has equated "fundamental frequency detector" with a frequency to square wave converter. But that limitation is unsupported in the claims. Claim 9, which depends from claim 1, discloses "[t]he power meter of claim 1 wherein said detector converts said fundamental frequency to a square wave." U.S. Patent No. 6,185,508 B1, col. 10, lines 21-22. Under the doctrine of claim differentiation, claim 1 is presumptively broader than this, including fundamental frequency detectors that do not convert frequency to square wave. See, e.g., Halliburton Energy Services, Inc. V. M-I LLC, 514 F.3d 1244, 1252 n.3 (Fed. Cir. 2008) ("Under the doctrine of claim differentiation, 'the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim.'") (quoting Phillips, 415 F.3d at 1315).

In light of all of the above, and having considered the language of the claims and the specification, the Court construes "fundamental frequency detector" to mean "a mechanism that receives an input signal and, using a low-pass filter, generates a modified output signal representative of the fundamental frequency."
In particular, ADE contends that the '118 "gallery" has integrity or an existence independent of the images displayed therein.

D.I. 312 at 2.

Although, as ADE correctly notes in its Markman briefs, the word "gallery" is used in the '118 with reference to a graphical spreadsheet, given the context in which the word is employed throughout the '118 disclosure, it is evident to this court that the inventors did not intended to incorporate a "spreadsheet" limitation with in dependent structure into the word "gallery." This court, therefore, will not read, as ADE suggests, a graphical spreadsheet limitation into the meaning of the word "gallery." Had the inventors intended this word to incorporate a form with independent structure separate and distinct from the images being displayed, they could have done so in their claims. The word "gallery" is, therefore, construed to mean a representation of one or more items. This is not to state, however, that other limiting language in the "gallery … means" elements of claim 7 and claim 13, as provided, infra, has no bearing on this discussion.

GO BACK

1836

3. "Game"

IGT's contends that the term "game" is indefinite, rendering the claim invalid. See infra. Arguing in the alternative, IGT proposes that the term "game" be construed in the following way. Aristocrat submits that the term needs no further construction.

<table>
<thead>
<tr>
<th>Term or Language Requiring Construction</th>
<th>Aristocrat's Proposed Construction</th>
<th>IGT's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;game&quot;</td>
<td>game</td>
<td>In the context of these claims, this term is indefinite and provides no clear criteria to distinguish between what is a first game and what is a second game. At the time, a person of ordinary skill would have understood the term to mean: A gambling activity played according to a set of rules. A game does not require user interaction. A game has a distinct beginning and ending. A game begins when a player irrevocably commits a wager that is not part of any previous game. A game ends when all transactions for the game have finished, including the loss or return of the wager and award of all prizes won. Second screen bonus features, free plays and the like are not separate games.</td>
</tr>
</tbody>
</table>

IGT contends that "game" is a term of art with a technical meaning to those skilled in the art. Because, according to IGT, the specification gives insufficient guidance as to the meaning of the term "game," the court should look to industry regulations
to determine an appropriate construction. IGT CC at 5. IGT's lengthy construction is composed largely of limitations culled from a variety of gaming regulations. Id. Australian regulations define a "game" as "a gambling activity played according to a set of rules." IGT CC at 6 (citing Australia/New Zealand Gaming Machine National Standards, Rev. 1.0 §§ 3.264-65 at 3-42 (1997), attached to Irvine Decl. at Ex. L). Nevada gaming regulations require that "gaming devices" have the capacity to display complete play histories of the nine games immediately preceding the most recent one. Id. (citing State of Nevada, Regulations of the Nevada Gaming Commission and State Gaming Control Board: Technical Standards for Gaming Devices, § 1.080(7)(November 1997), attached to Irvine Decl. at Ex. O). And Australian/New Zealand gaming regulations also provide that games begin and end with a wager and either loss or payment, respectively. Australia/New Zealand Gaming Machine National Standards, Rev. 1.0 §§ 3.264-65 at 3-43. Finally, the standards promulgated by Gaming Laboratories International, called the GLI-11: Gaming Devices in Casinos, 1 define "second screen bonus features, or free plays, as all part of a single game, and not as separate games." IGT CC at 6 (citing Gaming Laboratories International, GLI-11: Gaming Devices in Casinos, Ver. 1.4 § 4.2.4 at 66 (June 30, 2006), attached to Irvine Decl. at Ex. N.).

--- Footnotes ---

1 According to IGT's brief: "Like a restatement or uniform act in the law, the GLI-11 is an industry standard having widespread acceptance and setting forth the industry usage of "game" and "completion" of a "game." IGT CC at 6 n. 4.

--- End Footnotes ---

These limitations do not appear in the specification. Rather, the specification distinguishes "games" broadly by type of game (e.g., slot machines, cards, keno, bingo, or pachinko) (’215 Patent at 5:23-24; ’603 Patent at 4:49-53), and by the different prizes available from the game (a "jackpot feature game" is played for a jackpot prize (see ’215 Patent at 6:23-28), whereas a "main game" would likely award smaller "combination-triggered" prizes (see id. at 1:64-2:2)). The court finds that the term "game" as used in the specification and claims is meant to encompass a wide variety of game types. Indeed, the specification describes flexibility in game type and jackpot award as advantages over a single-game arrangement. See id. at 5:20-30, 43-45 ("Jackpot hit rates can now be changed without making changes to the base game. This was previously not possible using combination triggered jackpots.") The court finds that limiting games to gambling activities played according to a set of rules is appropriate since the subject matter of the payment relates both to gambling and games. Further limitation is not necessary. Accordingly, the court construes the term generally, that is "a gambling activity played according to a set of rules."

---

1837

1. "Gaming machine"

Claim 1 of the ’215 Patent and Claim 1 of the ’603 Patent begin with the phrase "[i]n a network of gaming machines," and the phrase "gaming machine" appears frequently in the claims of both patents. ’215 Patent at 8:45; ’603 Patent at 8:8. The parties propose the following constructions of "gaming machines":

<table>
<thead>
<tr>
<th>Term or Language Requiring Construction</th>
<th>Aristocrat's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;gaming machine&quot;</td>
<td>gaming device (i.e., not limited to any particular type of game such as poker)</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Term or Language Requiring Construction</th>
<th>IGT's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;gaming machine&quot;</td>
<td>poker machine</td>
</tr>
</tbody>
</table>

IGT relies for its construction on a sentence in the introductory paragraph in each patent which states: "[t]he present invention relates to apparatus for use with a system of linked poker machines and in particular the apparatus provides an improved jackpot mechanism for use with such a poker machine system." ’215 Patent at 1:6-9; ’603 Patent at 1:9-12. IGT contends that this statement defines the invention and that "the public is entitled to take the patentee at his word and the
word was that the invention" is a poker machine. Honeywell Int'l, Inc. v. ITT Industries, Inc., 452 F.3d 1312, 1318 (Fed. Cir. 2006) (holding "fuel injection system component" was limited to "fuel filter" because the written description called "the present invention" a fuel filter). In Honeywell, the court wrote that, although the prosecution history contained some suggestion that the invention, a "fuel injection system component," was broader than only fuel filters, "the entire specification of [the patent], as well as the sole drawing, describe the elements and operation of a fuel filter . . . . No other parts are described." Id. at 1316 (quoting district court order in Honeywell Int'l v. ITT Indus., 330 F.Supp.2d 865, 879 (E.D.Mich. 2004)). As a result, the court held that the invention was limited to a fuel filter. Id. at 1318.

The patents here refer to "poker" only in their introductory paragraphs. The specifications include descriptions of "gaming machines" and the language strongly suggests that the term "gaming machine" should not be limited to a "poker machine." For instance, the patents state in their "Detailed Description of the Preferred Embodiments" sections:

Feature jackpots in this format exhibit significant differences over previous jackpot systems:

(i) A jackpot game is provided which is compatible with any existing game combination within an installation independent of the platform, denomination or type of game (e.g. slot machines, cards, keno, bingo or pachinko). This will allow for the linking of games combinations between game type, platform type, and denomination."

'215 Patent at 5:19-26; '603 Patent at 4:47-53. In addition to the reference to multiple types of games, the context of the statement is important. It describes some of the advantages of using a "spin and hold"-type feature game over "conventional combination-triggered jackpots." In a spin and hold type game, a set of reels spin and, when the player stops the reels by pressing a button, the feature-prize score is determined by the sum of the points that appear on the center line of those reels. '215 Patent at 5:15-19; '603 Patent at 4:42-46, 7:12-18; See also id. at Fig. 3 (depicting set of five reels). A "combination triggered" jackpot, by contrast, awards a jackpot upon the occurrence of a particular game configuration (e.g., a certain combination of symbols). '215 Patent at 1:52-55; 2:26-29; '603 Patent at 1:56-60; 2:30-34. According to the specification, using a spin and hold feature game has the advantage of being usable with different types of main games. See '215 Patent at 5:21-25; '603 Patent at 4:47-58. In light of this claimed advantage in the preferred embodiments, limiting "game machine" to "poker machine" is not supported by the specification. The court therefore construes "gaming machine" as "gaming device which is not limited to any particular type of game such as poker."

1838

2. What is the meaning of the word "gap"?

At the close of the claim construction hearing, the court construed "gap" in the following manner:

The area of the substrate under the oxide mask grown during step (b) that is protected by the mask from the implantation of ions that reverse the polarity of the substrate and thereby create the source and drain regions.

This construction resulted from a combination of the claim language and the expert testimony offered at the claim construction hearing. Step (d) of claim 1 states that the "gap" must exist "between a side edge of the gate electrode and a side edge of the implanted region." The "implanted region" of step (d) is the "source/drain region" of step (d) that is implanted after the oxide mask of step (b) is grown. Therefore, at a minimum, the claim language requires the oxide mask to protect the "gap" from implants that will constitute the source and drain regions. According to the testimony of both parties' experts, the source and drain regions are created by implanting ions that reverse the polarity of a portion of the substrate. Thus, the "gap" must be the area under the oxide mask that is protected by the mask from the implantation of ions that reverse the polarity of the substrate, thereby creating the source and drain regions.

The specification and the prosecution history both support this construction. The specification states:

Because of the masking effect provided by the oxide on the sides of the gate electrode 16, the source/drain regions 20 and 22 are not implanted adjacent the vertical edges of the gate electrode. Rather, a gap is provided between the gate electrode 16 and the source/drain regions to allow for subsequent diffusion of the source/drain regions.

- 2215 -

PUBPAT
In other words, the oxide mask prevents the implantation next to the gate electrode of ions that would create the source and drain regions. Thus, the "gap" is the area of the substrate under the mask that is shielded from the implants that create those latter regions. Moreover, during the prosecution Manzo distinguished the Steinmaier patent, U.S. Patent No. 3,472,712, EPO publication 24 125, and EPO publication 34 508 because there was no "gap" between the sides of the gate electrode and the source and drain regions at the time of implantation. These prior art processes did not use a mask to prevent the implantation next to the gate of ions that would create the source and drain regions.

TENA objects to this construction of the word "gap." TENA argues that this construction expands the word "gap" beyond its ordinary usage, which merely implies a distance between two points. Moreover, TENA argues that this construction places limitations in the claims that are not supported by the evidence. Upon reflection, the court finds that TENA is partially correct and partially incorrect. TENA is correct that the word "gap" is not the proper source of these limitations. TENA is incorrect, however, because the claim language, the specification, the prosecution history, and the expert testimony all support these limitations. These limitations derive from reading step (d) of claim 1 as a whole, rather than just attempting to define the word "gap."

Step (d) of claim 1 states that the "gap" is "between a side edge of the gate electrode and a side edge of the implanted region." There is no dispute as to the location of the side edges of the gate electrode. In addition, there appears to be no dispute as to the location of the "side edge of the implanted region." As set out above, the source and drain regions form the "implanted region." Both parties' experts testified that the source and drain regions are regions of opposite polarity as compared to the substrate surrounding them. Thus, the side edge of a source or drain region is that area in the substrate where regions of opposite polarity meet; in other words, the side edge is where the concentration of N+ polarity equals the concentration of P+ polarity.

The logical conclusion is that the "gap" is simply the distance between the side edge of the gate electrode and the area in the substrate where the polarity reverses. Consequently, although the court's construction was correct when examining step (d) as a whole, the construction was slightly misleading in that it focused solely on the word "gap" in step (d) without also recognizing the implicit definition of the phrases "implanted region" and "a side edge of the implanted region."

In summary, the court will construe the word "gap" to have its ordinary meaning: "a distance between a side edge of the gate electrode and a side edge of the implanted region." The court will then construe the phrases "implanted region" and "source/drain region" to mean "regions of opposite polarity as compared to the substrate surrounding them." Finally, the court will construe the phrase "a side edge of the implanted region" to mean "where the concentration of N-type polarity equals the concentration of P-type polarity." This construction accurately captures the limitations of the claim as a whole while attaching each limitation to its corresponding claim language.
'419 patents. See '715 patent, 7:10-12 ("Deposit a low temperature oxide, any other desired glass dielectric..."); '419 patent, 7:1-4 (same). However, "gas dielectric" does not appear once as an isolated incidence of mistaken terminology. On the contrary, it is used twice within the claims of the '715 patent, twice within the claims of the '419 patent, and once within the specifications of each. See '715 patent, 8:22-24, 10:24-29, 5:50-52; '419 patent, 8:9-12, 8:50-53, 5:44-47.

In light of the fact that these repeated usages of "gas" have survived numerous revisions and amendments to the patents at issue, Ixys' characterization of "gas" as simply a typographical error strains credulity. Moreover, "it is important that the public be able to rely on the claims of a patent, in conjunction with the specification and file history, as indicating 'the metes and bounds of the claimed invention.'" International Visual Corp. v. Crown Metal Manufacturing Co., Inc., 991 F.2d 768, 775 (Fed. Cir. 1993) (citing London v. Carson Pirie Scott & Co., 946 F.2d 1534, 1538 (Fed. Cir. 1991). By using the word "gas" repeatedly, Ixys has created a reliance interest in the public (and particularly among potential infringers such as APT) that this court is reluctant to disturb. The court thus declines to substitute "glass" for "gas" where Ixys has failed to demonstrate the clear propriety of such a measure.

The question of the proper construction of "gas dielectric" itself nevertheless remains. Fortunately, "dielectric" is a well-known technical term: a dielectric is a non-conductor of electricity, otherwise known as an insulator. According to this understanding, the court construes the term at issue as follows: "gas insulator."

b. "gate electrode" and "source electrode"

LGD contends that the term "gate electrode" means "a patterned, electrically conductive material that controls current flow through the channel between the source electrode and drain electrode." D.I. 376 at Exh. C-11. LGD further contends that the term "source electrode" means "a patterned, electrically conductive material formed over the source region. Current flows through the channel between the source electrode and the drain electrode under control of the gate electrode." D.I. 376 at Exh. C-11. LGD further contends that the term "source electrode" means "a patterned, electrically conductive material formed over the source region. Current flows through the channel between the source electrode and the drain electrode under control of the gate electrode." D.I. 376 at Exh. C-11.

CMO's construction of gate electrode is the same as LGD's proposed construction. Id. at C-11. CMO's construction of source electrode is slightly different because CMO advocates construing "a source electrode and a drain electrode" together. Thus, CMO's definition of "source electrode" adds elements relevant to the drain electrode. Specifically, CMO contends that a "source electrode" is a "patterned electrically conductive material formed over the source region and drain region, respectively of a transistor. Current flows through the channel between the source electrode and the drain electrode of the transistor under control of the gate electrode." Id. at C-18.

AUO's construction of the term "gate electrode" is also similar to LGD's construction, but varies in where the patterned electrically conductive material is formed. Specifically, AUO contends that a "gate electrode" is "a patterned electrically conductive material formed in the gate region. Current flows through the channel between the source electrode and the drain electrode under control of the gate electrode." Id. at C-11. With respect to the term "source electrode," AUO agrees with LGD's construction. Id. at C-18.
Reviewing the specification and the claim language, the Court concludes that LGD's proposed constructions are most consistent with the claim language and the specification. '449 patent, col. 1, ll. 22-38, 56-60; col. 2, ll. 37-44, 56-61; col. 3, ll. 44-49; col. 4, ll. 47-53; col. 4, l. 65 - col. 5, l. 1, col. 5, ll. 29-38, Figs. 1-3. CMO's construction of "gate electrode" adds the term "drain electrode," and the Court is not persuaded that these terms must be construed together as CMO contends. Accordingly, the Court concludes that "gate electrode" means "a patterned, electrically conductive material that controls current flow through the channel between the source electrode and drain electrode," and "source electrode" means "a patterned, electrically conductive material formed over the source region. Current flows through the channel between the source electrode and the drain electrode under the control of the gate electrode."

G. Limitation 6: Gate electrode

34. The next element of Claim 1 is as follows: "gate electrode means on said gate insulation layer means and overlying said first and second channel regions." Again, various examples of this are described in the '699 written specification and drawings, including "ring-shaped gate 80" in Figures 7 and 8. The specification also notes that the "In carrying out the above invention, it should be noted that any type of contact material can be used to make the source and gate contacts. By way of example, aluminum could be used for the source electrodes while a polysilicon material can be used for the conductive gate 80 in FIG. 8 or the conductive gate 24 in FIG. 2" ('699 patent, col. 6, lines 59-64.) This element of Claim 1 is properly construed to embrace any aluminum, polysilicon or other gate electrode.

F. Limitation 5: Gate insulation

33. The next element of Claim 1 is as follows: "gate insulation layer means on said first surface, disposed at least on said first and second channel regions." Again, various examples of this are described in the '699 written specification and drawings, including "gate oxide 88" (Figure 8). Accordingly, this element of Claim 1 is properly construed to embrace any gate insulation layer.

1. Infringement

Defendants contend that plaintiff cannot establish defendants' products infringe certain claims of the '122 Patent. Because defendants' argument is based on defendants' proposed construction of "gate line," the Court first construes that term. Plaintiff argues that "gate line" should be construed according to its ordinary meaning, which, plaintiff submits, is "a conductor that connects a plurality of gate electrodes." (See Pl.'s Opp., filed May 20, 2005, at 10:16-17). Defendants do not argue that "gate line" has an ordinary meaning different from that proffered by plaintiff; rather, defendants argue that in the instant patent, the proper construction includes an additional limitation that the "gate line" is a "separate" component from the gate electrode. (See Defs.' Mot., filed May 6, 2005, at 10:21-22).

 Defendants, in support of their argument that gate lines are "separate" components from gate electrodes, rely primarily on language in claim 1 providing for "gate lines each connecting a plurality of said gate electrodes." See '122 Patent, col. 5, lines 35-37. To the extent the word "connect" might suggest gate lines and gate electrodes are separate components, the specification, which is the "single best guide to the meaning of a disputed term," see Vitronics Corp. v. Conceptronic, Inc., 90 F. 3d 1576, 1582 (Fed. Cir. 1996), suggests otherwise. See id. (holding "specification is always highly relevant to the claim construction analysis"). Specifically, the figures illustrating the preferred embodiment show the gate line as an extension of the gate electrode and without a break between them. See '122 Patent, Figure 1a. Consistent therewith, the specification states that the gate electrode "can include a gate line." See id., col. 4, lines 14-16. In other words, the
specification teaches that the gate line and gate electrode are not two "separate" components.

Such construction is supported by the prosecution history, in which the applicant, while discussing claims later allowed as claims 8 and 15, used the terms "gate line" and "gate electrode" interchangeably. (See Dang Decl., filed May 6, 2005, Ex. 3 at SHC 000894.) Such construction is further supported by the only extrinsic evidence offered as to the meaning of the two terms to those skilled in the art. Specifically, plaintiffs expert testified that "a particular part of the gate metal may be part of both a gate electrode and a gate line." See Silzars Decl., filed May 20, 2005, P 23; Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F. 3d 1298, 1309 (Fed. Cir. 1999) (observing district court may consider extrinsic evidence "to ensure that the claim construction it is tending to from the patent file is not inconsistent with clearly expressed, plainly apposite, and widely held understandings in the pertinent technical field").

1 The applicant stated as follows: "Further, with regard to claims 13 and 20, each gate line overlaps the periphery of a plurality of adjacent picture element electrodes, to thereby minimize light from leaking from each of the picture element electrodes. The area where each of the picture element electrodes overlaps each of the gate electrodes is preferably, as claimed in claims 13 and 20, located in a long, narrow strip fashion on the outskirts of the picture element electrodes." (See id.) (emphasis added).

2 Defendants do not offer any extrinsic evidence, from their expert or otherwise, to support a finding that persons skilled in the art would understand "gate line" and "gate electrode," as those terms are used in the '122 Patent, to refer to two separate components.

Accordingly, the Court construes "gate line" to mean "a conductor that connects a plurality of gate electrodes." Because defendants' motion for summary judgment on the issue of infringement of the '122 Patent is dependent on the Court's accepting defendants' proposed construction of "gate line," defendants are not entitled to summary judgment on the issue of infringement of the '122 Patent.

7. Gateway computer

This term is used in the '201 patent. Seven proposes that the term means "an intermediate computer." Pointing to the preferred embodiment, Visto contends that the term means "a FormLogic Server located between the client and a network having the data storage." The specification and the prosecution history refer to the gateway computer as an intermediate server between the client and the original server. Therefore, the court construes the term "gateway computer" to mean "an intermediate server between the client and the original server."

b. "Gateway Switch"

The term "gateway switch" appears only in the asserted claims 15, 32, and 34 of the '960 patent. As before the district court, RIM bases its construction of the term on its argument that Campana's "electronic mail system" implemented a "pull" email architecture. RIM contends that "a gateway switch is the mechanism for maintaining the mailboxes needed to implement the pull technology." The district court construed the term differently, as "[a processor in an electronic mail system which connects other processors in that system and has additional functions for supporting other conventional aspects of the electronic mail system such as receiving, storing, routing, and/or forwarding electronic mail messages." Claim Construction Order, slip op. at 6. As we have previously rejected RIM's argument that "pull" email architecture is required, see Section II.
A. 2. a, supra (construing "electronic mail system"), we are similarly compelled to reject its suggestion that "gateway switches" must enable this technology. In short, we agree with the district court's claim construction of "gateway switch."

A. "Gatherer","Gathering Software Agents","Gathering Cycle" ('077 and '910 Patents)

Generally speaking, the '077 claims a system and method for accessing a number of Internet sites on behalf of an end user, collecting information from those sites, and automatically downloading that information to the end user. The '910 patent is based on the same system, and claims a system and method for alerting end users when the information stored on those sites changes. For example, if a user has two bank accounts and is able to access those accounts from the Internet, the '077 patent describes a way to automatically retrieve the user's account balances from the banks' websites. The '910 patent provides a way of alerting the user when one of his bank account balances falls below a certain level. Both patents use the term "gather" to refer the process of collecting the personal information on the end user's behalf.

1. '077 Patent

"Gatherer" and "gathering software agents" appear in both independent claims (claims 1 and 7) of the '077 patent. Yodlee construes the terms to mean "a software component and/or related data that once processed can be employed to locate and retrieve information from Internet destinations based on user or enterprise request." CashEdge propose that "gatherer" be construed to mean "a summarization agent that combines data such that summary is not just an aggregated restatement of the gathered material, is programmable and is an interactive software application adapted to run on a network server." The Court finds that Yodlee's construction accurately describes the function of the gatherer. CashEdge's construction imports dependent claim 3 from the '077 patent, which deals with summarization, into claim 1; this would impermissibly render claim 3 superfluous. See TurboCare Div. of Demag Delaval Turbomachinery Corp. v. General Electric Co., 264 F.3d 1111, 1123 (Fed. Cir. 2001).

2. '910 Patent

The '910 patent uses the term "gatherer" in independent claim 1. CashEdge asserts that this element is written in means-plus-function form and is subject to 35 U.S.C. § 112(6). The element does not use the term "means," creating a presumption that it is not subject to § 112(6). Lighting World, Inc. v. Birchwood Lighting, Inc., 382 F.3d 1354, 1358 (Fed. Cir. 2004). This presumption can be overcome if it is demonstrated "the claim term fails to recite sufficiently definite structure or else recites function without reciting sufficient structure for performing that function." Id. (internal quotation marks omitted). Whether the term brings to mind a particular structure is not dispositive; instead, what is important is whether the term is understood to indicate structure. Id. at 1360.

Yodlee has submitted an expert declaration stating that, based upon the use of "gatherer" in the specification, it would have been apparent to someone skilled in the art at the time of this patent that the term "gatherer" referred to a software application. Papakonstantinou Decl. PP 16-18. The Court does not believe that this is sufficient. The Federal Circuit requires that "the term is one that is understood to describe structure, as opposed to a term that is simply a nonce word or a verbal construct that is not recognized as the name of structure." Lighting World, 382 F.3d at 1360 (emphasis added). In fact, the Federal Circuit implied that a "coined term" such as gatherer would be appropriate for means-plus-function analysis. Id. ("[T]he term 'detector, although broad, is still structural for purposes of section 112 P 6 because it is not . . . a coined term lacking a clear meaning such as 'widget' or 'ram-a-fram.'") As it is undisputed that "gatherer" is a "coined term lacking clear meaning," the Court finds that the above element is written in means-plus-function form.
1. "a general coupon template"

Southwest argues that the term means "a general form for a coupon which can require additional parameters particular or unique to the remote location where it is printed to be completed." 3T argues that the term means "a reusable generic coupon form which includes no information about a specific location."

Southwest argues that while 3T's proposed construction could be interpreted correctly, it might mislead the jury into thinking that a general coupon template must be incomplete. Southwest argues that its construction agrees with the specification:

A site specific coupon is created by using a general coupon template and modifying the template with information specific to a particular location. Some information like the product, product logo, legal disclaimer, and the like is fixed for all coupons while other information like the discount, expiration date, location and the like is variable. A general coupon template can either be a digital representation of a complete coupon including all art work, logos, and text, or it can be an incomplete coupon with art work, logos and general text with specific information missing such as the amount of the discount, valid hours and dates, particular product or valid location. If the general coupon template is a complete coupon the site specific information used to make the site specific coupon overwrites the corresponding information on the complete coupon replacing it when the site specific coupon is printed. Likewise, if the general coupon template is an incomplete coupon the site specific information is inserted into the blanks on the template, thereby creating a complete site specific coupon.

Referring now to FIG. 5A, block 602 represents loading a general coupon template on central server 12 from FIG. 1. The general coupon template from block 602 is the necessary art work, logos and general information to appear on the final coupon. The general coupon template can be a complete coupon including all necessary information, or can be an incomplete coupons which is missing the information that is particular to each individual site.

'673 patent, 7:1-19, 21:3-10 (emphasis added). Thus, Southwest argues that the general coupon template can be complete and usable right from the start or it can require additional information particular to each location.

3T argues that the actual dispute revolves around whether the term should be construed to exclude templates that contain information specific to a particular location. 3T argues that the specification uses the term "a general coupon template" to refer to a coupon that does not have information specific to a particular location and that is capable of being used and reused by multiple locations:

Yet another object of the invention relates to creating coupons that are individualized to specific remote locations. A general coupon template is provided, and details customized to a specific location are provided that are added to the general template to form a site specific coupon.

A site specific coupon is created by using a general coupon template and modifying the template with information specific to a particular location.

'673 patent, 3:52-56, 7:1-3. Further, 3T argues that if the general coupon template already contains information particular to a specific location it would be unnecessary to combine the template with the site specific information file to make a site specific coupon as required in claim 1, because the parties have already agreed that the term "site specific information file" includes information unique to a specific location. Thus, the general coupon template should not include information about a specific location. 3T argues that Southwest's proposed construction should be rejected because it may permit the template to include site-specific information.

The Court finds that the specification is clear that the general coupon template may be complete or incomplete. See '673 patent, 21:3-10. If the coupon is complete, "the site specific information used to make the site specific coupon overwrites the corresponding information on the complete coupon replacing it when the site specific coupon is printed." '673 patent, 7:13-16. The Court also finds that claim 1 expressly requires "combining the general coupon template and the site specific information file in the processing station to create the site specific coupon." Southwest's proposed construction implies that site specific information does not have to be combined with the template, and thus makes the language of claim 1 unnecessary which requires combining the general coupon template with the site specific information file to make a site
specific coupon. See Merck & Co. v. Teva Pharms. USA, Inc., 395 F.3d 1364, 1372 (Fed. Cir. 2005) ("A claim construction that gives meaning to all the terms of the claim is preferred over one that does not do so."). On the other hand, 3T's proposed construction does not take into account the fact that a general coupon template may be a complete coupon that may have site specific information wherein such information is replaced with the relevant site specific information when printed. To give full meaning to the claim language, and to allow the general coupon template to be a complete coupon or an incomplete coupon, the Court construes "a general coupon template" to mean "a generic form for a coupon which includes no site specific information with respect to the specific location where the site specific coupon is to be printed."

GO BACK

1851

5. "general information"

Southwest argues that the term means "information not particular to a specific remote location," whereas 3T argues that the term means "the maximum amount available for money orders, signature files, store IDs, and template." The parties provide no substantive analysis or discussion for their proposed constructions. The parties appear to rely upon different portions of the specification with different meanings of the term "general information." It appears that Southwest relies on the following portion of the specification for its construction:

Referring now to FIG. 5A, block 602 represents loading a general coupon template on central server 12 from FIG. 1. The general coupon template from block 602 is the necessary art work, logos and general information to appear on the final coupon. The general coupon template can be a complete coupon including all necessary information, or can be an incomplete coupons which is missing the information that is particular to each individual site.

'673 patent, 21:3-10 (emphasis added). It appears that 3T relies on a different portion of the specification for its construction:

The source code begins with a definition of variables used in program, and then loads general information into the printer like the maximum amount available for money orders, signature files, store IDs, and templates. At this point, the program is broken down into cases or objects that are called individually when needed by the program. Cases not specifically discussed below have been reserved for future use.

'673 patent, 22:58-65 (emphasis added).

Thus, in part, the Court must decide which specification portion is more relevant to the disputed claim language to determine the term's meaning. In relevant part claim 7 states the following: "The system of claim 6 wherein the general coupon template includes artwork, logos and general information, ..." The portion of the specification in which Southwest relies upon is very similar and states the following: "The general coupon template from block 602 is the necessary art work, logos and general information to appear on the final coupon." '673 patent, 21:5-7. The Court finds that the "general information" of claim 7 is referring to the specification portion relied upon by Southwest. Further, this portion of the specification references Block 602 as the general coupon template, and the corresponding Block 602 in Figure 5A states "receive templates without location specific information." Thus, consistent with Southwest's proposed construction, the Court construes the term "general information" to mean "information not particular to a specific remote location."

GO BACK

1852

A

All of the '685 claims require a "general purpose computer system" that is adapted to the specified purposes. The definition of "general purpose computer" was agreed by the parties as

a computer capable of running multiple unrelated programs, which are selected by the user and loaded into the device. It must feature at least: (1) a central processing unit, (2) one or more input devices that are not specific to any one program, (3)
memory, (4) mass storage devices (such as a disk drive) for storing large amounts of data, and (5) one or more output devices.

Zoll's device contains a Hitachi SuperH RISC (Reduced Instruction Set Computer) microprocessor. The district court observed that the '685 specification is specific to a general purpose computer and that all of the claims were so limited during prosecution. The court found that it was "implausible" for a RISC microprocessor to be deemed a general purpose computer, for RISC microprocessors have limited functionality. Thus the court held that "general purpose computer," as that term is used in the '685 patent, does not read on a RISC microprocessor and that the Zoll system thereby avoids infringement. Mr. Hutchins argues that his invention is readily performed using a RISC microprocessor. He points out that the Zoll system is intended to interface and work in conjunction with a standard IBM-PC, which is a general purpose computer, and that the Zoll device includes an interface for connection to a personal computer for purposes of review and archiving of data associated with a rescue; the Zoll manual states the minimum criteria for the personal computer as "Windows . . . IBM-compatible 486 (or higher) computer, 64 MB RAM, VGA monitor or better, CD-ROM drive, IrDA port, 2MB disk space."

The district court accepted the definition of "general purpose computer" that had been agreed by the parties; the court found that a RISC microprocessor does not meet that definition, and that the potential for connecting to a personal computer did not meet the claim limitation. We do not discern error in this finding, for the term "general purpose computer" was added to Hutchins' claims during prosecution in order to distinguish the '685 invention from prior art that showed similar devices with dedicated microprocessor units. This produced an estoppel against reading the term "general purpose computer" to include a dedicated microprocessor such as a RISC, for the claims had been amended in response to the PTO rejection, thereby estopping recovery of the same subject matter that the claims had been amended to exclude. See Alloc, Inc. v. ITC, 342 F.3d 1361, 1371-72 (Fed. Cir. 2003) (statements made during prosecution surrendering subject matter binding on later interpretation of the claims); see also Festo, 535 U.S. at 725 (estoppel arises upon amendment to "surrender the particular equivalent in question"); Bayer AG v. Elan Pharm. Research Corp., 212 F.3d 1241, 1252 (Fed. Cir. 2000) (an aspect expressly disavowed during prosecution of the patent cannot be reached under the doctrine of equivalents). The district court's ruling on this aspect is affirmed.

10. General purpose media processor/ General purpose programmable media processor/ Media processor/ Programmable media processor/ General purpose [multiple precision parallel operation] programmable media processor

Next, the court turns to the construction of the media processor terms. The plaintiff contends that the "general purpose media processor" is "a general purpose processor that also does media processing." The defendants urge that "general purpose media processor" means "a single programmable processor that processes multiple media data streams without external specialized processors." There are two disputes between the parties regarding the construction of this term and the remaining "media processor" terms. The primary dispute between the parties is whether the "media processor" operates without "external specialized processors." A second issue is whether the term "programmable media processor" is a claim limitation.

After considering the submissions and arguments of counsel, the court construes each of the disputed phrases above to mean "a processor having an execution unit capable of operating on different media types and data sizes." The court is not persuaded that the claim language or the specification necessarily excludes the presence of other, external processors, from the scope of the claim, as long as the processor itself has the requisite capabilities. With respect to the term "programmable media processor," the court concludes that this term is not a claim limitation for the same reasons provided with respect to the term "unified media processing."
The limitation of the general synchronization module appears in the '131, '192 and the '708 patents. Visto proposes this term means "software routines or code that perform the task of determining whether a workspace element and/or an independently modifiable copy thereof has (or have) been modified, based on one or more criteria." Seven proposes that the term "general synchronization module" means "a computer software module, including routines for determining whether the content of a workspace element and/or the content of an independently modifiable copy of the workspace element has been modified, and routines for reacting to a determination of a modification in content, for synchronizing workspace elements." Seven further proposes that "first general synchronization module means "a computer software module, including routines for determining whether the content of the 'first workspace element' has been modified, and routines for reacting to a determination of a modification in content, for synchronizing workspace elements." Finally, Seven proposes that the term "second general synchronization module" means "a computer software module located on a global server including routines for determining whether the content of the 'second workspace element' (i.e. the independently modifiable copy of the workspace element) has been modified, and routines for reacting to a determination of a modification in content, for synchronizing workspace elements."

The primary differences relate to the inclusion in Seven's definitions of the content limitation previously discussed and, in the "second general synchronization module" the additional inclusion of the global server. The rejects Seven's arguments that the claim language should be limited by implication to the embodiment disclosed in the specification. The court therefore defines the term "general synchronization module" to mean "software routines or code that perform the task of determining whether a workspace element and/or an independently modifiable copy thereof has (or have) been modified, based on one or more criteria."

D. "Generate" and "Generating"

The parties dispute the proper construction of the terms "generate" and "generating", which are used in the context of the generation of a message by the processing system in the '429 Patent, claims 1 and 23; the '064 Patent, claims 1 and 35; the '561 Patent, claims 1 and 24; and the '932 Patent, claims 1 and 18. In Vonage, Sprint argued that the term "generate/generating a message" meant assemble/assembling information into a message for the first time in connection with setting up a call; Vonage argued that the term meant create/creating for the first time. See 518 F. Supp. 2d at 1312-13. The Court resolved that dispute as follows:

Sprint correctly points out that the language of the various claims demonstrates that the messages are generated by assembling information because each of the claims requires the generation of a message that includes some particular content. [The Court then listed examples from the claims.]

Vonage relies on language contained in the specifications which states that the signaling processor "generates new signaling." This language introduces the concept that the generated message, or signaling, must be "new". This is not inconsistent with the generally accepted meaning of the term "generate". See Webster's, supra, at 945 (defining "generate" to include, for example, to bring into existence and/or to originate). Importantly, however, this language from the specification does not indicate that the content of the message must be new, but rather that the signaling itself must be new.

Ultimately, the court believes that the overall thrust of Sprint's proposed claim construction is essentially correct. Sprint has attempted to include the concept that the message itself must be new by incorporating the language "for the first time in connection with setting up the call." But, the "for the first time" language and its proposed placement within the properly construed claim term is confusing. Additionally, the language proposed by Vonage "create/creating for the first time" is redundant and confusing as to what, precisely, must be created for the first time. In an attempt to give more clarity to the term "generate", the claim term "message" must be modified to clarify that the message is what is being newly generated based on assembled information. Accordingly, the court construes the claim terms "generate a message" and "generating a message" to mean assemble/assembling information to create a message.

Id. (citations to patents omitted).
In the present case, Sprint asks the Court to reaffirm its construction of these terms from Vonage. Big River, on the other hand, asks the Court to construe "generate" and "generating" to mean create/creating rather than forward/forwarding. Big River argues that adding the distinction between creating and forwarding is necessary because the issue arose at the Vonage trial, as Sprint's expert conceded in his testimony that the processing system does not "generate" a message if it merely forwards a message, in the sense of sending on the exact message that it has received. The Court's prior reasoning in the Vonage order, however, is not inconsistent with the distinction urged by Big River. As the Court concluded previously, the signaling (message) must be new, but the content need not be new, and the signaling is generated by the assembling of information. See id. Big River has not suggested that that reasoning is flawed in any way.

Big River seeks to add language to the construction making clear that "generating" does not include "forwarding". The ordinary meaning of "create" (used in the Court's construction), however, already incorporates the idea that there must be a new signal, and that the processing system may not simply pass along an existing signal. Just as the Court concluded that "creating for the first time" was redundant in Vonage, see id. at 1313, it also concludes that the language "creating rather than forwarding" is redundant. Big River's addition, therefore, does not add anything to the construction.

Moreover, in its presentation to the Court at the claim construction hearing, Big River identified the "key point of dispute" with respect to this term as "whether 'generating' requires creating new message content." Clearly, as the Court reasoned in Vonage, the claims require new signaling, but they do not require new content. To the extent that Big River's construction relies on a contrary answer to that key question, then, it must be rejected.

Big River's reference to the prosecution history of the patents is unavailing. In that excerpt, the prior reference was distinguished as a system that merely routed signaling; thus, the reference does not indicate that the signal cannot include pre-existing content.

Finally, Big River would replace "assemble/assembling information to create" with "create/creating", based on its argument that the assembly of information is inherent in the act of "creating". The Court disagrees, however, that Big River's change would aid a jury; to the contrary, the "assembling" language, which has support in the claims and specifications, resolves the parties' "key" dispute by clarifying that the generated message may include pre-existing content.

Accordingly, the Court construes "generate" and "generating" in this context to mean assemble/assembling information to create.

With respect to the phrase "generating a control message indicating the network code," Sprint also asks the Court to construe "the network code" to mean "the code identifying the network element." The Court finds such further construction unnecessary, however, in light of its previous treatment of the term "network code".

Accordingly, the Court construes "generate" and "generating" in this context to mean assemble/assembling information to create.

7 With respect to the phrase "generating a control message indicating the network code," Sprint also asks the Court to construe "the network code" to mean "the code identifying the network element." The Court finds such further construction unnecessary, however, in light of its previous treatment of the term "network code".

1856

2. Generate.

Again, O2 contends that this term needs no construction because it is readily understood. TSE, by contrast, suggests that the court should define this term to mean "to bring into existence." O2 argues that TSE's true motive in suggesting a definition of generate is to obtain new constructions of the pulse signal limitations found in the patent. As noted below, however, the court has adopted Judge Wilken's constructions of each of the pulse signal limitations, notwithstanding TSE's arguments to the contrary. With respect to the present term, the court construes "generate" in accordance with its ordinary meaning—"to bring into existence." Webster's Third International Dictionary, 1993.
B. "To Generate"

The parties are in dispute over the correct meaning of the term "to generate" in the context of the '961 patent. Lansa argues that the term takes on a special meaning as evidenced by the specification, while ResQNet insists that the term is restricted to its ordinary meaning. Vitronics, 90 F.3d at 1582; see also Markman, 52 F.3d at 979-80.

The specification of the '961 patent does not provide a technical definition of the verb "to generate," leading one to believe that the term should be given its ordinary meaning. Vitronics, 90 F.3d at 1582 ("Although words in a claim are generally given their ordinary and customary meaning, a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning, as long as the special definition of the term is clearly stated in the patent specification or file history."). However, the specification discusses in detail the process of "generating" a screen ID, shedding light on the meaning of the verb in the context of the invention. The patent specification begins summarizing the invention by describing only one way of "generating" a screen ID, stating at column 3, lines 20-38:

The above and other problems of the prior art are overcome in accordance with the present invention which relates to a display routine which is based upon an algorithm which recognizes the screen by the layout and fields therein, not based solely upon the particular screen ID number. In accordance with the invention, an image recognition algorithm is utilized to recognize and display the information stored in buffer 103. The information is read from buffer 103 and processed by an algorithm which generates a unique ID number.

(emphasis added). As the discussion above concerning the information element demonstrates, the use of an algorithm is also referenced later in the description of the preferred embodiments. In introducing the one embodiment that is discussed in detail, it is stated that "the particular algorithm used to recognize the screen and generate the screen ID may vary from system to system, but a particular such algorithm will now be described." '961 Pat. at col. 5, ll. 34-36 (emphasis added). The specification then goes on to describe what it labels a "screen recognition algorithm." Id. at col. 5, l. 37. No other way "to generate" a unique screen ID is set forth in the specification, indicating that the invention of the '961 patent processes information and generates an ID via a screen recognition algorithm.

However, no other limitation or definition is provided in the specification or file history, suggesting that "to generate" should in other respects be given its ordinary meaning. The verb is commonly defined as "to bring into being" or "produce as a result of a chemical or physical process," and in the context of computer science it is defined as "to produce (a program) by instructing a computer to follow given parameters with a skeleton program." The American Heritage Dictionary of the English Language, Fourth Edition (2000). This definition is consistent with the discussion of the term in the '961 patent and with the limitations described above.

3 The parties dispute the meaning of the term "algorithm." Specifically, Lansa contends that the term must imply a mathematical process. The term is not defined in either the claim or the intrinsic evidence, and no detailed description of the process by which the screen recognition algorithm produces an ID is given in the '961 patent. Therefore, it is assumed by the Court that the term is given its common, ordinary meaning. Generally, the term is defined as "[a] step-by-step problem-solving procedure, especially an established, recursive computational procedure for solving a problem in a finite number of steps." The American Heritage Dictionary of the English Language, Fourth Edition (2000). The National Institute of Standards and Technology defines the term as "[a] computable set of steps to achieve a desired result." Paul E. Black's Dictionary of Algorithms, Data Structures, and Problems (http://www.nist.gov/dads). Accordingly, while the term certainly implies computation in a general sense, there is no specific support for otherwise labeling the process "mathematical."
8. "generate a display"

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>FotoMedia's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;display&quot;</td>
<td>data that may be viewed graphics and/or text</td>
<td>a fixed image that comprises graphics and/or text</td>
</tr>
<tr>
<td>&quot;generate&quot;</td>
<td>Plain and ordinary meaning. Alternatively, this term means &quot;create.&quot;</td>
<td>make a visual representation of</td>
</tr>
<tr>
<td>&quot;generate a display&quot;</td>
<td>generate data that may be viewed</td>
<td>make a visual representation of a fixed image that comprises graphics and/or text</td>
</tr>
</tbody>
</table>

The key dispute over these terms is whether the step of "generating a display" requires a process of visual representation of a fixed image. FotoMedia asks the Court to construe the terms "generate" and "display" separately.

FotoMedia's proposed construction of "display" is "data that may be viewed." FotoMedia finds support for this in the specification which teaches that the claimed system creates "custom generated HTML pages." '936 patent, col.14 ll.53-60. FotoMedia's proposed construction, however, fails to capture the visual nature of a display.

Defendants argue that the display must be a fixed image that contains graphics and/or text. Defendants contend that the specification repeatedly refers to the use of "fixed image files." See '936 Patent, col. 10, ll. 36-63, col. 12, ll. 31-67. Defendants argue that because the display may be composed of flattened image files, it too has to be is fixed. The specification discloses that the layout of the postcard is finalized as a "display" when the various data elements are compressed together in permanent image files such as a JPEG or GIF. The Court finds that these files need not necessarily be static or fixed.

"Display" is construed as an "image that comprises graphics and/or text."

The dispute over the construction of the terms "generate" and "generate a display" revolves around whether "generate" requires putting data into a visual form. FotoMedia proposes that "generate" should simply be construed as "create." Defendants, however, argue that claim 1 of the '936 patent restricts the use of a "display" for viewing purposes only. See '936 Patent, col. 14, l. 63 - col. 15, l. 2; see also id. at col. 2, ll. 62-64 ("data representing the display is in a format that allows for transmission to and viewing on a client computer"). The Court agrees that data should be in a format that allows representation of the display to the user.

Given the Court's construction of "display," the Court construes "generate a display" as "create a representation of an image that comprises graphics and/or text."

1859

e. "Generate a Fill Signal"

The term "generate a fill signal" appears in claim 146 of the 780 patent. IP asks the court to adopt the following definition: to generate a signal which indicates voids which may be filled by changing the image. Lexmark and Dell ask for a definition similar to the definition of "altering voids": to generate a signal which fills voids by varying the input signal without modifying the on and off times of the signal carrying the image.

As was the case for the related term "altering voids," we agree with a portion of Lexmark and Dell's argument, but they take
the concept too far. Therefore, the court adopts Lexmark and Dell's construction: to generate a signal which fills voids by varying the input signal without solely modifying the on and off times of the signal carrying the image.

1860

B. "Generate a Message" or "Generating a Message"

Claim 38 of the '572 patent, claim 1 of the '561 patent, claim 18 of the '932 patent, claim 1 of the '429 patent, and claim 1 of the '064 patent each recite the claim phrase "generate a message" or "generating a message." Sprint contends that these claim terms should be construed to mean assemble/assembling information into a message for the first time in connection with setting up a call. Vonage contends that they should be construed to mean create/creating for the first time.

Sprint correctly points out that the language of the various claims demonstrates that the messages are generated by assembling information because each of the claims requires the generation of a message that includes some particular content. For example, claim 38 of the '572 patent claims a processor to process signaling to select the second connection, and to "generate" first and second control messages that indicate that second connection. Claim 1 of the '561 patent claims a method for processing a signaling message to select a network code, and "generating" a control message indicating that code. Claim 18 of the '932 patent claims a communication system wherein the processing system is configured to receive and process the first message to select a narrowband switch, and to "generate" and transmit a second message based on the selected narrowband switch. Claim 1 of the '429 patent claims a method for processing information to select an identifier, and "generating" a message containing the identifier. And, claim 1 of the '064 patent claims a method for processing set-up signaling to select a DSO connection, and "generating" a message identifying the DSO connection.

Vonage relies on language contained in the specifications which states that the signaling processor "generates new signaling." See '429 Patent at 2:14-17; '572 Patent at 4:18-20. This language introduces the concept that the generated message, or signaling, must be "new." This is not inconsistent with the generally accepted meaning of the term "generate." See Webster's, supra, at 945 (defining "generate" to include, for example, to bring into existence and/or to originate). Importantly, however, this language from the specification does not indicate that the content of the message must be new, but rather that the signaling itself must be new.

Ultimately, the court believes that the overall thrust of Sprint's proposed claim construction is essentially correct. Sprint has attempted to include the concept that the message itself must be new by incorporating the language "for the first time in connection with setting up the call." But, the "for the first time" language and its proposed placement within the properly construed claim term is confusing. Additionally, the language proposed by Vonage "create/creating for the first time" is redundant and confusing as to what, precisely, must be created for the first time. In an attempt to give more clarity to the term "generate," the claim term "message" must be modified to clarify that the message is what is being newly generated based on assembled information. Accordingly, the court construes the claim terms "generate a message" and "generating a message" to mean assemble/assembling information to create a message.

1861

F. Generate Device Control Signals

Claim 1 provides that the device interface, network interface, and memory perform operations for sending customized software to the client machine over the network, and that such software "enables the client machine to generate device control signals . . . ." (Id. at c. 18, 11: 63-67.)

Digi asserts that this term should be defined as "to create digital data that comprise instructions for manipulating the device control circuitry." Lantronix contends that this term needs no construction beyond its plain meaning. The Court agrees that the phrase "generate device control signals" needs very little construction. The Court finds that the plain meaning of the term to a person of ordinary skill in the art would be that the software enables the client machine "to generate signals that control the device."
Specifically, representative claim 1 of the '867 patent claims:

A method of upscaling a source image frame in both vertical and horizontal directions to generate a destination image frame, the source image frame including a plurality of source scan lines, with each of said plurality of source scan lines including a plurality of source pixel data, the destination image frame including a plurality of destination lines, each of said plurality of destination lines including a plurality of destination pixel data, said method comprising the steps of:

(a) receiving said plurality of source pixel data included in said source image frame using a first clock signal;
(b) generating a second clock signal;
(c) upscaling said source image frame in both vertical and horizontal directions to generate said plurality of destination pixel data representative of said destination image frame; and
(d) providing said plurality of destination pixel data representative of said destination image frame using said second clock signal,

wherein said second clock signal is generated to have a clock period such that the time to provide said plurality of destination pixel data is equal to a period to receive said source pixel data in said source image frame.

'867 patent, col. 21, l. 62 - col. 22, l. 18 (emphasis added).

This appeal centers on the "wherein" clause of claim 1, which states that "said second clock signal is generated to have a clock period such that the time to provide said plurality of destination pixel data is equal to a period to receive said source pixel data in said source image frame." In the 481 Investigation the Commission determined that the "generated . . . such that" limitation required only that a second clock signal be "generated so as to be consistent with an equality of the source image frame and destination image frame periods." 481 Commission Decision, slip op. at 14-16 (emphasis added).

Further, in the 481 Investigation, the ALJ had determined that the "equality" referenced in the claim language required that the period of time to input active pixel data must equal the period of time to output active pixel data. 481 Initial Determination, slip op. at 90. However, the Commission rejected this construction, determining that the phrase required an "equality of the periods to receive the source image frame and to provide the destination image frame." 481 Commission Decision, slip op. at 12.

In the 491 Investigation, the parties disputed the meaning of "image frame;" Genesis contended that an "image frame" contains both active and blanking pixel data, while MStar contended that an "image frame" only contains active and horizontal blanking pixel data. However, the ALJ agreed with Genesis that the "equality" referenced in the claim language "mean[t] an equality of full frame periods." 491 Initial Determination, slip op. at 110. That is, the period of time required to input all the active pixel data, horizontal blanking pixel data and vertical blanking pixel data associated with an image must equal the amount of time required output all the active pixel data, horizontal blanking pixel data and vertical blanking pixel data associated with an image. The ALJ determined that, under such a construction, "it is undisputed that the accused chips maintain an equality of equal source and destination image frame periods" and that the "wherein" clause was met by the accused devices. Id., slip op at. 148. The Commission agreed with the ALJ's construction of the "wherein" clause and its infringement analysis. Consolidated Commission Decision, slip op. at 45-46.

On appeal, MStar argues that the decision below misconstrued these two aspects of the "wherein" clause of claim 1. First, MStar argues that the phrase "generated . . . such that" requires that the second clock signal "cause" the required equality. Further, MStar argues that the "equality" of periods refers to the period required to input and output active pixel data and horizontal blanking pixel data, but not vertical blanking pixel data. MStar argues that if it is correct with regard to either aspect of the construction of claim 1, it does not infringe. However, MStar does not appeal the Commission's infringement analysis under the claim construction that the Commission adopted.
We review legal conclusions of the ITC de novo SKF USA, Inc. v. ITC, 423 F.3d 1307, 1312 (Fed. Cir. 2005) (citing 5 U.S.C. § 706(2)(A) (2000); Checkpoint Sys. v. U.S. Int'l Trade Comm'n, 54 F.3d 756, 760 (Fed. Cir. 1995)). As claim construction is a question of law, Cybor Corp. v. FAS Techs. Inc., 138 F.3d 1448, 1451 (Fed. Cir. 1998), we review the Commission’s claim construction without deference.

The ‘867 patent requires that the upscaler have a second clock signal “wherein said second clock signal is generated to have a clock period such that the time to provide said plurality of destination pixel data is equal to a period to receive said source pixel data in said source image frame.” Noting that the conjunction “such that” is defined as “having a quality to a degree to be indicated,” see Merriam-Webster’s Collegiate Dictionary 1176 (10th ed. 1997), the ALJ found during the 481 Investigation that “the plain language of the claim requires generation of a second clock consistent with an equality of active periods but does not require synchronization of the first and second clocks or ’locking the clocks’ using a PLL [phase-locked loop]. It merely requires . . . that the second clock, on average, is set so that the period to receive the source pixel data is equal to the period to provide the destination pixel data.” 481 Initial Determination, slip op. at 100. The Commission adopted this construction, determining that the “generated . . . such that” limitation requires only that a second clock signal be "generated so as to be consistent with an equality of the source image frame and destination image frame periods." 481 Commission Decision, slip op. at 14-16 (emphasis added). For the 491 Investigation, both the ALJ and Commission adopted that same construction. 491 Initial Determination, slip op. at 109-10; Consolidated Commission Decision, slip op. at 30-40.

MStar argues that this claim construction was in error. In its initial brief to this court, MStar emphasized that the "generated . . . such that" language required that the second clock “cause” the claimed equality by being "locked" to the first clock. As such, MStar argued that the ‘867 patent discloses only one method for causing equality, "the use of a second signal tightly synchronized to the first clock signal," and cited portions of the specification describing how the source and destination clocks might be locked and the formula used to lock the signals.

In response, Genesis argued that signal-lock was merely a preferred embodiment. Further, Genesis noted that if claim 1 requires that the two clock signals are locked, claim 10 is redundant, as it contains only one additional limitation, that the "second clock is locked to said first clock signal in a proportion." ‘867 patent, col. 22, ll. 54-55. In its reply brief to this court, MStar disclaimed the argument that claim 1 requires signal-lock. MStar argued that the claim language only requires that the second signal "cause" the equality and that it does not require that the signals be locked.

However, MStar failed to explain how its claim construction, which would require that the second clock signal be generated so as to "cause" the equality of the frame periods, differs in any meaningful way from the Commission's claim construction, which requires that the second clock signal be generated so as to be "consistent" with an equality of the source and destination image frame periods. Both claim constructions require a logical relationship between the second clock signal and the claimed equality without specifying precisely how that logical relationship should work. Further, MStar does not demonstrate how the Commission's claim construction is broader than its preferred claim construction; MStar does not point to any embodiment of the invention that would fall within the "consistent" claim construction, but not within the "causation" claim construction.

Finally, contrary to MStar's arguments, the Commission's claim construction does not read the "generated . . . such that" limitation out of the claim language. MStar argues that if the second clock signal need only be consistent with the claimed equality, the wherein clause could simply read "wherein the time to provide said plurality of destination pixel data is equal to a period to receive said source pixel data in said source image frame." However, as noted above, the "consistent" claim construction requires a logical relationship between the second clock signal and the equality of time periods. Thus, under the Commission's claim construction, it is not sufficient that the time periods are equal, as MStar contends; rather, there must be a logical relationship of some sort between the second clock signal and the equality of the time periods.

4. Phrases including the term "phased burst signal."
Samsung seeks a construction of two other phrases which include this term. These phrases are "generating a plurality of phased burst signals" and "delaying at least one of said phased pulse signals." O2 contends that "generating" and "delaying" need no construction.

The phrase "generating a plurality of phase burst signals" appears in claim 27 of the '234 patent. Samsung seeks a construction of "generating" which means "bringing into existence." After considering the parties' arguments, the court adopts that construction.

B. Generating

The plaintiff contends that this term means the same as creating, and proposes a definition of "selecting, forming, or making." The defendants again urge their real time limitation and contend that the term means "defining, in real time, by the application of one or more rules or operations to given quantities." The patents use the terms "creating" and "generating" differently. In the context of "generating," the patents use the word to connote a meaning of "producing," such as in the context of "generating route schedules." After reviewing the briefs and the intrinsic record, the court therefore defines "generating" to mean "producing."

b. generating a bit stream

The crux of the parties' dispute concerning the phrase "generating a bit stream," is whether this language encompasses a stream in only serial configuration or a stream in either serial or parallel configuration. Bellcore contends that this language means generating bits or bytes at particular time intervals. (D.I. 142 at 25). Thus, according to Bellcore, the "bit stream" can be either a serial bit stream or a parallel bit stream that is "byte wide." In support of its position, Bellcore directs the Court to the preferred embodiment shown in Figure 12 of the '306 Patent. (D.I. 151 at 7-8; D.I. 142 at 25-27).

Figure 12 illustrates the framer circuitry performing the generating step by originating and processing data as a parallel bit stream (in byte format - multiple bits at one time). Bytes are transmitted between framers in a serial bit stream. In the language of the specification

The framer unit 200 may also be utilized to generate a chain of empty DTDM packets [sic] (see e.g., framer 52 in FIG. 4). In this case the serial input 202 and associated serial-to-parallel converter 212 are not utilized. Instead, the control 210 applies a periodic signal to tristate 222 so that a frame alignment word is periodically read from frame byte ROM 224 and transmitted via bus 219 to parallel-to-serial converter 216 and serial output 206 so as to define a train of empty DTDM frames.

( '306 Patent col. 16, line 63 - col. 17, line 2 (emphasis added).

An examination of Figure 12 shows a single line used where serial data is present, for example item 206, and a double line used where parallel data is represented, for example item 219. Therefore, Bellcore argues, to construe the phrase generating a bit stream to encompass only a serial configuration would exclude the preferred embodiment set out in Figure 12. (D.I. 151 at 7).

In response to Bellcore's interpretation, Fore contends that "generating a bit stream" means creating a serial configuration of bits, or stated another way, a continuous line of bits sent one at a time from one point to another. To this effect, FORE contends that a "bit stream" is not a "byte stream." (D.I. 153 at 5-6; D.I. 146 at 10-11). In support of its position, FORE direct the Court to Figure 3 of the '306 Patent and its accompanying text in the specification which provides that:

the DTDM bit stream leaves the serial data output of framer (sdo) of framer unit 52 and enters the serial data input of the
top most framer unit 53. The DTDM bit stream leaves the topmost framer 53 via its serial data output (sdo). The DTDM bit stream then enters the serial data input (sdi) of each succeeding framer unit and leaves via the serial data output (sdo) of each framer unit.

( '306 Patent, col. 8, lines 62-66 (emphasis added)).

In addition to Figure 3, Fore also contends that the preferred embodiment in Figure 12 and its accompanying text supports its claim interpretation. Fore contends that while it is possible that bytes may be used internally in transmission equipment (D.I. 146 at 10), the frames generated and sent over transmission lines are in a serial bit configuration, as evidenced by the fact that the portion of the specification describing Figure 12 states that the empty DTDM frames are defined by sending data to parallel-to-serial converter 216 and then to serial output 206.

Additionally, FORE directs the Court to that portion of the specification describing bit stream rates. According to FORE, the specification describes bit stream rates in terms of megabits per second, confirming that a bit stream is a serial configuration of bits and not a parallel byte wide configuration. (D.I. 153 at 5, citing '306 patent, col. 2, lines 25-35; col. 5, lines 13-22).

The Court disagrees with FORE's interpretation that the phrase "generating a bit stream" is limited to a serial configuration of bits. First, there is nothing in the plain language of the claim limiting a "bit stream" to a "serial bit stream." Indeed, the claim does not utilize the modifying or limiting word "serial" in describing the "bit stream." While it is true that the language used is "bit stream" and not "byte stream," it is also true that a byte is composed of bits. Therefore, the Court cannot conclude that the use of the word bit excludes eight bits in parallel, otherwise known as a byte.

With regard to FORE's argument that the specification refers to bit stream rates in terms of megabits per second, the Court is unpersuaded. The lines cited by FORE refer to rates measured in both Mb/sec and Mbit/sec, suggesting that Mb/sec might well mean megabytes per second.

As for Figure 12 and its accompanying text, the Court concludes that these references support Bellcore's position that the bit stream generated internally in the framer circuit begins in a parallel state and is then converted to a serial state before transmission. Accordingly, the Court concludes that the phrase "generating a bit stream" encompasses the creation of either serial or parallel bit streams.

2. "generating a high voltage charge when a shockable rhythm is detected"

Claims 5, 10, and 15 of the '969 Patent describe a function of the AED as "generating a high voltage charge when a shockable rhythm is detected." Philips asserts that this phrase should be construed as "starting to charge the high voltage capacitor at the time the device recognizes fibrillation." Cardiac Science contends that the term "generating" means "producing," but does not offer further construction for the phrase.

In support of its construction, Philips points to language from the specification, which states that "when a shockable rhythm is detected, processor 74 begins a first charge sequence by initiating the generation of a 'Charging.' voice prompt, and causes high voltage generation circuit 86 to operate in the charge mode." ('969 Patent at c. 6, ll: 7-10.) Cardiac Science, however, asserts that the specification distinguishes between generating the high voltage charge and charging the capacitors. Cardiac Science also asserts that dictionaries commonly define the term "generate" as "to produce," rather than "to start." n1

n1 The parties appear to agree that an initial source of dispute, whether "generating" means "discharging," is no longer at issue, because Cardiac Science conceded at oral argument that it was not attempting to equate "generating" with "discharging." (Tr. at 60.)
The specification does not distinguish between the charge mode of the high voltage generation circuit and the charging of the capacitors. The high voltage generation circuit consists, in part, of the capacitors. As the patent specification explains:

In response to charge controls provided by the processor 74, high voltage generation circuit 86 is operated in a charge mode during which one set of semiconductor switches (not separately shown) cause a plurality of capacitors (also not shown), to be charged in parallel to the 12 V potential supplied by power generation circuit 84.

('969 Patent at c. 4, ll: 3-9.) The device looks for a shockable rhythm, or fibrillation, and when that rhythm is detected, the device has to generate a very high voltage charge so that it can attempt to defibrillate the heart. As to this claim term, the word "generating" refers to the charging of the high voltage generation circuit, including the capacitors. (Id. at c. 6, ll: 7-10.) Thus, the Court finds that the term "generating a high voltage charge when a shockable rhythm is detected" should be construed as "initiating a charge in the high voltage generation circuit at the time that the device detects a shockable rhythm (or recognizes fibrillation)."

a. "generating a signal based on the measured pressure in said chamber and providing said signal to said control module"

Plaintiff contends that no additional construction is needed regarding this phrase. (Joint Final Claim Chart ("Chart") at 1.) Defendant, however, proposes that the phrase be reworded so that "based on" is replaced by "indicating" and changing the participles to present active verbs so that the phrase would state: "the pressure sensor generates a signal indicating the measured pressure in the chamber and provides that signal to the control module." (Id.) In response, Plaintiff argues that Defendant's construction is too narrow because it requires that the signal transmit the actual pressure measure of the chamber and does not specify which control module receives the signal. (Pl.'s Br. at 17-18.)

Defendant argues that the use of "based on" leaves open the possibility that the signal could have inputs in addition to the measured pressure. (Def.'s Br. at 12.) Defendant cites support from the patent specification and the prosecution history of the '945 Patent that the signal is "indicative of" the measured pressure. In addition to "indicative of," the specification also uses "based thereon," "based on," and "indication of," in various places. For example, both parties cite:

The control system 188, e.g., a microprocessor, is arranged to receive the digital signals from the transducers 180, 181 and determine the weight of the occupying item of the seat based thereon. In other words, the signals from the transducers 180, 181 are processed by the control system 188 to provide an indication of the weight of the occupying item of the seat, i.e., the force exerted by the occupying item on the seat support structure.

'945 Patent col. 151 l.27-34 (emphasis added).

Plaintiff makes clear that its concern is to clarify that the pressure sensor takes the raw data and converts it to a "digitized" signal that is derived from, or "based on," the measured pressure, rather than directly reporting, or "indicating," the measured pressure. (Pl.'s Reply Br. at 4-5.) The court finds Defendant's use of present active verbs makes the claim more understandable; however, Plaintiff has a valid argument regarding the signal that results from the measured pressure. The court finds Defendant's argument regarding the possibility that other inputs could be included if the signal is only "based on," rather than "indicated by," the measured pressure unpersuasive. A signal "based on" the measured pressure means that the measured pressure is derived from the signal, but it does not mean that it is derived from anything else. Because "'resort must be had in the first instance to the words of the claim,' words [which are ascribed] their ordinary meaning unless it appears the investor used them otherwise," Bell Comm'n's Research, Inc., 55 F.3d at 620 (quoting Envirotech Corp., 730 F.2d at 759), the court finds that it is not necessary to further construe the terms of this claim.

Finally, the court agrees with Defendant that replacing "said" with "the" increases the readability of the claim without changing its meaning. "The" is the definite article which denotes a particularly identified object. Because the claim describes an apparatus comprising "a control module," "the" is sufficient to identify that same control module. Contrary to Plaintiff's argument, the claim does not leave open the possibility that more than one control module will be part of the apparatus.
Accordingly, the court will construe "generating a signal based on the measured pressure in said chamber and providing said signal to said control module" as "generates a signal based upon the measured pressure in the chamber and provides that signal to the control module."

1868

6. "generating a transaction ID corresponding to the database entry" (claims 1 & 4) and "generating a unique transaction ID corresponding to the database entry" (claim 7)

The plaintiff defines these terms to mean "that a unique identifier is generated which corresponds to the database entry allowing the user to create, access, or update an entry." The defendant's proposed construction is "generating a unique identifier of an entry." The defendant further proposes that the "generating a transaction ID" step of the method occurs before the "creating a database entry" step. Both parties try to import limitations from the written description to the claims. Plaintiff suggests that the court should construe the claim to include functional limitations that are simply not supported by the record. The record makes it clear that a unique transaction ID is generated when the user adds a new entry to the database and that ID is effective for the life of the entry. See, e.g., 9:30-46. Plaintiff asks the court to construe the term to limit the purposes for which the transaction ID may be used. That limitation is not supported by the record.

Similarly, the defendant asks the court to add a limitation that is not supported in the record. Specifically, the defendant asks the court to construe this term so that the "generating a transaction ID" step occurs before the "creating a database entry" step. The intrinsic record cited by the defendant in support of its position, however, does not support this limitation. Indeed, there is no support in the record for importing this limitation into the claim language. In fact, the patent provides that "[w]hen the user chooses to add a new entry to the database, a unique transaction ID is created for that entry..." Id. The court construes "generating a transaction ID corresponding to the database entry" to mean "generating a unique identifier for a particular database entry" and rejects Defendant's proposed limitation that the "generating a transaction ID" step of the method occurs before the "creating a database entry" step.

1869

1. The '459 patent: claim 16: "Generating an analog image signal corresponding to the imagewise pattern of radiant light incident on a plurality of light sensing pixel elements"

Claim 16 of the '459 patent describes a process comprising the step of "generating an analog image signal corresponding to the imagewise pattern of radiant light incident on a plurality of light sensing pixel elements." The parties dispute whether this phrase is in step-plus function form. Canon contends that this phrase is a step-plus-function element. Canon contends that the disputed phrase describes an act and is not governed by Section 112, P 6.

After reviewing the claim language in light of the parties' respective positions, the Court concludes that the disputed phrase is not in step-plus-function form. Canon contends that because the claims could be rewritten to add the phrase "step for," Section 112, P 6 has been invoked. However, the language of the claim does not use the words "step for," and therefore, this element is presumed not to be in step-plus-function form. See Masco Corp. v. United States, 303 F.3d 1316, 1327 (Fed. Cir. 2002). In the Court's view, this presumption is not overcome, because the disputed phrase recites the definite act of "generating an analog image signal corresponding to the imagewise pattern of radiant light incident on a plurality of light sensing pixel elements." See Masco, 303 F.3d 1327 (holding "that where a method claim does not contain the term 'step[s]' for, a limitation of that claim cannot be construed as a step-plus-function limitation without a showing that the limitation contains no act"). Further, the Court concludes that, with the exception of terms previously construed by the Court, this phrase should be construed consistent with its ordinary meaning and no further construction is required by the Court.

GO BACK
E. "generating at least one reservation request" and "transmitting the reservation request"

The Defendants argue that these phrases are part of the means-plus-function construction of personal communication device. As discussed above, this argument is without merit. Setting aside this argument, the Defendants agree with the Plaintiff that "transmitting" does not require further construction. (Defs.' Responsive Claim Construction Br. at 8.) Webster's Dictionary defines "generate" as "to cause to be: bring into existence." Webster's Third New International Dictionary (Unabridged) 945 (1993). Therefore, incorporating the previous construction of "reservation request," the Court construes "generating at least one reservation request" to mean "bringing into existence at least one reservation request."

1871

7. "GENERATING DELIVERY-COMMENCEMENT INDICATIONS OF REAL-TIME INFORMATION [FORWARDED] TO THE USER"

AOL: "Creating data indicating the start of receipt of real-time information by the user."

TWM: No construction required.

In the alternative, "Generating data signifying the start of transmission of real-time information sent to the user."

The parties agree that this term should be construed consistently with the prior term. (D.E. 68, pg. 23). For the reasons detailed in the "determining the total delivery time" section, the Court does not construe this claim.

AOL: "Creating data indicating the end of receipt of real-time information by the user."

TWM: No construction required.

In the alternative, "Generating data signifying the end of transmission of real-time information sent to the user."

The parties agree that this term should be construed consistently with the prior term. (D.E. 68, pg. 23). For the reasons detailed in the "determining the total delivery time" section, the Court does not construe this claim.

1872

H. Generating one or more reports from the test methodologies

This disputed phrase is found in claims one and thirteen. The Plaintiff asserts that this term does not need construction, but also offers "using a computer to generate one or more reports based on the results of the test methodologies." The Defendants propose construing the phrase as "a server report spooler automatically generating one or more reports from the results of the test methodologies and automatically storing the report in a server project specific web site directory in response to the server computation engine storing the results of the test methodologies in the server project specific database" (emphasis added).

Here again, the Defendants include nearly identical language to the disputed phrase within the proposed construction. This is because the Defendants are not construing the claim in light of the specification, but they are importing elements found in the specification into the claim language. The Defendants do not make any new arguments in support of this proposed construction beyond repeating the theory that the claims should be limited to the specific embodiment in FIG. 2 and descriptions of that figure. The arguments regarding automation and the limitation to FIG. 2 to interpret the claim language have been rejected above and are rejected for the same reasons here.
The remaining dispute is whether a computer or a server must perform the step. The Defendants’ only support that the step of report generation must occur on a server is by arguing that the step is limited to the FIG. 2 embodiment. The Plaintiff argues that claim thirteen specifies a server is used, so claim one must mean something different under the rules of claim differentiation. Claim one also specifies that the server is located on a wide-area-network and that the information collected from the pavement construction material mixture goes to the server. The omission of specificity that the server must perform the steps of applying the test methodologies, generating the reports, and sending the reports to the project manager in close proximity to steps that specify the use of a server leads this Court to believe that those steps are not restricted to performance by a server in claim one. Since the parties agree that the preamble is limiting, this means that the steps are performed on a computer in the computer-implemented method.

Construction: Using a computer to generate one or more reports based on the results of the test methodologies.

1873

8. "Generating the motor signals in response to the spoken instructions." The computer/controller of the robotic surgical system generates motor signals in response to the surgeon's spoken instructions.

1874

5. "generating via said projector means a plurality of alignment images onto said display screen at predetermined locations" (claims 1 and 4)

PolyVision's proposed definition
Generating and projecting alignment images at a known point on the touch sensitive screen.

Smart's proposed definition
The alignment images are generated and projected onto the display screen at locations that are predetermined relative to the image being projected.

The dispute here is whether the alignment images are projected on a predetermined location of the display screen, as PolyVision contends, or at locations that are predetermined relative to the image itself, as Smart asserts. PolyVision contends that the language of the claim and the specification, (Col. 8, ll., 28-29 ("The marker is projected at a known point on the touch-sensitive screen 1.")), plainly shows that the alignment images are projected onto predetermined locations on the display screen. As Smart correctly notes, however, the purpose of the calibration routine is to determine the location of the projected image on the display screen, which may be unknown due to the random position of the projected image, through the sequence of alignment marks. The specification states:

FIG. 12 represents the touch board alignment procedure which ensures that the image on the touch-sensitive screen 1 corresponds with the image appearing on the display of computer 5. The purpose of this alignment procedure is to determine the position of the projected image on the touch-sensitive screen and to determine the corrections required to compensate for image projection problems.

(Col. 8, ll. 10-17.) Given the purpose of this procedure -- to correct for image projection problems, it would make no sense for the alignment marks to be projected onto the display screen at predetermined points having no relationship to the image; there would be no need for the alignment procedure because the image would already be aligned with the display screen. Accordingly, the Court concludes that Smart's construction is correct.

L. Ref. No. 21 "Generator of a voting session identifier for each voting session."
This phrase is recited or referred to in Claims 21, 76 and 82.

Defendants refer the Court to the previous argument regarding generators. That argument, however, is based upon a means-plus-function limitation. The instant claim construction is not. Here, the Court is asked to construe the phrase set forth above and the use of the term "generator."

As noted by Plaintiff, the '730 Patent provides numerous examples of generators in both the specification and in the claims. (See Col. 5, ll. 58-62; Col. 19, ll. 19-23; Col. 24, ll. 1-19; Claims 16, 21, 82.) These examples include random number generators, pseudo random number generators, and random character generators. The Court finds Plaintiff's construction to be a fair description of the claim. The Court, however, finds Plaintiff's language "and the like" excessively broadens the definition. Moreover, the term "for each voting session" is contained in the language of the relevant claims and should be included in the claim construction.

Therefore, the Court construes the term contained in Ref. 21 as follows:

A component of the voting machine (such as a processor, random number generator, processor with a random number generator) provides a random or pseudo-random, unique identifier for each voting session.

5. Claims 1, 7, 17 & 26 -- "Geographical Vicinity"

In their claim construction brief, CIVIX states that the parties agree on the definition of the term "geographical vicinity" to be "a geographic region which includes and surrounds selected items of interest." CIVIX cites the specification's definition of this term. ('525 Patent, Col. 2 lines 8-10). In their initial construction of terms mailed September 14, 1998, Defendants jointly agreed on this definition. However, in their claim construction brief and argument to the Court, they submitted new grounds for a narrower definition.

Defendants now argue that "geographic vicinity" is a pre-defined local area consisting of a pre-defined discrete point (represented by the positional coordinates) and the surrounding area that is within a limited distance. Defendants contend that this local area is smaller than a city, and is generally within walking distance. Although Defendants point to persuasive evidence in the '525 patent specification and prosecution history, they overlook the fact that the inventor acted as his own lexicographer in this instance and clearly defined the term in a portion of the patent containing definitions for other crucial terms. See, e.g., Process Control Corp., 190 F.3d at 1357 ("a patentee can act as his own lexicographer to specifically define terms of a claim contrary to their ordinary meaning. . . . We must construe the claims based on the patentee's version of the claim as he himself drafted it."); Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1344 (Fed. Cir. 1998) ("The actual words of the claim are the controlling focus. . . . The written description is considered, in particular to determine if the patentee acted as his own lexicographer, as our law permits, and ascribed a certain meaning to those claim terms.").

The summary of the invention provides the following:

"Geographic vicinity," and "map" are used to denote a geographic region which includes and surrounds selected items of interest.

Because the inventor has specified his own definition for this term, I reject Defendants' arguments for a narrower lexicography. The Federal Circuit has held that when "a patent applicant has elected to be a lexicographer by providing an explicit definition in the specification for a claim term . . . the definition selected by the patent applicant controls." See Renishaw, 158 F.3d at 1249. The Federal Circuit tempers this rule by stating that a patentee's definition must, of course, appear with reasonable clarity, deliberateness, and precision to affect the claim. See id. However, I find that the '525 patent's definition of "geographic vicinity" is sufficiently clear, deliberate, and precise, and therefore, CIVIX' definition controls.

- 2237 -
1877

1. Geometric Address Information and Corresponding to Geometric Address Information

As to the term "geometric address information," the '402 patent refers to it as head-cylinder-sector address information. Multiform Desiccants, Inc. v. Medzam, Ltd., 133 F.3d 1473, 1477, 1478 (Fed. Cir. 1998) (words used in the claims are to be read in light of the specification). See generally Col. 6:8-36; see Col. 6:18-21 ("translation circuit in the disk emulator instantaneously translates the geometric addresses from the SMD disk controller, the cylinder and head address, into higher order addresses for the DRAM array in the disk emulator."); Col. 25:13-15 ("Two different means are available for translating the geometrical form of the address information to the binary structure suitable for addressing solid state memory."). In addition, the prosecution history of the '474 patent reveals a consistent definition. See Lapple Decl. Ex. D at 51 ("[A] disk controller provides geometric addresses, head, cylinder, and sector, and not a volatile memory address."). Additionally, although the court's interpretation of "geometric address information" is somewhat consistent with the interpretation asserted by defendant, the language has a broader meaning than that ascribed to it by defendant. Specifically, "geometric address information" appears to cover both embodiments described in the '402 patent. See Col. 25:13-30. More specifically, "geometric address information" refers to (1) address information which represents or characterizes the physical geometry of a particular hard disk system and (2) address information in binary form which represents the geometry of a hypothetical or imagined hard disk system having a binary number of heads, cylinders and sectors. See Col. 25:13-30; Col. 32:16-28; Col. 25:20-22 ("In this method, the software disk driver is configured so that the driven disk has a binary number of heads, sectors, and cylinders."); Col. 32:20-30 ("the disk controller addresses the disk emulator with a binary format for the number of heads, sectors, and cylinders. . . . The geometric address signals . . . in this method are used directly to address the DRAM array.").

1878

1. "Gesture Action" ('053 patent, claims 1, 6, 20, 22) The patented inventions may be briefly described as methods for creating realistic computer animations of characters. The first term in dispute is "gesture action." Plaintiff's proposed construction is "a defined movement of joints over time which symbolizes or emphasizes an idea, sentiment or attitude." Defendant's proposed construction is "body part undulation executed under the control of a set of coupled frequency and range signals." Plaintiff principally objects to the word "undulation" in defendant's construction on the ground that the '053 patent describes at least one gesture action, the "casual pose," that does not entail any undulation. See transcript, 12/18/06 ("Tr."); at 9; '053 patent, 6:54-7:14. Plaintiff argues that the casual pose is "driven primarily by noise," see '053 patent at 7:11-14; '132 patent at 7:14-17, so that an observer viewing a figure in the "casual pose" would perceive movement that was random, rather than undulatory, see Tr. at 50-51. However, plaintiff's expert, Dr. Norman I. Badler, admitted that it would be "very unlikely" for the casual pose not to entail at least some undulation, see Tr. at 104-05; moreover, as defendant's expert Dr. Kellogg S. Booth noted, "the noise function[] constitute[s] undulation," see Tr. at 119; see also Tr. at 122, 147. More broadly, the Court agrees with Dr. Booth's testimony that neither the fact that certain gesture actions such as the casual pose entail less undulation than others, nor the fact that any gesture action can be "stopped" before undulation takes place, changes the fact that the essential nature of gesture actions is to provide for undulation. See Tr. at 109-10, 117-19, 146-49.

Plaintiff also objects to the phrase "executed under the control of a set of coupled frequency and range signals" in defendant's construction. Defendant's use of this phrase is supported, however, by the specification of the '053 patent (and the corresponding specification of the '132 patent) that introduces the phrase "gesture action" in the following terms:

The programmer/user can specify a sequence and/or combination of different gesture actions. Each action is implemented as a set of coupled frequency and range of pseudorandom time-varying signals set to each limb. The transition from one action to the next is smooth and life-like.

'053 patent at 2:47-52 (emphasis added); see also '132 patent at 2:51-56. Defendant's construction largely tracks this
language. Although plaintiff's expert, Dr. Badler, testified that the phrase "[e]ach action" in the above-quoted passage does not necessarily refer to a "gesture action," see Tr. at 36, and that the word "of," following the word "range," is an error and should be the word "or," see Tr. at 37, 40, the Court does not credit this testimony, finding it much more likely that the language means what it says.

Further, defendant's entire construction is supported by the deposition testimony of Dr. Kenneth Perlin, the inventor of the '053 and '132 patents, who testified that the '799 application (which underlies both patents) does not anywhere describe how to create a "gesture action" that is not a "body part undulation executed under the control of a set of coupled frequency and range signals." Declaration of Dr. Kellogg S. Booth dated November 12, 2006 ("Booth Decl."), Ex. 6 ("Perlin Dep.") at 101. Plaintiff argues that Dr. Perlin recanted this testimony by testifying later in his deposition that he thought he "could create a . . . gesture which is effectively a pose" with "[n]o time varying behavior," and that "this [would] describe how to create a gesture action that is not a set of coupled frequency and range values." Declaration of Paul D. Ackerman dated November 30, 2006 ("Ackerman Decl."), Ex. A at 281 (emphasis added). But this later testimony does not amount to a recantation because it says only what Dr. Perlin could create or describe now, and not what he did create or describe in the patents.

Accordingly, the Court adopts defendant's proposed construction of "gesture action."

1879

A. "Given Flow Temperature"

The meaning of the disputed term "given flow temperature," used twice in claim 1 of the '584 patent, is clear from a reading of the claim itself and the patent specification. Specifically, it is the temperature at which a particular ternary doped silicon oxide, heated for a specific period of time, and in a given atmosphere, will flow across the semiconductor body to form the insulating layer. As such, the "given flow temperature" for a particular layer is a definite, quantifiable temperature which serves as the key reference point in the two heating steps described in the patent. First, the ternary doped silicon oxide layer must be heated to the "given flow temperature" so that it will flow over the semiconductor body and create an insulating layer with a relatively smooth surface. Second, and after forming the contact holes, the ternary doped silicon oxide layer must be reheated to some temperature "below the given flow temperature" to soften, and only partially reflow the layer at the edges of the contact holes.

12 For example, the specification notes that a BPSG layer having about 3-3 1/2 wt % phosphorus and about 2-2 1/2 wt % boron will flow when heated to about 900 [degrees] C, in steam, for a period of about 30 minutes. If heated in helium, nitrogen, argon, or some other inert atmosphere, however, this BPSG will flow when heated to about 950 [degrees] C for 30 minutes. Similarly, a BPSG layer having about 4-5 wt % phosphorus and about 3-4 wt % boron will flow when heated to about 800 [degrees] C in steam, and about 850 [degrees] C when heated in helium, nitrogen, argon, or some other inert atmosphere. See '584 patent, col. 2, 11. 55-68; col. 3, 11. 5-11. 13 Steps 2 and 4 in the patented process.

1880

9. "out of band signal"

Dependent claim 9 provides that "K2 is selected so that the out of band signal is less than a given level." Subsequent to the parties' briefing and argument on this term, the parties have agreed by letter to the Court, dated April 7, 2010, that the term "out of band signal" means "power outside the frequency band." However, Defendants still argue that claim 9 is invalid for failing to meet 35 U.S.C. § 112. The Defendants do not argue that "out of band signal" is indefinite, but that the subsequent phrase "less than a given level" is indefinite. It appears that Defendants did not contend that "less than a given level" needed to be construed, or that the specific phrase was indefinite, until the Defendants' responsive claim construction brief. Thus,
Wi-LAN did not provide any proposed construction for the term and instead argued that the term "out of band signal" was not indefinite and had a particular meaning.

The Court finds that the phrase "less than a given level" is not indefinite. A claim is indefinite only if the "claim is insolubly ambiguous, and no narrowing construction can properly be adopted." Exxon, 265 F.3d at 1375; Honeywell, 341 F.3d at 1383-39. This term is not "insolubly ambiguous" so as to prevent construction. See Young, 492 F.3d at 1346 (claims are considered indefinite when they are "not amenable to construction or are insolubly ambiguous"). The specification contains examples from which one of ordinary skill in the art could determine the scope of the claim. For example, the "two tail slots act as guard bands to ensure that the out-of-band signal is below a certain power level" and "to ensure that the out-of-band signal is ydB or less relative to the in-band signal..." '222 patent, 5:36-44; 6:46-48. The specification then provides an explicit example of what, in a particular instance, the "less than a given level" should be: "[t]he two tail slots of 195.3 KHz each (i.e. 8 points each) ensure that the signal outside the entire band of 100.39 MHz is below -50 dB." '222 patent, 7:57-60. In addition, the specification teaches that "to allow use of the radio frequency spectrum...the system must satisfy federal regulations...[that] impose limits on the power and the frequency spread of the signals exchanged..." '222 patent, 1:50-54. The Court finds that there is sufficient guidance in the specification as to the meaning of "less than a given level" to one of ordinary skill in the art. See Exxon, 265 F.3d at 1375 ("If the meaning of the claim is discernible, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds.") The Court rejects Defendants' argument that because the "level" in the claim is unspecified, no meaningful bound is placed on the patent claim. Consistent with the parties' agreement, the Court construes the term "out of band signal" to mean "power outside the frequency band." The Court finds that the term "less than a given level" is not indefinite. The Court construes the term "less than a given level" to mean "less than a given power level to satisfy federal regulations."

6. **given observation plane** ('028 patent)

CEA contends that this term does not require construction, but provides a proposed construction of: "any plane of variable observations by the screen reader."

Samsung's proposed construction is "a plane perpendicular to the screen which corresponds to the most probable position of a screen reader, i.e., a vertical plane extending perpendicularly from the screen."

The court adopts Samsung's proposed construction.

The specification states, in the summary of the invention, that "[t]he compensation for a given observation plane, of the birefringence of the liquid crystal layer in its homeotropic structure, makes it possible to retain a high contrast in case of an oblique observation made in said observation plane . . . ." 21 That language indicates that there is a particular, or specific, observation plane. Figure 3 is described as "a diagrammatic view showing the observation plane of a cell according to the invention . . . ." 22 That figure "diagrammatically shows the observation plane P or main reading plane . . . . The observation plane P corresponds to the most probable position of the screen reader, the latter observing the screen under variable incidence." 23

The specification, therefore, supports Samsung's proposed construction which the court adopts: "a plane perpendicular to the screen which corresponds to the most probable position of a screen reader, i.e., a vertical plane extending perpendicularly from the screen." 24

24 The court rejects CEA's argument, with respect to this claim term, that Samsung's proposed construction improperly
imports a limitation from a preferred embodiment in light of the language of the summary of the invention section which is properly read as limiting the invention to a single viewing plane.

20 The term to be construed in claim 5 appears in claim 1, upon which claim 5 depends.

The parties both agree that a single construction is sufficient for all three claims terms. 21 Limelight seeks to add the limitation that the given content server be "a single, optimal content server." (Docket # 71, 50.) In claim 5, the contested term appears in a limitation of claim 1 requiring "the embedded object [to be] served from a given one of the content servers as identified by the first level and second level name servers." (703 Patent, Claim 1; accord id. Claim 15.) In C&W, the Federal Circuit refused to read any requirement for a load balancing mechanism into the word "identified" in this claim. C&W, 344 F.3d at 1193-94 ("[The plain meaning of the claim language] simply requires the embedded object to be served from 'the content servers as identified by the first level and second level name servers.'"). Similarly, it would be inappropriate to read a requirement for an "optimal" server into it as well.

21 The four claims use three similar terms with slightly different wording. The parties have consolidated these into two separate contested terms in their briefs; however, they each argue for the same (but different between the parties) construction for all three.

Additional language in claim 34 limits the "given one of the content servers" to a server which is "within the given region that is likely to host the embedded object and that is not overloaded." (703 Patent, Claim 34.) As discussed supra, Term 5, adding a requirement that the server be "optimal" is unnecessary and confusing, as the claim already provides a specific limitation, consistent with the specification, as to which content server's IP address should be returned to the client. Similarly, while independent claim 19 provides no particular limitations on which given content server serves the embedded object, subsequent dependent claims 20 through 22 limit the server selected in ways that would be redundant with Limelight's construction.

Akamai's proposed construction, however, reads out the word "given" from the claims. It is appropriate to construe the term as a referring to a "particular" server, to make clear that a selection is made.
K. Cladding/Glass cladding

Claim 25 recites "a waveguide having a tip with a glass cladding extending to a distal end of the tip." The parties dispute whether the Court should construe "cladding" or "glass cladding." AMS asserts that the Court should construe "cladding" and proposes as a construction "material(s) disposed between the core and the first air gap or outside medium." LP asserts that the Court should construe "glass cladding" and proposes as a construction "also known as core cladding, a layer of glass having a lower index of refraction than the fiber core that contacts the fiber core to create an interface to confine radiation at the fiber core."

The claims do not recite simply "cladding"; rather, they recite "glass cladding" and "core cladding." Claim 25 recites "a waveguide having a tip with a glass cladding." It does not contain any language indicating the meaning of "cladding" or "glass cladding." Claim 26, which depends from claim 25, recites "wherein the tip of the waveguide comprises a fiber optic segment, the fiber optic segment including a fiber core . . . and a core cladding." This difference suggests that "glass cladding" is different from "core cladding." See Phillips, 415 F.3d at 1314. The Court turns to the specification to aid in its construction.

AMS cites Figure 10 in support of its construction of "cladding" as "material(s) disposed between the core and the first air gap or outside medium." Figure 10 shows a cross-sectional view of the embodiment of Figures 9 and 9a. See '699 Patent col.11 ll.9-13. The embodiment disclosed in Figures 9 and 9a includes an additional hard plastic cladding layer and a nylon jacket which protects the hard plastic cladding from scratching or other damage, which are stripped away from the tip in that embodiment. '699 Patent col.10 ll.45-58. Consequently, the identification of the core, cladding, and air in Figure 10 does not indicate that "cladding" can be any material disposed between the core and the first air gap or medium because the nylon jacket, which the specification distinguishes from cladding, also is a "material disposed between the core and the first air gap or outside medium." AMS's reliance on the prosecution history, where the applicant distinguished a prior art reference by stating that while the reference "removed the cladding and the buffer coating" from the tip of the fiber, the claimed invention "achieved significant results by not removing these layers from the core," is unpersuasive for the same reason. Extrinsic evidence further supports the conclusion that not all materials disposed between the core and the air or external medium are "cladding." See Gerd Keiser, Optical Fiber Communications 26-27 (2d ed. 1991) (identifying the "cladding" and the "buffer coating" surrounding the cladding separately).

The specification refers to several different types of cladding, including "plastic cladding," which is removed from the distal end of the optical fiber shown in Figure 1; a "doped fused silica cladding layer," which is shown in Figures 5a-5c; and a "core cladding layer" shown in Figures 9 and 9a. 11 '699 Patent col.4 ll.59-60, col.6 ll.30-33, col.10 l.25. The first experiment described in the '699 Patent used a "micron fiber made out of pure fused silica core/doped fused silica or glass core cladding/hard plastic buffer cladding layer/nylon jacket." '699 Patent col.11 ll.45-49. This language indicates that there are many different types of "cladding."

11 LP contends the specification uses "core cladding" and "glass cladding" interchangeably. Two of the portions of the specification cited by LP, however, indicate simply that a core cladding may be made of glass. See '699 Patent col.10 ll.45-58 ("The core cladding layer 81 is constructed of glass. . .."). col.11 ll.46-48 (describing optical fiber used for experiment as "made out of pure fused silica core/doped fused silica or glass core cladding"). The other portions cited by LP, when taken in context, are abbreviated references to the "doped fused silica or glass core cladding" in the description of the experiments. See '699 Patent col.11 ll.58-62, col.11 ll.33-34. LP's reliance on these portions of the specification is unpersuasive.

In addition, when describing Figures 9 and 9a, the specification states:
The core cladding layer 81 is constructed of glass and positioned around the fiber core 82 using conventional manufacturing procedures. The "cladding" of a typical fiber optic includes an additional hard plastic cladding layer (not shown) which lies over the core cladding layer 81. The additional hard plastic cladding layer is used in case the fiber is bent so that the core cladding layer 81 suffers leakage due to increased incidence angles in the bent portion. Over the hard plastic cladding, a nylon jacket is applied to protect the hard plastic from scratching or other damage. The jacket and hard plastic cladding layer are stripped back away from the tip in this embodiment.

'699 Patent col.10 ll.45-58. This language indicates that a waveguide can have multiple layers of cladding where one layer--in the described embodiment, a hard plastic cladding--surrounds another layer--in the described embodiment, a core cladding layer made of glass. 12 This language also indicates that both cladding layers prevent leakage of electromagnetic radiation from the core. When describing the prior art optical fiber shown Figures 5a-5c, the specification states that the cladding "confin[es] radiation transmitted through the fiber to the fiber core." '699 Patent col.6 ll.39-43. This language indicates that cladding prevents leakage of electromagnetic radiation from the waveguide during communication of the electromagnetic radiation through the waveguide and protects the fiber core of the waveguide. Extrinsic evidence supports this construction. See Keiser, Optical Fiber Communications at 27 (describing the purposes of cladding as reducing scattering loss from dielectric discontinuities at the core surface, adding mechanical strength to the fiber, and protecting the core from absorbing surface contaminants).

AMS appears to argue, however, that cladding only confines light to the fiber core in the mid span of the optical fiber. In support of this argument, AMS cites Pon's testimony that "cladding could . . . in a long length of fiber, in the mid span of that length, it could help confine light within the core." Despite this testimony, nothing in the specification suggests that cladding confines electromagnetic radiation to the core only at the mid span of the waveguide; rather, the removal of the cladding in the embodiments shown in Figures 1, 6, 6a, and 6b suggests that the confining effect of cladding extends along the length of the waveguide. AMS further asserts that the cladding must not be construed as confining electromagnetic radiation within the core because electromagnetic radiation is transmitted through the cladding in certain embodiments of the invention. In those embodiments, described in Figures 9, 9a, and 10, electromagnetic radiation is transmitted through the transmitting surface after it has been reflected by the reflecting surface, not during its communication to the tip of the waveguide, and because a certain core-to-core cladding ratio exists. See '699 Patent col.10 ll.24-41, col.10 l.59-col.11 l.2. This result does not alter the cladding's purpose of confining electromagnetic radiation to the fiber core during its communication to the tip. The Court construes "glass cladding" as a "glass material that surrounds and protects a fiber core and confines electromagnetic radiation to the waveguide during its communication to the tip of the waveguide where the glass material need not contact the fiber core."

The parties dispute whether a cap or capsule fused to the cladding can constitute "cladding" or "glass cladding." 13 Insofar as the parties seek a determination of whether the capsule in the accused product constitutes glass cladding, the Court declines to prejudge the infringement analysis. See Wilson Sporting Goods, 442 F.3d at 1326-27.

AMS further contends that the cladding must be physically attached to the core. Pon testified that that "cladding could be--could be a material that was physically attached to the core." Pon's testimony as to one possible type of cladding does not support a construction requiring physical attachment of the cladding to the core.
The court finds "glass cladding" to mean "glass material that surrounds and protects a fiber core and confines electromagnetic radiation to the waveguide during its communication to the tip of the waveguide where the glass material need not contact the fiber core." The court finds "core cladding" to mean "a layer of material that surrounds a fiber core, that has an index of refraction lower than the index of refraction of the fiber core, and that is immediately adjacent to the fiber core."

Plaintiffs ask the court not to construe either term but to construe instead the general term "cladding." The claims nowhere refer to "cladding" independently; they refer only to "glass cladding" and "core cladding." Plaintiffs request that the court construe a term that does not appear in any claim, and the request is rejected.

Defendants ask the court to construe the terms "core cladding" and "glass cladding" identically. In doing so, the court would effectively find that the invention's core cladding is always made of glass and that glass cladding is never used anywhere but the core. This equation of "glass cladding" with "core cladding" is too restrictive and is rejected.

To defend their proposed construction, Defendants rely heavily on the patent specifications' occasional use of the phrase "doped fused silica" to refer to cladding. See e.g., the '699 Patent, col. 11, lines 45-57, cited in Defendants' Memorandum (Dkt. No. 89 at 17). Although it is axiomatic that "[t]he descriptive part of the specification aids in ascertaining the scope and meaning of the claims" and that "[t]he specification is, thus, the primary basis for construing the claims," Phillips v. AWH Corp., 415 F.3d 1303, 1315 (Fed. Cir. 1303)(internal citations omitted), the cited patent language does not in fact support Defendants' conclusion. The "doped silica" specification on which Defendants rely describes an experiment that used doped fused silica as core cladding. The '699 Patent, col. 11, line 47. An experiment's materials are necessarily particular; it does not follow that the chosen material is the only material contemplated by the invention or that all inventions citing that experiment may use only the described material. Defendants' other citations of the '699 Patent's supposed "synonymous usage" are similarly unsuited to generalization.

Moreover, Defendants ignore the key role played by the stipulated claim term "comprising." The parties stipulated to the definition of "comprising" as "including but not limited to the elements of the claim." See Dkt. No. 105-2; Dkt. No. 109-3. 3 The language of the claims describes core cladding and other components "comprising" particular materials. See, e.g., Claim 5, which describes, "core cladding comprising a transmissive material," the '699 Patent, col. 15, line 35 (emphasis added). In some cases, the listed materials are glass or something similar. See, e.g., Claim 24, which describes that the "core cladding comprises doped fused quartz." The '699 Patent, col. 17, lines 24-26 (emphasis added); and Claim 25, which describes a surgical probe "comprising: a waveguide having a tip with a glass cladding extending to a distal end of the tip." The '699 Patent, col. 17, lines 28-29 (emphasis added). See also the language of the specification: "the core cladding comprises doped fuse quartz", the '699 Patent, col. 5, lines 8-9 (describing the first embodiment of the invention) (emphasis added). Under the stipulated definition of "comprising," it is clear that the listed components, those that "comprise" glass or doped fused quartz materials, may include but are not limited to those materials.

--- Footnotes ---

3 This definition comports with the well-established meaning of that phrase as a term of art in the field of patent law. See Georgia-Pacific Corp. v. U.S. Gypsum Co., 195 F.3d 1322, 1327 (Fed. Cir. 1999)("The transitional term 'comprising' … is inclusive or open-ended and does not exclude additional, unrecited elements or method steps") (citing the Manual of Patent Examining Procedure).

--- End Footnotes ---

The intrinsic evidence contained in the patent, read in light of the claim terms whose meaning Defendants have stipulated to, squarely refutes Defendants' proposed equating of core and glass cladding. The court accordingly declines to adopt the proffered construction.
Judge Ericksen, in her Laser Peripherals memo, construed the term "glass cladding" as follows:

glass material that surrounds and protects a fiber core and confines electromagnetic radiation to the waveguide during its communication to the tip of the waveguide where the glass material need not contact the fiber core.

Regarding the final clause of the construction ("where the glass material need not contact the fiber core"), Judge Ericksen noted that the term "cladding," as used in the patent, is not limited to material in immediate contact with the fiber core. The description of Figures 9 and 9a states that, in a typical fiber optic, "an additional hard plastic cladding layer . . . lies over the core cladding layer." The '699 Patent, col. 10, lines 48-50. Where the patent refers to two distinct layers as "cladding," a court should not construe the term to refer solely to the layer immediately surrounding the fiber core. If "cladding" can encompass material one layer removed from the core, it is reasonable to conclude that "glass cladding" may also encompass material located at a layer's remove.

The Minnesota District Court's construction is entirely reasonable and consistent with the intrinsic evidence of the '699 Patent. Given the awkwardness posed for the parties were different district courts to construe the same patent term differently, and the sound foundation for Judge Ericksen's construction, this court will adopt her construction of the term "glass cladding."

The Laser Peripherals memo does not construe "core cladding." This court will therefore construe the term independently.

The court bases its construction of the term "core cladding" on two key facts: (1) "core cladding," as used in the claims, consistently refers to material immediately adjacent to the fiber core, and (2) in order for the electromagnetic radiation to propagate efficiently along the waveguide core, the material immediately adjacent to and surrounding the core must have an index of refraction lower than the index of refraction of the core material. The court adopts these two observations and construes "core cladding" so as to encompass any material so situated and so constructed, as set forth at the beginning of this subsection.

2. "global control system"

This term is also used throughout the Bittleston Patents. WG proposes seeks to construe this term as "a control system that sends commands to other devices in a system (e.g. local control systems)", while Ion proposes "system that monitors the position of the streamers and provides the desired forces or desired positioning information to the local control systems." Therefore, the parties disagree as whether this term should be limited according to the kind of information that the global control system sends out, and whether it requires the presence of a local control system.

As WG points out, only some of the claims that describe the global control system in the patents-in-suit identify a corresponding local control system. Others describe the global control system but make no mention of a local control system. (See '017 Patent, col. 11 ll. 1-11.) This would suggest, therefore, that the presence of a local control system is not required by the claim language.

Turning then to the specification, the '017 Patent states "[i]n the preferred embodiment of the present invention, the control system for the birds is distributed between a global control system . . . and a local control system located within or near the birds." (’017 Patent, col. 3 ll. 36-40.) According to this language, then, the presence of both a global and local control system is only a preferred embodiment of the invention. In addition, the specification notes that "[i]n a preferred embodiment of the present invention, the global control system monitors the actual positions of each of the birds." (’017 Patent, col. 3 ll. 61-63.) Thus, a global control system that monitors the position of each of the birds is only a preferred embodiment of the patents in suit. The specification also states that the global control system "is typically connected to the seismic survey vessel's navigation system and obtains estimates of system-wide parameters." (’017 Patent, col. 3 ll. 36-44 (emphasis added).) This language also thus suggests that the described functionality of the global control system is only the preferred embodiment of the patented invention.
Ion, however, points out that the specification also states that "[t]he inventive control system is based on shared responsibilities between the global control system . . . and the local control system" ("017 Patent, col. 9 ll. 42-44) and that "the global control system is tasked with monitoring the positions of the streamers and providing desired forces or desired position information to the local control system. (Id. col. 9 ll. 45-48.) According to Ion, precedent indicates that the use of the term "inventive control system" signals the inventor's understanding of the scope of his own invention. Because its construction tracksthe way the inventor described the invention, argues Ion, it is an appropriate construction of the term.

While the Court acknowledges that Ion's construction does track the manner in which the invention is described within the specification, the Court declines to construe the term "global control system" according to this language. First, although the specification does use the phrase "inventive control system" when stating that responsibility is shared between a global and local control system, the specification also states that it is only preferable that the control system be distributed between a global and local system. Ion therefore relies too heavily on the "magic words" of Honeywell, and ignores explicit language in the specification as well as the claim language that indicates that the global control system operating vis-a-vis a local control system is only a preferred embodiment of the invention.

Secondly, while Ion's construction may be a correct description of how the global control system generally functions in the claimed invention, the Court finds it redundant to construe the term according to these specifically named operations. Throughout the patents-in-suit, the individual claims themselves describe the way in which the global control system is to function within the scope of that claim, and also, when appropriate, the extent to which the global control system communicates with the local control system to control the positions of the streamers. As WG argued during the Markman hearing, at the stage of claim construction, the Court is tasked with construing the scope of specific claim terms within the patents, not with describing the operation of the entire invention through these disputed phrases. It is the claims themselves that are the primary indicators of the way in which individual components function to achieve their purpose. Thus, many arguments as to the reach and scope of the patent claims are more appropriate for the stage of infringement determinations. Therefore, the Court concludes that it is more appropriate to assign to this term a more general construction, and to leave it to the claim language to identify how the global control system operates vis-a-vis the streamer positioning device as well as the local control systems.

WG provides just such a construction. As such, the Court adopts WG's proposed construction of this claim term of "a control system that sends commands to other devices in a system (e.g. local control systems)."

1. "global identifier"

EMC asks the Court to construe this term as: "A global identifier identifies the mass storage devices in a logical set." HP proposes (in its opposition brief and at the claim construction hearing, see Transcript of April 6, 2004 Hearing, 151:14-22): "A value or data structure stored in the array controller that is compared to membership signatures in order to identify which mass storage devices are members of a logical set of mass storage devices." Essentially, then, the parties dispute whether the term has a location limitation.

The meaning of "global identifier" can be ascertained from the claim language, which indicates that a "global identifier" serves as a reference for identifying mass storage devices included in a logical set. HP incorrectly argues that this is not a definition of "global identifier" but instead describes a use of a "global identifier." The construction in fact is a definition: the global identifier is a reference with which each storage device in a logic set identifies. In other words, knowledge of the global identifier allows the system to identify members of the set.

Nothing in the intrinsic evidence indicates that this term must be defined in part according to its location, nor is the term defined according to a process or method of comparing it to something else or according to its purpose. Accordingly, HP's proposed limitation requiring that the global identifier be stored in the array controller is inappropriate. The Court construes this term as "a reference for identifying mass storage devices included in a logical set."
7. "global repository"

The term "global repository" appears in claims one through five of the '374 patent. Informatica proposes the construction "An abstraction for a database that stores metadata that is also accessible from one or more local database repositories." BODI proposes the construction "A repository is an abstraction for a database where metadata is stored. There are three types of repositories: independent, linked, and global. A global repository is distinguished from independent and linked repositories in that it is the only repository which stores metadata that can be shared with other linked repositories." The parties agree that the general meaning of the term "repository" is "an abstraction for a database," as set forth in the specification.

--- Footnotes ---

3 Informatica indicated in its opening brief that it does not object to the use of BODI's synonymous "linked repositories" language en lieu of "local database repositories."

--- End Footnotes ---

The parties proffer similar constructions, but for BODI's proposed language regarding the three types of repositories, independent, linked, and global. The Court finds the term global repository can be construed without reference to and discussion of the other types of repositories. The Court construes the phrase "global repository" to mean: An abstraction for a database that stores metadata that can be shared with other linked repositories.

1888

N. Global Server

Visto contends that the term "global server" means "a computer or a related set of computers that mediate connections between data stores within and without a secure network and that may store data." Seven argues that the term means "a server that is outside a corporate LAN and inside a global firewall that is widely accessible by users and stores independently modifiable copies of workspace elements and version information." With respect to this term, Seven has incorporated a location limitation that is found in the preferred embodiment. Seven has also urged that the server be "widely accessible" by users, and has incorporated this limitation into its definition as well. Seven also contends that the global server must store independently modifiable copies of workspace elements and version information.

The parties agree that this term had no accepted meaning in the art; therefore, resort to the specification is appropriate to glean the proper construction. Read as a whole, the specification defines the global server by the various functions it performs and by its accessibility to a remote user. One function the global server must perform is storing an independently modifiable copy of selected portions of workspace data. In the Summary of the Invention, the specification states "[t]he client is configured to synchronize selected portions of the first set of workspace data (comprising workspace elements) with the global server, which stores independently modifiable copies of the selected portions. '221 Patent, Col. 2, ll. 50-54 (emphasis added). In addition, the specification states that the "base system and synchronization agent automatically establish a secure connection therebetween and synchronize the selected portions of the first set of workspace data stored on the client and the second set of workspace data stored on the global server." '221 Patent, Col. 2, ll. 10-14 (emphasis added).

The description of the preferred embodiment indicates that "the global server 115 stores workspace data 163, which includes an independently modifiable copy of each selected workspace element in the selected portions of the workspace data." '221 Patent, Col. 6, ll. 23-26. Although the court rejects many of Seven's proposed limitations, one function that must be performed by the global server is the storage of selected portions of the workspace data. It is also clear that the global server must be accessible from remote locations, although adoption of Seven's limitation that the server be "widely accessible" is too limiting. '221 Patent, Col. 7, ll. 6-9. As such, the court defines the term "global server" to mean "a server accessible from
remote locations which stores independently modifiable copies of selected portions of workspace data."

1889

On October 16, 2006 the court filed a Markman decision in this case, construing claim terms of U.S. Patent No. 5,758,328 ("the '328 patent). Plaintiff, Source Search Technologies, LLC ("SST"), now moves pursuant to Local Rule 7.1(i) for reconsideration of that portion of the Markman Opinion that holds that "Goods and Services" is construed to mean "standardized articles of trade and performances of work for another." The court reached this conclusion by citing Defendants' contended definition and noting that "SST has not objected to Defendants' contention, and therefore, it will be accepted." (Opinion, at 28-29).

A motion for reconsideration shall be accompanied by a brief "setting forth concisely the matter or controlling decisions which the party believes the Judge or Magistrate Judge has overlooked." Local Rule 7.1(i) Ciba-Geigy Corp. v. Alza Corp., No. 91-5286, 1993 U.S. Dist. LEXIS 3971 1993 WL 90412, at 2-3 (D.N.J. Mar. 25, 1993). Such a motion is not to be used to simply reargue the same issues already rejected, or to voice disagreement with the court's decision on the merits.

It is readily apparent that SST has established the basis for reconsideration. The court, adopting Defendants' definition of goods and services, overlooked that SST strenuously disputed that definition. Defendants contended, based on their construction of the language of the patent, for a narrow definition of that term, namely, that goods or services must be standarized. SST, on the other hand, contended that goods and services needed no construction and that "the '328 patent merely stated that in order to ensure that there was no confusion about what is being requested by a buyer, either the descriptions of the products had to be standardized, or the products had to be described with text to be clear." (SST's Responsive Markman Brief at 45).

This difference of opinion was expressed in the parties' submissions and at the Markman hearing. Yet the court overlooked it in its Markman Opinion. Therefore, SST's motion for reconsideration will be granted.

The parties submitted everything they had to say on this issue prior to the Markman hearing; they argued the question at the hearing (a transcript of which the court has); they had the opportunity to give added emphasis to their views in connection with the motion for reconsideration. Therefore the court will conduct its reconsideration on the record before it without a further hearing.

The term "goods and services" is used constantly throughout the claims of the '328 patent. For example, claim 1 begins:

A computerized system for forming a computer based network of network members inclusive of network buyers and or network vendors for processing requests for quotation for goods and services through at least one central processing unit... It is Defendants' position that the specification explicitly disclains a broad reading of goods and services, i.e., that goods and services means any goods and services. They point to the following language:

The present invention is a computerized quotation system forming a computer based communications network for processing requests for quotations for goods and services from respective buyers or vendors who broadcast such requests to network members of the computerized system. There is no central pricing database to limit the number of buyers and vendors of goods and services or to limit the number of goods and services which can be processed.

However, the goods and services must be standadized items to ensure that there is no confusion as to what buyers are requesting and what sellers are offering to buyers. Fig. 1 shows the system of this invention as configured using the Internet as the communications network.

('328 patent, col. 3, ll. 55-67) (emphasis added).

This is pretty unambiguous language: "... the goods and services must be standardized items to ensure that there is no confusion as to what buyers are requesting and what sellers are offering to buyers." The cases have distinguished between the terms "must" and "may" or "can" as used in patents. The word "must" is mandatory language; whereas "may" and "can"
are permissive terms. See BBA Nonwovens Simpsonville, Inc. v. Superior Nonwovens, LLC, 303 F. 3d 1332, 1340 (Fed. Cir. 2002).

SST asserts that the paragraph of the specification that follows the paragraph upon which Defendants rely completes the teaching on the subject. It includes the statement:

Standardization of product or service descriptions is essential to avoid confusion unless a more text oriented specification is appropriate for the product or service type.

('328 patent, col. 4, ll. 9-16) (emphasis added).

It is SST's contention that the specification provides two options for identifying the goods and services for which a quotation is sought: i) requesting a quote for a standardized product or service, or ii) requesting a quote for a product or service for which a text oriented specification is appropriate. This would open up the request for goods and services to any product or service, standardized or not.

If one follows the pertinent language of the specification which incorporates all the language upon which the parties rely ('328 patent, col. 3, l. 55 to col. 4, l. 12), it becomes clear that Defendants' interpretation is the correct one.

It starts with the paragraph containing the language, "However, the goods and services must be standard items to ensure that there is no confusion as to what buyers are requesting and what sellers are offering buyers." ('328 patent col. 3, ll. 63-65). The next paragraph describes how network members can use the computerized system. Once again there is a reference to standardized goods or services: "The programming … which enables network members to interact with the network would include information sufficient for network members to identify standard goods or services that they wish to identify in a request for quotation." ('328 patent col. 4, ll. 4-9) (emphasis added).

The next sentence, the sentence upon which SST relies, simply suggests how the network member can identify the standard goods or services that are the subject of his request: "Standardization of product or service descriptions is essential to avoid confusion unless a more text oriented specification is appropriate to the product or service type." ('328 patent col. 4, ll. 9-12). This sentence in no way suggests that the particular product for which a "text oriented specification is appropriate" is not to be standardized.

This conclusion is illustrated by Figure 8 of the '328 patent to which SST refers. The quote given in Figure 8 is for 5000 "TYPE J RESISTOR[S] 5%." Thus a text oriented specification is provided, namely 5000 and 5%. Nevertheless, the underlying product - the Type J resistor - is a standardized item.

Having corrected the deficiency of the October 16, 2006 opinion by considering the matter it previously overlooked, the court arrives at the same conclusion it arrived at in that opinion. It reaffirms its holding that "Goods and Services" is construed to mean "standardized articles of trade and performances of work for another." The court will file an order implementing this opinion.

</thead>
<tbody>
<tr>
<td>ORM grammar</td>
<td>&quot;the extensible set of rules including syntax, for textually describing a mapping between an object-oriented system and a relational system in a declarative way&quot;</td>
<td>&quot;the extensible set of rules, that define syntax and vocabulary for generating and interpreting an ORM specification&quot;</td>
</tr>
</tbody>
</table>

- 2249 -
The Court begins by noting the specification states ORM grammar "define[s] the mapping between an object-oriented system and a relational system" by providing "the rules for textually describing an [ORM] in a declarative way," '776 Patent 5:42-48. The parties build on this initial definition to further clarify the term. Although they agree ORM grammar is an "extensible set of rules," they disagree as to whether it: 1) includes both syntax and vocabulary; 2) may be used to "textually describe[] a mapping . . . in a declarative way;" and 3) whether it must be used to "generate" an ORM specification.

Plaintiff argues the term "vocabulary" does not appear in the specification and therefore has no place in the Court's construction. PL.'S BR. at 7-8. Defendant cites a technical dictionary to describe a grammar as having a "set of rules" and an "alphabet" of symbols, which they analogize to syntax and vocabulary, respectively. DEF.'S BR. at 7. Defendant further cites the inventor's deposition testimony, wherein when asked "And by rules, you mean the set of vocabulary and syntax necessary to describe how you map an object to a relational database, right?" he responded, "Right, vocabulary, key words, syntax, semantics." Id. Plaintiff argues this testimony is unpersuasive because the inventor had previously described ORM Grammar as "defin[ing] the rules for textually specifying the [ORM] specification" and only used the term vocabulary in response to a leading question. PL.'S REPLY. at 2-3.

Defendant does not cite, and the Court does not find, anything in the intrinsic evidence supporting the inclusion of vocabulary in the construction of ORM grammar. Furthermore, the Court is not persuaded by Defendant's extrinsic evidence. See Phillips, 415 F.3d at 1317 (cautioning against reliance on extrinsic evidence); see also Voice Techs. Group, Inc. v. VMC Sys., Inc, 164 F.3d 605, 615 (Fed. Cir. 1999) (holding an "inventor can not by later testimony change the invention and the claims from their meaning at the time the patent was drafted and granted"). Accordingly, the Court declines to include vocabulary in its construction of the term.

Likewise, the Court is not persuaded by Defendant's argument that the phrase "The ORM Grammar 200 [sic] the rules for textually describing an [ORM] in a declarative way" describes the ORM specification, rather than the ORM grammar. DEF.'S BR. at 9-10 (quoting '776 Patent 5:46-48). Relying solely on attorney argument, Defendant states the terms "textually" and "declarative" describe the ORM specification. Despite the typographical error, the specification's meaning is clear. ORM grammar is the set of rules used to textually specify an ORM in a declarative way. '776 Patent 5:42-48. The Court finds it appropriate to include these terms in its construction.

Finally, the Court finds Defendant's proposal that the ORM grammar is "for generating and interpreting an ORM specification" overly limiting. Plaintiff argues this phrasing implies ORM grammar must be used to automatically create an ORM specification, thereby excluding disclosed embodiments where users can manually create an ORM specification. PL.'S BR. at 7 (citing '776 Patent 6:17-22). Defendant argues the specification expressly refers to using the ORM grammar to generate and interpret the ORM specification, DEF.'S BR. at 8 (citing '776 Patent 5:55-58), and contends manual creation is simply a form of "generation." Id. at 9 n.16. Defendant is correct that the specification teaches use of the ORM grammar to interpret and generate the ORM specification, see '776 Patent 5:55-58 (stating "the ORM Grammar 200 may in alternate embodiments be used to generate and interpret an ORM Specification 202")., and the Court agrees that an ORM grammar must be used to interpret or generate an ORM specification. Id. 21:10-11 (reciting the "ORM Specification [is based on an ORM Grammar]"). However, the Court agrees with Plaintiff that the word "generation" can mislead jurors by implying automation, to the exclusion of the manual creation embodiment. See '776 Patent 6:17-22 (stating "[a]ny one of a variety of text editor or graphical user interfaces can be used to create, modify and review ORM Specifications 202").

For the foregoing reasons, the Court adopts Plaintiff's proposal. In the Court's provisional claim construction order, the Court originally appended the phrase "and that may be used to generate and interpret an ORM specification" (Doc. No. 177 at 2). Having further considered the matter, the Court finds the phrase unnecessary. The Court originally suggested the phrase during the Markman hearing in an effort to find agreement between the parties' positions. The purpose of the language was to communicate that "generation," as understood to mean automated or computer-implemented, was not required in every case. Plaintiff's original proposal, however, does not use this potentially confusing word. The ORM grammar is a set of rules for textually describing an ORM specification, i.e., a textual description of a mapping between an object-oriented system and a relational system, in a declarative way. Plaintiff's original proposal accurately conveyed this meaning and this definition corresponds to the parties' agreed definition of ORM specification Accordingly, the Court revises its provisional construction and adopts Plaintiff's proposal as its final construction.

For the foregoing reasons, the Court finds the proper construction of this term is "the extensible set of rules, including syntax, for textually describing a mapping between an object-oriented system and a relational system in a declarative way."
1. "Graphical icon" (Claims 1, 17)

a. The Parties' Proposed Constructions

Motorola's Proposal: "An image that represents an object, process, concept, or function. A textual label by itself is not a graphical icon."

VTech's Proposal: "A graphical icon associated with a functional feature of a phone."

b. Discussion

Motorola argues its construction of "graphical icon" is consistent with the use of the term in claim 1. According to Motorola, the specification provides that "icons representative of work, car, home and a fax machine could be associated with entered numbers." This statement refers to Fig. 4F, which discloses pictorial images of a briefcase, car, house, and a piece of paper. Thus, Motorola asserts the "icon" portion of the term relates to something that represents something else (e.g., work phone number, car phone number, etc.) and the "graphical"portion of the term limits the "icon" to an image, not mere text. In addition, Motorola contends dictionaries and patents dated around the time the '356 patent was filed provide similar meanings for this term and its components.

Motorola argues VTech's proposed construction improperly focuses on what a "graphical icon" can represent by limiting the term to a subset of "graphical icons" that are functional, i.e., "functional icons." As described in the specification, "functional icons" are icons that represent functional features or "radio communication services" that a device can perform, e.g., phone, email, short messaging service ("SMS"). According to Motorola, these functional icons are specifically claimed in dependant claim 2 as each of the graphical icons disclosed therein must "represent[...]

Motorola also takes issue with VTech's construction because it restricts the term to only the icons described in the preferred embodiment. While the specification describes functional icons as one type of graphical icon, it also contemplates other types of icons. The Examiner stated that "[t]he graphical icons can be representative of, for example, each of the radio communication services available to the user." (Motorola Ex. PP (Paper 12 at 2))(emphasis added).

VTech asserts it has rebutted the presumption created by Motorola's claim differentiation argument. Arguing it is clear that the invention disclosed in the '356 patent is only directed toward the functional nature of the icons, VTech asserts the presumption should therefore not apply. Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1361, 1369-71 (Fed. Cir. 2007) (finding that statements in the specification and prosecution history overcame presumption of claim differentiation).

The abstract of the '356 patent states that: "The radio communication device preferably comprises a touch screen display for displaying functional icons stored with directory numbers to simplify the location of information and the transmission of messages." Under the section "Field of the Invention," the '356 patent states that: "Generally, the present invention relates to radio communications devices, and more particularly to radio communications devices having functional icons associated with stored directory number." (356, 1:5-8) (emphasis added). VTech's proposed interpretation uses similar language, but the Court is not convinced the proposal is correct.

Specifically, the Court is not convinced graphical icons must be associated with a functional feature of a phone. Although the specification gives a few examples of functional icons (telephone, email, fax, short messaging service), it later states: 

"Any number of other icons could be employed according to the present invention." (356, 2:24-25; 5:54-60). The Court disagrees with VTech that this sentence is specifically referring to other types of functional icons such as a cell phone,
That being said, the Court agrees with VTech that Motorola's construction is also incorrect as it uses terms like "process," and "concept" which might require their own construction. As for Motorola's proposed second sentence, "a textual label by itself is not a graphical icon," there is no support for this limitation in the specification. Therefore, this limitation should not be imported without further evidence from Motorola why such a limitation is warranted.

c. The Court's Construction

Accordingly, the Court construes "graphical icon" to mean: "a graphical image."

1892

C. Graphical keyboard area incapable of user termination independent of termination of the input area

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphical keyboard area incapable of user termination independent of termination of the input area</td>
<td>the graphical keyboard may not be terminated by the user unless the input area is also terminated</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphical keyboard area incapable of user termination independent of termination of the input area</td>
<td>a graphical keyboard area that is always present with the plurality of data input fields and cannot be removed, minimized, maximized, deleted, closed or resized independent of termination of the input area</td>
</tr>
</tbody>
</table>

The next contested phrase also comes from Claim One as part of an "invoking" step of the claimed method. Plaintiff's construction is all but a verbatim quotation of the claim language: "the graphical keyboard may not be terminated by the user unless the input area is also terminated." In contrast, Defendants' construction weighs down the definition with six terms they believe are synonymous with "user termination:" "a graphical keyboard area that is always present with the plurality of data input fields and cannot be removed, minimized, maximized, deleted, closed or resized independent of termination of the input area."

The court begins with the ordinary meaning of termination: "end in time or existence" MERRIAM-WEBSTER'S COLLEGIATE DICTIONARY at 1216 (10th ed. 1997). That ordinary meaning does not include minimizing, maximizing, or resizing. Any novice computer user, let alone someone skilled in the art, would not read "termination" to include minimizing, maximizing, or resizing. To overcome that ordinary meaning, Defendants must point to "contravening evidence from the specification or prosecution history." DSW, Inc. v. Shoe Pavilion, Inc., 537 F.3d 1342, 1347 (Fed. Cir. 2008).

Defendants believe that they have such evidence: their construction is based on a statement by the patentees to the patent examiner during prosecution: "Because the graphical keyboard of claim 1 is [incapable] of user termination independent of termination of the input area, a user cannot accidentally remove, minimize, maximize, delete, close or resize the graphical keyboard." (Pl's Ex. 2, at 177) (alteration, adopted by both sides, corrects typographical error). Plaintiff argues that the court should not rely on the statement because it was contradicted by a later statement in the prosecution. (Pl's Br., at 13.) The part of that later statement that Plaintiff emphasizes, though, that "the keyboard is provided when needed by an input area," (Pl's Ex. 2, at 221), says nothing about how to read the term "user termination."
Statements made during prosecution are part of the intrinsic evidence to be considered during claim construction, and patentees are held to what they declare during prosecution under the doctrine of prosecution disclaimer. Computer Docking Station Corp. v. Dell, Inc., 519 F.3d 1366, 1374-75 (Fed. Cir. 2008). The doctrine does not apply, though, where the statement during prosecution is so ambiguous that a person of ordinary skill in the art would not rely on it. Elbe Video, Ltd. v. Sensormatic Electronics Corp., 508 F.3d 1366, 1371-72 (Fed. Cir. 2007). Before going further, the court notes that this is a relatively unusual context for the doctrine of prosecution disclaimer because Defendants are arguing that the statement expands the scope of a claim term. In contrast, the doctrine is "typically invoked to limit the meaning of a claim term that would otherwise be read broadly." 800 Adept, Inc. v. Murex Sec., Ltd., 539 F.3d 1354, 1364 (Fed. Cir. 2008).

Plaintiff argues against Defendants' construction by pointing to differences between Claim One and Claim Ten. (Pl's Br., at 14; Pl's Resp., at 5-6.) Claim One refers only to preventing "user termination," while Claim Ten refers to taking away the user's ability to "move, resize, remove, or close" the keyboard. ('873 Patent, col. 20, ll. 62-63, col. 22, ll. 13-14.) Under the doctrine of claim differentiation, differences between claims can be a "useful guide in understanding the meaning of particular claim terms." Phillips, 415 F.3d at 1314. Thus, Claim Ten suggests that if the inventors had intended for Claim One to include more than just termination, they would have said so explicitly. Plaintiff's argument also finds support in the patentees' adoption of a definition for the word "immutable" that is identical to the meaning that Defendants want to attach to "terminated." (Pl's Resp., at 5-6.) As the specification explains, "The keyboard ... may not be minimized, maximized, deleted, closed or resized and is therefore immutable." ('873 Patent, col. 3:43-46.) In cases where a patentee defines a claim term, that definition governs. Honeywell Int'l, Inc. v. Universal Avionics Systems Corp., 493 F.3d 1358, 1361-62 (Fed. Cir. 2007). Thus, Plaintiff's construction finds further support in the presumption that different terms have different meanings. Innova/Pure Water, Inc. v. Safari Filtration Systems, Inc., 381 F.3d 1111, 1119-20 (Fed. Cir. 2004).

Defendants argue that the prosecution statement is actually supported by statements in the specification, but none of those statements give meaning to the word "termination." (Def's Br., at 26-27.) Each one merely suggests that an attribute of the invention was that it prevented more than just inadvertent closing of the keyboard; it also prevented minimizing, maximizing, and resizing. In other words, Defendants' references to the specification show only that Claims One and Ten, when read together, cover inadvertent closing of the keyboard as well as inadvertent moving, resizing, and removing.

For all these reasons, the court concludes that the patentees erred in making the statement during prosecution that equated "terminate" with "remove, minimize, maximize, delete, close or resize." Although the statement purportedly referred to Claim One, it actually referred to some functionality encompassed by Claim Ten. The patentees' error is not one that would mislead a person of ordinary intelligence because, as explained, it is contrary to the ordinary meaning of the word "terminate," it is contrary to a reading of the claims, and it is not required by a reading of the specification. Viskase Corp. v. American Nat'l Can Co., 261 F.3d 1316, 1322 (Fed. Cir. 2001); Biotec Biologische Naturverpackungen GmbH & Co. KG v. Biocorp, Inc., 249 F.3d 1341, 1348 (Fed. Cir. 2001).

The court thus moves to Plaintiff's proposed construction, which relies on the claim language itself, but rewrites it in a few very minor ways. Plaintiff provides no explanation for its proposed revision aside from saying that it is supported by the plain and ordinary meaning of the claim's language. (Pl's Br., at 12.) The court agrees that it is so supported, but does not see any advantage that the revision provides. The court is also puzzled by Plaintiff's unexplained proposal to read "graphical keyboard area incapable of user termination independent of termination of the input area" requires no further construction. O2 Micro Int'l Ltd. v. Beyond Innovation Tech. Co., 521 F.3d 1351, 1361 (Fed. Cir. 2008).

A. Construction of "said one or more visual representations comprising graphical objects"

The intrinsic evidence shows that whatever "graphical objects" means within the '801 patent, it does not include "text" alone. Beyond that, the intrinsic evidence provides little guidance to show what "graphical object" means, and so to construe
that term, the special master properly looked to extrinsic evidence. However, the court finds that the final sentence of the special master's construction is circular and modifies it in accordance with this opinion to remedy the problem.

1. Claims and Specification

Stryker argues that the claims show that "text" alone is not a type of "graphical object" under the doctrine of claim differentiation. Under this doctrine, each claim in the patent is presumptively different in scope. Intermatic Inc. v. Lamson & Sessions Co., 273 F.3d 1355, 1364 (Fed. Cir. 2001), vacated and remanded on other grounds by, 537 U.S. 1016, 123 S. Ct. 549, 154 L. Ed. 2d 423 (2002). The presumption is especially strong where, as here, there is a dispute over whether a limitation found in a dependent claim n4 should be read into an independent claim and that limitation is the only meaningful difference between the two claims. Ecolab, Inc. v. Paraclipse, Inc., 285 F.3d 1362, 1375 (Fed. Cir. 2002); Phillips v. AWH Corp., 415 F.3d 1303, 1314-15 (Fed. Cir. 2005) ("The presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim").

n4 A dependent claim refers to a previous claim and adds further limitations to it. 37 C.F.R. § 1.75(c).

Under the doctrine of claim differentiation, Claims 14 and 15 show that a "graphical object" cannot be "text" alone within the context of the '801 patent. Claim 14 n5 is an independent claim. It lays out several essential elements of the patented system and does not incorporate another claim. Claim 15 n6 is a dependent claim because it incorporates Claim 14 by reference. Thus, under the principles discussed above, Claim 15 is presumed to provide something distinct to Claim 14. The only discernable difference between the two claims is that Claim 15 allows visual representations to comprise "text." Claim 14 describes visual representations comprising "graphical objects." As the special master found, this is powerful intrinsic evidence that a person of ordinary skill in the art at the time of the invention would understand "graphical object" not to include "text" alone.

n5 Claim 14 states:

A system for acquiring images during a medical procedure and using the acquired images, comprising

at least one input device for obtaining said images,

at least one output device for using the images obtained by said input device to enable image data to be communicated to a medical practitioner,

a preference database for pre-storing, for each one of a plurality of users of said system, respective preference information that indicates one or more visual representations that said one of said plurality of users of said system prefers to be applied to said at least one output device together with said images obtained by said input device, said one or more visual representations comprising graphical objects, and

a processor for receiving an indication of an identity of one of said users, who is currently using said system, and, responsive to said indication of said identity of said one of said users who is currently using said system, for retrieving said preference information for said one of said users pre-stored in said preference database, for combining said one or more visual representations with said images obtained by said input device based on the preference information in said preference database that corresponds to said one of said users, and for applying said images to said at least one output device together with said one or more visual representations.

(Doc. No. 1, Ex. A, Claims, Col. 48, Ln. 11-37.)

n6 Claim 15 states:

A system in accordance with claim 14 wherein said one or more visual representations comprise text.
Furthermore, as Stryker points out, the patent specification and claims refer to "text" and "graphical objects" in the alternative multiple times. Thus, the specification indicates that a person of ordinary skill in the art at the time of the invention would believe that "text" alone was not a "graphical object."

Luma argues that the patent refers to "text" and "graphical objects" in the alternative because it refers primarily to operating systems using text-based (e.g. Microsoft DOS) versus graphic-based (e.g. Microsoft Windows) user interfaces. This argument was presented to the special master after Luma reviewed the master's draft report, and the master revised his construction based on it. The construction in the draft report contained the statement "graphical objects are not text." (See Doc. No. 433, Tab 10 at 2.) The master amended the construction in the final report to make clear that "text" can be a part of a "graphical object," but that it is not a "graphical object" by itself. (See Doc. No. 433 at 74.)

The special master's amendments to the draft report extend Luma's arguments as far as the evidence supports. Luma's argument supports the conclusion that "text" can be used as part of a "graphical object" created by the patented system for the user interface (e.g. in a menu). But it goes no further. Luma discusses how a software engine described in the '801 patent pulls together shapes, text, lines, buttons, backgrounds, etc. to form menus. (Doc. No. 433, Tab 10 at 3.) These form part of the program's interface with the user. But the use of text as a part of the user interface simply does not support Luma's contention that "text" alone can be a "graphical object" within the meaning of the '801 patent.

Moreover, the court finds no merit in Luma's argument that the seemingly dichotomous references to "text" and "graphical objects" within the '801 patent reflects the drafter's attempt to cover operating systems using text- as well as graphic-based user interfaces because that argument is in conflict with the intrinsic evidence. As discussed above, the intrinsic evidence treats the two terms as distinct items, though it indicates that the system can use "text" and "graphical objects" together. Therefore, based on the specification and claims, the court finds that a person skilled in the art at the time of the invention would conclude that a "graphical object" could not be "text" alone.

The special master's amendments to the draft report extend Luma's arguments as far as the evidence supports. Luma's argument supports the conclusion that "text" can be used as part of a "graphical object" created by the patented system for the user interface (e.g. in a menu). But it goes no further. Luma discusses how a software engine described in the '801 patent pulls together shapes, text, lines, buttons, backgrounds, etc. to form menus. (Doc. No. 433, Tab 10 at 3.) These form part of the program's interface with the user. But the use of text as a part of the user interface simply does not support Luma's contention that "text" alone can be a "graphical object" within the meaning of the '801 patent.

Moreover, the court finds no merit in Luma's argument that the seemingly dichotomous references to "text" and "graphical objects" within the '801 patent reflects the drafter's attempt to cover operating systems using text- as well as graphic-based user interfaces because that argument is in conflict with the intrinsic evidence. As discussed above, the intrinsic evidence treats the two terms as distinct items, though it indicates that the system can use "text" and "graphical objects" together. Therefore, based on the specification and claims, the court finds that a person skilled in the art at the time of the invention would conclude that a "graphical object" could not be "text" alone.

2. Patent Prosecution History

The '801 patent prosecution history shows that the patent examiner treated "graphical objects" and "text" differently. The examiner rejected Proposed Claim 22, which stated, "A system in accordance with Claim 21 [Patent Claim 14's predecessor n9], wherein said one or more visual representations comprise text." (Id.) At the same time, the examiner allowed Proposed Claim 24, which stated "A system in accordance with claim 21 wherein said one or more visual representations comprise graphical objects." (Id.) The language of Proposed Claim 24 was later incorporated into Patent Claim 14, but no longer appears as a separate dependent claim in the '801 patent. (See Doc. No. 437, Ex. 5, Response to PTO Office Action at 5-6.)
n9 Proposed Claim 21 became Patent Claim 14. (See Doc No. 437, Ex. 3, Patent Application, Ln. 8-10; Ex. 4, PTO Office Action Summary at 4; Ex. 5, Response to PTO Office Action at 5.) Proposed Claim 21 stated "respective preference information that indicates one or more visual representations. . . ." (Id.) The examiner rejected the claim as anticipated by a prior patent (Wilhelm '543). (Id., Ex. 4, Office Action Summary at 4.)

This history shows that the patent examiner saw a difference between a "graphical object" and "text." A claim including "visual representations comprising text" was rejected while a claim including "visual representations comprising graphical objects" was allowed. The prosecution history evidence is particularly persuasive because it is highly indicative of the understanding as it existed at the time of the invention, the legally determinative time frame. Thus, based on the prosecution history, the court finds that one skilled in the art at the time of the invention would conclude that "text" alone could not be a "graphical object."

3. Special Master's Use of Extrinsic Evidence

Luma objects to the special master's use of extrinsic evidence in construing the term "graphical object." In Phillips v. AWH Corporation, the Federal Circuit refined its guidance on the use of dictionaries in construing patent terms. See 415 F.3d 1303, 1320-24. The Federal Circuit made clear that judges may consult dictionaries and technical treatises for meaning as long as they do not contradict the patent documents, and that the court must focus on attaching the appropriate weight to the evidence. Id. at 1322-24. The underlying policy is to avoid reading limitations from the specification into the claims and to avoid systematic overbreadth in claims. Id. at 1322-23.

While the record amply shows that the term "graphical object" does not include "text" alone, it provides the court with little guidance on what the term does include. Because the meaning of "graphical object" is unclear from the intrinsic evidence, it is appropriate to consult extrinsic evidence, such as a dictionary, to aid the court's interpretation. See Hockerson-Halberstadt, Inc. v. Avia Group Int'l, Inc., 222 F.3d 951, 955 (Fed. Cir. 2000). Accordingly, the special master relied on a definition of "graphical" found in the Authoritative Dictionary of IEEE n10 Standards Terms 7th ed. (Doc. No. 433 at 77.) That definition states, "Graphical - pertaining to the pictorial representation of data." (Doc. No. 377, Ex. F.)

n10 "IEEE" stands for "Institute of Electrical and Electronics Engineers, Inc." who publishes the IEEE dictionary.

None of the parties provides a different dictionary definition or argues that the IEEE dictionary itself is contrary to the intrinsic evidence or otherwise problematic. n11 Luma offers a portion of a software treatise, which explains that an operating system using a graphic user interface displays text as pictures of text. (Doc. No. 433, Tab 10, Luma's Objection, Ex. A.) The court considered both and found that the IEEE dictionary definition of "graphical" is evidence of the pictorial nature of "graphical objects." Further, the definition was consistent with the conclusion drawn from the intrinsic evidence that "text" alone is not a graphical object. Accordingly, the court agrees with the special master that a person skilled in the art at the time of the invention would conclude that a "graphical object" pertains to a "pictorial representation of data." (See Doc. No. 433 at 74.)

n11 Luma argues that the court should not consult any extrinsic evidence, the court does not understand Luma to object to this dictionary particularly.

4. Modification of Special Master's Construction

After its de novo review, the court believes the final sentence of the special master's construction in Section 15 of the report...
is circular. Currently, that sentence states, "Text without a graphical object is not a graphical object." (Doc. No. 433 at 74.)
As stated above, the court believes the evidence shows that one skilled in the art at the time of the invention would conclude that "text" alone is not a "graphical object." To remedy the circularity in the special master's construction, and in accordance with the reasoning stated above, the court modifies the special master's construction as follows:

"'Said one or more visual representations comprising graphical objects' means one or more visual representation comprising graphical objects. A graphical object is a symbol and pertains to pictorial representations of data. Graphical objects are not text. Text is not a graphical object. A graphical object may include text. Text alone is not a graphical object."

The term "visual representations" "(# 6)" has been previously construed by the Master. That construction is incorporated in the Master's Construction of phrase "(# 15)".

REASONS

The Master has previously construed "visual representations" "(# 6)".

Phrase # 15's construction by the Master was scrutinized very closely by Luma and Stryker. Luma filed an objection (Tab # 10) to the Master's Draft Construction of phrase # 15. Stryker filed a response (Tab # 11) to Luma's objection. Luma filed a surrebuttal to Stryker's response (Tab # 12).

Luma and Stryker argued whether or not "graphical objects" must exclude text. The Master's Construction in the Master's DRAFT Report of June 30, 2005, page 71 of 97 stated that "Graphical objects are not text".

This issue, regarding the terms "graphical objects" and "text" and the relationship between the two terms, has been difficult for the Master to resolve. In view of the arguments presented by Luma and Stryker, the Master has revised the Construction in the Master's Draft Report of June 30, 2005 by adding further clarification to the construction. The Master's "Reasons" have been revised to explain the revised construction.

INTRINSIC EVIDENCE

The Patent Specification description refers to graphical objects (Col. 2, Ls. 32-35). It states that prompting is performed by, "a graphical object or a text clue imposed on the displayed image", (Col. 17, Ls. 45-48). It refers to "selects the text or graphical objects"; (Col. 19, Ls. 55-58); "the input device is also used to locate the text or graphical object on the image" (Col. 19, Ls. 59-61).

The above tells the Master that the Specification is treating "text" and "graphical objects" as two different separate items. It tells the master that "graphical objects" are different than "text".

The Master reviewed the language in claims 14 and 15 of the Patent. Claim 14 is an independent claim. Claim 15 depends upon claim 14. The result of this is that claim 15 is read to have all the limitations of claim 14 plus the further limitations of
claim 15. Claim 15 cannot eliminate an element from claim 14.

Claim 14 states (Col. 48; Ls. 23-24) "visual representations comprising graphical objects".

Claim 15 (Col. 48; Ls. 38-39) states, "A system in accordance with claim 14 wherein said one or more visual representations comprise text". Claim 15 further limits the term "visual representations". It does not further limit "graphical objects". The way this is interpreted is as follows: Claim 14 says, "visual representations comprising graphical objects." Claim 15 then, in effect, is read as -- visual representations comprise graphical objects and text --.

In order for something to come within the scope of claim 14, it must have a graphical object. In order for something to come within the scope of claim 15, it must have a graphical object and text. This tells the Master that the Patent is telling one skilled in the art "graphical objects" and "text" as the patentee used the terms at the time the patent application was filed was treating "graphical objects" and "text" as two separate items.

This same argument is presented from another perspective in Stryker's Response to Luma's Objection (Tab # 11). Stryker argues the well established doctrine of claim differentiation.

The description in the Specification is otherwise not informative to the Master to construe "graphical objects" and "text" and the relationship between the two terms.

The Master has turned to extrinsic evidence for further help to determine the meaning of "graphical objects".

EXTRINSIC EVIDENCE

Page 487 of the IEEE 100 The Authoritative Dictionary of IEEE Standards Terms 7TH Edition was offered by Stryker in Stryker Supplemental Claim Construction Brief Exhibit "F". That dictionary defines graphical as a symbol. Graphical is defined as pertaining to the pictorial representation of data.

STRYKER AND KSEA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

Stryker's and KSEA's construction is set forth in (Stryker/KSEA May 4, 2005, p. 7). Stryker argues for a construction that a "graphical object is a character symbol, excluding text".

KSEA argues the phrase should be construed as "non-text visual objects".

The Master agrees that "graphical objects" are not text for the reasons given. The Master has explained that graphical objects may include text and that a graphical object docs not cease being a graphical object if text is included.

LUMA'S POSITION WITH RESPECT TO STRYKER AND MASTER'S COMMENTS ON THAT POSITION

Luma's position is set forth in (Luma re: Stryker May 23, 2005, p. 6).

Luma argues that "graphical objects" has a commonly understood meaning and that Stryker is attempting to read a limitation ("excluding text") contrary to the plain meaning and not supported by the Patent. The Patent supports a difference between text and graphical objects. The Master explained the reasons above. The Master has construed the terms that:

(i) graphical objects are not text;

(ii) likewise, text is not a graphical object;

(iii) a graphical object may include text; and

(iv) text without a graphical object is not a graphical object as explained above.

LUMA'S POSITION WITH RESPECT TO KSEA AND MASTER'S COMMENTS ON THAT POSITION

- 2258 -
Luma's position is set forth in (Luma re: KSEA May 23, 2005, p. 6).

Luma argues that KSEA's proposed construction of "non-text visual objects" should be rejected. The Master has construed that "visual representations" #16 may include (although not limited) text as stated above. The Master has construed the term "graphical objects" that "text" is not a graphical object and that a "graphical object" may include "text" and still be considered a graphical object. This is explained above.

D. "graphical user interface"

<table>

<thead>
<tr>
<th>Term</th>
<th>Defendants' Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>graphical user interface</td>
<td>Defendants do not believe that a construction is required for this term.</td>
</tr>
</tbody>
</table>

If the Court concludes that a construction is required, the term should be construed as: "a type of environment that represents programs, files, and options by means of icons, menus, and dialog boxes on the screen"

The disputed term is located in each of the asserted independent claims: "an operating system including a graphical user interface." The term "graphical user interface" (or GUI), as used in the claims, is consistent with its meaning as understood by one of ordinary skill in the art. The parties' proposed definitions are different in two important respects. First, the plaintiff characterizes a GUI as a "presentation" whereas the defendant calls it an "environment." A GUI is interactive, as it is an "interface," and "presentation" only addresses one side of what a GUI is. On the other hand, "environment" does not connote the graphical nature of a GUI.

The specification explains a GUI by the manner in which it is used:

Generally, a particular application program presents information to a user through a window of a GUI by drawing images, graphics or text within the window region. The user, in turn communicates with the application by "pointing" at graphical objects in the window with a pointer that is controlled by a hand-operated pointing device, such as a mouse, or by pressing keys on a keyboard.

('850 patent, 5:10-16).

The Court adopts a hybrid of the parties' constructions. The Court construes "graphical user interface" to mean "computer environment wherein an application program presents graphical representations of data on a computer display screen and enables a user to make selections of the graphically represented data."
3. "Graphically displaying" is construed to mean "information shown by written text or pictures."

C. "graphics"

Touchtunes proposes that "graphics" be construed as "images on a computer screen." Arachnid seeks to define the term as "pictorial images created from image files."

The patents disclose both "graphics" and "pictorial graphics." As a matter of plain language, the term "pictorial graphics" describes a subset of the broader term "graphics," and therefore has a narrower meaning. Without any basis in the intrinsic record, Arachnid seeks to eliminate the distinction between these two terms, effectively proposing that the term "pictorial" be considered superfluous and that the narrower meaning of "pictorial graphics" be applied to the more general term "graphics" throughout the patents. The use of the term "pictorial graphics" means that "graphics" are not necessarily pictorial. See Phillips, 415 F.3d at 1314 (use of the term "steel baffles" "strongly implies that the term 'baffles' does not inherently mean objects made of steel"). Similarly, Arachnid's proposed restriction of graphics to "images created from image files" finds no support in any of the patents.

Consistent with the ordinary meaning of the claim term and the intrinsic evidence, "graphics" are therefore construed as "images on a computer screen."

Ground lines

The Court agrees with Samsung and construes "ground lines" in claims 1 and 3 of the '490 patent as "conducting paths that provide a connection to the ground." The parties agree that both ground lines are conducting paths. See Claim Const. Hr'g Tr. at 62. As discussed above for "power lines," MEI's construction of "ground lines"--"conducting paths, each independently providing a connection to ground"--improperly imports limitations from the preferred embodiment.

Universal next contends that the trial court erred in construing the term "ground proximity warning system" to be broader than the specific alerting systems approved by the Federal Aviation Administration at the time of the patent application, i.e., the prior art systems that were mandated for use at that time. Because the prior art systems did not use distance from an airport to trigger alerts, Universal contends that the district court's construction should have excluded any monitoring system (such as the accused system) that uses distance from an airport as a parameter to trigger a ground proximity alert.

Contrary to Universal's contention, the patent does not limit the phrase "ground proximity warning system" to the particular system or systems approved at the time of the application. The context makes it clear that the term is used generically, to describe any system that warns of ground proximity, regardless of whether the system is approved, manufactured, proposed, or otherwise. The specification refers generically to systems "that provide warning or advisory indications in the event of hazardous flight conditions," including "systems generally known as ground proximity warning systems for aircraft that serve to monitor the flight conditions of an aircraft and provide a warning if flight conditions are such that an inadvertent contact with the ground is imminent." '436 patent, col. 1, ll. 15--22. The specification further provides that the invention
"may be used to enable other warning modes and even used in control systems," id., col. 3, ll. 45--46, and "can be used in virtually any warning or control system where [a signal indicating when an aircraft is on final or missed approach] is required," id., col. 5, ll. 43--45. The claims use similarly generic language to describe ground proximity warning systems, such as "[a] warning system for use in an aircraft comprising: warning means for providing a ground proximity warning according to predetermined criteria," id., col. 7, ll. 64--66, and "warning means for providing a ground proximity warning when an aircraft encounters a hazardous flight condition," id., col. 8, ll. 19--21. In light of the language used in the specification and the absence of any contrary indication in the patent or the prosecution history, the district court properly declined to limit the term "ground proximity warning system" to any particular system, whether approved or designed to use particular factors in warning of ground proximity.

1. "Grounded" (Claim 6)

The parties agree that this term should be construed according to its plain and ordinary meaning: "Connected to ground." (See Broadcom Resp. at 12; Agere Reply at 3.)

2 Although the parties' original briefs indicated an agreement on this construction, Broadcom submitted supplemental briefing after the Markman hearing in order to "crystalize[the] dispute" regarding the term "grounded." (Broadcom's Submission of Information Requested by the Court at 3 [hereinafter Broadcom's Submission of Requested Information].) To the extent that Broadcom's post-Markman submission suggests a new proposed construction of "connected to a ground plane" that is different from plain and ordinary meaning of "connected to ground," Broadcom has failed to offer any support from the intrinsic record for such a limitation.

7. "[G]roup:" 9 "Two or more." This construction is consistent with the specification. (col. 2:12-14, 24-27) The specification refers to a "group" of conductor pairs as a plurality of conductor pairs, to wit, two or more conductor pairs. 10 (col. 2:60-66 ("The conductors of the second plurality of conductor pairs each has substantially the same conductor thickness which is different from that of the first plurality of pairs to provide a nominal characteristic impedance for each conductor pair of the second plurality which is within the desirable limits and also an acceptable signal attenuation.").

9 Id.

10 The Federal Circuit has interpreted "plurality" to mean "more than one." See, e.g., Bilstad v. Wakalopulos, 386 F.3d 1116, 1122-23 (Fed. Cir. 2004).

Consistent with the term's usage in the specification, the district court construed "group key" in claims 1 and 4 to mean a key associated with a subset of the total subscriber base. Irdeto challenges this construction on appeal, arguing that the district court departed from the ordinary meaning of the term "group." Relying on this court's pronouncements regarding the
"'heavy presumption' that [the claims] mean what they say," Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 913 (Fed. Cir. 2004), Irdeto proffers definitions from a general-usage dictionary to show that nothing in the "ordinary meaning" of the claim terms requires limiting "group" to fewer than all subscribers. Absent "clear disclaimer" or words of "manifest exclusion," Irdeto argues, the heavy presumption of ordinary meaning must apply. Here, Irdeto claims, the intrinsic record lacks such clear disavowal.

Echostar, on the other hand, contends that there can be no such "heavy presumption" where a disputed term lacks an accepted meaning in the art. We agree. As we held in J.T. Eaton, absent such an accepted meaning, we construe a claim term only as broadly as provided for by the patent itself. 106 F.3d at 1570. The duty thus falls on the patent applicant to provide a precise definition for the disputed term. Id. Moreover, where evidence such as expert testimony or technical dictionaries demonstrates that artisans would attach a special meaning to a claim term or would attach no meaning at all to the claim term independent of the specification "general-usage dictionaries are rendered irrelevant with respect to that term . . ." Vanderlande Indus. Nederland BV v. Int'l Trade Comm'n, 366 F.3d 1311, 1321 (Fed. Cir. 2004). "[A] general-usage dictionary cannot overcome credible art-specific evidence of the meaning or lack of meaning of a claim term." Id. (citation omitted).

Here, applicant informed the examiner and all competitors that the "key" modifiers -- "service," "group," and "box" -- have no accepted meaning in the art and "are very adequately described in the specification." The applicant's use of those terms in the specification thus controls their scope.

Irdeto faults the district court for reading the preferred embodiment into the claims. Just because the applicant told the examiner that the terms "service," "group," and "box" modifying "key" are "very adequately described in the specification," Irdeto maintains, does not transform every aspect of the preferred embodiment into a claim limitation. Irdeto points to language such as "for example," "may," and "normally" in the following specification passage as evidence of the district court's error:

For example, there may be a group composed of those interested in adult movies, those interested in opera, those interested in specific types of sports programs. The group may be formed of those in a geographical area. The number and types of groups are almost infinite and normally each subscriber will be able to belong to a plurality of groups and will have a group key and group ID associated with each such group.

'020 patent at col. 5, ll. 28-36. All examples in the specification, Irdeto argues, are permissive rather than mandatory, illustrative rather than exhaustive, and do not necessarily or explicitly exclude a group made up of all subscribers. Echostar responds that the specification describes every group as a subscriber subset and lacks any disclosure of a group that includes all subscribers.

Indeed, the specification consistently uses the term "group" to refer to a subset of all subscribers. The specification teaches that service key change messages take place in the "group key which is common to a group of subscribers, all of whom are to receive a specific type of broadcast." 020 patent at col. 2, ll. 22-24. "There may be a substantial number of groups associated with a specific communication system and an individual subscriber may itself belong to more than one of a plurality of groups." Id. at col. 2, ll. 24-28. As subscribers' "tastes and desires in programming change," it is "necessary to change groups, to reform groups and to add or delete subscribers from a particular group." Id. at col. 2, ll. 36-39. And,

if a substantial portion of a current group is to be involved in a new group, the broadcaster may address those subscribers to form the new group in the group key but with the message being preceded by the individual IDS of those particular subscribers. Thus the broadcaster may form new groups, delete subscribers from a particular group, etc., all by communicating to the subscribers within the concept of the group identification and the group key.

Id. at col. 5, ll. 42-51. Nowhere does the specification contemplate a single group made up of the entire subscriber base.

Instead, the specification consistently equates group with a subset of all subscribers. The passage characterizing the box address/box key pair as "simply . . . another subscriber subset (group)," 020 patent at col. 3, ll. 9-11 (emphasis added), is most telling. Irdeto attempts to explain away this passage by arguing that because a group may be a subset as small as one subscriber, in that particular instance, the group key/group address and box key/box address pairs overlap. Yet Irdeto cannot explain every example in the specification, all of which consistently point to an implicit definition of group as a subset of all subscribers.
subscribers in the system. See Bell Atl., 262 F.3d at 1271 ("Thus, when a patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning, he has defined that term 'by implication'."); see also Vitronics, 90 F.3d at 1582 ("The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication.").

Irdeto argues that only statements of "clear disclaimer" in language expressly indicating "manifest exclusion or restriction" can overcome the "heavy presumption" in favor of ordinary meaning, citing our recent cases such as Liebel-Flarsheim, 358 F.3d at 913; Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1301 (Fed. Cir. 2003); Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002). Relying on these cases -- with little or no analysis of their holdings -- does not help Irdeto.

The cited cases are not in conflict with Bell Atlantic, which held that terms may be redefined away from their ordinary meaning by their consistent use in the specification. In fact, Teleflex discusses Bell Atlantic without any disapproval of its methodology or result, stating that "although [in Bell Atlantic] the term's ordinary meaning may have supported a broader reading, we found that 'the patentees defined the term "mode" by implication, through the term's consistent use throughout the '786 patent specification.'" Teleflex, 299 F.3d at 1327 (citations omitted).

In Liebel-Flarsheim, the district court interpreted a claim that recited a "syringe receiving opening" to require that the claimed syringe loading system use pressure jackets, because all of the embodiments described in the specification featured such pressure jackets. 358 F.3d at 901. In reversing, this court noted that the specification did not define the term "opening" to require that the term, as used in each of the claims, be limited to an opening at the front end of a pressure jacket, nor did the court find anything in the specification that supported the district court's conclusion that the term "opening" was ambiguous as used in the patent. Moreover, the court concluded that the written description "does not contain a clear disavowal of embodiments lacking a pressure jacket" and does not "expressly or by clear implication restrict the scope of the invention to injectors using a pressure jacket." Id. at 908 (emphasis added). Once again, redefinition by implication was not criticized as a methodology.

In Liebel-Flarsheim, our construction found further support in the prosecution history, "squarely contrary" to limiting the claims to require pressure jackets. Id. at 909. Because patent applicants replaced claims referring to a pressure jacket with new claims removing all such references, we held that applicants clearly intended the asserted claims to cover injectors without pressure jackets. Id. The prosecution history thus affirmatively precluded a narrow reading of the claim language.

Similarly, in Brookhill, we declined to limit the term "remote location" to "a location outside the operating room" based on the single embodiment described in the specification, especially where amendments in the prosecution history specifically supported the broader construction. 334 F.3d at 1302. While the preferred embodiment contemplated a surgeon located outside of the operating room, the written description as a whole contained no specific parameters as to the distance between the surgeon and patient and generally taught that "a surgeon using the disclosed assembly may operate without directly touching the patient, the surgical instruments, or the endoscope -- regardless of the extent of the physical separation between the surgeon and the patient." Id. at 1300 (emphasis added). During prosecution, patentee overcame an indefiniteness rejection for the phrase "remote location beyond a range of direct visual contact," by replacing the word "visual" with "manual," clarifying that the amended text "means that the remote location is beyond the arm's reach of the patient." Id. at 1302. Accordingly, we construed "remote location beyond a range of direct manual contact" to encompass all locations where the surgeon is beyond direct physical contact with the patient, including inside the operating room, as in the accused system, and outside the operating room. As in Liebel-Flarsheim, the prosecution history specifically endorsed the broader construction.

Most importantly, neither Liebel-Flarsheim nor Brookhill nor Teleflex involved a situation where the applicant admitted that certain claim terms lacked any agreed upon meaning in the art -- i.e., ordinary meaning -- and unequivocally directed the patent examiner, as well as the public, to the specification as the complete source of meaning for the disputed terms by stating that those terms "are very adequately described in the specification and therefore there is a complete foundation for the use of those terms in the claims." Patentee's clear intent to rely on the four corners of his patent to define fully the terms at issue thus takes this case out of the "heavy presumption" regime of our cases.

In short, the district court correctly construed the term "group" in claims 1 and 4 to pertain only to a subset of all subscribers to the claimed broadcast system. A contrary result, moreover, would undermine the notice function of the patent itself. What
Irdeto, in effect, argues is that even after telling the PTO and the public that given the absence of ordinary meaning in the art for the term "group," the specification sets forth the full intended scope of that term, a patentee can nonetheless later lay claim to a broader, general-usage dictionary meaning of "group" absent explicit narrowing statements in the specification. This cannot be. Having conceded that the "key" modifiers have no accepted meaning in the art, the applicant expressly directed the public to the specification to discern that meaning and thus measure the scope of the claimed invention. And while the specification does not contain any statements of explicit disavowal or words of manifest exclusion, it repeatedly, consistently, and exclusively uses "group" to denote fewer than all subscribers, manifesting the patentee's clear intent to so limit the term. The specification also contains no affirmative indication that group can consist of all subscribers within the system. A reasonable competitor reading the patent could only understand "group" to refer to a subset of all subscribers. The claims must be limited accordingly.

Skill Group

The parties propose the following construction of "skill group:"

IEX: "Skill group" means "one or more agents, each agent having a particular sub-combination of skills."

Blue Pumpkin: "Skill Group" means a group consisting of "the set of all scheduled agents having a particular combination of skills."

The Court cannot find sufficient support in the intrinsic evidence for Blue Pumpkin's proposed construction, but can for IEX's.

The Court recommends that "skill group" be construed as "one or more agents, each agent having a particular sub-combination of skills."

Skill Group

Despite a rather clear statement in the patent's written description that "one or more agents are …organized into 'skill groups, '', the district court declined to accept the Magistrate Judge's "one or more" construction and instead determined that "skill group" referred to "a group of agents." 2003 U.S. Dist. LEXIS 26251 at *3. An interpretation that excludes a preferred embodiment is rarely, if ever, correct. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996). But while IEX asserts in briefing to this court that the patent does not rule out the possibility that a particular skill group might contain only one member depending on the circumstances, it represented to the district court that "at no time …has IEX ever accused the Blue Pumpkin products of infringing based on such a theory." (J. A. at 1645.) Rather, IEX now contends that its theory of infringement has always been that Blue Pumpkin organizes agents into skill groups typically containing many members. It comes as no surprise, then, that IEX does not expressly challenge the district court's "group of agents" construction on appeal. 2 Nonetheless, "skill group" correctly interpreted includes a group of one or more agents, and the district court erred when it construed "skill group" to require more than one agent.

Footnotes

2 Counsel for IEX went so far as to assert at oral argument that "within the scope of this appeal, the consequences of that single versus multiple agent really aren't relevant because we've produced infringement proof showing that the skill groups in Blue Pumpkin's product are comprised of multiple agents. So it doesn't matter, we're not relying on saying that a group is a single agent."

End Footnotes
Next, IEX disputes two additional limitations that it alleges were read into the phrase "skill group" by the Magistrate Judge upon recommending summary judgment. First, the Magistrate Judge stated that "each agent within the skill group [must] possess the same skills." 2003 U.S. Dist. LEXIS 26252 at *16. In reviewing this construction, we note at the outset that both parties at various times throughout the litigation have framed the question as whether skill groups can overlap, but this perspective is unhelpful. There is no doubt that skill groups can overlap insomuch as group A can include, for hypothetical purposes, agents with skills 1, 2 and 3, and group B can include agents with skills 2, 3 and 5. The patent expressly says as much. See '355 patent, col. 5, II. 9-12. The question instead is whether the patent requires that each skill group include only agents having identical skills, e.g., whether the patent precludes the inclusion of an agent with skills 1, 2, 3 and 4 within our hypothetical group A. We think that it does not.

Claims 1 and 19 both specify that each skill group includes "all scheduled agents having a particular combination of skills." Id. col. 11, II. 20-21; col. 13, II. 5-6. The written description explains that a skill group includes all agents with a particular combination, or a particular subcombination, of skills. See id. col. 2, II. 43-44 ("All agents having a particular combination of skills may be deemed a 'skill group'."); col. 3, II. 32-35 ("The plurality of scheduled agents are organized into 'skill groups' with each group including all scheduled agents having a particular combination of skills."); col. 5, II. 7-9 ("One or more agents are then organized into 'skill groups', each including all scheduled agents having a particular sub-combination of skills."). If accorded their plain meaning, these statements require only that all agents within a skill group have a particular combination of skills in common, not that they each have identical skills. 3 In other words, an agent with skills 1, 2, 3 and 4 has the same combination of skills as those within our hypothetical group A, that combination being skills 1, 2 and 3.

To be sure, the patent's written description specifies that "in the preferred embodiment, skill priorities are included when organizing agents into skill groups; in a particular skill group, all agents have the same skills at the same priority levels." Id. col. 5, II. 15-18 (emphasis added). But patent scope is not confined to preferred embodiments disclosed in the patent's written description, Cordis Corp. v. Medtronic AVE, Inc., 339 F.3d 1352, 1365 (Fed. Cir. 2003), and in any event, the patent makes clear that the claimed method "requires only that the skill group divisions in the agent population be understood and available to the method." '355 patent, col. 9, II. 8-10. A call center using the claimed method thus has some flexibility in defining a "skill group" to include all agents having a particular combination of skills or all agents having identical skills, so long as that definition is made known to the claimed method.

Second, the Magistrate Judge stated in his summary judgment recommendation that the "key to the success of the program is that there be some identification of agents with skills before the process can work. In another [sic] words, the process does not identify skill groups after application, but only before application." 2003 U.S. Dist. LEXIS 26252 at *12. Though this statement is somewhat ambiguous, IEX suggests that it was made in response to Blue Pumpkin's summary judgment argument that the '355 patent claims require that "the skill group availability data for each skill group must be calculated before agents are placed into the schedule." (J.A. at 1383.) We cannot be certain from the Magistrate Judge's statement that he intended to imply that the '355 patent precluded the input of an initial schedule into the method prior to the creation of skills group availability data. We nonetheless address the issue to clarify the district court's task upon remand.

It is true that the method claimed in the patent generates net staffing data and skills group availability data, which it ultimately uses as inputs into the generation of a work schedule. It is also true that skills group availability data is an estimate of a percentage of scheduled agents from each skill group that are available to handle a call. It therefore seems logical to assume that in order for the claimed invention to compile skills group availability data, skill groups must exist in some form. This assumption, however, begs a rather large question reminiscent of the famed chicken and egg controversy. How can the invention of the '355 patent generate net staffing data based in part on the given staffing level for a particular time period, and skills group availability data that define a skill group's availability for that time period, without first having agents actually scheduled during the relevant time period? In other words, which comes first, the skill groups used to
generate skills group availability data and thus a schedule, or some form of the schedule itself, which implicitly defines certain parameters needed to develop net staffing data and skills group availability data?

The patent solves this problem in the preferred embodiment by allowing rough estimates for the net staffing data and skills group availability data. '355 patent, col. 5, ll. 51-53 ("The initial estimates for net staff values need not be extremely accurate, as they are refined in later iterations of the method as will be described."); col. 6, ll. 8-12 ("The initial estimates for values in this array need not be extremely accurate, as they are refined in later iterations of the method as will be described. Thus, for example, the initial estimate may be '0' for any skill group that is not eligible at all for a call type, and '1/2' otherwise."). But nothing in the claims themselves or in the written description precludes the use of an initial schedule as an input into the iteration. In fact, by referencing "scheduled agents" in the preamble, claims 1 and 19 seem to contemplate this very thing. See id. col. 11, ll. 15-21; col. 12, l. 66-col. 13, l. 6. We thus hold that the '355 patent does not preclude the method's use of an initial schedule prior to the creation of skills group availability data.

1905
16. Group data handling operations

The court construes "group data handling operations" to mean "data handling operations applied to a group of partitioned fields."

1906
31. Group floating point operations

The court construes "group floating point operations" to mean "floating point operations applied to a group of partitioned operands."

1907
5. Group identifier.

Intergraph contends this term too is defined in the claims as an identifier indicative of a group of individual instructions to which the individual instruction is assigned for execution in parallel. Though again employing its moving target tactic described earlier, Intel's ultimate definition of the term is a tag assigned by the compiler to each instruction that identifies instructions that will execute in parallel (i.e., issued to different and separate processing pipelines on the same clock cycle and processed simultaneously by the pipelines). Intel claims this definition is made clear in the '028 patent's specifications and prosecution history. However, as discussed with respect to pipeline identifiers, these references provide little support for Intel's proposed construction in general. The Court construes "group identifier" as a designation indicative of a group of individual instructions, as that term has been previously defined. '028 patent 3:24; 5:10-14.

1908
IV. "group of collaboration types"

The phrase "group of collaboration types" appears in two dependent claims of the '547 patent. Claim 19 is representative:

19. The system of claim 11, wherein the system is configured:

(a) to allow a first user
(i) to use a first graphical user interface
(ii) to select a user
(iii) from a plurality of users; and

(b) to allow the first user
   (i) to use a second graphical user interface
   (ii) to select a collaboration type
   (iii) from a group of collaboration types; and

(c) to respond
   (i) by establishing communication
   (ii) of the selected collaboration type
   (iii) from the first user
   (iv) to the selected user.

'547 patent at 43:44-59.

CPI argues that the phrase "group of collaboration types" should be construed to mean "types of collaboration, such as telephone, videophone, email, snapshot sharing, application sharing, computer-integrated telephony, and computer-integrated fax." Tandberg argues that the phrase should be construed to mean "a group of methods by which information is synchronously and asynchronously shared between workstations." The parties' constructions differ in one respect: Tandberg's construction requires that the group contain both synchronous and asynchronous methods of sharing information. Synchronous methods, such as videoconferencing and data conferencing, involve the sharing of information in real time. Asynchronous methods, such as multimedia mail, involve the sharing of information that can be stored locally and retrieved at some later time.

In support of its contention that the group must include both synchronous and asynchronous collaboration types, Tandberg relies on the lists of possible collaboration types in the specification. According to Tandberg, the fact that the lists always include both synchronous and asynchronous collaboration types means that a CMW must be capable of both. Although the specification consistently uses the same list of possible collaboration types, and describes embodiments in which the CMW supports both synchronous and asynchronous collaboration types, nowhere does the specification support Tandberg's position that each CMW must support each collaboration type.

Other portions of the specification weigh against such a narrow reading. Before a CMW is permitted to place calls to other CMWs on the network, it must "register the collaborative services [it] provide[s] with the Service Server." Spec. at 20:66-21:1. "Examples of these services indicate [sic: include] 'video call', 'snapshot sharing', 'conference' and 'video file sharing.'" Id. at 21:1-3. A CMW need not include every possible collaborative service in its group of registered services. For instance, the specification provides an example of a "portable laptop implementation" of the CMW which is capable of participating in "voice and data communications," as well as "remote control of mail or presentation playback," but not the videoconferencing features provided through add-on videoconferencing hardware. Id. at 18:16-31. The specification expressly provides for the flexibility to register a limited number of collaboration types, and includes at least one example of a CMW that has less than the full complement of synchronous and asynchronous collaboration capabilities.
The court therefore adopts CPI's construction. The phrase "group of collaboration types" means "a group of types of collaboration, such as telephone, videophone, email, snapshot sharing, application sharing, computer-integrated telephony, and computer-integrated fax."

1. Groups/sets of individual instructions.

Relying on plain and ordinary meaning, Intergraph contends "group of individual instructions" simply means that individual instructions are organized into groups. Intel contends the phrase imports much more than this. However, Intel seems perplexed with determining just how much more the phrase imports, as it has tendered a different definition for "group of individual instructions" in the Joint Claim Construction Statement, in its claim construction brief, and in its presentation at the Markman hearing. Putting this moving target tactic aside, Intel's latest claim interpretation argues the phrase should mean a set of instructions that the compiler has determined will be executed in parallel. Intel further delineates its position with the following restrictions: 1) groups of instructions must be within a VLIW and 2) all instructions in each set must be executed in parallel and groups cannot be split across instruction frames.

Based on a review of the claim language and the intrinsic evidence, the Court cannot embrace either of these positions in whole. The Court construes "groups/sets of individual instructions" as a collection of one or more individual instructions that can be executed simultaneously (i.e. can be dispatched to parallel pipelines simultaneously). ’028 patent at 5:10-20.

"Group Virtual Address"

Cisco's proposed construction for "group virtual address" is "an address shared by a group of real network entities and corresponding to a virtual entity." Alcatel's proposed construction is "the MAC address and network layer address of the virtual router."

Both parties essentially rely on the same arguments put forth for the construction of "virtual router." In particular, Cisco's proposed construction is identical to the definition of "virtual address" provided in the patent. See id. at 4:33-34. However, following that definition, the patent states that "one router from among a group of routers emulates a virtual router by adopting one or more virtual addresses." Id. at 4:35-37. Therefore, in light of the Court's construction of "virtual router," which defines the requirement of the "virtual address", the term "group virtual address" is more accurately defined as "the address of the virtual router."

Thus, the Court construes "group virtual address" as "the address of the virtual router."

(iii) Guarantee of lifetime payments.

The Plaintiff is correct that "a guarantee of lifetime payments" by its definition contains the annuitization concept, and adding "in the post-annuitization phase" would be redundant. The word "payments" necessarily refers to distribution, payout, or post-annuitization phase. Therefore, although the Defendant insists that the phrase be qualified by inserting "in the post-annuitization phase," the addition is unnecessary as that meaning is already apparent. The Defendant otherwise agrees with the Plaintiff that "guarantee of lifetime payments" means a guaranteed distribution of money for the lifetime of a designated individual or individuals, and that is also the definition the Court finds to be appropriate.
"guaranteeing predetermined individual minimum bandwidths" is construed to mean "guaranteeing individual minimum amounts of data that can be sent per unit of time, determined beforehand."

Lucent contends that this phrase should be given its ordinary meaning. (D.I. 396 at 27-29.) Extreme contends that this phrase means "reserving predetermined, separate portions of the overall transmission capacity of the link at the output of the multiplexer to each of voice packet traffic and data packet traffic." (D.I. 395 at 23.) In support of its contention, Extreme cites statements in the Summary of the Invention section of the specification ('650 patent at 3:25-31, 3:2-6, 3:35-28.) Although that language can reasonably be understood as constituting a general description of the invention, the Court finds that it does not clearly define the term "guaranteeing predetermined individual bandwidths," representing a clear disavowal of claim scope. Thus, in the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

"Guard" appears in independent claim 1 of the '910 patent. As with the "gatherer" element as used in the '910 patent, the term "guard" is a "coined term" that was not known in the art. The Court therefore finds that it is subject to 35 U.S.C. § 112 P 6. Accordingly, the Court finds that the above element is restricted to the disclosures in the specification of the '910 patent. See '910 patent, col. 14, lines 18-64, col. 16, lines 38-47.

C. Construction of "Outer Electrostatic Discharge Guard Ring"

LPL's proposed construction of the phrase "outer electrostatic discharge guard ring" is "a closed or open ring, or open L or C-shaped line, outside the active matrix display to provide protection from electrostatic discharges." (D.I. 158 at 2.) CPT's proposed construction is "a ring of conductor, located external to the inner electrostatic discharge guard ring if the two rings are used together, for draining off electrostatic buildup to prevent electrostatic discharge." CPT does not dispute that the outer guard ring is "a closed or open ring, or open L or C-shaped line." (D.I. 144 at 6.) The parties do dispute whether the guard ring functions to prevent electrostatic discharge ("ESD") or only to protect against damage caused by ESD. n2 The parties also dispute the meaning of "outer."
The central dispute over the phrase "outer electrostatic discharge guard ring" is whether "outer" is used in reference to an inner ESD ring or to the entire display panel. CPT contends that "outer" must refer to the outer guard ring's position relative to the inner guard ring. (D.I. 137 at 8.) This contention is untenable. Independent claims 1 and 19 include an outer ESD guard ring, but no inner ESD guard ring. In the context of those claims, CPT's proposed construction would render the adjective "outer" meaningless.

On the other hand, LPL contends that "outer" refers to the outer guard ring's position relative to the active matrix display. CPT concedes that "active matrix display" as used in the '002 patent and in LPL's proposed construction means the entire finished display panel. (D.I. 164 at 3.) CPT argues that the Court should reject LPL's proposed construction because it is based on "the erroneous notion that the outer ring must be physically removed at the end of the manufacture." (Id.) As the Court concluded in section II.B. above, however, the intrinsic evidence indicates that physical removal of the outer guard ring is precisely what the patent teaches. Therefore, the Court will construe "outer electrostatic discharge guard ring" as "a closed or open ring, or open L or C-shaped line, outside the active matrix display to provide protection from electrostatic discharges.

6. Element [C] -- "Guest"

The parties dispute the meaning of the term "guest" in element [C] of claim 35. According to the WeddingChannel, a guest is a person seeking to purchase a gift for a registrant. According to the Knot, a guest is a purchaser of registry items.

WeddingChannel argues that the language of claim 35 includes no requirement that the guest actually purchase a gift. WeddingChannel argues that element [F] of claim 35 merely states that the shopping module comprises instructions for "identifying" an item in response to a guest's instructions; it does not say that a guest is required to purchase anything. Furthermore, WeddingChannel observes that when the inventors intended to signify that a purchase was required --e.g., in dependent claims 24 and 46 -- they stated as much explicitly. See '753 Pat. at col. 13, ll. 65-67 (stating in claim 24 that "[the method of claim 23, the method further comprising purchasing said first registry item using credit card information stored in said guest profile. . . ."] (emphasis added); id. at col 15, ll. 44-48 (stating in claim 46 that "the computer system of claim 45 wherein said resolving comprises deducting . . . those items that were purchased by said guest . . . .") (emphasis added). On this basis, WeddingChannel concludes that pursuant to claim 35, one can be a guest without purchasing a registry item.

WeddingChannel also argues that the patent specification confirms that the term "guest" does not necessarily entail a purchase of registry items or otherwise. According to WeddingChannel, the specification teaches that the term "guest" encompasses: (1) those seeking to "purchase registry items," id. at col. 5, ll. 10-11; (2) those "attempting to buy gifts for registrants," id. at col. 2, ll. 4-8; and (3) those purchasing gifts "directly from retailers without selecting a registry or accessing a registry database." Id. at col. 9, ll. 55-57.

WeddingChannel further argues that Figure 8 of the specification illustrates that the term "guest" can include one who views but does not purchase a registry item. The Knot argues that the term "guest" is expressly defined in the specification as "the purchasers of registration items from a registry," '753 Pat. at col 1, l. 45, and that this explicit definition should govern. See, e.g., Guttman, Inc. v. Kopykake Enters., 302 F.3d 1352, 1360 (Fed. Cir. 2002) (stating that ""the specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication") (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)). Furthermore, the Knot argues that the preamble of claim 35 -- "[a] computer system for purchasing a gift for a registrant of an event . . . " -- provides further supports its position that a "guest" is defined as one who purchases items from a registry.

The Knot argues that WeddingChannel's reliance on dependent claims 46 and 24 is misplaced. According to the Knot, these dependent claims actually support its construction: Dependent claim 24 describes how payment is affected pursuant to method claim 20, and claim 46 describes how the claim 35 computer system periodically updates the master registries maintained by registry database providers.

Finally, the Knot argues that the various excerpts from the specification quoted by the WeddingChannel, see '753 Pat. at col. - 2270 -
The specification also does not suggest any reason to deviate from the ordinary and customary meaning by imparting claim language does not imply a departure from that meaning.

As used in the specification, the term "guest" encompasses those seeking to purchase gifts for a registrant as well as those who actually purchase registry items. See 753 Pat. at col. 9, ll. 55-57; col. 5, ll. 10-11; col. 9, ll. 55-57. For example, the specification states that "when a registry is selected, it is opened, thus allowing the guest to review the registry over the Internet." Id. at col. 9, ll. 17-19. This passage, and others like it, make clear that the specification regards users of the system as guests even before they have purchased registry items. Moreover, the Knot is incorrect in its assertion that lines 44-45 of column 1 of the specification provide an explicit definition of the term "guest." These lines merely indicate that the term "guest" necessarily includes purchasers of registry items. These lines do not, however, exclude those seeking to purchase gifts from the definition of what constitutes a "guest."

On this basis, WeddingChannel's construction of the term "guest" is adopted.

Kapusta asserts that the district court erred in construing the claim term "hand-grip size case" to require the limitations that the case be "no smaller than the width of an adult palm, so that it can be grasped firmly in one's hand, no smaller than 1 inch in width, and of a rectangular shape." Kapusta contends that the court should have given the term its ordinary and customary meaning of "a case that is suited to a grip by the hand," and the court should not have added limitations for which there is no support in the intrinsic record. With respect to the "of a rectangular shape" limitation, Kapusta argues that the district court imported a limitation from the preferred embodiment of the specification into the claims. Furthermore, Kapusta argues that the district court erred by finding the term at issue to be ambiguous and then importing unnecessary limitations in order to preserve the patent's validity.

Gale counters that the added definitions of the term "hand-grip size case" are in the specification. Specifically, the figures portray the case to be of hand-grip size and of a rectangular shape. Furthermore, the specification notes that the case has a "top wall," which suggests a rectangular-shaped case. Gale also argues that the extrinsic evidence, including two prior art references introduced during litigation and expert testimony, disclose that a hand-grip size case does not encompass all portable devices smaller than Kapusta's device. According to Gale, the term at issue is ambiguous because it has an expansive meaning subject to different interpretations and thus, in light of the prior art introduced during litigation, it must be construed narrowly to preserve its validity.

We agree with Kapusta that the district court erred in its claim construction by including extraneous limitations. The court should have given the term "hand-grip size case" its ordinary and customary meaning. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) (explaining that unless the intrinsic evidence compels a contrary result, a claim term should be given its ordinary and customary meaning). The ordinary and customary meaning of "hand-grip size case" is a case of a size that can be gripped in a normal hand. We see no reason to depart from that ordinary and customary meaning or to add dimensions to the term, as there is no support for the district court's limitations in the intrinsic record.

Starting with the claim language itself, we see no evidence from this source to support the court's size limitations. The claim states that the test circuit is mounted in "a hand-grip size case," implying that the case is capable of being gripped in the hand of a normal person, and not of a size with specific dimensions. The straightforward mechanical technology of the invention and the understandable claim language give that meaning to this term. See Phillips, 415 F.3d at 1314 ("In some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words."). "Hand-grip" means what it says, i.e., capable of being gripped by the normal hand. The claim language does not imply a departure from that meaning.

The specification also does not suggest any reason to deviate from the ordinary and customary meaning by imparting
dimensions to the term. The specification consistently refers to the instrument as serving "in the hands of an operator." '663 patent, col. 1, II. 63-65, col. 2, II. 34-36. However, nowhere does the specification explicitly or implicitly ascribe numerical limitations to the case embodying the instrument. In fact, when mentioning the hand-grip size case, the specification states only that the case is "of preferred hand-grip size," suggesting that the dimensions of the case being of hand-grip size, while preferred, are not inflexible. The specification further mentions that the operator will "grasp the primary instrument," yet that description does not suggest any specific numerical dimensions of the case. '663 patent, col. 6, II. 22-25. In the few instances where the specification alludes to either the "hand-grip size case" or to grasping the instrument, it does not reference any dimensions. Because numerical dimensions are absent in the specification, it was improper for the district court to construe the claim term with the lower limit dimensions.

The district court stated that it established the size dimensions of the "hand-grip size case" from "a preferred embodiment described in the specifications and shown in the drawings. . . ." Claim Construction Order, at 5. It further appears to have determined the meaning of the "of a rectangular" shape limitation solely from figures 4-7 because that is the only place in the patent that suggests such a shape. However, we cannot accept the district court's analysis because case law is well established that, while a specification should be used to interpret the meaning of a claim, it should not be used to import unnecessary limitations into the claims. See Phillips, 415 F.3d at 1323. In particular, we have acknowledged that claims must not necessarily be restricted to those embodiments disclosed in the specification, even if a patent describes only a single embodiment. As we stated in Phillips, "although the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments . . . In particular, we have expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment." Id.

Here, the district court expressly ascertained the size limitations from a preferred embodiment and improperly construed the term to incorporate those limitations. The specification states that the figures are shown "for illustrative purposes" and thus the figures do not restrict the scope of the claims to that which is shown in the drawings. See '663 patent, col. 3, II. 66-67. The specification also states that figures 4, 5, and 6 depict "one of the featured companion test instruments," further suggesting that the scope of the claims should not be restricted exclusively to those figures. Id. at col. 5, II. 3-5. Because the specification does not indicate that the embodiment depicted in the figures is meant to be the only embodiment, and in fact implies otherwise, the claim term should not be limited to specific dimensions established from the figures.

The prosecution history also does not provide support for the addition of dimensions to the "hand-grip size case." On appeal from a rejection by the examiner, the Board of Patent Appeals and Interferences ("BPAI") rejected applicant's broad argument that the invention is distinguished over the prior art because it is "portable," but added that "there is no teaching or suggestion in [the references cited upon which the rejection was made] of a hand grip size case and therefore we will not sustain this rejection . . . ." Applicant thereafter amended claims from being only portable to incorporate the language specifying "a hand-grip size case in which said test circuit is mounted" to put the claims in condition for allowance. The BPAI implied that the invention was distinguishable over the cited prior art by the inclusion of a "hand-grip size case," but the BPAI did not ascribe any lower size dimensions to the case.

Moreover, with regard to the "of a rectangular" shape limitation, although figures 4-7 show the instrument as housed in a rectangular-shaped case, the specification never suggests that this shape is critical to the operation of the invention. An important object of the invention is to have the portable test instrument serve "in the hands of an operator." '663 patent, col. 1, II. 61-64. There is no reason why this objective could not be accomplished equally as well with a non-rectangular shaped case. As long as the instrument can serve "in the hands of an operator," it fulfills the objective of the patent, irrespective of the specific shape of the case. The specification does not assign any significance to the shape of the case, and there is otherwise no indication in the intrinsic evidence that the invention must be limited to the rectangular shape depicted in some of the figures.

Gale further contends that in addition to the figures, the reference in the specification to securing a connector to the "top wall" of the case implies that the case is rectangular. See '663 patent, col. 5, II. 32-34. We find this argument unpersuasive. Securing the connector on the "top wall" does not compel the use of only a rectangular shape because other shapes could include a top wall.

Finally, the court's finding that the term is ambiguous and should be construed to sustain its validity is without basis. The term "hand-grip size case" is not ambiguous. Although the term may be of a nonspecific size and shape, that does not render
the claim term ambiguous. Because the term is not ambiguous, the district court should not have applied the doctrine of construing claims to preserve their validity. Construing claims to sustain their validity has been limited to those cases in which "the court concludes, after applying all the available tools of claim construction, that the claim is still ambiguous." Phillips, 415 F.3d at 1327 (quoting Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 911 (Fed. Cir. 2004)). We have not applied the doctrine broadly and have "certainly not endorsed a regime in which validity analysis is a regular component of claim construction." Phillips, 415 F.3d at 1327. This is not one of those limited cases where the term cannot be construed using other available tools. Had the district court limited its construction to the ordinary and customary meaning, it would not have had to resort to construing the claim term more narrowly to preserve its validity.

In sum, we do not accept the limitations that the district court added to the term "hand-grip size case." We see no basis for incorporating specific dimensions and a specific shape into the claim construction. Because we disagree with the court's claim construction, we vacate the district court's finding of noninfringement of the '663 patent to the extent that it was based on an erroneous claim construction of the term "hand-grip size case." That term, as indicated above, simply means a case of a size that can be gripped in a normal hand. While we might, on the basis of that meaning, make our own judgment on the question of infringement, based on the record, the better practice is to have the district court make that factual determination on remand. We therefore remand for the court to redetermine whether Gale's Products meet the limitation as we have construed it.

8. a hard disk drive ... operatively coupled to receive and store n4

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

n4 The corresponding phrases are "a mass storage device ... operative coupled to receive and store;" "storing said picture image data in said hard drive;" and "to receive and store said copy of the contents of a memory of a digital camera."

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

The plaintiff argues that this phrase does not need construction. In the alternative, the plaintiff proposes "a hard disk drive ... effectively connected to receive and store." The defendants propose "a hard disk drive that is accessible to receive and temporarily store image files from an inserted flash memory module but is not accessible by the device to edit, manage or display image files that are stored on the hard disk drive." The defendants' construction again includes additional limitations not supported by the intrinsic evidence. The court agrees with the plaintiff that the terms used in this phrase are readily understandable and concludes that this phrase requires no construction.

GO BACK

1918

11. Password Data Security System

The term "password data security system" appears in dependent Claims 2, 9, and 14 as a permissible structure for the "means for locking the storage means" identified in Claims 1, 8, and 13. The specification indicates that the term should not be construed in a limiting sense. Rather, it describes the term as a known security system which locks the network until it is unlocked by a password. See Col. 4, ll. 46-67. Reference is made to the system described in U.S. Patent No. 5,375,243 as an example of a password security system that may be used with the current invention. That limitation need not be read into the claim. Accordingly, the Court construes the term "password data security system" to mean a security system which locks the network until it is unlocked by a password.

12. Hardware Key Data Security System

Like the term "password data security system," the term "hardware key data security system" in dependent Claims 3, 10, and 15 is a permissible structure for locking the data storage means. For the reasons set forth in the preceding section, the
Court construes the term as a security system which locks the network until it is unlocked by a hardware key.

1919

B. Hardware Related [Operating] Parameter (Claims 1 and 11)

PCTEL states that the term has a plain and understood meaning, and no construction of the term is necessary. Alternatively, PCTEL contends that the term should be construed as "characteristics relating to electrical/physical properties of circuitry." To support its alternative construction, PCTEL relies solely on its expert witness Dr. Wicker.

Agere and USR contend that this term is not amenable to construction, and thus is invalid as indefinite under 35 U.S.C. § 112, P 2. Alternatively, Agere and USR propose that the term should be construed as "an operating parameter that when changed requires a change in hardware configuration and not simply a change in the use of the hardware provided."

To support their alternative construction, Agere and USR rely upon the patent's claim language and the prosecution history. Agere and USR rely upon independent claim 1 that recites the element of a "means for changing a hardware configuration of said data communication apparatus in accord with said at least one hardware related parameter value." '561 patent, col. 11:36-39. Additionally, independent claim 10 recites the element of "using said at least one hardware related operating parameter to cause said means for changing the hardware configuration to change the hardware configuration of said modem. . . ." '561 patent, col. 13:20-25. Agere and USR assert that these limitations make clear that "hardware related operating parameters" cause changes in the "hardware configuration" of the modem.

Regarding the prosecution history, Agere and USR note that the PTO rejected the claims of the '195 patent as originally submitted as unpatentable over existing art on "multi-country" communication devices. In particular, the PTO found that it would have been obvious to incorporate prior art "multi-country" telephone dialers into a modem. (Malz Decl., Ex. 5 at AL 15224-25.) To overcome the PTO's rejection, the patentee amended the claims to require a "hardware related parameter." The prosecution history discloses that "[t]he applicant has amended the claims to require that at least one hardware related parameter be stored for a plurality of countries, and that the modem include means for changing the hardware accordingly." (Malz Decl., Ex. 6 at AL 15231-32.) Furthermore, the patentee stated as follows:

   It should be recognized that software parameters (such as e.g. make/break for pulse dialing) do not change the hardware configurations. Rather, they simply change the use of the hardware as provided. However, claim 1 (and claim 13), now requires a change in the actual hardware configuration such as would be required to change the line impedance or transmit line signal level.

(Malz Decl., Ex. 6 at AL 15232.) Based on these statements, Agere and USR conclude that the patentee made clear that hardware parameters require changing the actual hardware configuration rather than simply changing the use of the hardware as provided.

Thus, it appears that the critical disagreement between the parties stems from whether the '561 patent has properly distinguished hardware parameters from any other types of parameters including software parameters. n3 Initially, the Court disagrees with PCTEL's conclusion that "hardware related parameter" has a plain and understood meaning, and that no construction of the term is necessary. PCTEL's alternative construction of "characteristics relating to the electrical/physical properties of circuitry" is also unhelpful because it provides the Court no guidance with regard to differentiating a hardware parameter from any other type of parameter. Moreover, this construction finds no support in the intrinsic evidence or the prosecution history of the patent, and therefore must be rejected.

- - - - - - - - Footnotes - - - - - - - - - - - -

n3 The patent's specification certainly does not help clarify this distinction. In fact, the '561 patent specification confuses any potential distinction by stating: "[t]he terms 'hardware related parameters' and 'software parameters' should be understood in a liberal sense as the hardware related parameters described here are actually controlled by software and hence are 'hardware/software' parameters. Likewise, various of the 'software related parameters' may include hardware implementation depending on the particular product." '561 patent, col. 11:12-19.)

- 2274 -
The Court finds that Agere and USR's citation to the language of claim 1 and claim 10 are helpful in resolving the construction of "hardware operating parameter." The words of claim 1 indicate that the change in hardware configuration is in accordance with the operating or hardware parameter. '561 patent, col. 11:37-39. The language in claim 10 also supports this conclusion. Furthermore, the patentee explicitly identified "line impedance" and "transmit line signal level" as examples of "hardware related parameters." '561 patent, col. 10:37-54.

However, the prosecution history of the '561 patent conclusively establishes the required connection between the "hardware parameters" and the "hardware configuration." The patentee explicitly stated that "software parameters . . . do not change hardware configurations" but "simply change the use of the hardware as provided." (Malz Decl., Ex. 6 at AL 15232.) This statement strongly suggests, by negative implication, that hardware parameters must change hardware configurations and not just the use of the hardware as provided. The patentee further explained that the claims "require a change in the actual hardware configuration" in attempting to differentiate between hardware and software parameters. (Malz Decl., Ex. 6 at AL 15232.) Thus, Agere and USR's proposed construction incorporates the patentee's own explanation of the distinguishing features of the invention as well as the claim language itself. Thus, the Court construes "hardware operating parameter" as an operating parameter (such as "line impedance" or "transmit line signal level") that when changed requires a change in hardware configuration not simply a change in the use of the hardware provided.

4. "all kernels having signal"

Plaintiffs' construction: no construction needed

Defendant's construction: all zones with an average display pixel intensity significantly greater than the average predicted noise level

At the claim construction hearing, plaintiffs indicated that this term was no longer in dispute, and that they agreed that "kernel" may be construed properly as "zone." Transcript, dkt. # 80, at 36, lns. 18-24. I will adopt the agreed-upon construction.

Court's construction: all zones with an average display pixel intensity significantly greater than the average predicted noise level

C. "Headers"

Multi-Tech also argues that the district court erred in its construction of the term "headers" in claim 1 of the '649 patent and claims 1, 2, 5, 7, and 13 of the '627 patent. Multi-Tech maintains that the term "headers" should be given its ordinary meaning of "information structures that precede units of data, such as packets." Multi-Tech thus asserts that the headers attached to computer data packets need not identify packet type or packet length and that the headers attached to voice data packets need not identify whether the packets contain speech or silence. According to Multi-Tech, the district court improperly imported those additional limitations from the specification's preferred embodiments into the claims, despite the broader claim language.

Microsoft responds that the term "headers" has several ordinary meanings and that Multi-Tech's proposed definition is inconsistent with the specification's preferred embodiment and various dictionary definitions. Microsoft also argues that the specification requires both that the computer data packet headers identify packet type and packet length and that voice data packet headers indicate whether the packets contain speech or silence.
We agree with Multi-Tech that the district court's interpretation of the term "headers" was overly narrow. Claim 1 of the '649 patent refers to "placing headers" on the voice data packets as well as "placing headers" on the computer data packets. '649 patent, col. 47, ll. 5-13. Claims 1 and 7 of the '627 patent simply refer to voice data packets "having headers," '627 patent, col. 46, ll. 47-49; id. at col. 47, l. 14, while claim 13 recites "placing headers" on outgoing voice data packets, id. at col. 48, l. 39. We therefore start from the presumption that the term "headers" carries its ordinary meaning of "information structures that precede[] and identify the information that follows." Microsoft Computer Dictionary 215 (4th ed. 1999).

Considering both the claim language and the specification, we next conclude that the claimed "headers," at least in the '649 patent, must identify whether the packets are voice or computer data packets. To begin with, the claim language of the '649 patent separately refers to "placing headers" on voice data packets and "placing headers" on computer data packets. Moreover, the specification states that "the voice data packet information . . . uses a different header format [than does the computer data packet information] so the receiving site recognizes the difference between a data packet and a voice packet." '289 patent, col. 13, ll. 17-20. Such differentiation is necessary to enable the prioritization of voice data packets over computer data packets that, as discussed above, must occur when the two types of packets are multiplexed together. We therefore read the claim language, in light of the specification, as requiring that the "headers" of the '649 patent identify whether the following packets contain voice or computer data.

n7 In the '627 patent, the claimed "headers" need not distinguish between voice data packets and computer data packets because that patent involves only voice data packets.

We further conclude, however, that the claimed "headers" need not identify the computer data packets' type and length or whether the voice data packets contain speech or silence. To be sure, the specification does disclose a preferred embodiment in which the computer data packets begin with an "ID byte" specifying the type and length of the packet, id. at col. 20, ll. 36-43 & tbls. 3-5, and the voice data packets have a "sign byte" specifying whether the packet contains silent sound or speech information, id. at col. 34, l. 64 to col. 35, l. 2 & tbl. 15. The district court determined that such additional limitations must be read into the claims because they are necessary "for the preferred embodiment to function as specified." Markman Order, 2002 U.S. Dist. LEXIS 15960, slip op. at 37. n8 However, those statements are limited to descriptions of the "packet protocol" used in the preferred embodiments, see '289 patent, col. 18, l. 13; id. at col. 33, l. 61, and are merely illustrative of how the headers can be configured. We therefore conclude that the claimed "headers" need not identify the computer data packets' type and length or whether the voice data packets contain speech or silence.

n8 Our broader interpretation of the term "headers" does not exclude the use of the headers disclosed in the preferred embodiment; it simply does not require their use.

1922

II

Universal first argues that the district court erred in construing the term "heading of the aircraft" and that, under the proper construction, Universal is entitled as a matter of law to judgment of noninfringement. The term "heading of the aircraft" appears in the fourth and fifth limitations of the asserted claim, which reads in full as follows:

1. A system for use in an aircraft for providing an enabling envelope for a ground proximity warning system for an aircraft comprising:
[1] a first source of signals representative of the longitude and latitude of an airport;

[2] a second source of signals representative of the current longitude and latitude of said aircraft;

[3] means responsive to said first source of signals representative of the longitude and latitude of said airport and said second source of signals representative of the current longitude and latitude of said aircraft for

[a] computing the distance of said aircraft from said airport and

[b] providing an enabling envelope for enabling the warning system as a function of said distance of the aircraft with respect to said airport;

[4] a source of signals representative of the relative angular position of a particular runway with respect to the heading of the aircraft; and

[5] means responsive to said first and second sources of signals for providing a signal representative of the alignment of the aircraft with the runway by determining the angle between the runway and the heading of the aircraft.

'436 patent, col. 7, ll. 40--63. The district court concluded that the patentees used the term "heading of the aircraft" to refer to what would normally be referred to as the aircraft's "bearing," i.e., the direction to the aircraft from a runway. We agree. The conventional meaning of the terms "heading" and "bearing" is undisputed. "Heading" ordinarily refers to the direction in which an object is pointing. "Bearing" ordinarily refers to the direction from an observer to an object. The specification and prosecution history make clear, however, that the patentees used the term "heading" in a manner different from its ordinary meaning. When a patentee defines a claim term, the patentee's definition governs, even if it is contrary to the conventional meaning of the term. Phillips v. AWH Corp., 415 F.3d 1303, 1321 (Fed. Cir. 2005) (en banc) ("[T]he specification is the single best guide to the meaning of a disputed term, and . . . the specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." (quotation marks omitted)); Bell Atl. NetworkServs., Inc. v. Covad Commc'ns Group, Inc., 262 F.3d 1258, 1268 (Fed. Cir. 2001) (stating that "a patentee may choose to be his own lexicographer and use terms in a manner other than their ordinary meaning"). A claim term may be defined in a particular manner for purposes of a patent even "without an explicit statement of redefinition." Bell Atl., 262 F.3d at 1268.

The specification of the '436 patent clearly communicates the meaning the patentees have assigned to the term "heading." It does so by describing the claimed system's alignment determination as depending on the direction of the aircraft from the runway (i.e., what is conventionally known as the aircraft's bearing), not the direction in which the aircraft is pointing, resulting in "a signal which is representative of the aircraft's alignment with the particular runway." Id., col. 6, ll. 35--36. Thus, the specification makes it clear that in referring to the "alignment" of an aircraft with a runway, the patent denotes the extent to which the runway points at the aircraft, not the extent to which the aircraft points at the runway or points in the same direction that the runway points.

The specification discloses no other form of alignment. If Universal's construction were adopted, the disclosed embodiment would not relate to any limitation of the claimed invention, despite the clear link between the alignment computation discussed in the specification and the alignment computation called for by the claims. The specification refers to the calculation of the alignment of the aircraft with the runway as an "important feature of the present invention." '436 patent,
col. 6, ll. 6--7. That characterization indicates that the disclosed alignment computation is the claimed "alignment of the aircraft with the runway," and shows that the patentees used the term "heading of the aircraft" to refer to the line connecting a reference point on the runway to the position of the aircraft. Because that is the construction that "most naturally aligns with the patent's description of the invention," Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998), the district court properly held it to be the correct one.

The prosecution history confirms that when the patentees wrote "heading," they meant "bearing." Application claim 14, which became issued claim 1, initially phrased two of its limitations as follows:

- a source of signals representative of the relative angular position of a particular runway with respect to a datum and means . . . for providing a signal representative of the alignment of the aircraft with the runway.

The "source of signals" is provided by a database of the angular directions of various runways, and the reference "datum" is a direction, such as due north, against which the runway angles are determined. The specification stated, as it does now, that the alignment of an aircraft with a runway is determined by comparing the direction to the aircraft from the runway with the direction of the runway.

The examiner rejected application claim 14 based on his confusion about "how a runway is compared to a datum." In response, the patentees replaced the phrase "a datum" with "the heading of the aircraft," and they added the language "by determining the angle between the runway and the heading of the aircraft" to the last limitation. In their remarks about the amendment, the patentees explained that the claimed alignment determination requires comparing the direction of a runway against either a fixed reference line, such as a latitude or longitude line, or against the "heading" of the aircraft itself:

It should be clear that the angular position of a runway must be referenced to either a datum, for example, a reference latitude or longitude line, or to the heading of the aircraft in order for the angular difference between the heading of the aircraft and the heading of the runway to be computed to determine the alignment of the aircraft with the particular runway.

In that manner, the patentees explained that the angle used to determine alignment can be identified without mentioning a "datum" by simply identifying the two lines that form the angle: the line formed by the runway and the line from a point on the runway to the position of the aircraft (a line that the patentees called the "heading of the aircraft").

The examiner allowed application claim 14 as amended. At the same time, the examiner rejected two pending claims that claimed an alignment determination based on the position of the aircraft and the angle of the runway; those pending claims did not recite that the alignment computation involved the position of the runway or the "heading of the aircraft." In response to the examiner's rejection, the patentees added to each claim a limitation reciting that the alignment determination uses the position of the runway. They explained that the added limitation allowed the claimed invention to "determine the heading of the aircraft with respect to the nearest airport" using the trigonometric functions discussed in the specification (which, accurately labeled, compute the bearing of an aircraft from a runway). The patentees expressly stated that "the output of the arctan device [i.e., aircraft bearing] represents the heading of the aircraft."

Following a further rejection, the patentees added to those claims the same "heading of the aircraft" language that was used in application claim 14. They explained that they amended the pending claims "to conform their language to similar language contained in claims 14 and 19," thus harmonizing the relevant language of their pending claims and their allowed claims. After that amendment, the examiner allowed the pending claims without comment.

The specification and prosecution history both make clear that the patentees used the term "heading" to refer to the angular direction of an object from a point on a runway. Thus, the "heading of the aircraft" is the angular direction of the aircraft from a point on a runway, and the "heading of the runway" is the angular direction of the runway line from a point on that runway. To hold otherwise would not include within the scope of the claim a preferred embodiment that the patentees labeled an "important feature of the present invention" and would ignore the patentees' definition of the term "heading" and their consistent use of that term throughout the prosecution history. The jury's finding that Universal's accused device detects alignment by computing the "heading of the aircraft" within the meaning of the asserted claim is therefore based on a proper interpretation of that limitation.
PLAGER, Senior Circuit Judge, dissenting.

The patent in this case relates to the art of navigation, specifically the process for determining the location at any given time of a craft (airplane or ship) proceeding around the earth. This is a well-established art, in practice for centuries. In navigation, the ordinary meaning of "heading" is the compass direction in which a craft is moving, oriented to either magnetic or true north. A heading is understood to be quite different from a "bearing," which is the direction (expressed in compass terms) that one object bears from another at any given moment. It is hardly likely that the people who invented Honeywell's patented navigation system were unaware of these conventions.

Claim terms are generally given their ordinary meaning as understood by a person skilled in the art. Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc). While a patentee may choose to be his own lexicographer and use a term in a manner other than its ordinary meaning, and even though an "explicit statement of redefinition" is not always necessary, nevertheless the patentee must clearly express an intent to redefine the term. Bell Atl. Network Servs., Inc. v. Covad Commc'ns Group, Inc., 262 F.3d 1258, 1268 (Fed. Cir. 2001).

In my view, the patent in this case falls far short of anything that suggests a clear redefinition of the term "heading." The term itself does not appear anywhere in the patent's written description. The majority relies on an embodiment described in the patent that determines alignment as a function of the bearing of the aircraft from the runway. But the alignment discussion in the written description does not use the term heading to describe what is conventionally known as a bearing. Moreover, there is no clear connection between that passage and the alignment determination set forth in claim 1, which does use the term heading. This is not a case like Bell Atlantic in which the patentee implicitly redefined a claim term by using it throughout the written description in a manner consistent with an unconventional meaning. 262 F.3d at 1270-73. Here the patentees did not use the term at all in the written description.

Furthermore, the prosecution history does not show a clear redefinition of the term "heading." While the applicants at times used the word "heading" to refer to what is actually the bearing of the aircraft from the runway, they used the term in its conventional sense when they referred to "the heading of the runway" in their description of the invention. This inconsistent usage undercuts the argument that the applicants intended to adopt a different definition for the term "heading." Also, it is apparent from the examiner's citation of prior art references which use "heading" in the conventional manner that he understood the term to have its ordinary meaning. The applicants, cognizant of the examiner's understanding of the term and almost certainly aware of the distinction between a heading and a bearing, did not clearly signal the necessary intent to depart from the ordinary meaning of "heading."

At best, the patent and the prosecution history show that the inventors or their representatives who drafted the claims and prosecuted the patent left considerable confusion in the record about whether the claimed invention uses heading or bearing. However, it is not the province of the courts to salvage poorly--or incorrectly--drafted patent claims.

Fair notice to the public, and to competitors, of what is claimed depends on our holding patentees to what they claim, not to what they might have claimed. It is the responsibility of those who seek the benefits of the patent system to draft claims that are clear and understandable. When courts fail to enforce that responsibility in a meaningful way they inevitably contribute an additional element of indeterminacy to the system. Sometimes being kind to a party results in being unkind to the larger interests of the society. In my view this is such a case, and I respectfully dissent from the decision.

GO BACK

1924

As we alluded to above, the crux of Zebco's argument is that the '835 patent covers only those trolling motor-autopilot systems that include a compass or other directional indicator physically attached to the trolling motor. Zebco arrives at this
conclusion by the following route: (1) Zebco considers the "heading lock" invention of the '835 patent to be concerned only with the direction and orientation of the trolling motor rather than the boat; and (2) therefore the heading lock--which, according to claim 1, includes a heading detector "disposed to transmit . . . heading signals"--must be physically attached to the trolling motor. Because the accused AutoGuide systems undisputedly contain a directional indicator (a "heading detector") in a foot pedal--attached to the trolling motor via wires rather than mechanically--Zebco argues that Johnson's infringement claim must fail.

While Zebco recognizes that claim 1, the broadest claim at issue, does not explicitly require that the "heading detector" be mechanically coupled to the trolling motor, it nonetheless suggests that a proper interpretation of the terms "heading signal" and "coupled" in the language of claim 1 compels such a limited claim scope. In doing so, Zebco points out that Figure 1 of the '835 patent, and at least some of the language in the written description, suggest that the preferred embodiment of the invention includes a compass mechanically attached to the trolling motor. This case, then, presents the question of when it is permissible to narrow the scope of broad claim language by reference to embodiments described and depicted in the balance of the specification.

A

We begin, as with all claim interpretation analyses, with the language of the claims. See Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2D (BNA) at 1120; Abtox, Inc. v. Exltron Corp., 122 F.3d 1019, 1023, 43 U.S.P.Q.2D (BNA) 1545, 1548 (Fed. Cir. 1997); Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 619-20, 34 U.S.P.Q.2D (BNA) 1816, 1819 (Fed. Cir. 1995). The general rule is, of course, that terms in the claim are to be given their ordinary and accustomed meaning. See Renishaw, 158 F.3d at 1249, 48 U.S.P.Q.2D (BNA) at 1121; York Prods., Inc. v. Central Tractor Farm & Family Ctr., 99 F.3d 1568, 1572, 40 U.S.P.Q.2D (BNA) 1619, 1622 (Fed. Cir. 1996). General descriptive terms will ordinarily be given their full meaning; modifiers will not be added to broad terms standing alone. See, e.g., Virginia Panel Corp. v. MAC Panel Co., 133 F.3d 860, 865-66, 45 U.S.P.Q.2D (BNA) 1225, 1229 (Fed. Cir. 1997) (unmodified term "reciprocating" not limited to linear reciprocation); Bell Communications, 55 F.3d at 621-22, 34 U.S.P.Q.2D (BNA) at 1821 (unmodified term "associating" not limited to explicit association); Specialty Composites v. Cabot Corp., 845 F.2d 981, 987, 6 U.S.P.Q.2D (BNA) 1601, 1606 (Fed. Cir. 1988) (unmodified term "plasticizer" given full range of ordinary and accustomed meaning). In short, a court must presume that the terms in the claim mean what they say, and, unless otherwise compelled, give full effect to the ordinary and accustomed meaning of claim terms. See, e.g., Nike Inc. v. Wolverine World Wide, Inc., 43 F.3d 644, 646, 33 U.S.P.Q.2D (BNA) 1038, 1039 (Fed. Cir. 1994); E.I. Du Pont De Nemours & Co. v. Phillips Petroleum, 849 F.2d 1430, 1433, 7 U.S.P.Q.2D (BNA) 1129, 1131 (Fed. Cir. 1988); Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759, 221 U.S.P.Q. (BNA) 473, 477 (Fed. Cir. 1984).

In order to overcome this heavy presumption in favor of the ordinary meaning of claim language, it is clear that "a party wishing to use statements in the written description to confine or otherwise affect a patent's scope must, at the very least, point to a term or terms in the claim with which to draw in those statements." Renishaw, 158 F.3d at 1248, 48 U.S.P.Q.2D (BNA) at 1121. That is, claim terms cannot be narrowed by reference to the written description or prosecution history unless the language of the claims invites reference to those sources. See, e.g., McCarty v. Lehigh Valley R.R., 160 U.S. 110, 116, 40 L. Ed. 358, 16 S. Ct. 240 (1895) ("If we once begin to include elements not mentioned in the claim in order to limit such claim . . ., we should never know where to stop."); Renishaw, 158 F.3d at 1249, 48 U.S.P.Q.2D (BNA) at 1121. In other words, there must be a textual reference in the actual language of the claim with which to associate a proffered claim construction.

Our case law demonstrates two situations where a sufficient reason exists to require the entry of a definition of a claim term other than its ordinary and accustomed meaning. The first arises if the patentee has chosen to be his or her own lexicographer by clearly setting forth an explicit definition for a claim term. See In re Paulsen, 30 F.3d 1475, 1480, 31 U.S.P.Q.2D (BNA) 1671, 1674 (Fed. Cir. 1994); Intelicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387-88, 21 U.S.P.Q.2D (BNA) 1383, 1386 (Fed. Cir. 1992); Lear Siegler, Inc. v. Aeroquip Corp., 733 F.2d 881, 888-89, 221 U.S.P.Q. (BNA) 1025, 1031 (Fed. Cir. 1984). The second is where the term or terms chosen by the patentee so deprive the claim of clarity that there is no means by which the scope of the claim may be ascertained from the language used. See Eastman Kodak Co. v. Goodyear Tire & Rubber Co., 114 F.3d 1547, 1554, 42 U.S.P.Q.2D (BNA) 1737, 1741 (Fed. Cir. 1997) (looking past claim language because of lack of clarity), overruled on other grounds by Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 46 U.S.P.Q.2D (BNA) 1169 (Fed. Cir. 1998) (en banc); J.T. Eaton & Co. v. Atlantic Paste & Glue Co., 106 F.3d
1563, 1564, 41 U.S.P.Q.2D (BNA) 1641, 1646 (Fed. Cir. 1997) (Because "[the disputed claim term] is a term with no previous meaning to those of ordinary skill in the prior art[,] its meaning, then, must be found [elsewhere] in the patent."); North Am. Vaccine, Inc. v. American Cyanamid Co., 7 F.3d 1571, 1576, 28 U.S.P.Q.2D (BNA) 1333, 1336 (Fed. Cir. 1993) (using the specification for guidance "when the meaning of a claim term is in doubt"); E.I. Du Pont De Nemours, 849 F.2d at 1433, 7 U.S.P.Q.2D (BNA) at 1131 (Fed. Cir. 1988) (the written description can supply understanding of unclear claim terms, but should never trump the clear meaning of claim terms). Cf. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187, 48 U.S.P.Q.2D (BNA) 1001, 1005 (Fed. Cir. 1998) ("In this case, the [disputed term] has a clear and well-defined meaning. This term is not so amorphous that one of skill in the art can only reconcile the claim language with the inventor's disclosure by recourse to the specification."). In these two circumstances, a term or terms used in the claim invites--or indeed, requires--reference to intrinsic, or in some cases, extrinsic, evidence, see Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583, 39 U.S.P.Q.2D (BNA) 1573, 1577 (Fed. Cir. 1998) (reference to extrinsic evidence is proper when intrinsic evidence cannot resolve ambiguity in claim language), to determine the scope of the claim language.

B

Here, Zebco's primary claim interpretation argument is that the term "heading" in the phrase "heading signal" refers only to the direction of the trolling motor, thus requiring that the heading detector, "being disposed to transmit said heading signals," must be affixed to the trolling motor. Zebco, of course, recognizes that the ordinary and accustomed meaning of "heading" connotes only direction, rather than being limited to the direction of the trolling motor. Thus Zebco argues, as it must, for a more limited scope of "heading," to overcome the presumption in favor of the ordinary--and, in this case, broader--meaning.

Because Zebco does not suggest that the phrase "heading signal" lacks clarity as it is used in the claim, in order to establish a reason to import a narrow definition of the term, it must instead argue that the term "heading" has been given a particular meaning by the patentee. To this end, Zebco argues that language throughout the written description and prosecution history of the '835 patent demonstrates that "heading" in the context of the '835 patent is limited to the direction of the trolling motor. We find this unpersuasive, as did the district court. First, the written description does not describe "with reasonable clarity, deliberateness, and precision" the definition of "heading" proposed by Zebco. See In re Paulsen, 30 F.3d at 1480, 31 U.S.P.Q.2D (BNA) at 1674. Indeed, the many uses of the term throughout the '835 patent are consistent with a broader definition, one encompassing the directions of both the boat and the trolling motor unit. Compare, e.g., '835 patent, col. 3, lines 58-62 ("The electronic steering system of the present invention continues to monitor the current heading of the thrust motor" (emphasis added)) with '835 patent, col. 7, lines 37-39 ("Heading detector 204 continuously monitors the current heading of the boat" (emphasis added)). Varied use of a disputed term in the written description demonstrates the breadth of the term rather than providing a limited definition. See, e.g., Enercon GMBH v. International Trade Comm’n, 151 F.3d 1376, 1385, 47 U.S.P.Q.2D (BNA) 1725, 1731-32 (Fed. Cir. 1998) (refusing to limit a term used "interchangeably" in the written description to only one of the uses of the term). That the term "heading" is used at various points in the written description to refer to both the direction of the trolling motor and the boat is simply not "a special and particular definition created by the patent applicant," Renishaw, 158 F.3d at 1249, 48 U.S.P.Q.2D (BNA) at 1121, and is thus an insufficient reason to limit the scope of the term.

Contrary to Zebco's arguments, Laitram Corp. v. Morehouse Industries, Inc., 143 F.3d 1456, 46 U.S.P.Q.2D (BNA) 1609 (Fed. Cir. 1998), is inapposite. The court there held that a narrow interpretation of a disputed term was compelled because of statements in the written description that made clear that "the asserted claims will bear only one interpretation: that the 'driving surface' limitation is limited to flat driving surfaces," and that the "'driving surface' limitation ... requires flat driving surfaces." Id. at 1463, 46 U.S.P.Q.2D (BNA) at 1614-15 (emphasis added). Here, of course, there is no such unambiguous language in the written description; nothing suggests that "heading" is required to be the heading of the trolling motor. Cf. id.

Zebco also argues that the patentee ascribed a special meaning to the term "heading" in the prosecution history. See, e.g., Spectrum Int'l, Inc. v. Sterilite Corp., 164 F.3d 1372, 1378, 49 U.S.P.Q.2D (BNA) 1065, 1068-69 (Fed. Cir. 1998) (explicit meanings given to claim terms in order to overcome prior art will limit those terms accordingly); Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1576, 34 U.S.P.Q.2D (BNA) 1673, 1676 (Fed. Cir. 1995); Standard Oil Co. v. American Cyanamid Co. 774 F.2d 448, 452, 227 U.S.P.Q. (BNA) 293, 296 (Fed. Cir. 1985). In particular, Zebco argues that the applicant's statement, in a June 17, 1992 amendment to the '586 application, that "the heading signal . . . is dependent solely on the heading of the motor, and totally independent of the orientation of the vessel" is a clear definition of "heading signal"
as being limited to the direction of the thrust motor. However, Zebco overlooks the fact that the claims referred to in that passage, claims 4 and 14 of the '586 application, expressly included an additional limitation: that the compass be "in a substantially fixed relationship to said propulsion device," (claim 4) or likewise "in a predetermined relationship with said propulsion device" (claim 14). The argument referenced by Zebco was unquestionably focused on the requirement, in those claims, that the compass be attached to the trolling motor. The patentee's suggestion that, where the "substantially fixed relationship" or "in a predetermined relationship" claim limitation was present, the feedback signal (i.e., the heading signal) was dependent on the heading of the motor sheds no light on the meaning of "heading signal" in claims where that very limitation is not present. Rather, this exchange is an example of how carefully-crafted arguments in support of patentability can avoid creating ambiguous or adverse prosecution history. By stating clearly and particularly that the context of his remarks was in regards to claims 4 and 14, the applicant ensured that those of ordinary skill in the art—as well as courts, if need be—could evaluate the import and scope of his statements. Thus, because this argument was plainly limited to claims including a "fixed" or "predetermined" relationship between the compass and the trolling motor, it cannot be said to be a clear statement limiting the scope of "heading signal" in general. Zebco thus has not shown that sufficient reasons exist to import a limited definition of this term into the clear language of the claim.

We therefore agree with the district court that the ordinary and accustomed meaning of "heading signal" controls.  

1925

Claims 1-3, 5-7, and 15 of the '061 patent include a "heating station" limitation. The district court adopted Ventana's construction of the term "heating station" as to the number-of-slides limitation and provided a "glossary" to the jury that defined "heating station" as "a slide support and heating element capable of directly heating at least one microscope slide, but designed to hold and heat a number of slides by conductive heating, e.g., direct contact of a heated surface to a portion of the microscope slide to be heated." (J.A. at 30 (emphasis added).) Ventana urges on appeal that the district court's construction of "heating station" correctly requires each heating station to "hold and heat a number of slides." Under this construction, Ventana argues that the jury's verdict of infringement of claim 1 of the '061 patent is not supported by substantial evidence because each heating station of the accused devices holds and heats only a single slide. CytoLogix contends that the district court's construction of "heating station" is inconsistent with the plain language of the claims; that the correct construction covers devices in which only a single slide can be accommodated by each heating station; and that the evidence requires a verdict of infringement under this construction. n6

n6 CytoLogix also argues that substantial evidence supports the jury's verdict even under the district court's claim construction.

- - - - - - - - - - Footnotes - - - - - - - - - - -

CytoLogix is correct that the district court's claim construction conflicts with the plain language of the claims. Claim 1 of the '061 patent recites a "heating station adapted to support at least one microscope slide," meaning that a heating station that supports only one slide falls within the scope of the claim. '061 patent, col. 11, ll. 2-3. Furthermore, claim 2 recites "[a] microscope slide stainer as claimed in claim 1 wherein each of the heating stations supports a single microscope slide." Id. at col. 11, ll. 6-8. Claim 2 would be rendered meaningless if each heating station had to support multiple slides. An interpretation of one claim that renders another claim meaningless is disfavored. In re Cruciferous Sprout Litig., 301 F.3d 1343, 1349 (Fed. Cir. 2002). There is nothing in the specification that suggests a different construction. See Phillips, 415 F.3d at 1314.

Ventana points to the prosecution history of the '061 patent as support for the district court's claim construction. It argues that CytoLogix disclaimed individual slide heating. Ventana misreads the prosecution history. A precursor claim to issued claim 1 had claimed "electronic control for heating the individual heating surfaces" of the heating stations. (J.A. at 2748.) The examiner rejected the claim under 35 U.S.C. § 112 because the specification did not enable one skilled in the art to make or use the claimed "electric [sic] control for heating the individual heating surface." (J.A. at 2756.) CytoLogix amended the claim such that it recited "electronic control for the heating stations" rather than the "individual heating
surfaces." (J.A. at 2839.) CytoLogix also explained in its response that "claims 1-9 were rejected under 35 U.S.C. § 112, second paragraph, with respect to the recitation of individual heating surfaces heated or controlled individually. That feature is no longer recited in the claims." (J.A. at 2841.) The exchange during prosecution had nothing to do with the number of slides a heating station may accommodate; it only established that if a heating station accommodates more than one slide, all of the slides on that heating station must be heated as a group and not individually.

Thus, the claim term "heating station" is not limited to a device that holds and heats a number of slides. The term "heating station" is properly construed to mean "a slide support and heating element capable of directly heating at least one microscope slide by conductive heating, e.g., direct contact of a heating surface to a portion of the microscope slide to be heated."

Although the district court erroneously construed "heating station," a new trial is not required because the district court's instruction to the jury did not constitute prejudicial error. "To warrant a new trial . . . the erroneous jury instruction [must have been] in fact prejudicial. When the error in a jury instruction could not have changed the result, the erroneous instruction is harmless." Ecolab Inc. v. Paraclipse, Inc., 285 F.3d 1362, 1374 (Fed. Cir. 2002) (internal quotation marks omitted); see also Seachange Int'l, Inc. v. C-COR Inc., 413 F.3d 1361, 1381 (Fed. Cir. 2005); Weinar v. Rollform Inc., 744 F.2d 797, 808 (Fed. Cir. 1984). Prejudicial error only exists if "there was sufficient evidence at trial to support a finding of [non-infringement under a correct instruction." Ecolab, 285 F.3d at 1374. Although infringement under the district court's erroneous claim construction was debatable, infringement under the proper construction was not. n7 This was so because there was no dispute that the heating stations of the accused devices supported and heated at least one slide. We sustain the jury's verdict of infringement concluding that the "heating station" limitation of claims 1-3, 5-7, and 15 of the '061 patent is satisfied.

--- Footnotes ---

n7 See also Exxon Chem. Patents, Inc. v. Lubrizol Corp., 64 F.3d 1553, 1560 (Fed. Cir. 1995) (jury verdict reversed where insufficient evidence to support verdict under correct construction).

--- End Footnotes ---
Therefore, the Court construes the term "hello message to notify other routers" as "a message intended at least in part to notify other routers that the sending router is operational."

1927

B. Claims 2 and 15

Having found claims 1 and 23 anticipated by Adobe Photoshop, the district court concluded that the other asserted claims, each dependent upon claims 1 or 23, were also anticipated by this same reference. With respect to claims 2 and 15, however, the court further noted that, while these claims defined the first window as a help access window, this additional limitation was also met by Adobe Photoshop. Apple claims legal error in the district court's failure to consider these claims individually and in its broad construction of the term "help access window." We agree.

As Apple correctly points out, each claim of a patent is "presumed valid independently of . . . the other claims" and "dependent . . . claims shall be presumed valid even though dependent upon an invalid claim." 35 U.S.C. § 282 (1994); Bausch & Lomb, Inc. v. Barnes-Hind/Hydrocurve, Inc., 796 F.2d 443, 446, 230 U.S.P.Q. (BNA) 416, 418 (Fed. Cir. 1986). Thus, the district court improperly concluded that the dependent claims were invalid. Moreover, with respect to claims 2 and 15, the district court's interpretation of "help access window" was so broad as to read the "help" limitation out of the claim.

In support of the district court's construction of "help access window," Articulate points to the language of claim 2 and to the prosecution history. 8 Articulate notes that, as originally filed, claim 2 did not specify the meaning of help access window. Then, in response to an indefiniteness rejection, Apple broadly defined the help access window as: "said help access window being a window that contains one or more user interface controls for accessing information related to software that is loaded on said CPU." Having adopted such a broad definition within the text of the claim, Articulate argues, Apple cannot now narrow that definition. Accordingly, Articulate asserts that the district court's finding of anticipation of claims 2 and 15 was correct.

8 Claim 15 depends from claim 2 and incorporates its definition of help access window.

We cannot accept this argument. The claim interpretation Articulate asserts focuses on the words following "help access window" and ignores the limitation imposed by the word "help." The undeniably broad statement recited in claim 2 (and incorporated into claim 15) simply cannot read the qualifier "help" out of the definition of "help access window." Rather, the claim must be viewed as a whole. Gen. Foods Corp. v. Studiengesellschaft Kohle mb H, 972 F.2d 1272, 1274, 23 U.S.P.Q.2D (BNA) 1839, 1840 (Fed. Cir. 1992) ("each claim is an entity that must be considered as a whole"). Doing so reveals that the claimed window is not intended to access just any information on the CPU; it is intended to access help information. Moreover, the claim must be interpreted in light of the teachings of the written description and purpose of the invention described therein. Strattec Sec. Co. v. Gen. Auto. Specialty Co., Inc., 126 F.3d 1411, 1417, 44 U.S.P.Q.2D (BNA) 1030, 1034-5 (Fed. Cir. 1997) (holding that it was legal error for the district court to instruct the jury that the term "sheet" was not properly considered part of the claim); Gentry Gallery, Inc. v. Berkline Corp., 134 F.3d 1473, 1479, 45 U.S.P.Q.2D (BNA) 1498, 1503 (Fed. Cir. 1998) (relying, in part, on the stated purpose of the invention in construing the claims).

Reading the claim in this context reveals that the help access window serves to access help information from a help system or database. The written description describes in great detail how the help access window of the invention allows a user to access help information from the computer system. See '540 patent, col. 7, line 61 - col. 10, line 16.

Thus, this limitation cannot be given the broad interpretation adopted by the district court, and instead should be construed...
help access window - a window that contains one or more controls for accessing help information from a help system or database that has been loaded on the central processing unit (CPU).

Applying this construction of "help access window" Adobe Photoshop cannot anticipate claims 2 and 15 since the palette window cannot be considered a help access window.

This does not end the inquiry, however, because claims 2 and 15 may still be obvious in light of Adobe Photoshop and other prior art. The district court, having found the claims anticipated, never addressed the question of obviousness. Thus, we have no holding of obviousness to review. Accordingly, we remand the question of obviousness to the district court.

1. Claim construction

The claim limitation disputed by the parties is "heterogeneous computer system," and the primary issue is whether it should be restricted to encompass only systems in which at least two host computers use a different operating system as the district court held. In determining the meaning of the disputed claim limitation, we look primarily to the intrinsic evidence of record, examining the claim language itself, the written description, and the prosecution history, if in evidence. See Phillips v. AWH Corp., 415 F.3d 1303, 1312-1317 (Fed. Cir. 2005) (en banc). Each of the asserted claims includes the "heterogeneous computer systems" limitation, but the claims do not provide guidance on what that limitation means. While the written description does not expressly define the disputed limitation, it lists examples of the monitored computer system. Specifically, the specification of the '237 patent states that

"The computer system, which is to be monitored, may take many forms. For example, the computer system may be a data center, an enterprise computing system, a network of computers, a mainframe computer, a mini-computer, a server, a workstation, and/or a personal computer. Alternatively, the computer system may be an MVS operating system-based computer (or one of its derivative like IBM's OS/390), a UNIX operating system-based computer, an IBM AS400 computer, a Microsoft Windows operating system-based computer, an Apple Macintosh operating system-based computer, an OS/2 operating system-based computer, or a DOS-based computer."

'237 patent, col. 46, l. 62-col. 47, l. 6. Contrary to Global's assertions, the first portion of the cited text does not set forth computer systems with different hardware. Rather, it merely lists different forms of computer systems. The second portion of the text, however, distinguishes computer systems running different operating systems. Thus, the written description supports the conclusion that one of ordinary skill in the art would understand "heterogeneous computer systems" to refer to systems in which at least two host computers use different operating systems. Nowhere does the written description disclose or describe the context of the claimed invention in broader terms.

The prosecution history is consistent with the conclusion noted above. As the district court observed, the "heterogeneous computer system" limitation was added during prosecution in response to rejection of the claims over the prior art. In distinguishing over the prior art, the prosecuting attorney explained that "Any monitoring features performed by [Windows] NT are not with respect to heterogeneous computer systems. For example, [Windows] NT has no facility to monitor operational processes (as provided on the system console) in a VMS and MVS system." In other words, the prosecuting attorney clarified that the prior art did not encompass monitoring host computers with different operating systems, such as a VMS and MVS system. Additionally, during prosecution of the '264 patent, the prosecuting attorney stated that "the language of the claim has been clarified to indicate that the system of the claimed invention controls the operating systems of the heterogeneous computers." Thus, the prosecution history supports the district court's conclusion that the "heterogeneous computer systems" are restricted in scope to encompass only systems in which at least two host computers use different operating systems.

Global contests the district court's reliance on expert testimony in its claim construction ruling. Specifically, the district court noted that Global's own expert "expressly defined a 'heterogeneous computer system' as one that simultaneously controls multiple computers that use different operating systems." Non-infringement Order, 2005 U.S. Dist. LEXIS 42268 at 2285.
*13. In Phillips, we reaffirmed that "extrinsic evidence may be useful to the court, but it is unlikely to result in a reliable interpretation of patent claim scope unless it is considered in the context of the intrinsic evidence." 415 F.3d at 1319. Here, the district court considered the context of the intrinsic evidence and properly relied on the extrinsic evidence merely to support the conclusion reached on claim construction from the claims, the written description, and the prosecution history. We discern no error in the district court's analysis.

We disagree with Global's contention that the district court improperly imposed a "simultaneous" requirement in its claim construction. Indeed, we commend the district court for its thorough, careful, and precise analysis in this technically complex case. Recognizing that the two host computers are unable to communicate directly with each other because they speak different languages, the district court explained that "the monitoring and control computer must understand and speak the language of both host computers[, and thus] it simultaneously translates between the host computers." Non-infringement Order, 2005 U.S. Dist. LEXIS 42268 at *14-*15. The district court's use of the word "simultaneous" merely clarifies and explains a characteristic inherent in its claim construction of "heterogeneous computer systems," and does not further limit the claims.

---

1929

Hidden time-shared set of log-in information

In this phrase, the words "hidden" and "time-shared" are two separate modifiers to the claim term "set of log-in information," which the Court defines in a later section.

MyMail asserts that "hidden" means "not easily accessible to the user." Defendants assert that it means "unknown and inaccessible to the user." Because "hidden" is a normal, non-technical word, the Court notes that the definitions proposed by MyMail and Defendants are correct. Since the patent defines "hidden" as "not easily accessible to the user," the Court will adopt MyMail's definition. Col 18:25.

"Hierarchically arranged." Used in claims 1 and 16.

The specification states that all of the information in the database is "tagged" with indices to form a single hierarchical structure. 505 patent, col. 2, ll. 52-55. The purpose is to allow the subscriber to access various pieces of information in the database, which is sometimes done based upon information already accessed. Figure 9 of the patent shows various levels in a sample hierarchy. The arrows show that indices do not necessarily refer just to information in "lower" levels. Reference may be to a "higher" level. Indices may be "included in the root information (the basic information transmitted most frequently), and also may be embedded in various portions of the transmitted data for the purposes of cross-referencing related information." 505 patent, col. 13, ll. 32-36. Therefore DirecTV's original suggestion that indices are classified into "successive levels" is not the best way to define this term.

For these reasons, and based upon counsels' representations at the hearing, this term will be defined as follows:

"Hierarchically arranged set of indices" means "the indices are placed in some order based upon logical relationships between or among the indices."

B. "Hierarchically Arranged Set of Indices For Referencing Data in Said Information Database."

This term appeared in independent claims 1 and 16. Again, claim 16 recited in part (col. 21:34-43):

16. An information transmission method comprising the steps of: storing an information database on one or more memory devices; generating and storing on said memory devices a hierarchically arranged set of indices for referencing data in said information database, including distinct indices for referencing distinct portions thereof, and embedding said indices in said information database;

As to this term, Comcast proposes that an index means "a list of contents, which can be used to locate the items that are indexed," such that the entire term means "that the data in the information database is made available using indices that are ranked into successive levels, such that a higher-level index is used to access multiple lower-level indices." Finisar disagrees, and advances the following construction for the term: "a set of indices placed in some order based upon logical relationships between or among the indices, wherein the indices include pieces of digital information, (each of which contains an identification value plus, in many cases, other information) used to refer to specific items of information within the database." 2

--- Footnotes ---

2 The Texas Court separately construed the terms "set of indices for referencing data in said information database" and "hierarchically arranged." "Hierarchically arranged" was held to mean "the indices are placed in some order based upon logical relationships between or among the indices." The term "set of indices for referencing data in said information database" was construed as "the pieces of digital information, (each of which contains an identification value plus, in many cases, other information) used to refer to specific items of information within the database" (Melgar Decl. Exh. B at 7-8).

--- End Footnotes ---

The word "hierarchy" is defined as "a body of persons or things ranked in grades, 8 orders, or classes, one above another; a system or series of terms of successive rank." Oxford English Dictionary (2d ed. 2001). The plain meaning of the term
shows that the indices are D ranked or placed in some order. The use of the word "hierarchy" indicates something more than a "logical relationship" as Finisar proposes. A hierarchy is a logical relationship, but here a hierarchy implies a series of menus with submenus and sub-submenus. References in the specification to a tree and leaf-like structure of the indices also support this construction (col. 12:37-49, Fig. 8). Indices are placed in successive, subdivided levels (col. 13:38-62, Fig. 9).

To be hierarchical, the index must also include more than one level. Some branches may have only one entry without further subdivisions, but the entire index cannot be a single item. That would not be a hierarchy. It would not even be an index; it would only be a title.

The parties also disagree as to the indices' function. Again, Comcast would require that the indices make the information database "searchable," while Finisar contends that the indices need only "reference" the information. The intrinsic evidence supports Finisar's view. Claim 16 recites "distinct indices for referencing distinct portions [of the information database]." Furthermore, this order has already determined above that there is no explicit requirement that the information database be searchable in the same way as a database such as Westlaw or LexisNexis. The set of indices is essential to navigating the overall database. Thus, the indices must allow the system to locate information within the overall database and find the location for information.

Comcast also argues that the prosecution history of the '505 patent shows that the inventor went to great lengths to distinguish indices used for cross-referencing data from the hierarchically arranged indices of claim 16. Claim 13 was drawn to the "smart-look ahead" feature used for anticipating subscriber requests. In a response to an office action, the patentee amended claim 13 to further define that feature. The patentee argued (Krishnan Deci. Exh. G at 26):

The transmitted data contains embedded cross-referencing indices, which are similar to hyper-links between different sets of data. The filtering means automatically adds to its set of filter data the cross-referencing indices (or corresponding filter values) so that information cross-referenced by data that the subscriber has requested is automatically downloaded into the subscriber's computer, thereby anticipating likely future information requests by the subscriber. Thus, claim 13 is not directed to a hierarchy of indices, but rather is directed to a request anticipation scheme as part of an information distribution system.

The examiner later held the amendment to be sufficient to overcome a reference teaching a hierarchical set of indices. It is true, as Comcast contends, that the patentee explicitly distinguished between cross-referencing indices and the hierarchical set of indices during prosecution. These are two separate kinds of indices. Still, this does not show that the hierarchical indices render the information database searchable in the keyword sense. The hierarchically arranged indices allow access to the successively lower levels of information, while the cross-referencing indices can access information in distant branches of the hierarchy. This distinction is based on how the indices reference information, not whether the database is searchable.

A "hierarchically arranged set of indices for referencing data in said information database" is held to mean "a set of ranked indices used to reference data within the database, with the higher-level indices giving access to the lower-level indices." An index within the hierarchy may contain a single item.

<td></td>
<td>common root</td>
</tr>
</tbody>
</table>

The disputed term is located in each of the asserted independent claims: "said first menu stored on said data storage device
and displayable in a window of said graphical user interface in a hierarchical tree format." The specification uses the term "hierarchical tree format," but does not explicitly define it. In describing Figure 1 of the '850 patent, the specification states, "A hierarchical tree structure is used to show the different relationships between the menu categories . . . , menu items . . . , menu modifiers . . . and menu sub-modifiers . . . ." ('850 patent, 6:14-21). The patent's use of "hierarchical tree format" appears consistent with the dictionary definition of that term. 1

1 See, e.g., Dictionary of Algorithms and Data Structures, available at http://www.itl.nist.gov/div897/sqg/dads/HTML/tree.html (defining "tree" as "[a] data structure accessed beginning at the root node . . . ."); Webster's Computer Dictionary at 173 (defining "hierarchical file system" as "a method of organizing files in a tree structure. The topmost level, called the root directory, contains leaves, called subdirectories, that can in turn contain further subdirectories.")

Ameranth argues that "hierarchical tree format" does not require a common root. But to one of ordinary skill in the art, a tree data structure connotes one or more branch or leaf nodes linked to a single common root node. Nothing in the specification or claims appears to contradict this ordinary definition of "tree" or "hierarchical tree format." Figure 1 depicts a hierarchical tree format in which "Menu" is the root node. (See '850 patent, 4:32-33). The written description also discloses the following statements: "Menu categories are created from the root." ('850 patent, 7:60); "When building a menu, it should be kept in mind that the menu items are stored using a tree metaphor . . . . Below is an example of how an item may be configured: . . . . In the above example, Menu is the root." ('850 patent, 6:49-66).

Because "hierarchical tree format" requires a root node, the court adopts the following construction: "a format having one or more sublevels branching from a common root."
that a "hierarchy" may encompass multiple level systems such as that described in the embodiment of the '208 Patent (see col. 5:46-62), or single level of primitive elements that are operated upon in an ordered sequence. Accordingly, the Court construes "hierarchy of primitive elements which represent said system" as a set of primitive elements arranged in a ranked or ordered series that represent the designed system.

1936

IV. POSITIONS OF THE PARTIES

A. The Parties' Prior Positions Regarding Construction of the Phrase "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band"

In its Markman briefing and at the Markman hearing, Inline consistently argued that the disputed claim terms "a high frequency band of frequencies above the highest frequency of the telephone voice band," "high frequency band," and "high band of frequencies," recited in the '596 line of patents, 24 and that the disputed claim terms "a high band of frequencies above the highest frequency of the telephone voice band," "high frequency band," and "high band of frequencies," recited in the 718 patent, 25 should each be construed as "frequencies above the telephone voice band." 26

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

24 See, e.g., ’596 patent, cl. 61; ’446 patent, cl. 1, ’585 patent, cl. 1.

25 See, e.g., 718 patent, cl. 22.

26 See, e.g., D.I. 189 at 10; D.I. 207 at 244 ("All of the claims of all of the patents refer to frequency above the telephone voice band."). Both parties argued at the Markman hearing that each of the disputed phrases quoted above (i.e., those including "high frequency band" and "high band of frequencies") should be construed identically in all four of the patents-in-suit. See Markman Opinion, 302 F. Supp. 2d at 326 n.86. Since each of the patents-in-suit are continuations of the same patent application, common construction of these terms could be proper. See Arthur A. Collins, Inc. v. Northern Telecom Ltd. 216 F.3d 1042, 1044 (Fed. Cir. 2000) (Because two patents "shared the same written description," and the second patent "is a continuation of" the first patent, the district court's "determin[ation] that a common construction of" a limitation in the claims of the two patents "was appropriate."). To avoid unnecessary repetition, the court's references to "high frequency band" in this opinion apply to each of the disputed phrases containing variations of this language.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Defendants argued at the Markman hearing that the correct construction of "high frequency band" in each of the patents-in-suit is "any of the radio frequencies between 3 and 30 MHz." 27 As noted in the Markman Opinion, this construction was first recited in defendants' responsive Markman brief and was a change in the proposed construction offered by defendants in their opening Markman brief. 28 In their opening Markman brief, defendants argued that the proper construction of the phrase "a high frequency band of frequencies above the highest frequency of the telephone voice band" as recited in the '596 line of patents is "the band of frequencies above 1 Mhz." 29 Defendants argued that the proper construction of "high band of frequencies above a telephone voice band" as recited in the 718 patent is "the band of frequencies above 6 MHz." 30

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

27 Markman Opinion, 302 F. Supp. 2d at 320. Megahertz is defined as "one million cycles per second, used esp. as a radio-frequency unit." Webster's II New Riverside University Dictionary 739 (1988). The correct abbreviation of megahertz is "MHz." The patents-in-suit and the parties' briefing sometimes abbreviates megahertz as "Mhz." In this opinion, the court uses the abbreviation "MHz" unless quoting language using the abbreviation "Mhz."

28 Markman Opinion, 302 F. Supp. 2d at 320 n.61.

29 D.I. 187 at 43 (emphasis omitted).
In its Markman Opinion, the court construed "a high frequency band of frequencies above the highest frequency of the telephone voice band" to mean "frequencies above the telephone voice band between the range of 1 and 30 MHz." 31

B. The Parties' Current Positions Regarding Construction of the Phrase "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band"

Defendants contend that the construction set forth in the Markman Opinion should not be changed because it "was correctly guided by the governing Federal Circuit law and is firmly grounded in the intrinsic records of these patents." 34

C. The Parties' Positions on Reconsideration

Inline argues that "reconsideration of the Court's construction is required to avoid manifest injustice, as the current construction excludes valuable telephone wire spectrum from the literal scope of the claims and is based upon a misapprehension of the applicability of a dictionary definition and of the embodiments and teachings of the patents." 35

First, that the dictionary definition relied upon is not relevant to the patents-in-suit because that definition "refers to specific
radio frequency spectrums used historically and today by the Federal Communications Commission ('FCC') as a frequency nomenclature for regulating and allocating spectrum for wireless transmissions, not telephone wireline communications [which the patents teach and claim].

36 Second, that a definition including an upper limit is incorrect because "a high frequency band of frequencies above the highest telephone voice band of frequencies [sic]' contains a single limitation: that the lower limit of this high band of frequencies must be somewhere above the telephone voice band of frequencies." 37

Third, that many preferred embodiments disclosed in the patent specifications are erroneously excluded as a result of the court's construction. 38

36 Id. at 2 (emphasis in original).

37 Id. (emphasis in original).

38 Id. at 3.

Defendants' first response to Inline's Motion for Reconsideration is a procedural argument that plaintiff's motion does not satisfy the standard for a party seeking to alter or amend an order pursuant to Federal Rule of Civil Procedure 59(e) and that Inline failed to address the requirements for a motion for reargument under District of Delaware Local Rule 7.1.5. 39

39 D.I. 249 at 2. As explained in Section II above, the court has determined that the unique circumstances of this case warrant a modification of the court's prior construction. This opinion is not intended to be, nor should it be, viewed as an invitation for a disappointed party to seek "a second bite at the apple" through motions for reargument and/or reconsideration anytime the court determines an issue contrary to the result advocated by a party.

Defendants attack Inline's specific arguments for reconsideration with the contentions that: "neither the dictionary relied on by the Court nor any of the other dictionaries proffered by the parties distinguish between 'wireless' and 'wireline' transmissions"; "the Federal Circuit has specifically held that the ordinary meaning for the terms 'high frequency' in the context of wireline transmissions . . . is 3 MHz-30 MHZ"; "the teaching in the patent specifications . . . are contrary to Inline's position and certainly do not provide the type of clear definition or disavowal necessary to deviate from the ordinary meaning of 'high frequency' in the manner suggested by Inline"; and "the Federal Circuit has made clear that the type of 'after the fact' extrinsic evidence offered by Inline is not a substitute for the Court's careful analysis of the intrinsic record." 40

40 Id. at 3-4.

V. DISCUSSION

A. Inline's Argument that the Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band" is Erroneously Based on a Definition that Applies Only to Wireless Transmission

Inline's argument that the definition of "high frequency" relied upon by the court is inapplicable to the patents-in-suit for the reason that that definition "applies to wireless transmissions and broadcasts and not to telephone wires" 41 is not supported by the intrinsic record and is simply an expansion of the same argument made by plaintiff at the Markman hearing. 42
The definition of "high frequency" relied on by the court in the Markman Opinion, "any of the radio frequencies in the band between 3 and 30 MHz," is found in a dictionary entitled "Telephony's Dictionary: Defining 14,500 telecommunication words and terms" (the "Telephony's Dictionary"). 43 In its opening Markman brief, Inline proffered the Telephony's Dictionary as an appropriate reference for the court's claim construction and cited that dictionary as providing definitions supporting its proposed construction of the disputed term "a high frequency band of frequencies above the highest frequency of the telephone voice band," as well as the disputed terms "telephone exchange," and "signal interface." 44 Another technical dictionary cited by Inline in its opening Markman brief, Newton's Telecom Dictionary, 45 is consistent with the Telephony's Dictionary. That dictionary's definition of "frequency band" incorporates a chart of frequencies which includes "3-30 MHZ -HF- High Frequency" as one of "the accepted explanations of 'bands.'" 46 Inline proffered these telecommunications dictionaries for the court's claim construction during the Markman proceedings. It is hardly credible for plaintiff now to argue that particular definitions in those dictionaries which are inconsistent with its proposed construction of "high frequency band" are inapplicable to the patents-in-suit. Furthermore, the same definition of "high frequency" was relied upon by the Federal Circuit when construing the term "high frequency" in another patent concerning wireline transmissions.

44 See D.I. 189 at 11, 14, 17 (citing the Telephony's Dictionary at 86, 7, 104); D.I. 190 Ex. D. Inline consistently cited this dictionary as "Graham Langley, Telephony's Dictionary" in its opening Markman brief, see D.I. 189 at 11, 14, 17, but referred to this same reference as merely the "Graham Langley dictionary" in its Motion for Reconsideration. See D.I. 242 at 1 n.2.

45 Harry Newton, Newton's Telecom Dictionary (3rd ed. 1990) (emphasis added); See D.I. 189 at 16-17, 21, 35 (citing the definitions of "signal" and "interface" from Newton's Telecom Dictionary); D.I. 190 Ex. G. 46 D.I. 249 at 5 (quoting Newton's Telecom Dictionary at 52-53). This same chart of frequencies is also included in the definition of "radio frequency band" recited in the Telephony's Dictionary. See Telephony's Dictionary at 16; D.I. 242, Ex. A. A similar definition of "frequency band" was also included in the "Glossary of Dictionary Definitions Provided by Inline." See D.I. 176, Ex. 1 at 6. The partial quotation included in plaintiff's glossary recites: "in general the range of frequencies between specified upper and lower limits. In particular one of the following frequency ranges which are agreed internationally. . ." Id. (quoting S WAmos & R S Amos, Newnes Dictionary of Electronics 138 (3d ed. 1996)). What Inline elides through ellipses from that definition, however, is yet another chart of frequency ranges that, like the charts of frequency ranges contained in the Telephony's Dictionary and Newton's Telecom Dictionary, describes "high frequency" as "3-30 MHz." See Newnes Dictionary of Electronics at 138.

In Intellectual Property Development Corporation v. UA-Columbia Cablevision of Westchester, Inc., the Federal Circuit reviewed the district court's construction of the term "high frequency" as recited in a patent directed at "a wired broadcasting system." 47 The two sources relied upon by the district court included a technical dictionary which defined "high frequency" as "Federal Communications Commission designation for the band from 3 to 30 MHZ in the radio spectrum . . .[and a nontechnical dictionary which included] a radio frequencies table list[ing] high frequency as covering 3 to 30 megacycles." 48 The Federal Circuit held "that the district court correctly construed [the disputed term] 'high frequency' as including only any frequency between 3-30MHz," 49 Even though those definitions referred to "radio" frequencies and the invention concerned "a wired broadcast system," no distinction between wired and wireless
transmission systems was made by the Federal Circuit.

47 336 F.3d 1308, 1310 (Fed. Cir. 2003) (emphasis added).

48 Id. at 1314-15 (emphasis added) (first alteration in original) (citations omitted).

49 Id. at 1317.

Here, defendants cited Intellectual Property Development in their responsive Markman brief as supporting a definition of "high frequency band" as those frequencies from 3 MHz to 30 MHz. Defendants also argued at the Markman hearing that because the invention at issue in Intellectual Property Development concerned "a wired broadcasting system," the definition found in that case was also applicable to the wireline transmissions described in plaintiff's patents.

At the Markman hearing, Inline sought to distinguish Intellectual Property Development by arguing that the definition of "high frequency" in that case was not applicable to the patents-in-suit because the specification of the patent being construed in Intellectual Property Development did not describe particular frequency ranges where Inline's patents do contain such descriptions. Inline did not, however, attempt to distinguish Intellectual Property Development when it raised its wireline/wireless transmission argument at the Markman hearing. Since Inline was aware of defendants' reliance on that case from prior briefing and oral argument, it is telling that Intellectual Property Development was not even mentioned in its Motion for Reconsideration.

Finally, the '596 line of patents each: refer to radio frequency transmission (abbreviated RF); describe the invention as including "RF transmitters and RF receivers"; and describe the use of RF signals. Indeed, the '596 patent is titled "Two-Way RF Communication at Points of Convergence of Wire Pairs from Separate Internal Telephone Networks." "Radio frequency" is defined as "an electromagnetic wave frequency intermediate between audio frequencies and infrared frequencies used esp. in radio and television transmission." Nothing in that definition suggests a distinction between electromagnetic wave frequencies used in wireline transmission as opposed to those used in wireless transmission.
55 See, e.g., '596 patent, 9:9-54; 14:59-60 ("The solutions described herein take advantage of the improved ability of RF (radio frequency) signals . . . ."); Likewise, the '718 patent describes the use of radio frequency transmission. See, e.g., '718 patent, 9:58-62 ("In contrast to regulations covering radiation, no special legal problems are created in the U.S. by the connection of radio frequency devices to the public telephone network if those devices do not transmit energy below 6 Mhz.").

Inline acknowledges that "the term 'RF' is often used generically to describe all frequencies between audio and light frequencies" 57 but contends that "the specific frequency nomenclature relied upon by Defendants and the Court is reserved for the language of wireless spectrum allocation by the FCC." 58 Inline offers nothing other than the declaration of its expert, and other extrinsic evidence, to support this contention. Defendants correctly point out that Inline has not cited any dictionary that supports its argument that there were different ordinary and accustomed definitions of a "high frequency band" for wireline transmissions and for wireless transmissions at the time of the inventions described by the patents-in-suit. Nor has Inline pointed to any intrinsic evidence, and the court has found none, which would support that differentiation. 59

57 D.I. 242 at 2.

58 Id. (emphasis in original).

59 Inline's submission of extrinsic evidence (which post-dates the date of the invention by several years) is not needed for the court to construe "high frequency band." This is particularly evident in light of Inline's repeated assertions indicating that the intrinsic record is sufficient for the construction of the disputed terms in the patents-in-suit. See D.I. 189 at 1 (stating that the disputed claim terms "all have plain and ordinary meanings within the context of the claims in which these terms are used"); id. at 9-13 (citing only dictionary definitions and the specifications of the patents-in-suit in support of its proposed construction of "high frequency band"); D.I. 242 at 8 ("Here the claimed range of the high frequency control and video information signals . . . is readily gathered from reading the patents and their disclosure . . . ."); id. at 6 ("It cannot be argued that . . . the phrase 'a high frequency band of frequencies above the highest frequency of the telephone voice band' lacks meaning. . . ."); see also id. ("One reading the patent claims and specification would not search beyond the patents for meaning . . . . (citing the declaration of Inline's expert)). The court agrees and finds it unnecessary to address Inline's arguments that are based exclusively on a new declaration of its expert and other extrinsic evidence. See Vitronics, 90 F.3d at 1582 ("In most situations, an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term. In such circumstances, it is improper to rely on extrinsic evidence."); Bell & Howell Document Management Prods. Co. v. Altek Sys., 132 F.3d 701, 707 (Fed. Cir. 1998) ("Because the intrinsic evidence unambiguously defined the disputed claim limitation, the district court's reliance on the expert testimony . . . to contradict the intrinsic evidence when interpreting the claims was error." (citing Vitronics, 90 F.3d at 1583)). Additionally, Inline's extrinsic evidence need not be considered as that evidence is an attempt to supplement material in support of arguments already made by plaintiff and defendants at the Markman hearing. See BP Amoco Chem. Co. v. Sun Oil Co., 200 F. Supp. 2d 429, 432 (D. Del. 2002) ("[A] motion for reargument may not be used to supplement or enlarge the record on which the court made its initial decision." (citation omitted)).

Consequently, the court rejects Inline's argument that the dictionary definition of "high frequency" relied upon by the court is only applicable to wireless transmissions.

B. Inline's Argument that the Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band" is Erroneous for Including an Upper Limit
Inline's second argument for reconsideration is that "'high frequency band of frequencies above the highest telephone voice band of frequencies' contains a single limitation: that the lower limit of the high frequency band must be somewhere above the telephone voice band of frequencies." 60 The implication is that the court erred in selecting a construction of "high frequency band" that includes an upper limit as well as a lower limit. Inline's arguments in its Motion for Reconsideration substantially rehash those made during the Markman proceedings that were rejected by the court.

60 D.I. 242 at 2 (emphasis in original).

Inline's opening Markman brief contained the following argument:

The ordinary meaning of "frequency band" is "[a] range of frequencies between upper and lower limits." Graham Langley, Telephony's Dictionary …. The word "high" modifies the words "frequency band" to create the terms "high frequency band" and "high band of frequencies" which are explicitly defined in the claim language as frequencies above the voice band. In context, therefore, the high frequency band, and the high band of frequencies, specify a range of frequencies having a lower limit above the highest frequency of the telephone voice band. No requirement is placed on the upper limit of the frequency range. 61

61 D.I. 189 at 12-13 (emphasis added).

Within this single paragraph, Inline's own proffered definition of "frequency band," "[a] range of frequencies between upper and lower limits," flatly contradicts its position that "high frequency band" should be defined to have no upper limit. The court notes that the Telephony's Dictionary does not include the definition of "frequency band" quoted by Inline. This error was pointed out by defendants in their responsive Markman brief 62 and at oral argument. 63 Inline never addressed this error or indicated the source of its proffered definition of "frequency band." Upon review of the parties' Markman submissions, however, the court discovered the source of Inline's "frequency band" definition. "A range of frequencies between upper and lower limits" is the definition recited in the Telephony's Dictionary for "band," not "frequency band." 64 This was one of several definitions of "band" included in a "Glossary of Dictionary Definitions Provided by Inline" attached as Exhibit 1 to the parties' Joint Submission Regarding Claim Construction. 65 Each of technical dictionaries included in plaintiff's glossary define "band" to have both upper and lower limits. 66

62 See D.I .200 at 20.

63 See D.I. 207 at 252-53.

64 D.I. 176, Ex. 1 at 1 (quoting the Telephony's Dictionary definition of "band").

65 See id.

66 See id. In addition to the above-quoted definition of "band" recited by the Telephony's Dictionary, the Glossary of Dictionary Definitions Provided by Inline lists the following definitions of "band":

"2. (data transmission) Range of frequency between two defined limits." The Institute of Electrical and Electronics Engineers, Inc., IEEE Standard Dictionary of Electrical and Electronics Terms 79 (Frank Jay ed., 3rd ed. 1984);
"In data communication, the frequency spectrum between two defined limits." Jerry M. Rosenberg, Computers, Data Processing & Telecommunications 39 (1984);

The only dictionary included in plaintiff's glossary that did not explicitly define "band" as including upper and lower limits was the sole nontechnical dictionary included in that section. See id. (The New Merriam-Webster Dictionary 71 (Frederick C. Mish ed. 1989) (defining "band" as "3. A range of wavelengths (as in radio)").

Finally, the intrinsic record supports the conclusion that there is an upper limit to "high frequency band." The specifications of the '596 line of patents state "as mentioned above, there is an upper limit to the frequencies that can be useful for transmission of signals across a transmission path of a given length." 67

The court concludes, therefore, that there is both an upper and lower limit to the phrase "high frequency band" and rejects Inline's argument that the court's construction of that phrase was erroneous as a result of including an upper limit.

C. Inline's Argument that the Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band" Improperly Excludes Certain Embodiments Recited in the Patents-In-Suit

Inline contends that the court's construction of "a high frequency band of frequencies above the highest frequency of the telephone voice band" as "frequencies above the telephone voice band between the range of 1 and 30 MHz" improperly excludes several embodiments recited in the patents-in-suit. 68 Inline argues that a construction which excludes preferred embodiments from the scope of the claims is disfavored. 69 Inline's argument on this point has merit. Because the court determines that the proper construction of "high frequency band" is different for the '596 line of patents and the 718 patent, the appropriate modification of the court's prior construction for each will be discussed separately.

1. The Parties' Arguments with Regard to the '596 Line of Patents

During the Markman proceedings, Inline pointed to a control signal illustrated in figure 3a of the '596 line of patents as centered at 0.5 MHz as an example of frequencies improperly excluded from defendants' proposed construction of "high frequency band." 70
Inline reiterates this argument in its Motion for Reconsideration and also points to frequencies above 30 MHz that are excluded by the court's construction of "high frequency band." Inline again notes that figure 3a of the '596 line of patents describes an embodiment having a control signal with a lower limit at 0.25 MHz. 71 Inline cites each of the patents-in-suit as stating "the control signal is transmitted in a high frequency band." 72 Inline also contends that "the upper end, while not discussed by either party in the Markman briefs, is clearly disclosed with examples given at 100 MHZ and 5000 MHZ." 73

71 D.I. 242 at 4. The '596 line of patents describe control signals as having a 0.5 MHz bandwidth, therefore, the control signal illustrated in figure 3a spans a frequency band from 0.25 MHz to 0.75 MHz. See '596 patent, 41:12-14 & figure 8 (bandwidth examples).

72 D.I. 242 at 4 n.6 (citing '596 patent, cl. 24; '585 patent, cl. 3; '446 patent, cl. 6; '718 patent, 23:36-40).

73 Id. at 5 & 5 n.7 (citing '596 patent, 37:66-38:5 & figure 8); see also id. at 4 & 4 n.6.

Defendants' opposition to the Motion for Reconsideration never addresses Inline's argument that the court's construction of "high frequency band" improperly excludes frequencies above 30 MHz. Defendants focus solely on the lower limit of the court's construction. They argue that the patents describe the control signal disclosed in figure 3a as "Amplitude Modulation within a Low-Frequency channel." 74 Based on this language, defendants contend that this example of control signal transmission is not a "high frequency band" signal and, therefore, the court's construction of that phrase does not improperly exclude a preferred embodiment. 75 This is the same argument presented by defendants at the Markman hearing. 76

74 D.I. 249 at 9 (citing '596, patent 25:44-45 (emphasis added by defendants)).

75 See id.

76 See D.I. 207 at 256-57.

Defendants, however, have presented contradictory arguments with regard to the lower limit of the "high frequency band." In their opening Markman brief, defendants argued that "the proper construction of the phrase 'high frequency band of frequencies above the highest frequency of the telephone voice band' in these elements is 'the band of frequencies above 1 MHz.'" 77 In defendants' responsive Markman brief, they changed their proposed definition and argued for a construction of "high frequency band" having a lower limit of 3 MHz based on the definition of "high frequency" in the Telephony's Dictionary, "any of the radio frequencies in the band between 3 and 30 MHz." 78 In that same brief, defendants nevertheless conceded that "the specification is explicit that the high frequency signals are never lower than 1 MHz." 79 Although previously acknowledging that the "high frequency band" includes signals at least as low as 1 MHz, at oral argument, defendants took the position that the inventor described all frequencies below 3 MHz as "low frequency channels" and, therefore, signals below 3 MHz should not be included in the definition of "high frequency band." 80

77 D.I. 187 at 43 (emphasis omitted).

78 D.I. 200 at 20-22.

79 Id. at 22 (emphasis added).
If, as defendants now argue, the court's construction is correct in defining the lower limit of "high frequency band" to be 1 MHz, it is hard to reconcile their position that the control signal described in the same section of the specification is not also part of the "high frequency band." 84 Given defendants' inconsistent positions, the court believes it is more reasonable to accept Inline's argument that the frequencies of both the video signal component and the control signal illustrated in figures 3a and 3c are within the "high frequency band." Although not articulated by Inline, the description of "Amplitude Modulation within a Low-Frequency Channel" may be understood to refer to the lower frequencies of the "high frequency band." These figures, then, describe the use of comparatively lower frequency channels within the "high frequency band," i.e., frequencies which are lower than the transmission levels of the preferred embodiments described earlier in the patent specifications. 85

84 The court notes that defendants' argument that "the specification distinguishes between high and low frequency signals, consistently referring to signals below 1 MHz as low frequency signals," D.I. 249 at 11 n.5, and that nothing in the '596 line of patents "suggests placing such [high frequency] signals in the band below 1 MHz," id. at 10, is accurate only with respect to the transmission of video signals. The patents make clear that the invention is not limited to transmission of video signals but also includes the transmission of control, and other, signals. See '596 patent, 1:23-24 (describing the invention as "relating to a system for simultaneous two-way communication of video signals and other signals . . . ."); '596 patent, 1:56-64 ("The communication systems disclosed in the parent and first and second CIP applications are designed to simultaneously transmit telephone signals and non-telephonic signals (such as cable television signals, other video signals, audio signals, data signals, and control signals) across the active telephone wiring internal to . . . residences and other structures. The present invention adds to these techniques, providing distribution of all of these signals to a local network of active telephone wiring . . . .").

85 See '596 patent, 19:27-56 (describing preferred embodiments in the section titled "Minimum Frequency"); '596 patent, 25:10-11 (stating that the embodiments described in figures 3a and 3c "use frequencies below the lower limits suggested above[, i.e., the those described in the 'Minimum Frequencies' section]."
Because the court's prior construction of "high frequency band" excluded certain embodiments recited in the '596 line of patents, and because defendants have not argued that there is evidence that those embodiments are not covered by these patents, the court concludes that its prior construction was overly narrow and must be modified. 86

86 See Vitronics, 90 F.3d at 1583 (stating that a construction that excludes a preferred embodiment "is rarely, if ever, correct and would require highly persuasive evidentiary support."); see also Appler Corp. v. Micromass UK Ltd., 186 F. Supp. 2d 487, 504-08 (D. Del. 2002) (rejecting proposed construction that would read out preferred embodiment illustrated in figure); cf. Elekta Instrument S.A. v. O.U.R. Scientific Int'l, 214 F.3d 1302, 1308 (Fed. Cir. 2000) (illustrating "the rare case" in which the correct claim construction "excluded the preferred . . . embodiment disclosed in the specification . . . [because] the prosecution history and the unambiguous language of the amended claim" demonstrated that the preferred embodiment was not covered by the claim (citation omitted)).

2. The Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band" for the '596 Line of Patents

In order to modify properly its prior construction of the phrase "a high frequency band of frequencies above the highest frequency of the telephone voice band," the court must first determine precisely which words in that phrase are in dispute. Once that issue is resolved, the court will determine the ordinary and accustomed meaning of the disputed term as reflected in relevant dictionaries and then examine other intrinsic evidence to see if the patentee's use of that term is consistent with its ordinary meaning. 87

87 Neither party presented arguments based on the prosecution history with respect to the term at issue in the Motion for Reconsideration.

In its Motion for Reconsideration, Inline resurrects its argument that, in each of the patents-in-suit, the phrase "a high frequency band of frequencies above the highest frequency of the telephone voice band" means "the frequencies above the telephone voice band." 88 The embodiments described in the specifications of the '596 line of patents demonstrate that the lower limit of disputed phrase should include the lower limit of the control signal illustrated in figure 3a. The court must now determine which words in that phrase are in dispute and, thereafter, whether the claims should be construed as broadly as Inline suggests.

88 D.I. 242 at 10-11.
Having concluded its discussion of the first part of the phrase "a high frequency band of frequencies above the highest frequency of the telephone voice band," Inline stated that "'voice band' is a well-known term of art, which is a frequency 'band used on telephone equipment for the transmission of voice and data,' the highest frequency [of which] is not more than approximately 4000 Hz." 91 Plaintiff concluded that "by the plain claim language, the lower frequency limit of the high frequency band is above the voice band and is therefore above approximately 4000 Hz." 92

89 D.I. 189 at 11 (second alteration in original).
90 Id. at 11-12.
91 Id. at 12 (quoting Jerry M. Rosenberg, Computers, Data Processing & Telecommunications (1984)).
92 Id.

Defendants have consistently argued that Inline's proposed construction reads the words "high frequency" out of the claims. 93 Inline has provided no response to this argument. Defendants argue further that other claims in the '596 line of patents support its contention that "high frequency band" recited in the asserted claims can not simply mean all frequencies above the voice band. 94

93 See D.I. 207 at 258-59; D.I. 249 at 11 n.4.
94 D.I. 249 at 10-11.

For instance, Claim 1 of the '596 patent recites: "circuitry for transmitting said received video signal onto at least one of said telephone lines in a selected frequency range that is different from frequencies at which said voice signals are carried on said one telephone line . . . ." 95 Claim 13 of the '596 patent recites: "the system of claim 1 wherein said voice signals are carried by said telephone lines at voiceband frequencies and said selected frequency range exceeds said voiceband frequencies." 96 Since the asserted claims recite the more specific limitation of "high frequency band," defendants argue that Inline's proposed construction is inconsistent with other claim language used by the patentee. The court agrees with defendants on these points.

95 '596 patent, cl. 1 (emphasis added); see also '596 patent, cl. 9 (". . . a second selected frequency range that is different from said frequency range selected by said interface and different from frequencies at which said voice signals are carried on said telephone link . . . .") (emphasis added)).
96 '596 patent, cl. 11 (emphasis added); see also '596 patent, cl. 13 ("circuitry for changing the frequency of said video signal received from said telephone line to a frequency band that exceeds said voiceband frequencies . . . .") (emphasis added)).

The parties agree that the "highest frequency of the telephone voice band" is approximately 400 Hz. 97 Therefore, the dispute centers on the meaning of the words "high frequency band." Inline's argument that "high" modifies "frequency band" and, thus, that the disputed phrase simply means "frequencies above the voice band" unquestionably reads "high
frequency band" out of the claim. The entire disputed phrase reads:

"a high frequency band of frequencies above the highest frequency of the telephone voice band."

Inline's proposed construction of that phrase is:

"frequencies above the telephone voice band." 98

In essence, that construction merely excises "a high frequency band" from the disputed phrase and gives no meaning whatsoever to those words.

97 See D.I. 197 at 18 (Plaintiff states that "all parties accept that the telephone voice band is the band that carries voice telephone signals, which is commonly understood to be between approximately 0 and 4 KHz."). Defendants apparently do not challenge plaintiff's definition of "voice band." See D.I. 187 at 44 ("Because the top end of the voiceband is approximately 4KHz . . . ").

98 D.I. 189 at 10; see also D.I. 242 at 1 (suggesting modification of the court's construction to read "frequencies above the voice band" or, alternatively, "a range of frequencies above the telephone voice band").

Defining "high" as simply meaning that the "frequency band" is "above" the voice band, as Inline suggests, would make the words "high frequency band" superfluous since the entire phrase in question already requires the "high frequency band" to be limited to those "frequencies above the highest frequency of the telephone voice band." A construction that does not give meaning to all the words in a disputed phrase is disfavored. 99 The more logical construction, and the one which gives meaning to all the words in the disputed phrase, is that "high frequency" modifies "band." This construction does not render any words of the asserted claims superfluous.

99 See Pickholtz v. Rainbow Techs., Inc., 284 F.3d 1365, 1373 (Fed. Cir. 2002) ("Interpretations that render some portion of the claim language superfluous are disfavored. . . .")

Defendants' argument regarding other claim language reciting broader limitations also supports the rejection of Inline's proposed construction. Examining these other claims is consistent with the Federal Circuit's mandate that in construing claims the court is to read the disputed language in the context of the entire patent. 100 Independent claim 1 of the '596 patent includes the limitation that frequencies are transmitted "in a selected frequency range that is different from frequencies at which said voice signals are carried on said one telephone line . . . ". 101 Claim 11 of the '596 patent, which depends from claim 1, contains the narrower limitation that "said selected frequency range exceeds said voiceband frequencies." 102 The plain meaning of the limitation recited in claim 11 is the same as Inline contends this court should apply to "high frequency band" in the asserted claims. When the patentee sought to limit a claim to transmission of frequencies that are merely "different from" or "exceed" (or are "above") the voice band, he knew how to do so. 103 That is not the limitation included in the asserted claims, however. Those claims include the more specific limitation to transmissions of frequencies in the "high frequency band." 104 The court concludes, therefore, that in the disputed phrase "high frequency band," the term "high frequency" modifies the term "band." The court must now determine the ordinary and accustomed meanings of these terms.

100 See Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1299 (Fed. Cir. 2003) ("While certain terms may be at the center of the claim construction debate, the context of the surrounding words of the claim also
must be considered in determining the ordinary and customary meaning of those terms. While dictionaries and treatises are useful resources in determining the ordinary and customary meaning or meanings of disputed claim terms, the correct meaning of a word or phrase is informed only by considering the surrounding text. This is why consulting dictionary definitions is simply a first step in the claim construction analysis and is another reason why resort must always be made to the surrounding text of the claims in question, the other claims, the written description and the prosecution history.

101 '596 patent, cl. 1 (emphasis added).

102 '596 patent, cl. 11 (emphasis added).

103 See Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1304-05 (Fed. Cir. 1999) (The court rejected defendant's proposed construction as contrary to the language of the asserted independent claims and noted that a nonasserted independent claim which included the limitation argued for in the asserted claims supported this rejection. The court stated, "had [plaintiff] intended or desired to claim [the proposed limitation] in the asserted claims, it could have done it explicitly, as in claim 11. The absence of any such explicit language, however, shows that the [asserted claims] do not include [the proposed limitation]."); see also Forest Labs., Inc. v. Abbott Labs., 239 F.3d 1305, 1310 (Fed. Cir. 2001) ("Where claims use different terms, those differences are presumed to reflect a difference in the scope of the claim."); General American Transp. Corp. v. Cryo-Trans, Inc., 93 F.3d 766, 770 (Fed. Cir. 1996) (rejecting district court's construction which rendered a particular claim requirement superfluous); RF Delaware, Inc. v. Pacific Keystone Techs., Inc., 326 F.3d 1255, 1264 (Fed. Cir. 2003) (rejecting proposed construction for asserted claim that would render "redundant or meaningless" a limitation in unasserted claims). 104 This analysis also compels the court to reject Inline's argument that the "patent specifications define high frequency as: 'high-frequency (i.e., non-voice band) signals." D.I. 242 at 7 (quoting '446 patent, 54:25; '585 patent, 54:11; and '596 patent, 53:61 (emphasis added)). That parenthetical reference is far from an explicit definition of "high frequency band" as all frequencies above the highest frequency of the telephone voice band.

Defendants contend that the proper construction of "high frequency band" is determined by the definition of "high frequency" contained in the Telephony's Dictionary; "any of the radio frequencies in the band between 3 and 30 MHz." As noted above, this definition is one of several consistent definitions recited in dictionaries proffered by Inline as appropriate for the court's construction of the disputed terms of the patents-in-suit. Inline has offered no other dictionaries available at the time of invention expanding this definition of "high frequency." 105 The definition of "band" recited in several dictionaries proffered by Inline is "a range of frequencies between upper and lower limits." 106 By combining the definitions of "high frequency" and "band," the court concludes that the ordinary and accustomed meaning of the phrase "high frequency band" at the time of the inventions at issue was "the range of radio frequencies between 3 MHz and 30 MHz." 107

105 See Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002) ("If more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all consistent meanings.").

106 See footnote 66, above.

107 See Alloc, Inc. v. ITC, 342 F.3d 1361, 1368 (Fed. Cir. 2003) ("Claim language generally carries the ordinary meaning of the words in their normal usage in the field of invention at the time of the invention.").

Because the court has already determined that the intrinsic record describes certain embodiments in the '596 line of patents having frequencies outside of the range of frequencies to which the ordinary meaning of "high frequency band" is limited, the court will not construe the disputed phrase to be so limited. 108 This is not problematic, however. The Federal Circuit has stated that:

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -
the specification or the prosecution history of a patent may alter the meaning of a claim term from its conventional usage. A patent applicant may consistently and clearly use a term in a manner either more or less expansive than its general usage in the relevant art, thereby expanding or limiting the scope of the term in the context of the patent claims. 109

Here, the embodiments described in the specifications make clear that the patentee used the term "high frequency band" more expansively than its ordinary and accustomed meaning. Moreover, it is entirely proper to construe that term by examining the specifications' description of preferred embodiments, even if the term "high frequency band" is not explicitly defined therein. 110

--- Footnotes ---

108 See Texas Digital, 308 F.3d at 1204 ("[If] the intrinsic record . . . shows that the specification uses the words in a manner clearly inconsistent with the ordinary meaning reflected, for example, in a dictionary definition . . . the inconsistent dictionary definition must be rejected.").

109 Alloc, Inc., 342 at 1368 (emphasis added); accord Genzyme Corp. v. Transkaryotic Therapies, Inc., 346 F.3d 1094, 1098 (Fed. Cir. 2004) ("In other words, a patent applicant may consistently and clearly use a term in a manner either more or less expansive than its general usage in the relevant community, and thus expand or limit the scope of the term in the context of the patent claims." (citing Ballard Med. Prods. v. Allegiance Healthcare Corp., 268 F.3d 1352, 1361 (Fed. Cir. 2001); Middleton, Inc. v. Minnesota Mining & Mfg. Co., 311 F.3d 1384, 1388 (Fed. Cir. 2002)).

110 See SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1344 (Fed. Cir. 2001) (holding the written description of the preferred embodiment "can provide guidance as to the meaning of the claims, thereby dictating the manner in which the claims are to be construed, even if the guidance is not provided in explicit definitional format"); Vitronics 90 F.3d at 1582 ("The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." (emphasis added)).

--- End Footnotes ---

Inline argues only that "high frequency band" is "frequencies above the highest voice band" and defendants argue that the court's prior construction of "frequencies above the telephone voice band between the range of 1 and 30 MHz" is correct. Because the court concludes that neither party's position is correct, this leaves it to the court to determine the proper limits of the term "high frequency band" on its own. These limits can be ascertained from the intrinsic record and do not require consideration of extrinsic evidence.

Inline notes that the specifications of the '596 line of patents, recite: "to minimize the highest frequency used for transmission, it is recommended that the first channel be placed as close to the voiceband as feasible . . . ." 111 Examination of the specifications reveals the lowest "feasible" frequency contemplated by the patentee. Under the heading "Minimum Frequency," the following preferred embodiments are described: "if AM is used to transmit video signals, it is preferred that the picture carrier of the first such channel be located above 4.25 Mhz" 112 and "for FM transmission, it is preferred that the low end of the first channel be 4 Mhz." 113 These embodiments contemplate transmission of multiple channels above the voice band. The transmission of multiple channels is clearly the goal of the inventions. 114 The patents also describe more limited embodiments which are only capable of transmitting a single signal, however, and these embodiments recite the lowest transmission frequencies described in the '596 line of patents.

--- Footnotes ---

112 '596 patent, 19:28-30.

113 '596 patent, 19:43-44.

114 '596 patent, 1:23-24 ("The present invention relates to a system for simultaneous two-way communication of video
In a section titled "Transmitting a Single Video Signal over Long Transmission Lengths (FIGS. 3A-3C)," the specifications state that "in these types of situations, use of extended pairs 405 to communicate multiple signals over a large frequency range many not be feasible. A system that communicates only a single video signal, however, can still be very useful in many important applications." The embodiments capable of transmitting only one video channel described in this section of the specifications represent the outer limit of transmission that is feasible. In discussing these outer-limit transmissions the patents describe "using frequencies below the lower limits suggested [in the "Minimum Frequency" section."] The patents state, with respect to figures 3a and 3c, that "there is room to transmit a narrow band of control signal between the voiceband and the video signal." The lowest frequency at which video signals are transmitted is 1 MHz and is illustrated in figure 3a. "Figure 3a shows the spectrum of such signal. The carrier frequency is 1.25 Mhz, with the lower sideband substantially suppressed below 1 Mhz."

This court is mindful of the Federal Circuit's admonition not to read limitations from patent specifications into the claims as well as that court's acknowledgment that there is "sometimes a fine line between reading a claim in light of the specification, and reading a limitation into the claim from the specification." For instance, in Comark the Federal Circuit determined that defendant's proposed construction seeking to limit the disputed term "to its functional purpose as disclosed in the preferred embodiment" was an improper attempt to read limitations from the specification into the claims. Conversely, the patents in this case make clear that the 1 MHz lower limit of video transmission of a "high band of frequencies" does not merely represent a functional purpose of a preferred embodiment. The patent states that "one of the disadvantages of lower frequencies is that the filtering that separates these signals from voiceband signals is more expensive because of the sharp cutoff required between the upper end of the voiceband and 1 Mhz." Rather than fulfilling the functional purpose of this embodiment, the specification makes clear that 1 MHz is a functional limitation of the invention. Therefore, the court concludes that lowest feasible frequency at which the invention can transmit "high frequency band" video signals is 1 MHz.

This court recognizes that it must interpret the claims in light of the specification, . . . yet avoid impermissibly importing limitations from the specification. . . . That balance turns on how the specification characterizes the claimed invention. . . . In this respect, this court looks to whether the specification refers to a limitation only as a part of less than all possible embodiments or whether the specification read as a whole suggests that the very character of the invention requires the limitation be a part of every embodiment." (emphasis added) (citations omitted)).

120 Comark, 156 F.3d at 1187.

This case is likewise distinguishable from the Federal Circuit's recent decision in Gemstar-TV Guide Int'l, Inc. v. ITC, 383 F.3d 1352, No. 03-1052, 2004 WL 2059279, at *10 (Fed. Cir. Sept. 16, 2004). There, the defendant argued that the claim limitation "visual identification" recited in one of the patents at issue was limited to "an innovative cursor" based on language in the written description which stated "an innovative cursor 32 . . . for the irregular array . . . is required which satisfies several conflicting requirements." Id. at *8-*9 (emphasis added). The Federal Circuit rejected that argument stating that "in the context of the disclosure of the preferred embodiment of the '204 patent, the statement that 'innovative cursor 32 . . . is required,' is not the 'use [of] words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope.' . . . Properly read . . . the statement merely conveys the advantages of 'innovative cursor 32' over prior art conventional cursors in the preferred embodiment." Id. at *10 (citations omitted) (alteration in original). Here, the "sharp cutoff required" below 1 MHz is not recited as a comparison to prior art. Also, while described as one of three "disadvantages" of the embodiment illustrated in figure 3a, this disadvantage was not one which might be overcome with stronger filtering or would merely be more expensive; the 1 MHz limit is a functional requirement. Cf. '596 patent, 25:65-26:4 (The patents describe two disadvantages of the lower frequency transmissions illustrated by figure 3a, in addition to the "sharp cutoff required" below 1 MHz: "[a] second disadvantage is that the harmonics of the telephone signals at lower frequencies are stronger, meaning that stronger filtering of the harmonics is required to protect against interference from these signals. A third disadvantage is that the modulation electronics becomes more expensive as the picture carrier approaches DC.").

As discussed above, it is reasonable to conclude that the control signal described in figure 3a is also included in the "high frequency band." The lower limit of this "narrow band" of signals is 0.25 MHz. Again, this appears to be the lowest limit at which it is feasible to transmit a "high frequency band" control signal. Other than Inline's insistence that the "high frequency band" includes all frequencies above the voice band, which the court has rejected, plaintiff has not pointed to any intrinsic evidence which contradicts this conclusion. 124

 Inline notes that "the upper end [of the high frequency band] . . . was not discussed by either party in the Markman briefs . . . ." 125 The failure of the parties to present arguments regarding the upper end of the high frequency band is undoubtedly due to the fact that the accused products operate at a range near the voice band and, therefore, the parties likely view the upper range of the high frequency band to be irrelevant to the question of infringement presented in these proceedings. Because the parties provided no argument at all concerning the appropriate upper limit of the "high frequency band," the court determines that it is unable to define a precise upper limit on this disputed term.
3. The Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Voice Band" for the '718 Patent

Although the court previously construed "high frequency band" as having the same meaning in both the '596 line of patents and the '718 patent, after a thorough review of the parties' arguments and the patents-in-suit, the court concludes that "high frequency band" must be construed more narrowly for the '718 patent than for the '596 line of patents. Having already determined that the ordinary and accustomed meaning of "high frequency band" is "the range of radio frequencies between 3 MHz and 30 MHz," the court must determine whether the intrinsic evidence demonstrates that the patentee used that term more or less expansively in the '718 patent. 126

--- Footnotes ---

126 The court notes again that the disputed language in the '718 patent, "a high band of frequencies above a telephone voice band," is a slight variation of the disputed language in the '596 line of patents, "a high frequency band of frequencies above the highest frequency of the telephone voice band." Neither party argued that this distinction was relevant to the court's construction of those phrases and stated that "high band of frequencies" and "high frequency band" are interchangeable and mean the same thing. See footnote 26, above.

--- End Footnotes ---

As described above, defendants' opening Markman brief argued for a construction of "high frequency band" in the '718 patent as limited to those frequencies above 6 MHz and for a construction of that phrase in the '596 line of patents as limited to those frequencies above 1 MHz. Defendants then changed their proposed constructions and argued at the Markman hearing for one construction of "high frequency band" to be applied to all of the patents-in-suit. The court's review of the record reveals that, with respect to the '718 patent, defendants' initially-proposed construction is correct. 127

--- Footnotes ---

127 Plaintiff had full opportunity to present arguments as to why it opposed this construction and, as plaintiff stated at the Markman hearing, the constructions set forth in defendants' opening Markman brief are those plaintiff was prepared to argue against at the Markman hearing.

--- End Footnotes ---

In support of that construction, defendants' opening Markman brief pointed to language in the '718 patent which states that governmental regulations restrict transmission of non-telephone signals below 6 MHz in the system described. Defendants also pointed out that the '718 patent specifically distinguishes the Tatsuzawa prior art patent on the basis that Tatsuzawa uses frequencies between 0 and 4 MHz, which "creates legal problems" 128 that are avoided by the invention described in the '718 patent.

--- Footnotes ---

--- End Footnotes ---

Plaintiff never specifically responded to either of defendants' arguments concerning the '718 patent's distinguishing of the Tatsuzawa prior art patent or that patent's references to regulations restricting transmission of signals below 6 MHz. In its opening Markman brief, Inline cited the '718 patent's statement that:

The technique disclosed herein embodies an extension designed to avoid interference with telephone signals. The extension calls for the frequency of the electrical version of the control signals to be converted to a higher band before transmission across the wiring. This band will be high enough to eliminate interference with the telephone or low-frequency communication signals. 129
Inline argued that:

It is clear from the above language that all of the patents contemplate selecting frequencies for the "high frequency band" that are sufficiently separate from the voice band to avoid causing interference with the telephone signals in the voice band during shared transmission on telephone wiring. The precise choice of frequency above the voice band is not important to the invention as long as interference is avoided with the voice band. 130

Inline contended that "there is no support in the plain language of the claims or the intrinsic evidence [to impose a 6 MHz lower limit]." 131

--- Footnotes ---
129 D.I. 189 at 12 (quoting '718 patent, 13:22-31 (emphasis added by Inline)).
130 Id. at 13.
131 Id.
--- End Footnotes ---

In its responsive Markman brief, Inline argued that "the patents explicitly teach putting high frequency bands as low as possible and as close as possible to the telephone voice band to avoid signal attenuation . . . [and that] Defendants' construction would create a gap of between [sic] frequencies that is contrary to the teaching of the patents." 132 Inline responded to defendants' argument that, for the '596 line of patents, "high frequency band" should be construed as limited to frequencies above 1 MHz by pointing out that such construction would exclude the preferred embodiment illustrated in figure 3a of the '596 line of patents. 133 Again, Inline did not respond to defendants' arguments regarding regulations restricting transmission of signals below 6 MHz and the Tatsuzawa prior art patent.

--- Footnotes ---
132 D.I. 197 at 18.
133 Id.
--- End Footnotes ---

Moreover, Inline failed to address directly those arguments at the Markman hearing. Inline merely stated that "a six megahertz barrier . . . is an example[, and all the '718 patent is] talking about is you configure these frequencies in a lot of ways, and here's one example [of] how you can do that …" 134 Giving plaintiff the benefit of the broadest reading possible of that statement, Inline might be understood to contend that defendants' proposed construction would improperly read the description of a preferred embodiment limitation from the specification into the claims. Even that reading is unavailing. References in the '718 patent to the 6 MHz limitation are not descriptions of a preferred embodiment selected by the patentee; they are descriptions of a restriction imposed by government regulations. The '718 patent specifically references this restriction three times.

--- Footnotes ---
134 D.I. 207 at 246.
--- End Footnotes ---

The first reference is in connection with a discussion of the Tatsuzawa prior art patent. The Tatsuzawa invention is described as:
depending on electrical characteristics particular to frequencies between 0 and 4 Mhz, limiting the transmission of frequency to that band. This creates legal problems because in the U.S., for example, regulations severely limit the RF energy below 6 Mhz that can be fed to wiring that is connected to the public telephone network. 135

135 '718 patent, 3:16-21 (emphasis added).

Next, the patent reiterates that there can be "legal problems" pertaining to electromagnetic radiation created when video signals are transmitted across telephone wiring. 136 The patent states that these legal problems are avoided by transmitting video signals above 6MHz: "in contrast to regulations covering radiation, no specific legal problems are created in the U.S. by the connection of radio frequency devices to the public telephone network if those devices do not transmit energy below 6 Mhz." 137

136 '718 patent, 9:51-55.

Finally, in discussing control signals, the '718 patent again references the regulations concerning transmission of energy below 6 MHz but notes that those regulations are not a problem for the invention described therein because "the U.S. Federal Communications Commission imposes no restrictions on signals above 6 Mhz, leaving ample room [for transmission of a control signal] between that frequency and the video signals, even if a channel below VHF 2 is used." 138

138 '718 patent, 13:52-57 (emphasis added).

The '718 patent, therefore, identifies 6 MHz as the lower limit of frequency transmission permitted by government regulations and not a merely as an example of a limitation described as part of a preferred embodiment which should not be read into the claims. This restriction is described as affecting both transmission of video and control signals. Furthermore, nothing in the intrinsic record contradicts this conclusion and no preferred embodiments are read out of the patent as a result of defining 6 MHz as the lower limit of the "high frequency band." In fact, the preferred embodiments described in the '718 patent describe transmission of video signals at frequencies significantly higher than 6 MHz.

The patent states that "the most natural choices for transmission frequencies are the channels in the low VHF range . . . [which are] VHF channels 2 through 6, which extend from 54 Mhz to 88 Mhz." 139 The lowest frequency band at which the inventors conducted video-transmission experiments was in the channel spanning from 24 MHz to 30 MHz. 140 With regard to control signals, the preferred embodiment describes transmission of a control signal at 10.7 MHz. 141 As noted above, however, the specification indicates that control signals can be transmitted in a range between 6 MHz and the lower limit of a transmitted video signal. Nowhere does the specification suggest transmission of any video or control signal below 6 MHz. 142

139 '718 patent, 10:60-63.

142 See '718 patent, 21:1-3 (In describing "Systems for RF Conversion to Achieve Transmission below VHF Channel 2," the specification states that "at the video source end, the transceiver must convert the signal from the frequency at which it is supplied to a band between 6 Mhz and 54 Mhz." (emphasis added)).

In light of plaintiff's deafening silence in response to defendants' specific argument regarding the government regulations restricting transmissions below 6 MHz, the court can only assume it had no viable argument to make. The court therefore concludes from this silence, and its review of the intrinsic evidence, that the lower limit of the "high frequency band" claimed in the '718 patent is 6 MHz. As with the '596 patent, the parties failed to present any argument concerning the upper limit of the "high frequency band" claimed in the '718 patent. This failure again precludes the court from defining the upper limit of "high frequency band" other than to note that the '718 patent includes several examples of transmission at frequencies above the limit of 30 MHz to which the court's prior construction limited this phrase. 143

Consequently, the court construes "high frequency band" as claimed in the '718 patent to mean "frequencies above the telephone voice band between 6 MHz and an undetermined upper limit." 144

143 See, e.g., '718 patent, 10:60-67; figure 3.

144 If the parties wish to present arguments to the court concerning the upper limit of the phrase "high frequency range" for any of the patents-in-suit, they may notify the court of this desire and a briefing schedule will be determined at that time. If the parties ultimately submit further briefing on the upper limit of "high frequency band" as claimed in the '596 line of patents, the court directs the parties' attention to the following language in those patents:

At higher frequencies, the 10 dB advantage of a 15 MHz FM signal may not be sufficient to overcome the extra attenuation. The solution, in that case, is to use wider FM bandwidths which produce a greater SNR improvement at the receiver. This, of course, brings one to even higher frequencies more quickly with each channel that is added. Because of this, the inventors expect that higher frequencies will not be useful beyond some point, and certainty not beyond 1000 Mhz." '596 patent 21:12-20 (emphasis added). Referencing this statement, the specification acknowledges that "as mentioned above, there is an upper limit to the frequencies that can be useful for transmission of signals across a transmission path of a given length." '596 patent 21:62-64 (emphasis added).

Any submissions should address this language and its effect on the parties' analyses.

VI. CONCLUSION

For the reasons set forth above, the court modifies its prior construction of the disputed terms of the patents in suit as follows:

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>Court's Construction</th>
</tr>
</thead>

frequencies" (596 line of patents)

"a high band of frequencies above a telephone voice band of frequencies"; "high frequency band"; and "high band of frequencies"

(718 patent)

1937

(2) high bandwidth bus

National asserts that this term does not need construction. N-Data and Dell agree on the general definition, but disagree as to the examples listed. N-Data incorporates all of the Dell examples and adds two additional ones—FDDI-II and P1394. The court agrees with N-Data; if multiple examples are incorporated into a definition, it would be misleading to exclude others when there are only a few that are excluded, as in this case. N-Data references two instances in the intrinsic record in which the patent expressly provides for two additional examples. See ’395 Patent, col. 3, ll. 42-43; U.S. Patent App. No. 07/969,916, col. 32, ll. 15-18.

Accordingly, the court defines "high bandwidth bus" as "a bus having a bandwidth capable of transmitting the collective isochronous data streams arriving from all nodes connected to a hub, e.g., a time slot interchange, "TSI" ring, FDDI-II, and P1394."

1938

24. High bandwidth external interface

The plaintiff argues that "high bandwidth external interface" means "an interface between the media processor and external sources of data capable of operating at or near a rate that maintains substantially peak operation of the media processor."

The defendants urge that "high bandwidth external interface" means "an interface between the media processor and external sources of data that operates at or near the peak data throughput rate of the execution units [sic] of the media processor."

The court construes "high bandwidth external interface" to mean "an interface between the media processor and external sources of data that is capable of operating at or near the peak data throughput rate of the execution unit of the media processor."

1939

4. high contrast (’028 patent)

CEA contends that this term does not require construction, but provides a proposed construction of: "a luminosity ratio between the on and off states of at least about 10:1."

Samsung argues that "high contrast" is indefinite. It contends that "contrast" is the ratio of light intensity in the bright state to light intensity in the dark state of a liquid crystal cell and that the ’028 patent does not provide information regarding what "high" means.

At oral argument, Samsung stated that if the court accepts its proposed construction of "means for polarizing" and "thickness of the [liquid crystal] layer" for the ’028 patent, it agreed with CEA that this term does not require construction. Having agreed with those definitions proposed by Samsung, the court determines that no construction of this term is necessary.

- 2311 -
Lucas claims that the Court erred as a matter of law by holding that this claim language means "that the voltage converter produces a high DC output voltage to some value relatively greater than the convertor input." Lucas Aerospace Ltd. v. Unison Industries, L.P., 890 F. Supp. 329, 1995 WL 362387 at *12. Lucas contends the Court's construction of this language is in error because "had Unison intended the 'high' [DC output voltage] to be in reference to the 'low' voltage from the system source, then the proper way to draft the claim language would have been to use the term 'relatively high voltage.'" D.I. 394 at 15. Lucas also argues that because Unison used a relative term in the claim language, the Court must refer to the patent specification to interpret this disputed claim language. Id. at 16. Finally, Lucas argues that the Court must define the phrase "high DC output voltage" in reference to the preferred embodiment because "no other element of claim 1 addresses a boosting of the voltage to obtain the high voltage that is required to fire the plug." Id. at 17.

These arguments fail to demonstrate that the Court has erred in its interpretation of this claim language. First, Lucas offers no valid support for its proposition that "the proper way to draft the claim language would have been to use the term 'relatively high voltage.'" Id. at 15 (citing Steven A. Becker, Patent Applications Handbook 1995 Edition, Section 6.04(4] at 6-31 (1995 ed.)). As Lucas's citation to the Patent Applications Handbook suggests, when the patentee uses relative language in the patent claims, the relative language must have a point of reference for comparison. Claim 1 of the '073 patent provides a comparator for the 'high DC output voltage,' the voltage converter input received from the system source. '073 Patent, col. 15 at In. 66-68. Lucas's suggestion that Unison should have used the term 'relatively' to connote a comparison between the voltage converter output and the voltage converter input does not change the meaning of the claim language. Contrary to Lucas's suggestion, if the claim had read "a voltage converter for receiving a relatively low voltage from a system source and converting it to a relatively high DC output voltage output," the word 'relatively' would modify 'low' and 'high' in the phrase but would not provide any further datum to compare the voltage converter inputs and outputs. Furthermore, when the claim uses the phrases 'relatively slow current rise,' id. col. 16 at In. 17, and 'relatively fast di/dt,' id., col. 16 at In. 21-22, the word 'relatively' does not provide a point of reference for the comparison between the two values but modifies the rate of current rise, or 'di/dt,' just as the words 'fast' and 'slow' do.

The Court's construction of the claim also comports with language from the Patent Applications Handbook that Lucas omitted from its brief. According to the Patent Applications Handbook at 6-32 "the language, 'said inverter having a threshold within the range of .4 to .7 volt' would be favorably received by the examiner. However, this limitation is usually excessively narrow. It would be preferable to define the threshold as being relative to another level in the claim, e.g., 'said first inverter having a threshold higher than that of second inverter.'" That is exactly what Unison has done in this claim. In sum, the Court finds nothing ambiguous about this claim language that requires reference to the specification.

Citing Intervet America, Inc. v. Kee-Vet Lab., Inc., 887 F.2d 1050 (Fed. Cir. 1989), Lucas nevertheless urges the Court to interpret the claim language in light of the patent specification because the disputed claim language contains a relative term. Intervet America, Inc. v. Kee-Vet Lab. stands for a different proposition. Far from requiring a quantitative definition of all relative terms by reference to the specification, the Intervet America court found that the district court erred by reading a relative limitation into the claim that "meant nothing without knowing the reference point from which attenuation [the extraneous limitation] is being measured." Id. at 1055; see also id. ("Here again,...the court was reading limitations into the claims which cannot be found there;...it was reading them in from remarks made by the attorney in the course of arguing distinctions from a cited reference. We have set forth the asserted claims in full above and it is clear that they make no reference whatever to attenuation."). Furthermore, even if Intervet America did stand for the proposition cited by Lucas, Lucas's suggested reference to the patent specification does not support its position that "800 volts [the Lucas devices' voltage converter output] could never qualify as a 'high output voltage.'" D.I. 394 at 16 (citing '073 Patent, col. 1 at In. 47). Column 1 line 47 discusses 1000 volts as a low voltage for creating sparks at the igniter plug. In contrast, the claim language at issue involves low voltages coming from a system source and not low voltages for igniting sparks; the phrase 'low voltage' when used in the context of igniting fuel simply does not relate to the system source voltage. See also Lucas Aerospace, Ltd. v. Unison Industries, L.P., 890 F. Supp. 329, 1995 WL 362387 at *3 (noting that most aircraft electronic supply voltages are 28 volts, which, when compared to either 1,000 or 2,500 volts, is 'low').
Finally, in a refinement of its earlier arguments, Lucas contends the phrase 'high DC output voltage' and the phrase 'a high voltage,' as used in the fifth element of the '073 patent, must have the same values because '073 patent inventor John Frus testified that his invention, or at least the preferred embodiment of his invention, uses approximately the same voltage at the plug as is produced at the voltage converter. The structure of claim 1 belies this assertion. First, if the patentee had desired that these two phrases have the same meaning, the patentee would have used the phrase "the high DC output voltage (or the high voltage from the voltage converter) appears across the gap of the igniter plug…." Cf. Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987) ("There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims") (discussing the doctrine of claim differentiation).

Second, and more importantly, claim 1 of the '073 is an open-ended claim comprised of a series of elements. As such, if an allegedly infringing device contains all of these elements, that device would be considered to infringe the patent, even if the device includes additional structures. Amstar Corp. v. Envirotech Corp., 730 F.2d 1476, 1482 (Fed. Cir.) ("Modification by mere addition of elements of functions, whenever made, cannot negate infringement") (citations omitted), cert. denied, 469 U.S. 924, 83 L. Ed. 2d 240, 105 S. Ct. 306 (1984). An additional structure to boost the voltage converter output to a higher voltage as seen at the igniter plug is not precluded by the language of claim 1. In sum, Lucas has not demonstrated that the Court has erred as a matter of law in its construction of the phrase "high DC output voltage."

1941

High Density Memory Array

The Court next addresses the term "high density memory array" in claim 23 of the Edwards patent. ST proposes that the term mean "a memory array having a large number of memory cells for a given area." ST's proposed construction mirrors the plain language of the term and illustrates that none of the four words in this term have a meaning of ordinary skill in the art would not understand. In contrast, Motorola proposes that the Court construe the term to mean: "an array of high density memory cells. 'High Density' memory would have been understood by one of ordinary skill in the art in the early 1980's as including high impedance resistive load SRAM, DRAM, thin film transistors and three-transistor memory cells, but not including depletion transistor loads or complimentary pull-up transistors." Whereas ST’s proposed construction simply reflects the plain meaning of the term's four words, Motorola's construction requires importing limitations from the specification and speculating on what a person of ordinary skill in the early 1980's would have thought.

The Court adopts ST's proposed construction. First, as noted above, the Court finds that ST's proposed construction mirrors the plain and ordinary meaning of the term's words. Sunrace Roots Enter. Co., LTD v. SRAM Corp., 336 F.3d 1298, 1302 (Fed. Cir. 2003) (finding a "heavy presumption" that claim terms carry their ordinary and customary meaning which is only rebutted if the patent "expresses an intention to impart novel meaning to [them]"). Second, although the specification does mention the limitations that Motorola would import, the Court finds that those limitations are examples rather than a disclaimer of claim scope. To support its construction, Motorola cites specification language declaring "this example uses static RAM cells (SRAM) using high impedance resistive load SRAM, DRAM, thin film transistors and three-transistor memory cells, but not including depletion transistor loads or complimentary pull-up transistors." Whereas ST’s proposed construction simply reflects the plain meaning of the term's four words, Motorola's construction requires importing limitations from the specification and speculating on what a person of ordinary skill in the early 1980's would have thought.

Finally, in a refinement of its earlier arguments, Lucas contends the phrase 'high DC output voltage' and the phrase 'a high voltage,' as used in the fifth element of the '073 patent, must have the same values because '073 patent inventor John Frus testified that his invention, or at least the preferred embodiment of his invention, uses approximately the same voltage at the plug as is produced at the voltage converter. The structure of claim 1 belies this assertion. First, if the patentee had desired that these two phrases have the same meaning, the patentee would have used the phrase "the high DC output voltage (or the high voltage from the voltage converter) appears across the gap of the igniter plug…." Cf. Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987) ("There is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims") (discussing the doctrine of claim differentiation).
8. "material having a high electrical resistance"

This phrase is found in Claims 1 and 16. Plaintiff argues that this phrase should be construed as "a metal, alloy or other material, such as tungsten, molybdenum or Elkonite (copper-tungsten alloy) having a higher electrical resistance than copper." Defendants assert that the phrase need not be construed, and the Court agrees. Because the Court sees no ambiguity as to the meaning of the phrase "material having a high electrical resistance" and because its ordinary and customary meaning is clear to one skilled in the art, the Court declines to construe the phrase as it is used in the '015 Patent.

3. Application to the Instant Action

Judge Sotomayor construed "high frequency" to encompass 54 to 216 MHz, "received by conventional television receivers of the time." The opinion indicates that the "conventional television receivers" meant in the definition were those found in the United States. IPD II, 1998 U.S. Dist. LEXIS 3901, 1998 WL 142346, at *5. Cablevision and TCI assert that "high frequency" means 3 to 30 MHz. (Defs.' Br. at 5.) In short, defendants' interpretation is based on the assertions that (1) the ordinary and accustomed meaning of "high frequency" is 3-30 MHz; (2) the specification is consistent with that definition; (3) the prosecution history confirms the definition; and (4) the Canadian prosecution history and other evidence affirm that definition.

IPD and CPL contend that "high frequency" should maintain the definition as construed: 54-216 MHz. (Pls.' Br. at 1.) IPD and CPL assert that Judge Sotomayor interpreted the claim based upon intrinsic evidence, yet also assert that the Court relied on the testimony of the parties' experts. (Pls.' Br. at 3.) IPD and CPL conclude that because the definition was based on intrinsic evidence, it should not be altered by Cablevision and TCI's new extrinsic evidence.

4. The Intrinsic Evidence

a. The '202 Patent Claims

The 202 patent never defines "high frequency." Although Claim 1 employs the phrase three times, it does not provide a definition. (202 Patent, col. 4, ll. 18, 22, 26.) Nor does Claim 1 imply which frequency range was meant by "high frequency." For example, Claim 1 states that the "high frequency carrier radio wave signals modulated with video broadcast signals" are applied to a "conventional television receiver without further processing" by way of a "means coupling" the signals from the receptor position to the subscriber stations. (202 patent, col. 4 ll. 24-31.) This phrase is ambiguous because the claim fails to specify the frequencies such a television could receive, and whether the term "conventional television" refers to one found in the United States or in England, where Mr. Cutler and IPD resided and the invention originated. A person skilled in the art would recognize that while the patent was prosecuted in the United States, the claims might refer to an English television.

In addition, it is unclear whether the word "receiver" is used to indicate that the television acts as a device that "receives" the signal, or, alternatively, that the signal is applied to a receiver device in the television itself.
b. The Ordinary Meaning of "High Frequency"

Because the claims do not specify the frequency range, one skilled in the art would presume that "high frequency" would have its ordinary meaning, unless the patent applicant clearly assigns a different meaning to the term. See Vitronics Corp., 90 F.3d at 1582 (citing Hoechst Celanese Corp., 78 F.3d at 1578). Thus this Court reviews "the specification to determine whether the inventor has used [the term] in a manner inconsistent with [its] ordinary meaning." Vitronics, 90 F.3d at 1582 (citing Markman, 52 F.3d at 979).

One skilled in the art at the time of the application would have understood "high frequency" in the 202 patent to mean 3-30 MHz. A technical dictionary published in 1974 defines the term as "Federal Communications commission designation for the band from 3 to 30 MHz in the radio spectrum. Abbreviated HF." (Sirota Decl. Ex. 4: Dictionary of Scientific and Technical Terms 690 (Daniel N. Lapedes ed., McGraw-Hill 1974).) Similarly, a radio frequencies table lists high frequency as covering 3 to 30 megacycles. (Sirota Dec. Ex. 4: Webster's Seventh New Collegiate Dictionary 705 (G.& C. Merriam Co. 1967)(1961).)

In addition, CPL's statements to the Canadian patent examiner provide further understanding of how one skilled in the art would regard the term "high frequency" in 1976. Although varying legal and procedural requirements for obtaining patent protection in foreign countries might render consideration of certain types of representations inappropriate, instructions to foreign counsel and representations to foreign patent offices must be considered when such matters comprise relevant evidence. Caterpillar Tractor Co., 714 F.2d at 1116 (citing Stratoflex, Inc. v. Aeroquip Corp., 713 F.2d 1530, 1538-39 (Fed. Cir. 1983)); see also Tanabe Seiyaku Co. Ltd. v. U.S. Int'l Trade Com'n., 109 F.3d 726, 733 (Fed. Cir. 1997) (noting that statements made to foreign patent examiner by inventor were indicative of understanding of one skilled in the art).

Both the Canadian Patent Office and the U.S. PTO require an applicant to distinguish the claimed invention from the prior art. (See Sirota Decl. Ex. 14: Canadian Patent Office Examiner's Report at 2 (rejecting claims as obvious in light of prior art); 35 U.S.C. § 102.) IPD's patent application in Canada as of November 7, 1977 corresponded with the 202 patent's application in the United States. (See Sirota Decl. Ex. 15: Nov. 7, 1977 Response.) Thus, the discussion of prior art in the Canadian prosecution is relevant to claim interpretation in the instant action. See Caterpillar Tractor Co., 714 F.2d at 1116.

In its communications with the Canadian patent examiner, CPL made it clear that one skilled in the art would understand "high frequency" to mean 3-30 MHz. In response to an Office Action rejecting Claim 1, IPD referred to its invention as "h-f", (Sirota Decl. Ex. 17: May 31, 1978 Response), and classified high frequency as 3-30 MHz. (Sirota Decl. Ex. 19: Oct. 3, 1978 Response.) While distinguishing its invention from U.S. Patent No. 3,617,750 ("the Walker patent"), IPD represented that these systems must be in the very high or ultra high frequency range in view of the bandwidth occupied by a single television signal. The F.C.C. Official designation of frequencies classifies high frequency as covering 30-300 MHz [sic, 3-30 MHz] and classifies very high frequency as covering 30 to 300 MHz. Thus, the system set forth by Walker is completely different in its conception from that of the present invention.

(Sirota Dec. Ex. 19: Oct. 3, 1978 Response.) 5 Moreover, to avoid rejection based on obviousness in light of the very high frequencies employed by the prior art, IPD defined the range denoted by "high frequency" as that pertaining to televisions receptive to the 3-30 MHz range, such as the "HF systems which have found wide application in, for example, the United Kingdom. . . . Persons experienced in the wired CATV business would not however fail to appreciate the significance of the term 'high frequency'" (Sirota Decl. Ex. 19: Oct. 3, 1978 Response.) Lastly, to distinguish itself from the prior art, CPL advised the Canadian examiner that "the new claims are distinguished from the prior art which does not suggest H.F. carry a modulation." (Sirota Decl. Ex. 15: Nov. 7, 1977 Response.) In sum, in prosecuting its patent in Canada, CPL asserted that the ordinary meaning of "high frequency" was 3-30 MHz, and relied upon that definition to demonstrate that one skilled in the art would understand the invention of the 202 patent to employ carriers with a frequency of 3-30 MHz.

5 IPD later corrected the phrase to define high frequency as 3-30 MHz. (See Sirota Decl. Ex. 20: Letter.)
c. The Specification

The 202 patent does not define "high frequency" at variance with the ordinary meaning of 3-30 MHz. In describing the prior art upon which the 202 patent improves, the specification states that in one wired broadcasting system, "commonly the range of frequencies employed extends throughout the VHF spectrum, for example, from about 40-300 MHz." (202 patent at col. 1, ll. 14-16.) Thus the patent equates VHF, or very high frequency, with frequencies from about 40 to 300 MHz. In the following description of prior art, the specification states that "commonly the signals all have the same nominal carrier frequency somewhere in the range 2-20 MHz." (202 patent col. 1, ll. 24-26.) Thus the patent does not equate the 2-20 MHz range with VHF. In its critique of the prior art operating in the 40-300 MHz range, the patent attributes "relatively high" transmission losses to the "frequencies involved," (202 patent col. 1, ll. 29-31), and then asserts that the invention in the 202 patent is an improvement that minimizes "the disadvantages of the currently known systems." (202 patent col. 1, ll. 39-41.) Thus, the VHF range, with its attendant transmission losses will be improved upon in the 202 patent. One skilled in the art could interpret this stated improvement over the prior art to mean that the disclosed invention would not use the VHF 40-300MHz range, as a way to avoid the transmission losses. Thus, the specification loosely implies that "high frequency" would not be 40-300 MHz.

In explaining Figure 1, the specification notes that "in the event that said signals are high frequency modulated carrier waves the output signals provided by the photosensitive detectors 6, 7, may be of a form suitable for direct application to the television receivers 10, 11 if these are of a type designed for use in high frequency wired broadcasting systems." (202 patent col. 2, ll. 53-58)(emphases added.) That tentative language, including "in the event," "may" and "if," provides no guidance; the sentence fails to clarify whether the television receiver is "conventional" as described in Claim 1, or to state the frequency range for the television receivers.

The description of Figure 2 contains similarly indefinite language: "In this system it is convenient to arrange that the modulation signals applied to the line 15 comprise high frequency modulated carrier waves. In this event, the launching amplifier 19 and receivers 21, 22 may be of the kind presently employed in high frequency wired broadcasting systems. " (202 patent col. 3, ll. 6-11.) (emphases added.) That language of contingency makes it difficult to determine the MHz range of "high frequency." By referring back to the patent's description of the prior art, one might speculate that Cutler is referring to frequencies outside the 40-300 MHz range. But language inviting conjecture does not clearly define the term such that one skilled in the art would disregard the term's customary meaning. See Vitronics Corp., 90 F.3d at 1582 (citing Hoechst Celanese Corp., 78 F.3d at 1578). 6 In sum, the specification does not clearly imply or express a special definition for the term "high frequency."

6 In other instances, the specification uses the term "high frequency" without adding further clarification of its meaning. (See 202 patent col 2, ll. 4-6, 35-36, 49.)

d. The Prosecution History

During the prosecution of the 202 patent, Cutler, through his attorney, amended Claim 1 to include the phrases "a high frequency carrier in the range 40-300 MHz" and "conventional television receivers at the subscriber stations responsive to receive high frequency carriers in the range of 40-300 MHz." (Declaration of Neil P. Sirota in Support of Defendants Telecommunications, Inc.'s and UA-Columbia Cablevision of Westchester, Inc.'s Omnibus Motion for Summary Judgment ("Sirota Decl.") Ex. 5: August 10, 1977 Amendment at 2.) The Remarks portion of the amendment does not directly discuss that new definition. (Sirota Decl. Ex. 5: Amendment at 3-6.) Nine days later, Cutler retracted the amendment by deleting "in the range of 40-300 MHz." (Sirota Decl. Ex. 6: August 19, 1977 Supplemental Amendment at 2.) The Remarks section states "upon review of the amendment filed August 11, 1977, it is not seen that the Specification would adequately support the particular frequency range stated. . . It is not seen that this specific change will affect the patentability other than as above stated." (Sirota Decl. Ex. 6: Supplemental Amendment at 2.) For purposes of patentability, then, Cutler disclaimed the 40-300 MHz frequency range. During claim construction, a patent owner cannot expand the meaning of a claim to recapture subject matter disclaimed during prosecution. See Southwall Techs., 54 F.3d at 1576, Festo Corp., 234 F.3d at 576 (claim
amendments "must be strictly construed against the inventor and in favor of the public, and looked upon as in the nature of disclaimers." (citing Hubbell, 179 U.S. at 82). Therefore, in the 202 patent, "high frequency" does not include 40-300 MHz.

The prior Markman decision in this action acknowledged the ambiguity surrounding Cutler's retraction of 40-300 MHz; the Remarks do not provide a detailed rationale for the retraction, nor do they specify which MHz range corresponds with the specification. IPD II, 1998 U.S. Dist. LEXIS 3901, 1998 WL 142346, at *5 n.3. Indeed, "the Remarks standing alone do not definitively answer what 'high frequency' means as recited in Claim 1." IPD II, 1998 U.S. Dist. LEXIS 3901, 1998 WL 142346, at *5 n.3. However, the new evidence related to the August 1977 amendment and retraction, and the clarification of extrinsic evidence's role in claim construction as set forth in Pitney Bowes confirm that "high frequency" means 3-30MHz in the 202 patent.

5. The New Extrinsic Evidence

In an effort to clarify the definition of "high frequency", TCI and Cablevision offer evidence regarding the prosecution of the 202 patent that surfaced after the Court issued its claim construction. (Defs.' Br. at 7-9.) CPL directed the prosecution of the 202 patent, (Sirota Decl. Ex. 21: Kenneth C. Quinton Depo. at 116: 11-19), by directing its U.S. patent prosecutor through its British patent agent. In a letter to its British patent attorney, CPL explained the invention as "having a particular frequency related to [Rediffusion's] HF receivers," and that "the HF carriers were chosen to minimize the patterning effects overcome by our previous inventions." (Sirota Dec. Ex. 8: Letter.) The U.S. patent prosecutor submitted the August 10, 1977 amendment that added "40-300MHz" without CPL's prior approval. After reviewing the amendment, CPL advised its British patent agent that (1) the frequency range should have been defined as 3-30 MHz, not 40-300 MHz and (2) Claim 1 should read "conventional HF television receivers." (Sirota Dec. Ex. 10 Telex.) The British patent agent responded that "hopefully it will be fairly easy to make the necessary corrections as the frequency range given is clearly at variance with the words 'a high frequency carrier' to which the range is intended to relate." (Sirota decl. Ex. 11 Letter.) Collectively, that evidence demonstrates that (1) the "conventional" televisions in the specification refer to Rediffusion's HF televisions and (2) the Supplemental Amendment disclaimed the 40-300 MHz range because the 3-30 MHz range complied with the specification. This new evidence confirms that 3-30 MHz is the range in the 202 patent. See Cybor Corp., 138 F.3d at 1455; Pitney Bowes, 182 F.3d at 1309.

The parties have submitted expert testimony concerning how one skilled in the art would have interpreted "high frequency" in the 202 patent. The experts present varied definitions of "high frequency." See, e.g., Decl. of Bernard J. Lechner dated February 7, 1997 at P 38; Decl. of Archer S. Taylor dated March 24, 1997 at P 21.) Thus, this claim construction relies on more objective evidence as described in Vitronics Corp., which states that expert testimony may only be relied upon if the patent documents, taken as a whole, are insufficient to enable the court to construe disputed claim terms. Such instances will rarely, if ever, occur. . . Even in those rare instances, prior art documents and dictionaries, although to a lesser extent, are more objective and reliable guides. Unlike expert testimony, these sources are accessible to the public in advance of litigation. They are to be preferred over opinion testimony.

Vitronics Corp., 90 F.3d at 1585 (citing Markman, 52 F.3d at 983). This opinion does not rely on the experts to explain the underlying technology of frequency ranges; understanding the difference between frequency ranges is not difficult, and the expert reports provide little technical information to explicate frequencies generally. Moreover, this Court's claim interpretation does not adopt any expert's legal conclusion, but rather considers both intrinsic evidence and other more objective extrinsic evidence.

Finally, IPD and CPL submit numerous patents and articles to demonstrate that engineers used the terms "high frequency" or "very high frequency" as "generic, context-dependant" terms. (Plaintiff's Trial Memorandum of Law; Markman Hearing, at 21-22.) As Judge Sotomayor observed, however, "these materials clearly specified the frequency range the author intended by the use of high frequency and Cutler did not. A person skilled in the art, however, would have understood to look to the context of Cutler's use of high frequency within the claim and prosecution history . . . ." IPD II, 1998 U.S. Dist. LEXIS 3901, 1998 WL 142346, at *9. Accordingly, this Court finds that "high frequency" in the 202 patent encompasses a range of 3-30 MHz, based on the intrinsic evidence as confirmed by the extrinsic evidence.
IPD argues that the district court erred in reconsidering Judge Sotomayor's construction of the term "high frequency carrier." Specifically, it asserts that the intrinsic evidence, including the claim language, the specification, and the prosecution history, establishes that "high frequency" encompasses any frequency at which a conventional TV receiver can receive and display a signal. It also contends that the district court erroneously resorted to selected extrinsic evidence, including dictionaries, to construe the term "high frequency."

Cablevision argues that the district court properly construed the term "high frequency carrier" in claim 1. It asserts that the intrinsic as well as extrinsic evidence supports the district court's construction. In the alternative, it argues that if IPD is correct that "high frequency" includes 3-300 MHz, then the '202 patent is invalid under 35 U.S.C. § 102(f) for lack of inventorship. As explained below, we agree with Cablevision that the district court did not err in construing "high frequency" to mean a frequency in the range of 3-30 MHz.

We begin our claim construction analysis with the words of the claim. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). "In construing claims, the analytical focus must begin and remain centered on the language of the claims themselves, for it is that language that the patentee chose to use to 'particularly point[] out and distinctly claim[] the subject matter which the patentee regards as his invention.'" Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323, 1331 (Fed. Cir. 2001) (citing 35 U.S.C. § 112, P 2). The words used in the claims are examined from the perspective of a person skilled in the art. Tegal Corp. v. Tokyo Electron Am., Inc., 257 F.3d 1331, 1342 (Fed. Cir. 2001). In the absence of an express intent to impart a novel meaning to claim terms, the words are presumed to take on the ordinary and customary meanings attributed to them by those of ordinary skill in the art. See, e.g., Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002). The ordinary and customary meaning of a claim term may be determined by reviewing a variety of sources. Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 2003 U.S. App. LEXIS 13861, No. 02-1145, slip op. at 8-9 (Fed. Cir. June 27, 2003). Some of these sources include the claims themselves, see Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357 (Fed. Cir. 1999); dictionaries and treatises, Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202 (Fed. Cir. 2002); and the written description, the drawings, and the prosecution history, see, e.g., DeMarini Sports, Inc. v. Worth, Inc., 239 F.3d 1314, 1324 (Fed. Cir. 2001).

The district court noted that because claim 1 of the '202 patent does not specify a frequency range, one skilled in the art would presume that "high frequency" would have its ordinary meaning, unless the patentee clearly assigned a different meaning to the term. Summary Judgment Order at 22. Starting from that premise, the court concluded that one skilled in the art at the time of the patent application (December 2, 1974) would have understood "high frequency" in the '202 patent to mean a frequency between 3-30 MHz. Id. The court noted two dictionary definitions that defined "high frequency" as covering frequencies between 3-30 MHz:

Id. 6

6 "Sirota Decl." refers to the declaration submitted by Neil P. Sirota in support of Cablevision's summary judgment motion.

IDP argues that the district court "put the cart before the horse" by looking at dictionary definitions first instead of the specification to determine the meaning of the term "high frequency." We disagree. As we have noted, "consulting the written description and prosecution history as a threshold step in the claim construction process, before any effort is made to discern the ordinary and customary meanings attributed to the words themselves, invites a violation of our precedent counseling
against importing limitations into the claims." Tex. Digital, 308 F.3d at 1204 (citations omitted). In fact, we have noted that
dictionaries, encyclopedias, and treatises, publicly available at the time the patent is issued, are objective resources that
serve as reliable sources of information on the established meanings that would have been attributed to the terms of the
claims by those of skill in the art:

Such references are unbiased reflections of common understanding not influenced by expert testimony or events
subsequent to the fixing of the intrinsic record by the grant of the patent, not colored by the motives of the parties, and not
inspired by litigation. Indeed, these materials may be the most meaningful sources of information to aid judges in better
understanding both the technology and the terminology used by those skilled in the art to describe the technology.

Id. at 1202-03. Accordingly, the district court did not err in looking to dictionary definitions before consulting the written
description or the prosecution history to determine the meaning of the term "high frequency." Indeed, we agree with the
district court that, based on the dictionary definitions of "high frequency," one skilled in the art at the time of the patent
application would have understood "high frequency" in the '202 patent to mean a frequency between 3-30 MHz.

In addition, IPD argues that the use of dictionaries as a claim construction tool in this case is inappropriate because there are
different dictionary definitions of "high frequency," some of which place "high frequency" outside a range of 3-30 MHz.
IPD relies on the Oxford English Dictionary and notes that it defines "high frequency" as "[a] frequency . . . having a
relatively large number of cycles in a second." IPD further notes that the Oxford English Dictionary refers to the Dictionary
of Electronics and that the Dictionary of Electronics defines "high frequency" as "[a] general term used to distinguish
signals of radio frequency from those of audio frequency."

We have noted that "because words often have multiple dictionary definitions, some having no relation to the claimed
invention, the intrinsic record must always be consulted to identify which of the different possible dictionary meanings of
the claim terms in issue is most consistent with the use of the words by the inventor." Tex. Digital, 308 F.3d at 1203 (citation
omitted). In this case, as will be seen next, the dictionary definition that is most consistent with the specification and the
prosecution history is the definition that defines "high frequency" as including frequencies in the range of 3-30 MHz. See
Communications Commission designation for the band from 3 to 30 megahertz in the radio spectrum"); Webster's Seventh
New Collegiate Dictionary 705 (1967) (defining "high frequency" as "3 to 30 megacycles").

7 We note that even the dictionaries that IPD relies on have a definition for "high frequency" that is consistent with the
definition used by the district court and advanced by Cablevision. For example, the Oxford English Dictionary defines high
frequency as:

A frequency (see FREQUENCY 4b) having a relatively large number of cycles in a second. Applied esp. to an electric
current or voltage, an electromagnetic wave or a sound wave. Abbrev. H.F., esp. in radio and telecommunications, where it
also refers specifically to electromagnetic waves of 3-30 MHz.

(emphasis added). Similarly, the Dictionary of Electronics defines "high frequency" as:

(1) A general term used to distinguish signals of radio frequency from those of audio frequency. (2) A relative term used
to describe frequencies at the upper end of a particular frequency band. (3) Term of specific application to radio waves in
the frequency range between 3 and 30 Mc/s, i.e. of wavelengths from 100 m down to 10m.

(emphasis added).

The '202 patent's written description supports the district court's conclusion that "high frequency" in the claim term "high
frequency carrier" refers to a frequency in the range of 3-30 MHz. The written description should be examined in every case
to determine if the presumption of ordinary and customary meaning is rebutted. Brookhill-Wilk, slip op. at 6 (citing
Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1250 (Fed. Cir. 1998)). The presumption will be rebutted
where the patentee, acting as his or her own lexicographer, has clearly set forth a definition of a claim term that is different from the term's ordinary and customary meaning. Id. at 6-7 (citing In re Paulsen, 30 F.3d 1475, 1480 (Fed. Cir. 1994); Intellicall, Inc. v. Phonometrics, Inc., 952 F.2d 1384, 1387-88 (Fed. Cir. 1992)). It also will be rebutted if the inventor has disavowed or disclaimed scope of coverage, by using words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope. Id. at 7 (citing Teleflex, 299 F.3d at 1324).

The district court noted that the specification of the '202 patent does not define "high frequency" in a way that is at variance with the ordinary meaning of 3-30 MHz. Summary Judgment Order at 25. The court stated that "the specification does not clearly imply or express a special definition for the term 'high frequency.'" Id. at 27. We agree. Nowhere in the specification does the patentee, acting as his or her own lexicographer, clearly set forth a definition of "high frequency" different from its ordinary and customary meaning. If anything, the specification of the '202 patent supports the ordinary meaning of "high frequency" as being 3-30 MHz. It does so because it provides a definition for very high frequency, or VHF, as 40-300 MHz. '202 patent, col. 1, ll. 14-16 (stating that "commonly the range of frequencies employed extends throughout the VHF spectrum, for example, from about 40-300 MHz" (emphasis added)). Under these circumstances, we conclude that since the patentee defined a range for VHF, it certainly could have defined a range for high frequency and that, since it did not, high frequency should be given its ordinary and customary meaning of 3-30 MHz.

We have noted that, like the specification, the prosecution history may demonstrate that the patentee intended to deviate from a term's ordinary and accustomed meaning, i.e., if it shows that the patentee characterized the invention using words or expressions of manifest exclusion or restriction before the United States Patent and Trademark Office. Teleflex, 299 F.3d at 1326. The prosecution history limits the interpretation of claims so as to exclude any interpretation that may have been disclaimed or disavowed during prosecution in order to obtain claim allowance. Id. In this case, however, nothing in the prosecution history demonstrates that the patentee intended to deviate from the term "high frequency"'s ordinary and accustomed meaning of 3-30 MHz.

Lastly, IPD argues that the following language in claim 1 supports its construction that "high frequency" also includes frequencies in the VHF range: "conventional television receivers at the subscriber stations responsive to receive said high frequency carrier modulated with video broadcast signals." '202 patent, col. 4, ll. 20-23 (emphasis added). IPD relies on Judge Sotomayor's earlier claim construction ruling in support of this argument. Judge Sotomayor stated that the use of the phrase "conventional television receivers" in connection with "high frequency transmission" would have meant to a person skilled in the art that the inventor was referring to a VHF system operating in at least a range of 54 to 216 MHz. Claim Construction Ruling at 17. Judge Sotomayor reached this conclusion by noting that a person skilled in the art in the United States would have understood a reference to a conventional television receiver in the claim to mean a VHF television receiver. Id. at 18. We do not agree. In our view, the ordinary meaning of "high frequency" helps define the term "conventional television receivers," not the inverse. That is so because claim 1 refers to "conventional television receivers at the subscriber stations responsive to receive said high frequency carrier." '202 patent, col. 4, ll. 20-23 (emphasis added). The quoted language establishes that "conventional television receivers" are properly read as a subset of all television receivers, i.e., those responsive to a high frequency signal.

In sum, we hold that the district court correctly construed "high frequency" as including only any frequency between 3-30 MHz. Because we agree with the district court's construction of the term "high frequency carrier," we affirm the court's grant of summary judgment of non-infringement in favor of Cablevision. The accused systems operate in the VHF range, i.e., in the 30-300 MHz range, and thus fall outside the literal scope of the '202 patent. 8

---Footnotes---

8 As noted above, the district court also granted summary judgment of non-infringement under the doctrine of equivalents in favor of Cablevision on the ground that prosecution history estoppel precludes IPD from arguing that the "transmission means" limitation of claim 1 is infringed under the doctrine of equivalents. Summary Judgment Order at 56. Because IPD has not raised infringement of the "high frequency" limitation under the doctrine of equivalents and in view of our conclusion that the district court correctly granted summary judgment of no literal infringement with respect to the "high frequency carrier" limitation, we do not reach the issue of whether the district court correctly granted summary judgment of non-infringement under the doctrine of equivalents.

---End Footnotes---
IV. POSITIONS OF THE PARTIES

A. The Parties' Prior Positions Regarding Construction of the Phrase "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band"

In its Markman briefing and at the Markman hearing, Inline consistently argued that the disputed claim terms "a high frequency band of frequencies above the highest frequency of the telephone voice band," "high frequency band," and "high band of frequencies," recited in the '596 line of patents, 24 and that the disputed claim terms "a high band of frequencies above the highest frequency of the telephone voice band," "high frequency band," and "high band of frequencies," recited in the 718 patent, 25 should each be construed as "frequencies above the telephone voice band." 26

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

24 See, e.g., '596 patent, cl. 61; '446 patent, cl. 1, '585 patent, cl. 1.
25 See, e.g., 718 patent, cl. 22.
26 See, e.g., D.I. 189 at 10; D.I. 207 at 244 ("All of the claims of all of the patents refer to frequency above the telephone voice band."). Both parties argued at the Markman hearing that each of the disputed phrases quoted above (i.e., those including "high frequency band" and "high band of frequencies") should be construed identically in all four of the patents-in-suit. See Markman Opinion, 302 F. Supp. 2d at 326 n.86. Since each of the patents-in-suit are continuations of the same patent application, common construction of these terms could be proper. See Arthur A. Collins, Inc. v. Northern Telecom Ltd. 216 F.3d 1042, 1044 (Fed. Cir. 2000) (Because two patents "shared the same written description," and the second patent "is a continuation of" the first patent, the district court's "determination that a common construction of" a limitation in the claims of the two patents "was appropriate."). To avoid unnecessary repetition, the court's references to "high frequency band" in this opinion apply to each of the disputed phrases containing variations of this language.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Defendants argued at the Markman hearing that the correct construction of "high frequency band" in each of the patents-in-suit is "any of the radio frequencies between 3 and 30 MHz." 27 As noted in the Markman Opinion, this construction was first recited in defendants' responsive Markman brief and was a change in the proposed construction offered by defendants in their opening Markman brief. 28 In their opening Markman brief, defendants argued that the proper construction of the phrase "a high frequency band of frequencies above the highest frequency of the telephone voice band" as recited in the '596 line of patents is "the band of frequencies above 1 Mhz." 29 Defendants argued that the proper construction of "high band of frequencies above a telephone voice band" as recited in the 718 patent is "the band of frequencies above 6 MHz." 30

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

27 Markman Opinion, 302 F. Supp. 2d at 320. Megahertz is defined as "one million cycles per second, used esp. as a radio-frequency unit." Webster's II New Riverside University Dictionary 739 (1988). The correct abbreviation of megahertz is "MHz." The patents-in-suit and the parties' briefing sometimes abbreviates megahertz as "Mhz." In this opinion, the court uses the abbreviation "MHz" unless quoting language using the abbreviation "Mhz."

28 Markman Opinion, 302 F. Supp. 2d at 320 n.61.
29 D.I. 187 at 43 (emphasis omitted).
30 Id. at 45 (emphasis omitted).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -
In its Markman Opinion, the court construed "a high frequency band of frequencies above the highest frequency of the
telephone voice band" to mean "frequencies above the telephone voice band between the range of 1 and 30 MHz." 31

31 Markman Opinion, 302 F. Supp. 2d at 326. This construction was applicable to both the '596 line of patents and the '718 patent.

B. The Parties' Current Positions Regarding Construction of the Phrase "A High Frequency Band of Frequencies Above the
Highest Frequency of the Telephone Voice Band"

In its Motion for Reconsideration, Inline requests that the court modify the construction of "high frequency band" in the
Markman Opinion, "frequencies above the telephone voice band between the range of 1 and 30 MHz, " by deleting the
words "between the range of 1 and 30 MHz," or alternatively, by construing the disputed phrase as "a range of frequencies
above the telephone voice band." 32 Again, this the same construction proposed by Inline in its Markman briefing and at the
Markman hearing that was rejected by the court. 33

32 D.I. 242 at 1.

Defendants contend that the construction set forth in the Markman Opinion should not be changed because it "was correctly
guided by the governing Federal Circuit law and is firmly grounded in the intrinsic records of these patents." 34

34 D.I. 249 at 3.

C. The Parties' Positions on Reconsideration

Inline argues that "reconsideration of the Court's construction is required to avoid manifest injustice, as the current
construction excludes valuable telephone wire spectrum from the literal scope of the claims and is based upon a
misapprehension of the applicability of a dictionary definition and of the embodiments and teachings of the patents." 35

Inline sets forth three distinct arguments it believes compel modification of the court's construction.

35 D.I. 242 at 1.

First, that the dictionary definition relied upon is not relevant to the patents-in-suit because that definition "refers to specific
radio frequency spectrums used historically and today by the Federal Communications Commission ('FCC') as a frequency
nomenclature for regulating and allocating spectrum for wireless transmissions, not telephone wireline communications
[which the patents teach and claim]". 36 Second, that a definition including an upper limit is incorrect because "a high
frequency band of frequencies above the highest telephone voice band of frequencies [sic]" contains a single limitation: that
the lower limit of this high band of frequencies must be somewhere above the telephone voice band of frequencies." 37

Third, that many preferred embodiments disclosed in the patent specifications are erroneously excluded as a result of the court's construction. 38

36 Id. at 2 (emphasis in original).

37 Id. (emphasis in original).

38 Id. at 3.

Defendants' first response to Inline's Motion for Reconsideration is a procedural argument that plaintiff's motion does not satisfy the standard for a party seeking to alter or amend an order pursuant to Federal Rule of Civil Procedure 59(e) and that Inline failed to address the requirements for a motion for reargument under District of Delaware Local Rule 7.1.5. 39

39 D.I. 249 at 2. As explained in Section II above, the court has determined that the unique circumstances of this case warrant a modification of the court's prior construction. This opinion is not intended to be, nor should it be, viewed as an invitation for a disappointed party to seek "a second bite at the apple" through motions for reargument and/or reconsideration anytime the court determines an issue contrary to the result advocated by a party.

Defendants attack Inline's specific arguments for reconsideration with the contentions that: "neither the dictionary relied on by the Court nor any of the other dictionaries proffered by the parties distinguish between 'wireless' and 'wireline' transmissions"; "the Federal Circuit has specifically held that the ordinary meaning for the terms 'high frequency' in the context of wireline transmissions . . . is 3 MHz-30 MHZ"; "the teaching in the patent specifications . . . are contrary to Inline's position and certainly do not provide the type of clear definition or disavowal necessary to deviate from the ordinary meaning of 'high frequency' in the manner suggested by Inline"; and "the Federal Circuit has made clear that the type of 'after the fact' extrinsic evidence offered by Inline is not a substitute for the Court's careful analysis of the intrinsic record." 40

40 Id. at 3-4.

V. DISCUSSION

A. Inline's Argument that the Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band" is Erroneously Based on a Definition that Applies Only to Wireless Transmission

Inline's argument that the definition of "high frequency" relied upon by the court is inapplicable to the patents-in-suit for the reason that that definition "applies to wireless transmissions and broadcasts and not to telephone wires" 41 is not supported by the intrinsic record and is simply an expansion of the same argument made by plaintiff at the Markman hearing. 42

41 D.I. 242 at 5 (emphasis in original).
The definition of "high frequency" relied on by the court in the Markman Opinion, "any of the radio frequencies in the band between 3 and 30 MHz," is found in a dictionary entitled "Telephony's Dictionary: Defining 14,500 telecommunication words and terms" (the "Telephony's Dictionary"). In its opening Markman brief, Inline proffered the Telephony's Dictionary as an appropriate reference for the court's claim construction and cited that dictionary as providing definitions supporting its proposed construction of the disputed term "a high frequency band of frequencies above the highest frequency of the telephone voice band," as well as the disputed terms "telephone exchange," and "signal interface." Another technical dictionary cited by Inline in its opening Markman brief, Newton's Telecom Dictionary, is consistent with the Telephony's Dictionary. That dictionary's definition of "frequency band" incorporating a chart of frequencies which includes "3-30 MHZ -HF- High Frequency" as one of "the accepted explanations of 'bands.'" Inline proffered these telecommunications dictionaries for the court's claim construction during the Markman proceedings. It is hardly credible for plaintiff now to argue that particular definitions in those dictionaries which are inconsistent with its proposed construction of "high frequency band" are inapplicable to the patents-in-suit. Furthermore, the same definition of "high frequency" was relied upon by the Federal Circuit when construing the term "high frequency" in another patent concerning wireline transmissions.

In Intellectual Property Development Corporation v. UA-Columbia Cablevision of Westchester, Inc., the Federal Circuit reviewed the district court's construction of the term "high frequency" as recited in a patent directed at "a wired broadcasting system." The two sources relied upon by the district court included a technical dictionary which defined "high frequency" as "Federal Communications Commission designation for the band from 3 to 30 MHZ in the radio spectrum . . . [and a nontechnical dictionary which included] a radio frequencies table listing high frequency as covering 3 to 30 megacycles." The Federal Circuit held "that the district court correctly construed [the disputed term] 'high frequency' as including only any frequency between 3-30 MHZ." Even though those definitions referred to "radio" frequencies and the invention concerned "a wired broadcast system," no distinction between wired and wireless transmission systems was made by the Federal Circuit.
Here, defendants cited Intellectual Property Development in their responsive Markman brief 50 and at the Markman hearing as supporting a definition of "high frequency band" as those frequencies from 3 MHz to 30 MHz. 51 Defendants also argued at the Markman hearing that because the invention at issue in Intellectual Property Development concerned "a wired broadcasting system," the definition found in that case was also applicable to the wireline transmissions described in plaintiff's patents. 52

At the Markman hearing, Inline sought to distinguish Intellectual Property Development by arguing that the definition of "high frequency" in that case was not applicable to the patents-in-suit because the specification of the patent being construed in Intellectual Property Development did not describe particular frequency ranges where Inline's patents do contain such descriptions. 53 Inline did not, however, attempt to distinguish Intellectual Property Development when it raised its wireline/wireless transmission argument at the Markman hearing. 54 Since Inline was aware of defendants' reliance on that case from prior briefing and oral argument, it is telling that Intellectual Property Development was not even mentioned in its Motion for Reconsideration.

At the Markman hearing, Inline sought to distinguish Intellectual Property Development by arguing that the definition of "high frequency" in that case was not applicable to the patents-in-suit because the specification of the patent being construed in Intellectual Property Development did not describe particular frequency ranges where Inline's patents do contain such descriptions. 53 Inline did not, however, attempt to distinguish Intellectual Property Development when it raised its wireline/wireless transmission argument at the Markman hearing. 54 Since Inline was aware of defendants' reliance on that case from prior briefing and oral argument, it is telling that Intellectual Property Development was not even mentioned in its Motion for Reconsideration.

Finally, the '596 line of patents each: refer to radio frequency transmission (abbreviated RF); describe the invention as including "RF transmitters and RF receivers"; and describe the use of RF signals. 55 Indeed, the '596 patent is titled "Two-Way RF Communication at Points of Convergence of Wire Pairs from Separate Internal Telephone Networks." "Radio frequency" is defined as "an electromagnetic wave frequency intermediate between audio frequencies and infrared frequencies used esp. in radio and television transmission." 56 Nothing in that definition suggests a distinction between electromagnetic wave frequencies used in wireline transmission as opposed to those used in wireless transmission.

55 See, e.g., '596 patent, 9:9-54; 14:59-60 ("The solutions described herein take advantage of the improved ability of RF
(radio frequency) signals . . . ."); Likewise, the '718 patent describes the use of radio frequency transmission. See, e.g., '718
patent, 9:58-62 ("In contrast to regulations covering radiation, no special legal problems are created in the U.S. by the
connection of radio frequency devices to the public telephone network if those devices do not transmit energy below 6
Mhz.").
- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - Inline acknowledges that "the term 'RF' is often used generically to describe all frequencies between audio and light
frequencies" 57 but contends that "the specific frequency nomenclature relied upon by Defendants and the Court is reserved
for the language of wireless spectrum allocation by the FCC." 58 Inline offers nothing other than the declaration of its
expert, and other extrinsic evidence, to support this contention. Defendants correctly point out that Inline has not cited any
dictionary that supports its argument that there were different ordinary and accustomed definitions of a "high frequency
band" for wireline transmissions and for wireless transmissions at the time of the inventions described by the patents-in-suit.
Nor has Inline pointed to any intrinsic evidence, and the court has found none, which would support that differentiation. 59
- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 57 D.I. 242 at 2.
58 Id. (emphasis in original).
59 Inline's submission of extrinsic evidence (which post-dates the date of the invention by several years) is not needed for
the court to construe "high frequency band." This is particularly evident in light of Inline's repeated assertions indicating
that the intrinsic record is sufficient for the construction of the disputed terms in the patents-in-suit. See D.I. 189 at 1
(stating that the disputed claim terms "all have plain and ordinary meanings within the context of the claims in which these
terms are used"); id. at 9-13 (citing only dictionary definitions and the specifications of the patents-in-suit in support of its
proposed construction of "high frequency band"); D.I. 242 at 8 ("Here the claimed range of the high frequency control and
video information signals . . . is readily gathered from reading the patents and their disclosure . . . ."); id. at 6 ("It cannot be
argued that . . . the phrase 'a high frequency band of frequencies above the highest frequency of the telephone voice band'
lacks meaning. . . ."); see also id. ("One reading the patent claims and specification would not search beyond the patents for
meaning . . . ." (citing the declaration of Inline's expert)). The court agrees and finds it unnecessary to address Inline's
arguments that are based exclusively on a new declaration of its expert and other extrinsic evidence. See Vitronics, 90 F.3d
at 1582 ("In most situations, an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term.
In such circumstances, it is improper to rely on extrinsic evidence."); Bell & Howell Document Management Prods. Co. v.
Altek Sys., 132 F.3d 701, 707 (Fed. Cir. 1998) ("Because the intrinsic evidence unambiguously defined the disputed claim
limitation, the district court's reliance on the expert testimony . . . to contradict the intrinsic evidence when interpreting the
claims was error." (citing Vitronics, 90 F.3d at 1583)). Additionally, Inline's extrinsic evidence need not be considered as
that evidence is an attempt to supplement material in support of arguments already made by plaintiff and defendants at the
reargument may not be used to supplement or enlarge the record' on which the court made its initial decision." (citation
omitted)).
- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - Consequently, the court rejects Inline's argument that the dictionary definition of "high frequency" relied upon by the court
is only applicable to wireless transmissions.
B. Inline's Argument that the Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency
of the Telephone Voice Band" is Erroneous for Including an Upper Limit
Inline's second argument for reconsideration is that "'high frequency band of frequencies above the highest telephone voice
band of frequencies' contains a single limitation: that the lower limit of the high frequency band must be somewhere above
the telephone voice band of frequencies." 60 The implication is that the court erred in selecting a construction of "high

- 2326 -


frequency band" that includes an upper limit as well as a lower limit. Inline's arguments in its Motion for Reconsideration substantially rehash those made during the Markman proceedings that were rejected by the court.

60 D.I. 242 at 2 (emphasis in original).

Inline's opening Markman brief contained the following argument:

The ordinary meaning of "frequency band" is "[a] range of frequencies between upper and lower limits." Graham Langley, Telephony's Dictionary . . . . The word "high" modifies the words "frequency band" to create the terms "high frequency band" and "high band of frequencies" which are explicitly defined in the claim language as frequencies above the voice band. In context, therefore, the high frequency band, and the high band of frequencies, specify a range of frequencies having a lower limit above the highest frequency of the telephone voice band. No requirement is placed on the upper limit of the frequency range. 61

61 D.I. 189 at 12-13 (emphasis added).

Within this single paragraph, Inline's own proffered definition of "frequency band," "[a] range of frequencies between upper and lower limits," flatly contradicts its position that "high frequency band" should be defined to have no upper limit. The court notes that the Telephony's Dictionary does not include the definition of "frequency band" quoted by Inline. This error was pointed out by defendants in their responsive Markman brief 62 and at oral argument. 63 Inline never addressed this error or indicated the source of its proffered definition of "frequency band." Upon review of the parties' Markman submissions, however, the court discovered the source of Inline's "frequency band" definition. "A range of frequencies between upper and lower limits" is the definition recited in the Telephony's Dictionary for "band," not "frequency band." 64 This was one of several definitions of "band" included in a "Glossary of Dictionary Definitions Provided by Inline" attached as Exhibit 1 to the parties' Joint Submission Regarding Claim Construction. 65 Each of technical dictionaries included in plaintiff's glossary define "band" to have both upper and lower limits. 66

63 See D.I. 207 at 252-53.

64 D.I. 176, Ex. 1 at 1 (quoting the Telephony's Dictionary definition of "band").

65 See id.

66 See id. In addition to the above-quoted definition of "band" recited by the Telephony's Dictionary, the Glossary of Dictionary Definitions Provided by Inline lists the following definitions of "band":

"2. (data transmission) Range of frequency between two defined limits." The Institute of Electrical and Electronics Engineers, Inc., IEEE Standard Dictionary of Electrical and Electronics Terms 79 (Frank Jay ed., 3rd ed. 1984);

"2. In data communication, the frequency spectrum between two defined limits." Jerry M. Rosenberg, Computers, Data Processing & Telecommunications 39 (1984);

"Range of frequency spectrum between two limits." John Douglas-Young, Illustrated Encyclopedic Dictionary of
The only dictionary included in plaintiff's glossary that did not explicitly define "band" as including upper and lower limits was the sole nontechnical dictionary included in that section. See id. (The New Merriam-Webster Dictionary 71 (Frederick C. Mish ed. 1989) (defining "band" as "3. A range of wavelengths (as in radio)").

Finally, the intrinsic record supports the conclusion that there is an upper limit to "high frequency band." The specifications of the '596 line of patents state "as mentioned above, there is an upper limit to the frequencies that can be useful for transmission of signals across a transmission path of a given length." 67

C. Inline's Argument that the Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band" Improperly Excludes Certain Embodiments Recited in the Patents-In-Suit

Inline contends that the court's construction of "a high frequency band of frequencies above the highest frequency of the telephone voice band" as "frequencies above the telephone voice band between the range of 1 and 30 MHz" improperly excludes several embodiments recited in the patents-in-suit. 68 Inline argues that a construction which excludes preferred embodiments from the scope of the claims is disfavored. 69 Inline's argument on this point has merit. Because the court determines that the proper construction of "high frequency band" is different for the '596 line of patents and the 718 patent, the appropriate modification of the court's prior construction for each will be discussed separately.

1. The Parties' Arguments with Regard to the '596 Line of Patents

During the Markman proceedings, Inline pointed to a control signal illustrated in figure 3a of the '596 line of patents as centered at 0.5 MHz as an example of frequencies improperly excluded from defendants' proposed construction of "high frequency band." 70

Inline reiterates this argument in its Motion for Reconsideration and also points to frequencies above 30 MHz that are excluded by the court's construction of "high frequency band." Inline again notes that figure 3a of the '596 line of patents...
describes an embodiment having a control signal with a lower limit at 0.25 MHz. 71 Inline cites each of the patents-in-suit as stating "the control signal is transmitted in a high frequency band." 72 Inline also contends that "the upper end, while not discussed by either party in the Markman briefs, is clearly disclosed with examples given at 100 MHZ and 5000 MHz." 73

--- Footnotes ---

71 D.I. 242 at 4. The '596 line of patents describe control signals as having a 0.5 MHz bandwidth, therefore, the control signal illustrated in figure 3a spans a frequency band from 0.25 MHz to 0.75 MHz. See '596 patent, 41:12-14 & figure 8 (bandwidth examples).

72 D.I. 242 at 4 n.6 (citing '596 patent, cl. 24; '585 patent, cl. 3; '446 patent, cl. 6; '718 patent, 23:36-40).

73 Id. at 5 & 5 n.7 (citing '596 patent, 37:66-38:5 & figure 8); see also id. at 4 & 4 n.6.

--- End Footnotes ---

Defendants' opposition to the Motion for Reconsideration never addresses Inline's argument that the court's construction of "high frequency band" improperly excludes frequencies above 30 MHz. Defendants focus solely on the lower limit of the court's construction. They argue that the patents describe the control signal disclosed in figure 3a as "Amplitude Modulation within a Low-Frequency channel." 74 Based on this language, defendants contend that this example of control signal transmission is not a "high frequency band" signal and, therefore, the court's construction of that phrase does not improperly exclude a preferred embodiment. 75 This is the same argument presented by defendants at the Markman hearing. 76

--- Footnotes ---

74 D.I. 249 at 9 (citing '596, patent 25:44-45 (emphasis added by defendants)).

75 See id.

76 See D.I. 207 at 256-57.

--- End Footnotes ---

Defendants, however, have presented contradictory arguments with regard to the lower limit of the "high frequency band." In their opening Markman brief, defendants argued that "the proper construction of the phrase 'high frequency band of frequencies above the highest frequency of the telephone voice band' in these elements is 'the band of frequencies above 1 MHz.'" 77 In defendants' responsive Markman brief, they changed their proposed definition and argued for a construction of "high frequency band" having a lower limit of 3 MHz based on the definition of "high frequency" in the Telephony's Dictionary, "any of the radio frequencies in the band between 3 and 30 MHz." 78 In that same brief, defendants nevertheless conceded that "the specification is explicit that the high frequency signals are never lower than 1 MHz." 79 Although previously acknowledging that the "high frequency band" includes signals at least as low as 1 MHz, at oral argument, defendants took the position that the inventor described all frequencies below 3 MHz as "low frequency channels" and, therefore, signals below 3 MHz should not be included in the definition of "high frequency band." 80

78 D.I. 200 at 20-22.

79 Id. at 22 (emphasis added).

80 D.I. 207 at 256-57; see also id. at 256 ("If you go to the '596 patent, you are not going to find any expressed teaching in the patent that would cause one of skill in the art or cause this court to deviate from the plain meaning of high frequency being between 3 and 30 megahertz.").
In their opposition to the Motion for Reconsideration, defendants repeat this last argument stating that "this purported example of a 'high frequency' control signal being transmitted at a frequency below 3 MHz is in fact, according to the specification itself, an example of a 'low frequency transmission.'" 81 In the very next paragraph, however, defendants again contradict that assertion by arguing that "the specification distinguishes between high and low frequency signals, consistently referring to signals below 1 MHz as low frequency signals." 82 That 1 MHz limit is described in the section of the specification titled "Amplitude Modulation within a Low-Frequency Channel," 83 the same section of the specification defendants previously argued, in their opening Markman brief and conceded in their responsive Markman brief, supported a construction of "high frequency band" including signals at 1 MHz and above.

If, as defendants now argue, the court's construction is correct in defining the lower limit of "high frequency band" to be 1 MHz, it is hard to reconcile their position that the control signal described in the same section of the specification is not also part of the "high frequency band." 84 Given defendants' inconsistent positions, the court believes it is more reasonable to accept Inline's argument that the frequencies of both the video signal component and the control signal illustrated in figures 3a and 3c are within the "high frequency band." Although not articulated by Inline, the description of "Amplitude Modulation within a Low-Frequency Channel" may be understood to refer to the lower frequencies of the "high frequency band." These figures, then, describe the use of comparatively lower frequency channels within the "high frequency band," i.e., frequencies which are lower than the transmission levels of the preferred embodiments described earlier in the patent specifications. 85

81 D.I. 249 at 9.
82 Id. at 11 n.5; see also id. at 9-10 ("There is nothing in this section of the specification [concerning low-frequency channels'] or elsewhere that suggests placing such [high frequency] signals in the band below 1 MHz.").

84 The court notes that defendants' argument that "the specification distinguishes between high and low frequency signals, consistently referring to signals below 1 MHz as low frequency signals," D.I. 249 at 11 n.5, and that nothing in the '596 line of patents "suggests placing such [high frequency] signals in the band below 1 MHz," id. at 10, is accurate only with respect to the transmission of video signals. The patents make clear that the invention is not limited to transmission of video signals but also includes the transmission of control, and other, signals. See '596 patent, 1:23-24 (describing the invention as "relating to a system for simultaneous two-way communication of video signals and other signals . . . ."); '596 patent, 1:56-64 ("The communication systems disclosed in the parent and first and second CIP applications are designed to simultaneously transmit telephone signals and non-telephonic signals (such as cable television signals, other video signals, audio signals, data signals, and control signals) across the active telephone wiring internal to . . . residences and other structures. The present invention adds to these techniques, providing distribution of all of these signals to a local network of active telephone wiring . . . .").
85 See '596 patent, 19:27-56 (describing preferred embodiments in the section titled "Minimum Frequency"); '596 patent, 25:10-11 (stating that the embodiments described in figures 3a and 3c "use frequencies below the lower limits suggested above[, i.e., the those described in the 'Minimum Frequencies' section]."

Because the court's prior construction of "high frequency band" excluded certain embodiments recited in the '596 line of patents, and because defendants have not argued that there is evidence that those embodiments are not covered by these
patents, the court concludes that its prior construction was overly narrow and must be modified. 86

86 See Vitronics, 90 F.3d at 1583 (stating that a construction that excludes a preferred embodiment "is rarely, if ever, correct and would require highly persuasive evidentiary support."); see also Applera Corp. v. Micromass UK Ltd., 186 F. Supp. 2d 487, 504-08 (D. Del. 2002) (rejecting proposed construction that would read out preferred embodiment illustrated in figure); cf. Elekta Instrument S.A. v. O.U.R. Scientific Int'l, 214 F.3d 1302, 1308 (Fed. Cir. 2000) (illustrating "the rare case" in which the correct claim construction "excluded the preferred . . . embodiment disclosed in the specification . . . [because] the prosecution history and the unambiguous language of the amended claim" demonstrated that the preferred embodiment was not covered by the claim (citation omitted)).

2. The Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Telephone Voice Band" for the '596 Line of Patents

In order to modify properly its prior construction of the phrase "a high frequency band of frequencies above the highest frequency of the telephone voice band," the court must first determine precisely which words in that phrase are in dispute. Once that issue is resolved, the court will determine the ordinary and accustomed meaning of the disputed term as reflected in relevant dictionaries and then examine other intrinsic evidence to see if the patentee's use of that term is consistent with its ordinary meaning. 87

87 Neither party presented arguments based on the prosecution history with respect to the term at issue in the Motion for Reconsideration.

In its Motion for Reconsideration, Inline resurrects its argument that, in each of the patents-in-suit, the phrase "a high frequency band of frequencies above the highest frequency of the telephone voice band" means "the frequencies above the telephone voice band." 88 The embodiments described in the specifications of the '596 line of patents demonstrate that the lower limit of disputed phrase should include the lower limit of the control signal illustrated in figure 3a. The court must now determine which words in that phrase are in dispute and, thereafter, whether the claims should be construed as broadly as Inline suggests.

88 D.I. 242 at 10-11.

In prior briefing, Inline supported its proposed construction by stating that the Telephony's Dictionary provides the "ordinary meaning of 'frequency band' [as] '[a] range of frequencies between upper and lower limits.'" 89 As recited above, plaintiff argued that:

the word "high" modifies the words "frequency band" to create the terms "high frequency band" and "high band of frequencies" which are explicitly defined in the claim language as frequencies above the voice band. In context, therefore, the high frequency band, and the high band of frequencies, specify a range of frequencies having a lower limit above the highest voice frequency of the telephone band. 90

Having concluded its discussion of the first part of the phrase "a high frequency band of frequencies above the highest frequency of the telephone voice band," Inline stated that "'voice band' is a well-known term of art, which is a frequency 'band used on telephone equipment for the transmission of voice and data,' the highest frequency [of which] is not more than
approximately 4000 Hz." 91 Plaintiff concluded that "by the plain claim language, the lower frequency limit of the high frequency band is above the voice band and is therefore above approximately 4000 Hz." 92

Defendants have consistently argued that Inline's proposed construction reads the words "high frequency" out of the claims. 93 Inline has provided no response to this argument. Defendants argue further that other claims in the '596 line of patents support its contention that "high frequency band" recited in the asserted claims can not simply mean all frequencies above the voice band. 94

For instance, Claim 1 of the '596 patent recites: "circuitry for transmitting said received video signal onto at least one of said telephone lines in a selected frequency range that is different from frequencies at which said voice signals are carried on said one telephone line . . . ." 95 Claim 13 of the '596 patent recites: "the system of claim 1 wherein said voice signals are carried by said telephone lines at voiceband frequencies and said selected frequency range exceeds said voiceband frequencies." 96 Since the asserted claims recite the more specific limitation of "high frequency band," defendants argue that Inline's proposed construction is inconsistent with other claim language used by the patentee. The court agrees with defendants on these points.

95 '596 patent, cl. 1 (emphasis added); see also '596 patent, cl. 9 (". . . a second selected frequency range that is different from said frequency range selected by said interface and different from frequencies at which said voice signals are carried on said telephone link . . . ." (emphasis added)).
96 '596 patent, cl. 11 (emphasis added); see also '596 patent, cl. 13 ("circuitry for changing the frequency of said video signal received from said telephone line to a frequency band that exceeds said voiceband frequencies . . . ." (emphasis added)).

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The parties agree that the "highest frequency of the telephone voice band" is approximately 400 Hz. 97 Therefore, the dispute centers on the meaning of the words "high frequency band." Inline's argument that "high" modifies "frequency band" and, thus, that the disputed phrase simply means "frequencies above the voice band" unquestionably reads "high frequency band" out of the claim. The entire disputed phrase reads:

"a high frequency band of frequencies above the highest frequency of the telephone voice band."
Inline's proposed construction of that phrase is:

"frequencies above the telephone voice band." 98

In essence, that construction merely excises "a high frequency band" from the disputed phrase and gives no meaning whatsoever to those words.

--- Footnotes ---

97 See D.I. 197 at 18 (Plaintiff states that "all parties accept that the telephone voice band is the band that carries voice telephone signals, which is commonly understood to be between approximately 0 and 4 KHz."). Defendants apparently do not challenge plaintiff's definition of "voice band." See D.I. 187 at 44 ("Because the top end of the voiceband is approximately 4KHz . . . .").

98 D.I. 189 at 10; see also D.I. 242 at 1 (suggesting modification of the court's construction to read "frequencies above the voice band" or, alternatively, "a range of frequencies above the telephone voice band").

--- End Footnotes ---

Defining "high" as simply meaning that the "frequency band" is "above" the voice band, as Inline suggests, would make the words "high frequency band" superfluous since the entire phrase in question already requires the "high frequency band" to be limited to those "frequencies above the highest frequency of the telephone voice band." A construction that does not give meaning to all the words in a disputed phrase is disfavored. 99 The more logical construction, and the one which gives meaning to all the words in the disputed phrase, is that "high frequency" modifies "band." This construction does not render any words of the asserted claims superfluous.

--- Footnotes ---

99 See Pickholtz v. Rainbow Techs., Inc., 284 F.3d 1365, 1373 (Fed. Cir. 2002) ("Interpretations that render some portion of the claim language superfluous are disfavored. . . .")

--- End Footnotes ---

Defendants' argument regarding other claim language reciting broader limitations also supports the rejection of Inline's proposed construction. Examining these other claims is consistent with the Federal Circuit's mandate that in construing claims the court is to read the disputed language in the context of the entire patent. 100 Independent claim 1 of the '596 patent includes the limitation that frequencies are transmitted "in a selected frequency range that is different from frequencies at which said voice signals are carried on said one telephone line . . . ." 101 Claim 11 of the '596 patent, which depends from claim 1, contains the narrower limitation that "said selected frequency range exceeds said voiceband frequencies." 102 The plain meaning of the limitation recited in claim 11 is the same as Inline contends this court should apply to "high frequency band" in the asserted claims. When the patentee sought to limit a claim to transmission of frequencies that are merely "different from" or "exceed" (or are "above") the voice band, he knew how to do so. 103 That is not the limitation included in the asserted claims, however. Those claims include the more specific limitation to transmissions of frequencies in the "high frequency band." 104 The court concludes, therefore, that in the disputed phrase "high frequency band," the term "high frequency" modifies the term "band." The court must now determine the ordinary and accustomed meanings of these terms.

--- Footnotes ---

100 See Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 334 F.3d 1294, 1299 (Fed. Cir. 2003) ("While certain terms may be at the center of the claim construction debate, the context of the surrounding words of the claim also must be considered in determining the ordinary and customary meaning of those terms. . . ." While dictionaries and treatises are useful resources in determining the ordinary and customary meaning or meanings of disputed claim terms, the correct meaning of a word or phrase is informed only by considering the surrounding text. This is why consulting dictionary definitions is simply a first step in the claim construction analysis and is another reason why resort must always be made
the surrounding text of the claims in question, the other claims, the written description and the prosecution history.

101 '596 patent, cl. 1 (emphasis added).

102 '596 patent, cl. 11 (emphasis added).

103 See Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1304-05 (Fed. Cir. 1999) (The court rejected defendant's proposed construction as contrary to the language of the asserted independent claims and noted that a nonasserted independent claim which included the limitation argued for in the asserted claims supported this rejection. The court stated, "had [plaintiff] intended or desired to claim [the proposed limitation] in the asserted claims, it could have done it explicitly, as in claim 11. The absence of any such explicit language, however, shows that the [asserted claims] do not include [the proposed limitation]."); see also Forest Labs., Inc. v. Abbott Labs., 239 F.3d 1305, 1310 (Fed. Cir. 2001) ("Where claims use different terms, those differences are presumed to reflect a difference in the scope of the claim."); General American Transp. Corp. v. Cryo-Trans, Inc., 93 F.3d 766, 770 (Fed. Cir. 1996) (rejecting district court's construction which rendered a particular claim requirement superfluous); RF Delaware, Inc. v. Pacific Keystone Techs., Inc., 326 F.3d 1255, 1264 (Fed. Cir. 2003) (rejecting proposed construction for asserted claim that would render "redundant or meaningless" a limitation in unasserted claims). 104 This analysis also compels the court to reject Inline's argument that the "patent specifications define high frequency as: 'high-frequency (i.e., non-voice band) signals." D.I. 242 at 7 (quoting '446 patent, 54:25; '585 patent, 54:11; and '596 patent, 53:61 (emphasis added)). That parenthetical reference is far from an explicit definition of "high frequency band" as all frequencies above the highest frequency of the telephone voice band.

--- End Footnotes ---

Defendants contend that the proper construction of "high frequency band" is determined by the definition of "high frequency" contained in the Telephony's Dictionary; "any of the radio frequencies in the band between 3 and 30 MHz." As noted above, this definition is one of several consistent definitions recited in dictionaries proffered by Inline as appropriate for the court's construction of the disputed terms of the patents-in-suit. Inline has offered no other dictionaries available at the time of invention expanding this definition of "high frequency." 105 The definition of "band" recited in several dictionaries proffered by Inline is "a range of frequencies between upper and lower limits." 106 By combining the definitions of "high frequency" and "band," the court concludes that the ordinary and accustomed meaning of the phrase "high frequency band" at the time of the inventions at issue was "the range of radio frequencies between 3 MHz and 30 MHz." 107

--- Footnotes ---

105 See Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002) ("If more than one dictionary definition is consistent with the use of the words in the intrinsic record, the claim terms may be construed to encompass all consistent meanings.").

106 See footnote 66, above.

107 See Alloc, Inc. v. ITC, 342 F.3d 1361, 1368 (Fed. Cir. 2003) ("Claim language generally carries the ordinary meaning of the words in their normal usage in the field of invention at the time of the invention.").

--- End Footnotes ---

Because the court has already determined that the intrinsic record describes certain embodiments in the '596 line of patents having frequencies outside of the range of frequencies to which the ordinary meaning of "high frequency band" is limited, the court will not construe the disputed phrase to be so limited. 108 This is not problematic, however. The Federal Circuit has stated that:

the specification or the prosecution history of a patent may alter the meaning of a claim term from its conventional usage. A patent applicant may consistently and clearly use a term in a manner either more or less expansive than its general usage in the relevant art, thereby expanding or limiting the scope of the term in the context of the patent claims. 109
Here, the embodiments described in the specifications make clear that the patentee used the term "high frequency band" more expansively than its ordinary and accustomed meaning. Moreover, it is entirely proper to construe that term by examining the specifications' description of preferred embodiments, even if the term "high frequency band" is not explicitly defined therein. 110

108 See Texas Digital, 308 F.3d at 1204 ("[I]f the intrinsic record . . . shows that the specification uses the words in a manner clearly inconsistent with the ordinary meaning reflected, for example, in a dictionary definition . . . the inconsistent dictionary definition must be rejected.").

109 Alloc, Inc., 342 at 1368 (emphasis added); accord Genzyme Corp. v. Transkaryotic Therapies, Inc., 346 F.3d 1094, 1098 (Fed. Cir. 2004) ("In other words, a patent applicant may consistently and clearly use a term in a manner either more or less expansive than its general usage in the relevant community, and thus expand or limit the scope of the term in the context of the patent claims." (citing Ballard Med. Prods. v. Allegiance Healthcare Corp., 268 F.3d 1352, 1361 (Fed. Cir. 2001); Middleton, Inc. v. Minnesota Mining & Mfg. Co., 311 F.3d 1384, 1388 (Fed. Cir. 2002)).

110 See SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1344 (Fed. Cir. 2001) (holding the written description of the preferred embodiment "can provide guidance as to the meaning of the claims, thereby dictating the manner in which the claims are to be construed, even if the guidance is not provided in explicit definitional format"); Vitronics 90 F.3d at 1582 ("The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication." (emphasis added)).

Inline argues only that "high frequency band" is "frequencies above the highest voice band" and defendants argue that the court's prior construction of "frequencies above the telephone voice band between the range of 1 and 30 MHz" is correct. Because the court concludes that neither party's position is correct, this leaves it to the court to determine the proper limits of the term "high frequency band" on its own. These limits can be ascertained from the intrinsic record and do not require consideration of extrinsic evidence.

Inline notes that the specifications of the '596 line of patents, recite: "to minimize the highest frequency used for transmission, it is recommended that the first channel be placed as close to the voiceband as feasible . . . ." 111 Examination of the specifications reveals the lowest "feasible" frequency contemplated by the patentee. Under the heading "Minimum Frequency," the following preferred embodiments are described: "if AM is used to transmit video signals, it is preferred that the picture carrier of the first such channel be located above 4.25 MHz" 112 and "for FM transmission, it is preferred that the low end of the first channel be 4 Mhz." 113 These embodiments contemplate transmission of multiple channels above the voice band. The transmission of multiple channels is clearly the goal of the inventions. 114 The patents also describe more limited embodiments which are only capable of transmitting a single signal, however, and these embodiments recite the lowest transmission frequencies described in the '596 line of patents.

113 ’596 patent, 19:43-44.

114 ’596 patent, 1:23-24 ("The present invention relates to a system for simultaneous two-way communication of video signals . . . ." (emphasis added)).
In a section titled "Transmitting a Single Video Signal over Long Transmission Lengths (FIGS. 3A-3C)," the specifications state that "in these types of situations, use of extended pairs 405 to communicate multiple signals over a large frequency range may not be feasible. A system that communicates only a single video signal, however, can still be very useful in many important applications." The embodiments capable of transmitting only one video channel described in this section of the specifications represent the outer limit of transmission that is feasible. In discussing these outer-limit transmissions the patents describe "us[ing] frequencies below the lower limits suggested [in the "Minimum Frequency" section]." The patents state, with respect to figures 3a and 3c, that "there is 'room' to transmit a narrow band of control signal between the voiceband and the video signal. " The lowest frequency at which video signals are transmitted is 1 MHz and is illustrated in figure 3a. "F[igure] 3a shows the spectrum of such signal. The carrier frequency is 1.25 Mhz, with the lower sideband substantially suppressed below 1 Mhz."

115 '596 patent, 24:64-65 (emphasis added).
116 '596 patent, 25:1-5.

--- End Footnotes ---

This court is mindful of the Federal Circuit's admonition not to read limitations from patent specifications into the claims as well as that court's acknowledgment that there is "sometimes a fine line between reading a claim in light of the specification, and reading the limitation into the claim from the specification." For instance, in Comark the Federal Circuit determined that defendant's proposed construction seeking to limit the disputed term "to its functional purpose as disclosed in the preferred embodiment" was an improper attempt to read limitations from the specification into the claims. Conversely, the patents in this case make clear that the 1 MHz lower limit of video transmission of a "high band of frequencies" does not merely represent a functional purpose of a preferred embodiment. The patent states that "one of the disadvantages of lower frequencies is that the filtering that separates these signals from voiceband signals is more expensive because of the sharp cutoff required between the upper end of the voiceband and 1 Mhz." Rather than fulfilling the functional purpose of this embodiment, the specification makes clear that 1 MHz is a functional limitation of the invention. Therefore, the court concludes that lowest feasible frequency at which the invention can transmit "high frequency band" video signals is 1 MHz. 

--- Footnotes ---

120 Comark Communs. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998); see also Alloc, Inc., 342 F.3d at 1370 (This court recognizes that it must interpret the claims in light of the specification, . . . yet avoid impermissibly importing limitations from the specification. . . . That balance turns on how the specification characterizes the claimed invention. . . . In this respect, this court looks to whether the specification refers to a limitation only as a part of less than all possible embodiments or whether the specification read as a whole suggests that the very character of the invention requires the limitation be a part of every embodiment." (emphasis added) (citations omitted)).
121 Comark, 156 F.3d at 1187.
123 This case is likewise distinguishable from the Federal Circuit's recent decision in Gemstar-TV Guide Int'l, Inc. v. ITC, 383 F.3d 1352, No. 03-1052, 2004 WL 2059279, at *10 (Fed. Cir. Sept. 16, 2004). There, the defendant argued that the claim limitation "visual identification" recited in one of the patents at issue was limited to "an innovative cursor" based on language in the written description which stated "an innovative cursor 32 . . . for the irregular array . . . is required which
satisfies several conflicting requirements." Id. at *8-*9 (emphasis added). The Federal Circuit rejected that argument stating that "in the context of the disclosure of the preferred embodiment of the '204 patent, the statement that 'innovative cursor 32 . . . is required,' is not the 'use [of] words or expressions of manifest exclusion or restriction, representing a clear disavowal of claim scope.' . . . Properly read . . . the statement merely conveys the advantages of 'innovative cursor 32' over prior art conventional cursors in the preferred embodiment." Id. at *10 (citations omitted) (alteration in original). Here, the "sharp cutoff required" below 1 MHz is not recited as a comparison to prior art. Also, while described as one of three "disadvantages" of the embodiment illustrated in figure 3a, this disadvantage was not one which might be overcome with stronger filtering or would merely be more expensive; the 1 MHz limit is a functional requirement. Cf. '596 patent, 25:65-26:4 (The patents describe two disadvantages of the lower frequency transmissions illustrated by figure 3a, in addition to the "sharp cutoff required" below 1 MHz: "[a] second disadvantage is that the harmonics of the telephone signals at lower frequencies are stronger, meaning that stronger filtering of the harmonics is required to protect against interference from these signals. A third disadvantage is that the modulation electronics becomes more expensive as the picture carrier approaches DC.").

As discussed above, it is reasonable to conclude that the control signal described in figure 3a is also included in the "high frequency band." The lower limit of this "narrow band" of signals is 0.25 MHz. Again, this appears to be the lowest limit at which it is feasible to transmit a "high frequency band" control signal. Other than Inline's insistence that the "high frequency band" includes all frequencies above the voice band, which the court has rejected, plaintiff has not pointed to any intrinsic evidence which contradicts this conclusion.

The video signal illustrated in figure 3a is described "a frequency slightly above voiceband." '596 patent, 25:14-15 (emphasis added). Figure 3a is also captioned "Spectrum of an Amplitude Modulated NTSC Signal Near Voiceband" (emphasis added). Figure 3c is similarly captioned "Spectrum of an FM NTSC Signal Near Voiceband" (emphasis added). In figure 3c, the control signal is centered at 1 MHz and the lower limit of the video signal is located at 3 MHz. The control signal illustrated in figure 3a is described as being near the voiceband. See '596 patent, 25:34-38 ("Because placing narrowband signals near the voiceband reduces filtering costs, . . . this is a preferred method of transmitting these signals. Thus FIGS. 3a and 3c allocate a small part of the spectrum between the voiceband and the video signal to these selection signals."). Indeed, when discussing figure 3a at the Markman hearing, Inline described the control signal centered at 0.5 MHz as "real close to that 4,000 [Hz] we looked at before." D.I. 207 at 247.

Inline notes that "the upper end [of the high frequency band] . . . was not discussed by either party in the Markman briefs . . . " 125 The failure of the parties to present arguments regarding the upper end of the high frequency band is undoubtedly due to the fact that the accused products operate at a range near the voice band and, therefore, the parties likely view the upper range of the high frequency band to be irrelevant to the question of infringement presented in these proceedings. Because the parties provided no argument at all concerning the appropriate upper limit of the "high frequency band," the court determines that it is unable to define a precise upper limit on this disputed term.

Consequently, the court construes "high frequency band" as claimed in the '596 line of patents to mean "frequencies above the telephone voice band between 0.25 MHz and an undetermined upper limit."

3. The Court's Construction of "A High Frequency Band of Frequencies Above the Highest Frequency of the Voice Band" for the '718 Patent

- 2337 -
Although the court previously construed "high frequency band" as having the same meaning in both the '596 line of patents and the '718 patent, after a thorough review of the parties arguments and the patents-in-suit, the court concludes that "high frequency band" must be construed more narrowly for the '718 patent than for the '596 line of patents. Having already determined that the ordinary and accustomed meaning of "high frequency band" is "the range of radio frequencies between 3 MHz and 30 MHz," the court must determine whether the intrinsic evidence demonstrates that the patentee used that term more or less expansively in the '718 patent.

As described above, defendants' opening Markman brief argued for a construction of "high frequency band" in the '718 patent as limited to those frequencies above 6 MHz and for a construction of that phrase in the '596 line of patents as limited to those frequencies above 1 MHz. Defendants then changed their proposed constructions and argued at the Markman hearing for one construction of "high frequency band" to be applied to all of the patents-in-suit. The court's review of the record reveals that, with respect to the '718 patent, defendants' initially-proposed construction is correct.

In support of that construction, defendants' opening Markman brief pointed to language in the '718 patent which states that governmental regulations restrict transmission of non-telephone signals below 6 MHz in the system described. Defendants also pointed out that the '718 patent specifically distinguishes the Tatsuzawa prior art patent on the basis that Tatsuzawa uses frequencies between 0 and 4 MHz, which "creates legal problems" that are avoided by the invention described in the '718 patent.

Plaintiff never specifically responded to either of defendants' arguments concerning the '718 patent's distinguishing of the Tatsuzawa prior art patent or that patent's references to regulations restricting transmission of signals below 6 MHz. In its opening Markman brief, Inline cited the '718 patent's statement that:

The technique disclosed herein embodies an extension designed to avoid interference with telephone signals. The extension calls for the frequency of the electrical version of the control signals to be converted to a higher band before transmission across the wiring. This band will be high enough to eliminate interference with the telephone or low-frequency communication signals.

Inline argued that:

It is clear from the above language that all of the patents contemplate selecting frequencies for the "high frequency band"
that are sufficiently separate from the voice band to avoid causing interference with the telephone signals in the voice band during shared transmission on telephone wiring. The precise choice of frequency above the voice band is not important to the invention as long as interference is avoided with the voice band. 130

Inline contended that "there is no support in the plain language of the claims or the intrinsic evidence [to impose a 6 MHz lower limit]." 131

In its responsive Markman brief, Inline argued that "the patents explicitly teach putting high frequency bands as low as possible and as close as possible to the telephone voice band to avoid signal attenuation . . . [and that] Defendants' construction would create a gap of between [sic] frequencies that is contrary to the teaching of the patents." 132 Inline responded to defendants' argument that, for the '596 line of patents, "high frequency band" should be construed as limited to frequencies above 1 MHz by pointing out that such construction would exclude the preferred embodiment illustrated in figure 3a of the '596 line of patents. 133 Again, Inline did not respond to defendants' arguments regarding regulations restricting transmission of signals below 6 MHz and the Tatsuzawa prior art patent.

Moreover, Inline failed to address directly those arguments at the Markman hearing. Inline merely stated that "a six megahertz barrier . . . [is an] example[, and all [the '718 patent is] talking about is you configure these frequencies in a lot of ways, and here's one example [of] how you can do that . . . ." 134 Giving plaintiff the benefit of the broadest reading possible of that statement, Inline might be understood to contend that defendants' proposed construction would improperly read the description of a preferred embodiment limitation from the specification into the claims. Even that reading is unavailing. References in the '718 patent to the 6 MHz limitation are not descriptions of a preferred embodiment selected by the patentee; they are descriptions of a restriction imposed by government regulations. The '718 patent specifically references this restriction three times.

The first reference is in connection with a discussion of the Tatsuzawa prior art patent. The Tatsuzawa invention is described as:

depending on electrical characteristics particular to frequencies between 0 and 4 Mhz, limiting the transmission of frequency to that band. This creates legal problems because in the U.S., for example, regulations severely limit the RF energy below 6 Mhz that can be fed to wiring that is connected to the public telephone network. 135
Next, the patent reiterates that there can be "legal problems" pertaining to electromagnetic radiation created when video signals are transmitted across telephone wiring. The patent states that these legal problems are avoided by transmitting video signals above 6 MHz: "in contrast to regulations covering radiation, no specific legal problems are created in the U.S. by the connection of radio frequency devices to the public telephone network if those devices do not transmit energy below 6 Mhz."  

Finally, in discussing control signals, the '718 patent again references the regulations concerning transmission of energy below 6 MHz but notes that those regulations are not a problem for the invention described therein because "the U.S. Federal Communications Commission imposes no restrictions on signals above 6 Mhz, leaving ample room [for transmission of a control signal] between that frequency and the video signals, even if a channel below VHF 2 is used."  

The '718 patent, therefore, identifies 6 MHz as the lower limit of frequency transmission permitted by government regulations and not as merely an example of a limitation described as part of a preferred embodiment which should not be read into the claims. This restriction is described as affecting both transmission of video and control signals. Furthermore, nothing in the intrinsic record contradicts this conclusion and no preferred embodiments are read out of the patent as a result of defining 6 MHz as the lower limit of the "high frequency band." In fact, the preferred embodiments described in the '718 patent describe transmission of video signals at frequencies significantly higher than 6 MHz. The patent states that "the most natural choices for transmission frequencies are the channels in the low VHF range . . . [which are] VHF channels 2 through 6, which extend from 54 Mhz to 88 Mhz." The lowest frequency band at which the inventors conducted video-transmission experiments was in the channel spanning from 24 MHz to 30 MHz. With regard to control signals, the preferred embodiment describes transmission of a control signal at 10.7 MHz. As noted above, however, the specification indicates that control signals can be transmitted in a range between 6 MHz and the lower limit of a transmitted video signal. Nowhere does the specification suggest transmission of any video or control signal below 6 MHz.
the specification states that "at the video source end, the transceiver must convert the signal from the frequency at which it is supplied to a band between 6 Mhz and 54 Mhz." (emphasis added)).

In light of plaintiff's deafening silence in response to defendants' specific argument regarding the government regulations restricting transmissions below 6 MHz, the court can only assume it had no viable argument to make. The court therefore concludes from this silence, and its review of the intrinsic evidence, that the lower limit of the "high frequency band" claimed in the '718 patent is 6 MHz. As with the '596 patent, the parties failed to present any argument concerning the upper limit of the "high frequency band" claimed in the '718 patent. This failure again precludes the court from defining the upper limit of "high frequency band" other than to note that the '718 patent includes several examples of transmission at frequencies above the limit of 30 MHz to which the court's prior construction limited this phrase. 143

Consequently, the court construes "high frequency band" as claimed in the '718 patent to mean "frequencies above the telephone voice band between 6 MHz and an undetermined upper limit." 144

143 See, e.g., '718 patent, 10:60-67; figure 3.

144 If the parties wish to present arguments to the court concerning the upper limit of the phrase "high frequency range" for any of the patents-in-suit, they may notify the court of this desire and a briefing schedule will be determined at that time. If the parties ultimately submit further briefing on the upper limit of "high frequency band" as claimed in the '596 line of patents, the court directs the parties' attention to the following language in those patents:

At higher frequencies, the 10 dB advantage of a 15 MHz FM signal may not be sufficient to overcome the extra attenuation. The solution, in that case, is to use wider FM bandwidths which produce a greater SNR improvement at the receiver. This, of course, brings one to even higher frequencies more quickly with each channel that is added. Because of this, the inventors expect that higher frequencies will not be useful beyond some point, and certainly not beyond 1000 MHz." '596 patent 21:12-20 (emphasis added). Referencing this statement, the specification acknowledges that "as mentioned above, there is an upper limit to the frequencies that can be useful for transmission of signals across a transmission path of a given length." '596 patent 21:62-64 (emphasis added).

Any submissions should address this language and its effect on the parties' analyses.

VI. CONCLUSION

For the reasons set forth above, the court modifies its prior construction of the disputed terms of the patents in suit as follows:

"high frequency band"; and "high band undetermined upper limit of frequencies" ('718 patent)

1946

A. "A high-frequency power MOSFET device" (’715 patent, claim 23)

Both parties agree generally that a high-frequency device in this context is one that operates at between 1 Mz and 900 Mz. However, the parties disagree about what it means for a device to "operate." Defendant claims that the word operate is itself ambiguous and must therefore be defined with respect to extrinsic evidence, namely the declaration of Douglas Pike, while plaintiffs argue that it would contravene Vitronics either to engage in the construction of specification language (rather than claim language) or to employ extrinsic evidence where the meaning of a term is clear from the language and specifications of the claim itself. Vitronics, 90 F.3d at 1583.

This court is mindful of the fact that it must interpret only claim terms, not specification language, and of the fact that it must not employ extrinsic evidence (particularly expert testimony) unless language of the claims and specifications do not fully answer the questions at hand. Vitronics, 90 F.3d at 1584-85. At the same time, it would be nonsensical, not to mention hardly efficacious, for this court to employ a term that was itself materially ambiguous in construing claim language. Yet "operate" is not a particularly unclear term, even in this context, and certainly not to the degree defendant suggests. A device that "operates" in a certain frequency range is one that "functions properly" or "functions as intended" within that range, with all of the attendant limitations implied by that language. This court is reluctant to apply defendant's particularized limitation of "capable of delivering at least a 50% duty cycle" where that language may be both under- and over-inclusive of a device's "operation." The court thus adopting plaintiff's construction, minus the qualifier "about," which appears nowhere within the specification. The court construed this claim to mean: "A power MOSFET device which operates between 1 Mz and 900 Mz."

1947

2. "Power Supply Circuit"

Claims 28, 36 and 38 of the Reissue Patent incorporate a power supply circuit. The principle area of dispute, it appears, is the parties' disagreement over whether terms such as "constant current" and "high impedance," as used in the context of the Reissue Patent, are too ambiguous and require a precise numerical value. In regards to the power supply circuitry of claim 28, Rockford argues that: (a) the term "constant current" is limited to current deviations less than 0.1% per volt change in input source reference potential because the specification only shows circuits that have currents with less deviation; (b) the term "high impedance" is limited to impedances greater than 25 kilo-ohms because the specification only shows circuits having higher impedance; and (c) the phrase "increase electrical isolation between the first stage and the at least return signal" lacks definite meaning because the first stage is not isolated from the return reference potential, and the patent provides no baseline for measuring increase. (Def.'s Markman Br. at 2-3, 32-44.)

Rockford argues that the terms "constant current" and "high impedance" require some absolute numerical value because they are ambiguous and indefinite. Id. at 23-27. According to Rockford, the term "constant current" of claim 28 of the Reissue Patent is limited to current deviations less than 0.1% per volt change in input source reference potential because the specification only shows circuits that have currents with less deviation. (Def.'s Markman Br. at 2.) Rockford also alleges that the term "high impedance" is limited to impedances greater than 25 kilo-ohms because the specification only shows circuits having higher impedance. Id. Finally, Rockford concludes that the phrase "increase electrical isolation between the first stage and the at least one return reference signal" lacks definite meaning because the first stage is not isolated from the return reference potential, and the patent provides no baseline for measuring an increase. Id. at 2-3.

Fiori counters that the intrinsic evidence clearly demonstrates that the claim language of the patents-in-suit were presented and approved by the PTO examiners, and therefore do not violate 35 U.S.C. § 112 (2) or require some absolute numerical
value. (Pl.'s Markman Br. at 11.) Fiori asserts that "[t]he specification and Figures provide a complete definitional framework" for its claims. (Pl.'s Markman Br. at 20.) He contends that the Reissue Patent defines "constant current" as an exact current precisely metered through each transistor to operate the op-amps. Id. at 27. Fiori claims that the specification of the Reissue Patent teaches and defines that this power supply provides a current to the first stage preamplifier circuit that does not respond to changes in the potential of the supply pins of the op-amps (e.g., 38) so that the first stage is able to track the input reference signal without inducing any corrupting noise variations in the preamplifier circuit or in the return input reference signal current pathway. Id. According to Fiori, because the current is metered precisely, any changes and potential of the op-amp supply pins will have no bearing on the current delivered. Id. As a result, the effective impedance of the power supply is extremely high. n28 Id. Fiori further contends that "constant current," defined in the specification with precision, is a "degree term." (Pl.'s Markman Br. at 11 n.5.)

n28 Figure 3 in the specification similarly describes an alternative power supply for providing a constant current.

The Federal Circuit has consistently held that terms of "degree" such as "high", "low", "substantially", "significantly", "approach each other", "close to", "substantially equal", and "closely approximate" are definite under 35 U.S.C. § 112 (2) and do not require further mathematical precision. See Seattle Box Co. v. Industrial Crating & Packing, 731 F.2d 818, 826 (Fed. Cir. 1984) (citing W.L. Gore & Assoc's., Inc. v. Garlock, Inc., 721 F.2d 1540, 1557 (Fed. Cir. 1983), cert. denied, 469 U.S. 851, 105 S. Ct. 172, 83 L. Ed. 2d 107 (1984)) ("substantially equal" is a term of degree, and that its acceptability depends on "whether one of ordinary skill in the art would understand what is claimed . . . in light of the specification"); see also Shatterproof Glass Corp. v. Libbey-Owens Ford Co.,758 F.2d 613, 624 (Fed Cir. 1985) cert. denied, 474 U.S. 976, 106 S. Ct. 340, 88 L. Ed. 2d 326 (1985) (citing W.L. Gore & Assoc's., Inc. v. Garlock, Inc., 721 F.2d 1540, 1557 (Fed. Cir. 1983), cert. denied, 469 U.S. 851, 105 S. Ct. 172, 83 L. Ed. 2d 107 (1984)). The Federal Circuit has noted in Andrew Corp. v. Gabriel Electronics, Inc., 847 F.2d 819, 821 (Fed. Cir. 1988), such words are ubiquitous in patent claims. Such usages, when serving reasonably to describe the claimed subject matter to those of skill in the field of the invention, and to distinguish the claimed subject matter from the prior art, have been accepted in patent examination and upheld by the Courts. See Rosemount Inc. v. Beckman Instruments, Inc., 727 F.2d 1540 (Fed. Cir. 1984). Furthermore, when a claim term is expressed in general descriptive words, the Court will not limit the terms to a numerical range that may appear in written description or in other claims. See Modine Mfg. Co. v. U.S. Int'l Trade Comm'n, 75 F.3d 1545, 1551 (Fed. Cir. 1996) (citation omitted). Accordingly, this Court finds that Rockford's interpretation that the terms "constant current" and "high impedance" require some absolute numerical value is unpersuasive. The general descriptive terms in which the terms are expressed are acceptable under the present state of the law.

In regards to the power supply circuitry of claims 36 and 38, Rockford argues that: (a) the location of the "constant current" in both claims is between the power supply and the first power supply circuit because claims 36 and 38 state that the first power supply circuit draws the current from the power supply; and (b) the elements of the voltage regulation means in claim 38 include a bias voltage circuit. (Def.'s Markman Br. at 24-30.)

In its Markman brief, Rockford first contends that the ordinary meaning of the words of claims 36 and 38 place the "constant current" between the power supply and the first power supply circuit. Id. at 25. According to Rockford, analogous to a "farmer drawing n29 water from a well," the first power supply circuit performs the act of drawing and the power supply circuit draws current toward itself from the power supply. Id. at 26. Thus, Rockford believes that the location of the "constant current," as described in both claims, must be restricted because the limitations refer "to the particular water the farmer takes from the well" . . . and do "not refer to water used in the barn where animals drink." Id.
This Court does not agree. As previously stated, "if the claims, read in the light of the specification, reasonably apprise those skilled in the art both of the utilization and scope of the invention, and if the language is as precise as the subject matter permits, the courts can demand no more." Shatterproof Glass Corp. v. Libbey-Owens Ford Co., 758 F.2d 613, 624 (Fed Cir.) cert. dismissed, 474 U.S. 976, 106 S. Ct. 340, 88 L. Ed. 2d 326 (1985) (quoting Georgia-Pacific Corp. v. U.S. Plywood Corp., 258 F.2d 124, 136, cert. denied, 358 U.S. 884, 79 S. Ct. 124, 3 L. Ed. 2d 112 (1958)). Here, the term "constant current," as described in claims 36 and 38, is specifically defined in the specifications and claims and is not required to be situated between the first power supply circuit and the power supply. As such, Rockford's construction of claims 36 and 38 is too narrow in scope and its "farmer and the well" rationale is tenuous and unpersuasive. Rockford further asserts that the "voltage regulation means" of claim 38 includes the voltage regulator circuitry found within the constant current circuits. Despite the parties stipulating that "voltage means" includes transistors 22, 24, resistors 21, 25, and op-amps 23 and 26, Rockford interprets the pertinent language of the specification n30 of claim 38 to include elements 80, 82 and 84 and 85 and the op-amps requiring a bias voltage circuit. Id. at 2, 25, 27-30. According to Fiori, the first and second stage recitals of claim 38 are identical in scope to claim 36 and the power supply in claim 38 is recited as comprising a voltage regulating means for drawing the constant current from the first power supply with respect to the changes in the input source reference potential to isolate the first power supply circuit from the first stage. (Pl.'s Markman Br. at 29.) Moreover, Fiori contends that the specification describes the voltage regulation means as the transistors 47, 22, 50 and 24 in combination with the resistor and op-amps and zener diode 43 and 45. Id.

n30 The op-amps provide the biasing necessary for the transistors to conduct exactly that current required to produce that voltage across the resistors that match the biasing voltages produced by zener diodes 80 and 85 in combination with resistors 82 and 84. The Reissue Patent, column 5, line 18-27. Capacitors 81 and 86 are included to further reject any interference which may be present on the power supply as provided by contacts 91, 89 and 90. In this way, an exact current is precisely metered through each transistor to operate op-amps 13, 16, 38 and 41. Id. The op-amps provide the biasing necessary for the transistors to conduct exactly that current required to produce that voltage across the resistors that match the biasing voltages produced by zener diodes 80 and 85 in combination with resistors 82 and 84. Id. Capacitors 81 and 86 are included to further reject any interference which may be present on the power supply as provided by contacts 91, 89 and 90. Id. In this way, an exact current is precisely metered through each transistor to operate op-amps 13, 16, 38 and 41. Id.

n31 Similarly, Rockford's argument that Fiori's claim constructions are unfounded in an effort to cover up the flaws of Plaintiff's case, is irrelevant for purposes of this Markman process. (Def.'s Rebuttal Br. at 25-30.)

IV. CONCLUSION

The Court concludes that the disputed terms have the following meanings:

1. "Input Portion" of claims 1 and 17 of the '148 Patent shall mean a specifically defined physical structure, connected to two conductors and recited as generating an intermediate signal.

2. "Output Portion" of claims 1 and 17 of the '148 Patent shall mean a physical structure, specifically defined as op-amp 65, which is separate, independent and isolated from the input operational amplifier and recited as generating a destination signal and a corresponding destination reference signal.

3. "Second Stage" of claim 28 of the Reissue Patent shall mean a stage, operatively coupled to the first stage, n32 generating
an output signal which is a sum of the at least one intermediate signal generated in the first stage minus a potential of the at least return reference signal plus an output return reference signal.

4. "High Impedance" of claim 28 of the Reissue Patent shall mean a mathematically sufficient term of degree for providing a constant current power supply circuit coupled to said first stage to increase electrical isolation between the first stage and the at least one return reference signal.

6. High Impedance Condition

The parties generally agree that the term impedance is well-known to those with ordinary skill in the art, and refers to the resistance in an electrical circuit to the flow of a current. Both parties also agree that in the context of the '183 patent, the impedance is sufficiently high to disable communication between the AUI and the twisted pair link. The only disagreement between the parties with respect to this term is whether it can include an automatic switch.

Seeq, citing to the first Office Action, relies on the examiner's conclusion that an automatic switch would have been obvious from the prior art. During the Office Action, the examiner stated:

"It would have been obvious to use the automated selector of Strecker et al in place of the jumper as it is well known that manual switches may be replaced by automate switches. . . . The high impedance state would have been obvious as the selector switch of Strecker et al connects either one bus or the other, hence, the inactive bus is disconnected from the receive processing circuit in a high impedance state."

Guy Decl., Ex. B at 3.

However, Seeq fails to account for the amendment submitted by applicants discussing the invention in light of the prior art. Nor does Seeq address the fact that the amended patent application was subsequently allowed. As Level One points out, in response to the rejection by the examiner, applicants submitted that none of the prior art enabled a computer to communicate over both an Ethernet bus and a twisted pair link; rather it taught how to mediate access to the Ethernet bus to prevent monopolization of it. Plaintiff. Opp'n, App. B at 8. Applicants further noted that switches are not interchangeable, but instead, must be designed to appropriately interface the circuits that one desires to join. The Applicants' 10Base-T MAU not only provides interface signal conditioning between the AUI and the twisted pair links but also provides jabber control and collision avoidance circuitry. Thus, the Applicants' invention allows data terminal equipment to communicate with other data terminal equipment via an Ethernet bus or alternatively over a twisted pair link.

Applicants point out that Strecker does not disclose means for interfacing an attachment unit interface to a twisted pair media.

Plaintiff. Opp'n, App. B at 7. Seeq's argument that the term high impedance condition cannot include in its scope an automatic switch is based on an incomplete account of the prosecution history and is therefore unpersuasive. Seeq is correct, however, that the '183 patent is directed only to a twisted pair MAU and not a coaxial MAU and that it does not encompass a switch that operates on both MAUs. Yet the claimed invention could encompass an automatic switch that controlled the twisted pair MAU alone. Based on this court's reading of the prosecution history the term does not preclude use of an automatic switch directed to a twisted pair MAU.
Accordingly, high impedance condition is construed to mean an impedance sufficient to disable communication between the AUI and the twisted pair link.

1949

(5) In claims one and three, the term "high instantaneous energy." 9 Defendants argue that the term must be read in light of the entire claim and that a person of ordinary skill in the art would understand the term to mean that the light pulses from the laser have enough energy or power to produce fluorescence when two photons of long wavelength light are absorbed and their energies are combined in the fluorophore. 613 Patent 2:32-59; 3:9-22; 6:22-24. In their claim construction brief, Plaintiffs argued the term should mean about 25 milliwatts, consistent with the definition in the specification. 613 Patent 7:40.

In support of Defendants' position, Dr. Walmsley testified that one of ordinary skill in the art would understand the term to mean the "instantaneous intensity required to produce two photon fluorescence in the target material." Tr. 206. The patent demonstrates that the high instantaneous energy is determined by reference to the particular fluorophore. Tr. 208; 613 Patent 2:52 ("Because of the high instantaneous power provided by the very short duration intense pulses focused to the diffraction limit, there is an appreciable probability that a fluorophore, contained in the target material, and normally excitable by a single high energy photon having a short wavelength, typically ultraviolet, will absorb two long wavelength photons from the laser source simultaneously."). Dr. Walmsley explained that equation two in the patent demonstrates that the level of energy depends on the power of the laser, pulse duration and repetition rate. Tr. 211-13. The prosecution history also supplies a definition. It states the long wavelength pulses provide "sufficient instantaneous power to produce simultaneous absorption of two incident photons to excite fluorescence in the target material." Prosecution History at 117.

Further, Defendants' second expert, Dr. Svoboda, explained that high instantaneous energy is required to make two photon microscopy work. Tr. 319-20 (discussing 613 Patent at 2:52, 3:9, 6:22). More importantly, Dr. Svoboda explained that the 25 milliwatts referred to in the patent refers to the average power of the laser. Tr. 325; 613 Patent at 7:42. High instantaneous power refers to the "very, very high power that occurs only very, very briefly during a pulse. The average power, though, is much lower than the peak power because it's averaged over the whole time . . . ." Tr. 325. If 25 milliwatts was used as the instantaneous energy intensity, Dr. Svoboda believes it would take a week to form an image. Tr. 327.

At the Markman hearing, Plaintiffs appeared to abandon their dispute concerning this term. Dr. Fraser testified that high instantaneous energy did not have to be constrained to 25 milliwatts. Tr. 534. Accordingly, the Court interprets the terms "high instantaneous energy" and "high intensity" to mean: "The pulses of light generated by the laser produce sufficient energy so that two photons will be absorbed by the fluorophore in the target material to produce fluorescence."

1950

A. Meaning of "High Level Commands"

Veritas argues that the term "high level commands" in claim 1 is neither commonly understood in the art nor expressly defined in the specification. SCC relies on language in the specification that it argues defines "high level commands" by example:

The file system supervisor 32 operates to determine the appropriate file-level applications for receipt of the files received from the client computer 10. The file system supervisor implements file specific routines on a common format file system. Calls made to the file systems supervisor are high level, such as Open, Close, Read, Write, Lock, and Copy.
Id. at 82 (col. 4, l. 22-28).

Veritas responds that other parts of the specification also use "high level" to refer to volume, array and block level commands. See id. 83-84 (col. 5-7). That is true. However, as SCC points out, those references are used in the context of other parts of the patent. What is high level in one context may very well be different in another. Those alternate uses of "high level" do not detract from the explanatory force of the quoted language. The Court holds that the specification sufficiently explains the term "high level commands" as used in claim 1 as being file-level commands such as open, close, read, write, lock, and copy.

1951

C. High Order Commands (Claims 1, 11)

HP suggests the following construction of "high order commands": "commands that cause the performance of operations, such as, but not limited to, 'display,' 'write,' 'erase,' or 'read,' on the designated system." Intergraph proposes the following construction of the disputed phrase: "a message that has to be parsed, and once parsed, causes the performance of a necessary operation, such as display or write, on the entire design represented by the hierarchy."

HP’s proposed construction relies upon language in the preferred embodiment which states that "[a]ccess to the tree of data records is through high order commands such as those indicated at 35-38 [in Fig. 8]. These . . . perform operations, such as DISPLAY and WRITE, on the entire design which the designer has laid out." '208 patent, col. 5:62-65. HP explains that software applications implementing the '208 patent will include a set of "high order commands" unique to the particular system being designed, which invoke the various operations that are conducted on the primitive elements of the designed system.

Intergraph’s proposed construction relies heavily upon language in the specification. Intergraph argues that the concept of parsing the high-level programs is prevalent throughout the '208 Patent. See e.g., '208 Patent, col. 5:65-67 ("Note that only these high level programs need to be parsed to interpret the character string to determine what operation is to be performed."); see also col. 6:4-6 ("Only the high level commands, such as 35-38, require time for the interpretation of character strings.").

Once again, Intergraph has attempted to import a limitation from the preferred embodiment into the claims. Neither the term "message" nor the term "parsed" appear anywhere in the patent claims. Therefore, Intergraph's proposed construction is simply too narrow. Likewise, HP's proposed construction also relies too heavily upon language from the preferred embodiment by using such terms as "display" and "write." Most helpful to the Court is language from the specification that states "[a] series of high order, very simple, commands operate selected manipulative programs in the hierarchy." This language appears to mirror claim 1, which states that "high order commands . . . operate selected manipulative programs in said hierarchy." Likewise, claim 11 states that "high order commands . . . provide access to the hierarchy of data objects." Based primarily on language of claims 1 and 11, along with the cited language in the specification, the Court construes "high order commands" as commands which provide access to selected manipulative programs which cause the performance of operations on the designed system.

1952

(6) In claim one, the term "high repetition rate." This term is used to characterize the rate of subpicosecond laser light pulses directed at the target material. According to Defendants, the use of 80 megahertz (MHz) in the specification is only an example and not a precise definition. Rather, a high repetition rate is one in which the laser light pulses are repeated frequently enough so that a fluorophore that is normally excitable by a single high energy photon with a short wavelength will absorb two long wavelength photons from the laser source simultaneously to produce fluorescence. Plaintiffs, on the other hand, argue that the specification dictates that the rate be about 80 MHz. 613 Patent 2:48 ("repetition rate of about 80MHz"); 6:38 ("at about 80 MHz repetition rate"); 7:5 (same).
On behalf of the Defendants, Dr. Walmsley explained that the patent language demonstrates that the term relates to a stream of rapidly repeating high intensity pulses of light. Tr. 204; see e.g., 613 Patent 3:13 ("stream of fast, high intensity pulses"), equation two (demonstrating inventors understood the rate to be variable). He also explained that in his field of expertise tens of megahertz to hundreds of megahertz would be considered a high repetition rate. Tr. 205. Dr. Svoboda added that to a person of ordinary skill the term would mean a rate "sufficiently high for practical two-photon excitation microscopy." Tr. 341.

Dr. Fraser testified that a colliding pulse mode locked laser is offered as the only embodiment of the patent and it had a repetition rate of 80 megahertz. On cross examination, he admitted that the repetition rate could vary according to equation two in the patent. Tr. 532.

Again, the Court will not limit the term to the one embodiment described in the patent. Karlin, 177 F.3d at 973. As it is agreed that equation two allows for a variable repetition rate, the Court will not limit the term to 80 megahertz. Accordingly, the Court interprets the term to mean: "The light pulses produced by the laser are repeated at a rate high enough so that a fluorophore normally excitable by a single high energy photon having a short wavelength will absorb two long wavelength photons from the laser source simultaneously to produce fluorescence and an image may be acquired in a practical amount of time."

4. High speed

The term "high speed" appears in claims 12 (by its dependence from claim 11), 39, and 52 of the '121 patent, and in claim 119 of the '845 patent. The parties agree that the term "high speed" shares a common construction with the term "multi mega bit per second." Therefore, the court concludes that the term "high speed" means "an aggregate data transmission rate of 10 or more megabits per second."

5. The Preamble

The district court held that the preamble phrase "high speed manufacture of a single copy of a book" does not limit the claim to immediate printing or require that only one copy be printed, and instructed the jury that:

The phrase "high speed manufacture" in the preamble does not limit the claim to require that all other steps, such as a customer's scanning sales information, selecting a book, and then printing and binding a book must take place within a short period of time. The preamble also does not limit the claim to the manufacture of a "single copy" of a book, as opposed to manufacturing several or multiple copies. . . . and does not require that the book be bound with a cover.

The defendants argue that this instruction is incorrect, and that the preamble explicitly limits the claim, in that it states the invention to which the claim is directed. They also point out that clauses [9], [10], and [11] require a cover.

In considering whether a preamble limits a claim, the preamble is analyzed to ascertain whether it states a necessary and defining aspect of the invention, or is simply an introduction to the general field of the claim. In Kropa v. Robie, 38 C.C.P.A. 858, 187 F.2d 150, 152, 1951 Dec. Comm'r Pat. 177 (CCPA 1951), the court aptly described the inquiry as whether the preamble is "necessary to give life, meaning and vitality to the claims or counts." See, e.g., Poly-America, L.P. v. GSE Lining Tech., Inc., 383 F.3d 1303, 1309-10 (Fed. Cir. 2004) (the specification described the "blown-film" as a fundamental characteristic of the invention, and its use in the preamble limited the claims); In re Cruciferous Sprout Litigation, 301 F.3d 1343, 1347-48 (Fed. Cir. 2002) (the preamble phrase "rich in glucosinolates" was limiting because the patentee relied on the preamble to distinguish the prior art in prosecution); General Elec. Co. v. Nintendo Co., Ltd., 179 F.3d 1350, 1361-62 (Fed. Cir. 1999) (where the specification made clear that the invention was a mode of display of binary data on a raster scanned
display device rather than all display devices, the preamble language "displaying a pattern on a raster scanned display device by mapping bits" was a claim limitation).

The preamble serves to focus the reader on the invention that is being claimed. We conclude that the preamble in this case necessarily limits the claims, in that it states the framework of the invention, whose purpose is rapid single-copy printing of a customer's selected book as stated in clauses [5], [6], [7], and [8]. The high speed manufacture of a single copy is fundamental to the Ross invention, for the specification highlights that the customer may have a printed and bound copy within "three to five minutes." Col. 2, line 33. While ODMC points out that Lightning Source's web site touts "In one week, we craft 70,000+ books, one at a time," such mass production is not the invention described and claimed by Ross.

The district court's instruction that the preamble in this case does not limit the claim was incorrect, for the entirety of the claim implements the preamble's high speed manufacture of a single copy, upon customer review of the stored sales information, promptly printing and binding the single copy in response to the customer's selection. The preamble embraces the totality of these limitations, and limits the claim to the subject matter of the preamble.

1955

E. Highest H[\text{max}] and lowest H[\text{min}]

Finally, Honeywell appeals the district court's claim construction of the requirement of a "highest H[\text{max}] and lowest H[\text{min}]." Claim 1 of the '009 patent requires the terrain display to include "the highest h[\text{max}] and lowest h[\text{min}] terrain levels of said portion of the terrain." The district court construed this phrase to require "that the display show a numeric value for the highest and lowest points." Claim Construction Decision, 264 F. Supp. 2d at 155. The district court stated that "without numeric values, the highest and lowest points display would be useless to the pilot because he would have no frame of reference of the terrain relative to the aircraft." Id.

Once again, as occurred with the numeric inclusion above, the district court included an unnecessary limitation in the claim. Indeed, dependent claim 21 specifically discloses a display with numeric information. '009 patent col.40 ll.8-10 ("The system of claim 1 wherein said contour means additionally displays on said cockpit display a range value.") As this court has noted, "the claims themselves provide particular meaning to claim terms." Phillips, 415 F.3d at 1314. "Other claims of the patent in question, both asserted and unasserted, can also be valuable sources of enlightenment as to the meaning of a claim term." Id. (citing Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed Cir. 1996)). Finally, "the presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." Phillips, 415 F.3d at 1315 (citing Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 910 (Fed. Cir. 2004)). Thus, the language of claim 21 is strong evidence against limiting claim 1 to require a numeric display. As such, this court construes the claim phrase "highest h[\text{max}] and lowest h[\text{min}]" to require only an apparatus that shows the highest and lowest points of the terrain within the portion of terrain displayed.

1956

2. "Highly collimated projected scanning pattern"

Plaintiff Metrologic argues that "highly collimated" refers to the requirement that the infringing device must have a rich pattern into which bar coded items can be presented for reading irrespective of orientation. See Pl.'s '852 Markman Br. at 13. Plaintiff asserts that this construction follows directly from the language in Limitation 15 which reads "the code symbol is scanned omnidirectionally by said highly collimated scanning pattern . . . ." '852 Patent, col. 12, 11. 53-54. In addition, as discussed below, plaintiff relies upon the file history of the '232 patent, a parent application to the '852 patent.

PSC construes "highly collimated" to mean that the rays of light must be made as close to parallel as possible. Defendant asserts that this limitation should be construed to mean that the "scan pattern [] changes as little as is practically possible in size and shape over the entire range of distances from the window of the scanner over which a bar code may be read." Def.'s
'852 Br. Mot. Summ. J. at 18. Thus, defendant contends, the size and shape of the pattern varies very little throughout the entire operating range of the scanner, thereby creating a column-like pattern as it is projected out of the scanner. Id. at 18-19. Plaintiff specifically contests PSC's construction that the rays of light be "as close to parallel as possible," stating that the "highly collimated" phrase refers to a "rich set of lines in which a bar code can be read omnidirectionally." Pl.’s ’852 Markman Br. at 14.

The Court herein reviews the claim language, the specification, and the prosecution history. The claim language of patent ’852 states:

(h) control means within said compact housing for controlling the operation of said counter-top projection laser scanner so that, during scanner operation, the laser beam produced from said laser beam producing means passes along a portion of said central reference plane, to the first, second and third rotating light reflective surfaces of said laser beam sweeping means, and as the laser beam sequentially reflects off said first, second and third rotating light reflective surfaces, the laser beam is repeatedly swept across said first, second, third, and fourth and fifth stationary light reflective surfaces thereby producing first, second, third, and fourth and fifth groups of plural scan lines, respectively, which are projected out through said light transmission window and intersect about a projection axis within a narrowly confined scanning volume extending from adjacent said light transmission window to at least about six inches therefrom so as to produce a highly collimated projected scanning pattern within said narrowly confined scanning volume, . . .

'852 Patent, col. 12, 11. 26-45. The contours of the phrase "highly collimated projected scanning pattern" is given by the claim language directly preceding it. The "projected scanning pattern" encompasses five groups of plural scan lines, created by passing a laser beam off a central reference plane, and sweeping the laser beam off of three rotating light reflective surfaces and five stationary light reflective surfaces. These five groups of plural scan lines are projected out through the light transmission window about six inches or so and intersect about an axis. Reference to the "highly collimated projected scanning pattern" being produced within said "narrowly confined scanning volume" and extending to at least six inches from the light transmission window indicates that the pattern is projected within the narrow volume of light emitted from the scanner. Because the pattern is confined to this volume, yet is at least half a foot in length, this falls in favor of construing the term "collimated" to mean that the projection of the scanning pattern is columnar, rather than that it encompasses a rich pattern of scan lines, thereby allowing items to be read omnidirectionally, as proposed by plaintiff.

Subsection (i) of claim 1 also refers to the "highly collimated scanning pattern" as being "within" the "highly collimated scanning volume." This claim language provides:

Said compact housing being supportable relative to a counter-top surface so that, during scanner operation, said highly collimated scanning pattern is projected above said counter-top surface within said highly collimated scanning volume . . .

'852 Patent, col. 12, 11. 46-50 (emphasis added). That the term "highly collimated" describes both the scanning pattern as well as the scanning volume indicates reference to the shape of both the volume and the pattern, not that the term refers to a rich set of lines in which a bar code can be read omnidirectionally. Additionally, subsection (h)'s reference to the scanning volume as a "narrowly confined scanning volume," '852 Patent, col. 12, 11. 44-45, indicates the interchangeability of the terms "highly collimated" and "narrowly confined," and creates the strong implication that the term "highly collimated" refers to the columnar nature of both the volume and the projected pattern.

That the term "highly collimated" refers to the projected scanning pattern being as parallel as is possible is supported by the ordinary dictionary definition of the term "collimated." The ordinary meaning of the term "collimated" is "to make (as light rays) parallel," Merriam-Webster’s Collegiate Dictionary (1993), Palmer Decl. Ex. D; Def.’s Markman Ex. 34, the term "highly collimated" refers to a shape in which the light rays are as parallel as possible. The McGraw-Hill Dictionary on Scientific and Technical Terms also defines a "collimated beam" as "beam of radiation or matter whose rays or particles are nearly parallel so that the beam does not converge or diverge appreciably." Hyun Decl. P11.

Plaintiff Metrologic argues that the dictionary definition in and of itself does not give meaning to the term "highly collimated," and that the plaintiff is its own lexicographer. If plaintiff is its own lexicographer, its definition must be "clearly stated in the patent specification or file history." Vtronics, 90 F.3d at 1582 (citing Hoechst Celanese Corp., supra, 78 F.3d at 1578). Although plaintiff urges this Court to construe "highly collimated" to refer to a rich set of lines in which bar code items can be presented and read in varying orientations, there is no definition to this effect in the specification, claim
language, or file history.

Rather, with respect to the rich set of scan lines, the description of the preferred embodiment in the specification provides:

The scanning pattern of the subject invention is confined within a relatively narrow, yet diverging volume centered about a projection axis from the scanner (as will be described later) and includes plural groups of intersecting scan lines to create a "rich" pattern. This "rich" pattern ensures that sufficient lines of the pattern will sweep across the entire bar code to enable the proper reading or decoding thereof by conventional decoding means located within the scanner 20, irrespective of the orientation of the bar code within the scanning pattern. Moreover, by virtue of the fact that the volume or space in which scanning pattern is projected is somewhat narrow or confined, the amount of counter space which must be kept clear of other bar coded items to enable the proper scanning of the selected bar coded item, can be kept to a minimum.

'852 Patent, col. 4, ll. 46-60. While it is true that a purpose of the invention is to scan objects irrespective of their orientation and to prevent unintentional scanning of objects, no reference to "collimated" as being defined by the "rich" set of scan lines is made.

The specification instead supports a construction of "highly collimated" as referring to the columnar nature of the projected scanning pattern, as the Summary of the Invention provides that

The scanning pattern is generally confined within a relatively narrow, yet diverging, volume, e.g., pyramid, cone, frustum, etc., centered about a projection axis which is substantially but not precisely perpendicular to the plane of the window. '852 Patent, col. 3, ll. 15-20. Moreover, in conjunction with the claim language's usage of the terms "highly collimated" and "narrowly confined" interchangeably, discussed above, this language implies that the scanning pattern and volume share a "relatively narrow, yet diverging" shape. The specification language also refers to the term "highly collimated" as coterminous with "focused," with respect to the volume: "The highly collimated or focused volume of the scan prevents unintentional scanning of nearby objects." '852 Patent, col. 11, ll. 24-25.

Although defendant argues that "highly collimated" refers to light rays that are as close to parallel as is possible, the Summary of Invention provides that "the scanning pattern comprises plural, e.g., five, groups of plural, e.g., four, parallel scan lines." '852 Patent, col. 3, ll. 8-10. This indicates that the lines included within the scanning pattern consist of groups of scan lines, each individually consisting of parallel lines. The scanning pattern itself contains these groups of parallel lines, and, therefore, may not be completely parallel or linear, as a result of the groups of lines protruding from different angles.

As for prosecution history, defendant PSC counters that there have been 7 rejections by the PTO of the '852 patent, therefore resulting in a patent requiring very narrowly termed claims that necessarily point to "highly collimated" as referring to the laser beam shape, not the rich set of lines as plaintiff contends. Exhibit 20 from defendant PSC's presentation on the '852 patent lists 7 rejections based on prior art under 35 U.S.C. §§ 102, 103, and 112. See Def.'s '852 Markman Presentation, Slide 20; Vinti Decl. Ex. D. PSC argues that plaintiff in these amendments sought to differentiate its invention from previous inventions, and in so doing, cannot claim that which it disclaimed. Defendant's argument that Metrologic should be estopped from disputing the accuracy of that definition, citing to Jonsson v. Stanley Works, 903 F.2d 812, 818 (Fed. Cir. 1990) is persuasive. In that case, the patent holder had argued in the patent prosecution that "diffuse light" refers to light emanating from multiple emitters. Although the patent holder argued that "diffuse" did not require production from multiple sources, the Federal Circuit determined that the district court did not err in its determination that he was estopped from asserting that his patent was not limited to multiple emitters. This case presents a similar situation. For example, one amendment after final rejection dated September 10, 1990, provides that plaintiff attempted to differentiate itself from prior art scanners by stating that previous "slot or counter type scanners produce a scanning pattern which is not collimated, but rather which spreads out or diverges widely."

Thus, in plaintiff's own words, "collimated" should be construed as the opposite of "diverging widely" or "spread out widely." In other words, as consistently used by plaintiff in the prosecution history, "collimated" is understood to mean that little divergence occurs. In addition, although plaintiff had used the term "substantially collimated scanning pattern," the PTO rejected this application based on prior art, thus causing plaintiff to amend the claim to read "highly collimated," rather than "substantially collimated." Thus, as defendant successfully argues, plaintiff is estopped from asserting that the claim language "highly collimated" refers to anything other than "roughly columnar," opposite from widely divergent.
Plaintiff argues that the file history of the '232 patent, a parent application to the '852 patent, mentioned above, favors its claim construction. On May 20, 1992, the Patent Examiner rejected claims in the '232 patent application on the basis of a Japanese patent to Watanuki. See Office Action in Application No. 07/580738, 5/20/92, Pl.'s '852 Markman Br. Ex. B. Plaintiff states that the Examiner concluded that Watanuki disclosed a laser scanner producing a laser light having a "generally narrow volume." Id. at 5. Plaintiff claims it overcame this rejection by distinguishing Watanuki on the basis that it did not disclose a rich set of scan lines for omnidirectional scanning, and that it was thus allowed to amend its claims by adding limitations requiring a "highly collimated projected scanning pattern within which a bar code symbol can be scanned independent of the orientation of said bar code symbol in said highly collimated scanning pattern." Id. at 4.

As the amendment and plaintiff's remarks in the prosecution history shows, it is true that plaintiff distinguished its patent from Watanuki's scanners because it did not disclose a rich set of scan lines:

As stated during the interview the subject invention constitutes a scanner which produces a rich scanning pattern of plural groups of parallel scan lines which intersect each other in a highly collimated or confined volume. That highly collimated scan pattern is projected from the scanner's window out a substantial distance, e.g., at least six inches, for reading a bar code which is merely presented to it (e.g., brought into, but not necessarily moved through, the pattern). This is to contrasted with the prior art slot or counter type scanners, like the scanner of the Watanuki reference, which require that the bar code be carried, moved, or passed through the scanning pattern . . ., typically in one direction, to ensure that the bar code is read. One reason such motion is required is that the scanning pattern is not rich with lines.

However, plaintiff explained further in the Amendment that it attempts to add the term "highly collimated" to distinguish prior art scanners which diverged widely:

Moreover, slot or counter type scanners produce a scanning pattern which is not collimated, but rather which spreads out or diverges widely. Thus, in order to ensure that the bar code is swept by the outgoing laser beam the bar code must be moved substantially through the scanning pattern to be transversed by the laser beam.

Moreover, the widely divergent scanning patterns produced by slot or counter type scanners renders such scanners unsuitable for various scanning applications, e.g., small or mid-size drug, convenience, or other retail stores, wherein various bar coded items are commonly located on the counter at the check-out site for point of sale purposes. Thus, in such applications a typical counter or slot scanner, with its widely diverging scanning pattern, could inadvertently scan a bar code item displayed on the counter adjacent the scanner.

Id. at 9. Thus, in plaintiff's own words, the term "highly collimated" refers to the fact that the scanning pattern does not diverge widely or spread out, as is the case with prior art scanners and the Watanuki scanner. Plaintiff's own remarks in explaining its invention demonstrate that the addition of a rich set of scan lines was not intended to define the term "highly collimated" in the claimed invention. Rather, Metrologic's amendment of its claim to add a rich scanning pattern of plural groups of parallel scan lines is only an additional way in which the claimed invention purportedly differed from the prior art.

Defendant asserts that a claim cannot be construed any broader than its unambiguous scope, citing Amhil Enterprises, Ltd. v. Wawa, Inc., 81 F.3d 1554, 1562 (Fed. Cir. 1996). In that case, the patentee submitted responses in the prosecution history using "substantially vertical" and "vertical" interchangeably. The Federal Circuit determined that this prosecution history provided a further indication that the patentee thought of his substantially vertically faces as essentially vertical, especially if they were created to avoid prior art that outwardly extended projections with variously sloped faces. Similarly, in this case, where the patentee contrasted the claimed invention with the prior art, which was "divergent" or "wide," the unambiguous implication is that the "highly collimated" term refers to the columnar projection of the scan lines within the scanning pattern, not to the richness of the scan lines within the scanning pattern. UnderAmhil, this indicates plaintiff's understanding of the term "highly collimated," as conveyed in its patent prosecution history, as the opposite of "widely divergent" or "spread out."

After consideration of the claim language, the specification language, and the prosecution history, this Court construes the
claim language "highly collimated projected scanning pattern" as a scanning pattern of scan lines that is columnar in nature, or as columnar as possible, given practicable design constraints. The Court does not construe "highly collimated" as referring to the richness of the scan pattern into which bar coded items can be presented for reading irrespective of orientation. Rather, "highly collimated" refers to the columnar nature of the laser light projection containing the scan pattern.

1. The Whereby Clause

A. Whether the Whereby Clause is a Claim Limitation

DTL argues that the language, "whereby said acoustic signal is converted to a digital signal, transmitted to said remote receiver in digital form, and utilized by said digital system located at said remote location such that said digital system at said remote location receives a highly faithful digital representation of said acoustic signal" should not be construed as part of the function because it adds nothing substantive to the claim limitation. Cingular's position is that the whereby clause is meaningful and limiting.

Where the words following "whereby" simply state a result, they are not considered to be part of the function, or even a claim limitation because it adds nothing to the patentability or substance of the claim. Lockheed Martin Corp. v. Space Sys./Coral Inc., 324 F.3d 1308, 1319 (Fed. Cir. 2003); In re Krodel, 223 F.2d 285, 42 C.C.P.A. 993, 1955 Dec. Comm'r Pat. 305 (Cust. & Pat.App. 1955). On the other hand, a whereby clause limits a claim when it recites a capability that was "an integral part of the invention" based on the specification and prosecution history. See Hoffer v. Microsoft Corp., 405 F.3d 1326, 1330 (Fed. Cir. 2005)(per curium). The terms of a whereby clause must be regarded as an essential feature of the invention if it is used to distinguish the invention over the prior art during prosecution of the patent. Eltech Sys. v. PPG Indus. Inc., 710 F.Supp. 622, 633 (W.D.La. 1988), aff'd 903 F.2d 805 (Fed. Cir. 1990).

It is clear from the prosecution history that the terms of the whereby clause was used to overcome the prior art, namely U.S. Patent No. 4,370,523 ("the Bader patent"). In particular, the applicants repeatedly argued that the fidelity of transmission was a critical feature distinguishing their invention over that of Bader:

The fidelity of Bader's conversion is inherently very poor, in contrast to the nearly perfect transmission of applicant's invention. Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-00089 P 8 [Doc. # 60, Attachment #4, p. 81 of 175].

The Bader reference alone or modified as suggested is incapable of fulfilling the essential objective of high quality, high resolution conversion accurately representing the incoming sounds. In contrast to Bader, Applicant's claimed invention is capable of 90 - 120 dB of dynamic range, .1 dB frequency response to 20kHz, and distortion better than .005%. Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-00095 P 22 [Doc. # 60, Attachment # 4, p. 87 of 175].

Bader, even with the suggested modifications, produces a low quality conversion, with poor fidelity, bad frequency response and little dynamic range . . . Applicant's claimed invention produces the new and unexpected result of a self-contained, hand-held microphone with high quality professional audio reproduction. Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-000105 P 42 [Doc. # 60, Attachment # 4, p. 97 of 175].

The language in the specification is consistent with the statements in the prosecution history that the listed features in the whereby clause are required, rather than a hoped-for result of the invention or a laudatory phrase. When describing the prior art, the specification states: "The fidelity of analog transmission is restricted by interference, such as noise, . . . etc. The limited dynamic range (60-70dB) and high (up to 3%) harmonic distortion of the analog recording and reproduction process has hitherto masked the transmission effects." '799 patent, col. 1, ll. 44-50. The specification proclaims that one object of the invention is to "provide[] for the most accurate possible reproduction of the transducer output." '799 patent, col. 2, ll. 60-62. To achieve that objective, the patent states: "Virtually any form of varying energy could be transduced and transmitted over any distance with real life fidelity of up to 96-140 dB of dynamic range, and with virtually no distortion, using the present invention." '799 patent, col. 3, ll. 29-33 (emphasis added). The whereby clause in Claim 18 does not merely state a result, but rather, delimits how accurate the reproduction of the input must be.
DTL points to the examiner's statement that "there is no claim limitations [sic] addressing fidelity or frequency response" in support of its argument that the whereby clause only states the result of the prior limitations. 3 Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-000118 P 7 [Doc. # 60, Attachment # 4, p. 110 of 175]. It is the applicants' statements that matter when construing the scope of an invention, not whether the examiner accepted or rejected them. See Lifestream Diagnostics, Inc. v. Polymer Tech. Sys., Inc., 109 Fed. Appx. 411, 414 (Fed. Cir. 2004)(stating that the "public notice function of a patent and its prosecution history requires that a patentee be held to what he declares during the prosecution of his patent.")

--- Footnotes ---

3 The court notes that in Claim 15, the claim states, not in a whereby clause, that "said transmission will be performed in a highly faithful manner." '799 patent, Col. 14, ll. 67-68.

--- End Footnotes ---

In fact, the patent examiner held an interview with the applicants to discuss Claim 1, which also has a whereby clause that its system is able to transmit the input "faithfully." At the interview, the examiner reiterated that Claim 1 "did not have specific language showing a functional conclusion of accurate reproduction." Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-000128 P 3 [Doc. # 60, Attachment # 4, p. 120 of 175]. In response, the applicant "argued that the word 'faithfully' in the conclusion of the claim . . . implies sufficient frequency response and good fidelity for accurate reproduction of the input." Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-000129 P 18 [Doc. # 60, Attachment # 4, p. 121 of 175]. At the hearing, DTL admitted that "[t]here is not a distinction between 'highly faithful' and 'faithful.'" Trans. at p. 32. Because the applicants consistently argued during the prosecution of their patent application that the invention required an accurate reproduction of the analog signal, the court finds that when the patent containing the whereby clause ultimately issued, the terms of the whereby clause are interpreted as a limitation on the scope of the patent that was granted.

B. Whether the Term "Highly Faithful Digital Representation" is Indefinite

Cingular asserts that the term is indefinite and, hence, invalid under 35 U.S.C. § 112 P 2. To invalidate a patent for indefiniteness, the Federal Circuit has stated that the evidence must be shown by "clear and convincing evidence." Datamize, LLC v. Plumtree Software, Inc., 417 F.3d 1342, 1348 (Fed. Cir. 2005). In determining whether the claim at issue "particularly point[s] out and distinctly claim[s] the subject matter which the applicant regards as his invention," the claim should be construed in light of the specification as interpreted consistent with the level of the ordinary skill in the art practiced in the invention. See Eibel Process Col. v. Minnesota & Ontario Paper Co., 261 U.S. 45, 65-66, 43 S. Ct. 322, 67 L. Ed. 523, 1923 Dec. Comm'r Pat. 623 (1923). That some claim language may not be precise, however, does not automatically render a claim invalid. Seattle Box Co. Inc. v. Industrial Crating & Packing, Inc., 731 F.2d 818, 826 (Fed. Cir. 1984).

Looking to the specification of the '799 patent, the phrase "highly faithful digital representation" is given defining limits first, by describing the object of the invention: "It is therefore an object of the present invention to provide better audio reproduction with increased dynamic range, and reduced distortion and noise." '799 patent, col. 2, ll. 50-53. The reproduction is "virtually perfect, and there is no effect of any interference or noise in the transmission process." '799 patent, col. 6, ll. 55-60. Given the problem addressed by the invention and the specification language describing the '799 patent's solution to the problem, the phrase "highly faithful digital representation" is sufficiently defined to those skilled in the art to avoid invalidity.

c. Construction of the Whereby Clause

The parties focus on three terms within the whereby clause, "said remote receiver," "digital form," and "highly faithful digital representation." Of the three terms, the parties agreed on the definitions of "said remote receiver" and "digital form" if the court considers the whereby clause to be a limitation. Therefore, only "highly faithful digital representation" requires discussion.
The specification states that DTL argues that "highly faithful digital representation" should be construed as "a digital signal that is an accurate representation of the original analog signal." This is a generic definition that fails to differentiate "highly faithful" requirement in Claim 18 from "faithful" in Claim 1. '799 patent, col. 2, ll. 60-62. The applicants had argued that the word "faithfully" implies "accurate reproduction" of the input. By stating that the whereby clause requirement of a "faithful" transmission in Claim 1 imposed an "accurate" reproduction, a "highly faithful" transmission must, a fortiori, impose at least greater fidelity and frequency response requirements.

Cingular proposes "highly faithful digital representation" requires "representation with at least: a) 90 dB dynamic range, b) 0.1 dB frequency response to 20 kHz, and c) distortion better than 0.005%." There are several fallacies in Cingular's formulation. One is that it focuses upon the application of the invention, which is beyond the control of the inventors, rather than the structure of the invention itself. The specification teaches that if an A/D converter with 20 bit resolution is used, the dynamic range of signals can be greater than 118dB. '799 patent, col. 9, ll. 25-27. If a low cost, low power integrated circuit converter is used, the performance would be lessened by noise and distortion of 5-10dB. '799 patent, col. 9, ll. 41-45. The specifications detail a preferred embodiment using a 16 bit A/D converter to provide a theoretical 144 dB (24 bit) dynamic range. '799 patent, col. 10, ll. 25-27.

Cingular analyses the prosecution history in isolation from the specification and claim language. It is perhaps true that the applicants' claimed invention is "capable of 90-120 dB of dynamic range, .1 dB frequency response to 20kHz, and distortion better than .005%," but that is not required by the claim language. (emphasis added). The applicants may merely have been indicating that the Bader patent could not achieve such reproduction, unlike the present invention. Exhibit A of Pl.'s Opening Claim Construction Brief, DTL-00095 P 22 [Doc. # 60, Attachment # 4, p. 87 of 175]. Neither the language of the claim nor the specification requires, or even hints, that such a narrow definition must be adopted for this claim term.

The specification states that patent creates a reproduction that "is virtually perfect, and there is no effect of any interference or noise in the transmission process. '799 patent, col. 6, ll. 57-60. Accordingly, the court defines the terms as follows:

"Said remote receiver" means: a receiver.

"Digital form" means: a format that represents data by numerical digits or discrete units.

"Highly faithful digital representation . . ." means: the representation that is virtually perfect, with no effect of any interference or noise in the transmission process.
history portion usually consists of queries about the patient's current health, previous problems and any related family or social problems." '443 Patent, col. 4:6-8. In light of this language, Prompt construes the term to mean "information including the patient's current health, previous medical problems, and/or any related family or social problems that becomes the basis of the patient's medical record and required documentation." Conversely, Defendants originally proposed the construction "information consisting of the patient's current health, previous medical problems, and any related family or social problems that becomes the basis of the patient's medical record and required documentation."

Prompt argues that the nature of the history component mandates Prompt's proposed construction. Prompt produces both intrinsic evidence and an American Medical Association ("AMA") publication to show how the historical component is broken down into different types of patient history analysis, characterized by their level of detail. A physician who conducts a "problem focused history" records the patient's chief complaint and a brief history of the present illness or problem.

CELESTE G. KIRSCHNER, ET AL., AM. MED. ASS'N, PHYSICIANS' CURRENT PROCEDURAL TERMINOLOGY: CPT '95 7 (1995) ("CPT '95"). A physician conducting an "expanded problem focused history" records the same information that is collected for a problem focused history, along with a problem pertinent system review. Id. A physician conducting a "detailed history" records the same information collected for an expanded problem focused history but extends the problem pertinent system review to "a limited number of additional systems" and also records pertinent past, family and/or social history directly related to the patient's problems. Id. Finally, a physician conducting a "comprehensive history" records the same information collected for a detailed history, except that he also reviews systems directly related to the problems identified in the present illness's history, conducts a review of all additional body systems, and obtains a complete past, family, and social history. Id. The specification lists several decision matrix charts in Appendix B that reference these different types of histories, as well as figures displaying situations where only a problem focused history is taken, but more detailed histories are possible. See '443 Patent, Figs. 1A-1C; Appendix B (decision matrix charts for new patients and established patients).

Prompt contends that because the patient encounter is a "flexible event" involving fact-sensitive inquiries and decisions, medical coding must be flexible enough to permit physicians to conduct any or all of these histories. Thus, Prompt argues that only its use of the terms "including" and "and/or" correctly sets the parameters of a medical coding technology designed to afford physicians the ability to decide which type(s) of historical information they wish to collect. Likewise, Prompt argues that Defendants' proposed construction requires physicians in all cases to obtain full-scale histories. Prompt also argues that the specification's use of "usually" requires "and/or" in the construction of "historical data." See '443 Patent, col. 4:6-8. Finally, Prompt contends Defendants' construction excludes preferred embodiments by restricting a physician's freedom to not discuss the existence of "related family or social problems" or to not ascertain more detailed aspects of a patient's history. This is because, as Prompt argues, the Patent and Trademark Office defines the "[t]he transitional phrase 'consisting of' to exclude[,] any element, step, or ingredient not specified in the claim." n2 Recognizing Prompt's concerns, Defendants proposed the following modified construction: "information consisting of the patient's current health and any taken previous medical history and/or related family or social problems that becomes the basis of the patient's medical record and required documentation." This construction, Defendants argue, avoids a construction that would require physicians in all cases to take more extensive histories, but at the same time avoids a result that would permit a physician to elicit a history without ascertaining the patient's current health -- a result that Defendants characterize as absurd. Indeed, Prompt made no convincing argument that the history component would ever not include information about a patient's current health. Thus, the parties essentially agree that a patient's current health is a necessary sub-component of the history component. Nevertheless, Prompt still argues that Defendants' modified construction unduly excludes preferred embodiments and only the use of "including" and "and/or" provides physicians appropriate flexibility.

--- Footnotes ---

n2 See MPEP § 2111.03 (internal citations omitted; second and third alterations added).

--- End Footnotes ---

Prompt's arguments are unconvincing. The specification clearly uses the terms "consists of" and "and" when describing data ascertained in the historical component. A patentee is free to act as his or her own lexicographer and is free to set forth special definitions of claim terms in the specification that disclaim other potential definitions. Schoenhaus v. Genesco, Inc., 440 F.3d 1354, 1358 (Fed. Cir. 2006); Phillips, 415 F.3d at 1316. The patentees did so here when they identified the universe of physician queries related to patient history-queries about the patient's current health, previous health problems,
and related family or social problems -- and specified that patient history "consists of" those queries. Although Prompt correctly notes that the sentence in column 4, lines 6 to 8 uses the qualifier "usually," all Prompt argues is that "the history portion usually, but not always, consists of queries." Prompt does not explain why the patentee's use of "usually" calls for a construction that employs the open-ended word "including" and disregards the language that the patentees used to follow the qualifier. The specification's use of "usually" signifies to skilled artisans that the physician may opt to utilize only a subset of the universe of queries -- for example, a physician or other health worker may opt to elicit information only about the patient's current health and previous medical problems. Further, Defendants' use of the phrase "and any taken previous medical history" n3 and modified placement of "and/or" helps to properly encapsulate a physician's option to elicit or not to elicit historical information in addition to the patient's current health.

n3 Defendants' use of "previous medical history" in lieu of the patent's less exact phrase "previous problems" does not raise concerns. Both sides' original competing constructions reflected the parties' agreement that "previous problems" meant "previous medical problems." Given that this entire construction dispute pertains to the historical component, the words "history" and "problems" seem relatively interchangeable in this instance. Moreover, the decision matrices in Appendix B of the '443 Patent specifically identify "Medical History" as one of the major areas of physician-elicited information within the historical component.

Prompt's citation to the decision matrix charts and figures 1A-1C simply does not support a construction that employs "including." Likewise, Prompt's extrinsic evidence, though informative as to the types of historical information that a physician has the option of collecting, does not alter the clear meaning of the language, which both sides agree forms the basis for the definition of "historical data." Neither the charts nor the figures, nor any other part of the patent, nor Prompt's extrinsic evidence, identify or define other queries or data that a physician may elicit in addition to the universe of queries set out in the sentence at column 4, lines 6 to 8.

Defendants indicated during oral argument that more exact language than the phrase "and any taken" could be used to reinforce the necessary and optional aspects of the historical component. Strategic placement of the adverb "optionally" reinforces those aspects more precisely. Accordingly, the Court construes the term "historical data" to mean "information consisting of the patient's current health and, optionally, any previous medical history and any related family or social problems that becomes the basis of the patient's medical record and required documentation." This construction more precisely captures the '443 Patent's expression of "historical data." The commas that bound "optionally" clarify that the adverb is to be distributed both to "any previous medical history" and "any related family or social problems." Retaining the verb conjugation "becomes" clarifies that the patient's medical record and required documentation are based on all the information that makes up "historical data," not merely information pertaining to related family or social problems. Finally, the Court opts to use the phrase "consisting of" as opposed to "that consists of" to avoid repetitive and possibly confusing use of the word "that."

F. "Hold"

The term "hold" in the context of the '725 patent means, "A notation limiting access to funds in a checking, savings or automated teller machine account."

This term appears in the claims as follows:

Wherein the central processing device determines whether a hold for prohibiting a withdrawal is placed on at least one of a checking account, a savings account, and an automated teller machine account, and further wherein the central processing device disallows the banking transaction. (Claims 135 and 164).

Plaintiffs would have this court construe the term "hold" as "something that prohibits something from happening." Again,
the proposed definition is insufficiently specific to connote anything remotely related to the patent in suit.

Noting that the invention relates to banking, defendants point out that the term "hold" is a term of art in the banking industry. The construction it proposes comes directly from the BARRONS' BUSINESS GUIDE, DICTIONARY OF BANKING TERMS (4th ed. 2000):

"A notation limiting an account owner's access to his or her funds."

Plaintiff protests that this definition is too restrictive -- even though it would qualify as the "plain and ordinary meaning" of the word to anyone familiar with the banking industry -- because their invention is intended to be used by the owner of an account to prevent others from obtaining access to his or her funds. See '725 Patent, "BACKGROUND OF THE PRESENT INVENTION," at Col. 2, line 60-Col. 3 line 35.

The confusion arises because the person not skilled in the art of banking thinks about a "stop payment" order very differently than a banker does. When the average person writes a check to someone and then directs the bank to stop payment on it, he naturally is trying to prevent the person holding the check from getting at the account owner's money. But to a person skilled in the art of banking, when a check is presented for payment, it is the owner of the account who is trying to access his own money. He is trying to access it so that it can be remitted to some third party. The check, written and signed by him, is the method by which he accesses his funds. If at some point he changes his mind, the owner of the account directs the bank to stop payment on the check. As far as the bank is concerned, the stop payment order limits the owner's ability to access the funds in his account by negating the owner's prior instruction (via the check) that the funds should be accessed.

It seems clear that plaintiffs contemplate that their invention will be used for something in addition to the traditional "stop payment" -- specifically, that an account owner will utilize it to prevent a third party from making an unauthorized withdrawal from the owner's account, most likely from an ATM machine. The unauthorized withdrawal could be innocuous, as when a child tries to use his parents' ATM card to withdraw more money from his parents' account than the parent will allow (this assumes, of course, that there are parents so foolish as to permit their children to use their ATM cards). Or it could be pernicious, as when an identity thief or computer hacker uses a fraudulent ATM card or stolen account numbers to try to empty the owner's account. In either event, the initiator of the transaction is not the account owner -- a fact that differentiates these situations from the more common "stop payment" on a check. And it appears to me that plaintiff is using the common banking word "hold" to apply to these uncommon -- potentially criminal -- transactions.

By omitting the modifier "account owner's" before the word "access" in defendants' proposed definition, we solve this problem and allow the word to make sense in all the contexts in which plaintiffs use it in their patent.

1961

4. "Holding in reserve . . . ; Initially causing the resources of the first base station to remain held" (Claims 1 and 18)

Claim One states that what is claimed is a "mobile station for use with a network . . . that achieves a handover from the first base station to the second base station by: storing link data . . . , holding in reserve for the link resources of the first base station, and when the link is to be handed over to the second base station: . . . initially causing the resources of the first base station to remain held in reserve . . . ." '830 Patent at 8:12-25. HTC asks that the Court find this limitation incapable of construction because "holding in reserve" is indistinguishable from "initially causing the resources of the first base station to remain held." IPCom argues that "holding in reserve" means "temporarily keeping back resources of the first base station" and that "initially causing the resources of the first base station to be held" means "at least temporarily keeping back the resources of the first base station." Neither is correct.

What is claimed, of course, is a cell phone that works within a network that includes at least two base stations. Therefore, the actions of "holding" and "initially causing" must occur within the mobile station as it implements its handover algorithms, which are the focus of the '830 Patent and are described at length in the specification. The structure of the Patent makes it clear that the first base station responds to messages (signals) from the mobile station to "hold in reserve" certain resources and the mobile station "initially cause[s]" the first base station to continue to hold those resources in reserve.
during the actual handover to the second base station. Claim One states that what is claimed is a mobile station that achieves a handover in a network by "holding in reserve for the link resources of the first base station, and . . . initially causing the resources of the first base station to remain held in reserve . . . ." '830 Patent at 8:12-25 (emphasis added). These messages from the mobile station to the base station occur at slightly different times during a handover. The mobile station first causes the first base station to store link data and to hold resource in reserve for the link; ever so slightly later, "when the link is to be handed over to the second base station," the mobile station tells the first base station to maintain the storage of the link data and causes the resources of the first base station "to remain held in reserve" until a fixed period of time expires and then the link data is deleted from the first base station. See id. at 8:19-27.

Thus, HTC incorrectly argues that these are the same limitation. IPCom incorrectly gives them the same construction. "Holding in reserve" is construed to mean "causing a first base station to preserve resources for a link." "Initially causing the resources of the first base station to remain held in reserve" is construed to mean "causing a first base station to continue to hold link resources while a handover to a second base station is attempted."

"Home Gateway"

Cisco's proposed construction for the term "home gateway" is "a method, device, or system that permits ingress to and egress from a network." Alcatel's proposed construction is "a network element running layer 2 forwarding protocol application software for performing protocol translation."

Both parties admit that the term "gateway" had meaning to one of ordinary skill in the art in 1996. According to Cisco, the term meant "the combination of hardware and software which, among other functions, decided whether data sent to a network would be allowed in, and data attempting to leave a network would be allowed out." Leifer '019 Report, at 15. According to Alcatel, the term in this context referred to a network layer relay "that stores and forwards packets between dissimilar networks." Lazar '019 Decl., at P 39. Additionally, as was known at that time, "a gateway performed a translation, so that networks running different protocols could exchange information." Id., Ex. B (Andrew S. Tanenbaum, Computer Networks (3d ed. 1996)), at 16.

Thus, while the parties disagree as to the specific functions of the "gateway," they do agree that a gateway is a combination of hardware and software that operates as an interface between networks. 67 More specifically, the gateway in the '019 patent controls access to and from a network. See Cisco's '019 Opening Brief, at 17 ("The claims of the '019 Patent use the term 'home gateway' in its ordinary sense to refer to the gateway on the local or 'home' network which employs authentication processes to decide whether or not a tunnel will be established for the purpose of sending data to and from the local network."); Alcatel's '019 Opening Brief, at 14 ("In the context of the '019 patent, the home gateway serves as the point through which the 'private local network' gains access to, and permits authorized access from, an internet."). 68

67 According to the claim language and the specification, the "home gateway" appears to serve several functions, such as authenticating remote clients, encapsulating packets, and establishing tunnel connections. See, e.g., Valencia, at 5:43-6:4, 18:39-49. Therefore, the term will not be construed to limit the home gateway to any particular function.

68 Despite its acknowledgment of the gateway's general purpose, Alcatel seeks to limit the construction of the term "home gateway" to performing only protocol translation of the layer 2 forwarding protocol. However, the language of the patent does not support such a limited construction.

Furthermore, while neither party claims that "home gateway" has an ordinary meaning, it is clear from a reading of the patent language that the word "home" was intended to refer to the gateway of the local or private network. When the term "home gateway" is introduced in both the claims and the specification, the term is used in conjunction with the terms "private network" or "local network." See Valencia, at 1:22-24 ("The home gateway includes a firewall that prevents
unauthorized external access into the private network through internet.

Therefore, the Court construes the term "home gateway" as "a combination of hardware and software that controls access to and from the local network."

"Home Gateway Name"

Cisco's proposed construction for the term "home gateway name" is "name ascribed to a home gateway." Alcatel's proposed construction is "the IP address of the home gateway."

Cisco's proposal is no more than a rearrangement of the words in the disputed term, and provides little, if any, guidance to understand the term's meaning. On the other hand, Alcatel's proposal seeks to limit the home gateway's name to only an Internet Protocol (IP) address, which may be limiting the claim language to a narrow reading of the specification. Clearly, the "home gateway name" is an identifier of the "home gateway." The only further clarification needed is to determine what type of identifier is authorized under the patent.

Alcatel argues that the identifier must be an IP address because the specification describes only a tunnel running from an internet service provider (ISP), through the Internet, to the home gateway. In this regard, the only method of identifying the home gateway from the Internet is by the use of an IP address. See Lazar '019 Decl., at PP 44-45. In contrast, Cisco correctly points out that nowhere in the patent is the address of the home gateway expressly required to be an IP address, much less limited to only an IP address.

At the outset, the Court recognizes that the "home network name" must be a network address of some kind, because its purpose is to be identified by the network access server seeking to transmit information from the remote client to the local network through an intermediary. Additionally, in claim 2, the only claim in which this term appears, the claim language specifically describes the home gateway name being transmitted from the remote client to the internet service provider. See Valencia, at 15:24-26. Accordingly, the network address must be capable of allowing the ISP to locate the home gateway. While both parties agree that an IP address satisfies this purpose, and was possibly even the only logical method for accomplishing this goal at the time, nothing in the patent suggests that another type of network address could not be used if it would be sufficient to allow the ISP to locate the home gateway.

Therefore, the Court construes the term "home gateway name" as "the network address of the home gateway."

"home page"

Plaintiff argues that the term "home page" should be construed as "the first screen containing information you see when you arrive at a website," relying on the Dictionary of Computer and Internet Words and the Shames Declaration. (Dkt. 86 at Ex. 1, p. 3). Defendants argue that the term "home page of a website" should be construed as "the entry page for a set of related HyperText Markup Language (HTML) documents on the World Wide Web." (Dkt. 86 at Ex. 2, p. 1). Defendants cite to the '229 patent specification, the Microsoft Computer Dictionary and Resonate, Inc. v. Alteon Websystems, Inc., 338 F.3d 1360, 1361-62 (Fed. Cir. 2003) (providing that "every web page has a home page, which is identified by a URL and is the first document users see when they first connect to the web site").

It is unnecessary to construe the commonly understood term "website". It is only necessary to construe the term "home page." A person skilled in the art would understand "homepage" of a website to mean "entry page" of a website.

The plain language of Claim 1 states that browser-based subscribers have electronic access to a home page which provides
access via an ISP to a database server. ('229 patent, col. 5, ll. 55-59). This home page provides only secure access to subscriber areas. (Id., col. 5, ll. 60-62). The specification reiterates that "each of the subscribers 12 and 20 enter the system 11 via a home page 18 of a website of the system 11." (Id., col. 3, ll. 51-52) (emphasis added). The specification further provides that "the home page provides secure access by each subscriber to each of a plurality of subscriber areas within the system." (Id. col. 2, ll. 54-55).

While the plain language of the claim focuses on the function of the home page once accessed, the specification illustrates that the home page is the entry point to the embodiment contained in Figure 1 and the browser-based portion of the system contained in Figure 3. The parties' proposed constructions are based largely on their respective dictionary definitions. The actual definition for "home page," as cited by Defendants, is "an entry page for a set of Web pages and other files in a Web site." (Dkt. 68 at p. 3-4 citing Microsoft Computer Dictionary 221 (4th Ed. 1999). While the parties' proposed definitions appear to be consistent with the patent specification, Defendants' use of the term "entry page" is more consistent with the patent specification. The Court construes "homepage" of a website, therefore, to mean "entry page" of a website.

3. Home Position Data

Lectrolarm proposes that "home position data" should be construed to mean "information (represented by angles of rotation, polar coordinates, or any other suitable units) necessary to specify the locations of prescribed home positions. Home position data is inputted by the user through the control pad, buttons (including the home position buttons), and switches on the operating panel." The Defendants would interpret "home position data" to mean "information identifying one or more home positions. 'Home position' is a stored position." The parties agree that "home position data" is information that specifies the position of, or identifies, home positions.

The first parenthetical in Lectrolarm's proposed definition, "(represented by angles of rotation, polar coordinates, or any other suitable units)," has no basis in the specification. The patent does not speak to the nature of the data saved to identify the home positions.

The second sentence of Lectrolarm's proposed definition, describing how "home position data" is entered into the system, is unnecessary. The court's construction of the function of the second input means already discusses the manner in which "home position data" is inputted.

The court defines "home position data" as "information identifying one or more home positions that is set through use of the structure of the second input means. 'Home position' is a stored position."

7. homeotropic direction; homeotropic structure ('028 patent and '412 patent) 25

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
25 At oral argument, the parties agreed that the same construction should apply to "homeotropic direction" and "homeotropic structure." See footnote 11.
- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

CEA's proposed construction is "substantially perpendicular to the adjacent surfaces of the substrates."

Samsung's proposed construction is "the direction perpendicular to the glass plates of the cell."

At oral argument, Samsung expressed its view that "substantially" should not be included in a phrase reciting a particular "direction," i.e., "homeotropic direction," but that it was not adverse to having "substantially" included in the construction of
the term. 26 Samsung also stated that it did not believe the parties' proposed constructions reciting "perpendicular to the adjacent surfaces of the substrates" versus "perpendicular to the glass plates of the cell" were significant differences. 27 The court agrees that the differences in the parties' proposed constructions are primarily semantic and, in light of Samsung's position at oral argument will construe "homeotropic direction" and "homeotropic structure" as meaning "the direction substantially perpendicular to the adjacent surfaces of the substrates."

26 D.I. 1053 at 81-82. 27 Id. at 82.

1967

2. Claims 20, 32 and 48: "hook flash signal"

a) The Parties' Proposed Construction and Arguments

Claims 20, 32 and 48 are asserted independent claims, and are reproduced in full below. The disputed language is in boldface:

20. An apparatus for use in conjunction with local telephone equipment in telecommunication with a remote telephone, wherein said remote telephone has a three-way calling service which is not associated with the apparatus, which apparatus is capable of determining whether a remote party using the remote telephone has performed a specific act that is consistent with an attempt to initiate a three-way call utilizing a hook-flash signal comprising:

   means for the detection of an energy pulse received by the local telephone equipment having a frequency characteristic of the hook-flash signal; and

   response means for implementing a predetermined response when said energy pulse is detected.

32. An apparatus for use in conjunction with local telephone equipment in telecommunication with a remote telephone, wherein said remote telephone has a three-way calling service which is not associated with the apparatus, which apparatus is capable of determining whether a remote party using the remote telephone has performed a specific act that is consistent with an attempt to initiate a three-way call utilizing a hook-flash signal comprising:

   means for the detection of an energy pulse received by the local telephone equipment having a frequency characteristic of the hook-flash signal;

   window analyzation means for cooperating with said energy detection means to detect a specific event(s) occurring during a predetermined time window following the detection of the energy pulse, the detection of the specific event(s) confirming whether the remote party has performed a specific act that is consistent with an attempt to initiate a three-way call; and response means for implementing a predetermined response when the remote party's performance of a specific act that is consistent with an attempt to initiate a three-way call has been confirmed.

48. A method for determining whether a remote party using a remote telephone in telecommunication with local telephone equipment, wherein said remote telephone has a three-way calling service which is not associated with the apparatus, has performed a specific act that is consistent with an attempt to initiate a three-way call utilizing a hook-flash signal comprising:

   detecting an energy pulse received by the local telephone equipment having a frequency characteristic of the hook-flash signal; and

   responding in a predetermined manner when said energy pulse is detected.
The term "hook-flash signal," of course, appears in the claim preambles and the term "frequency characteristic of the hook flash signal" appears in the body of the patents. Global has also argued that the preamble is limiting.

Global's Proposed Construction

A "hook flash signal" means a temporary interruption of loop current at the remote telephone, for example, caused by briefly depressing and releasing the hook switch or rotary dial, consistent with an attempt to initiate a three-way call.

T-Netix's PowerPoint presentation at the Markman Hearing, Slide 53.

A "hook flash signal" means:

1. An electrical energy pulse having a frequency of about 270 Hz, but not more than 300 Hz, on the caller's end of the telephone line;
2. No additional sounds from the called party telephone; and
3. A return hook flash with similar sound at about 270 Hz but at a lower intensity. Global's PowerPoint presentation at the Markman Hearing, Slide 24.

b) Discussion

Whether elements recited in a preamble should be construed as limiting the scope of the claim is an issue the U.S. Court of Appeals for the Federal Circuit (CAFC) has visited on numerous occasions. One CAFC test requires a limiting construction for the preamble if it is "necessary to give life, meaning, and vitality" to the claim. The CAFC has stated, "When the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects." Conversely if the "body of the claim sets out the complete invention," then the language of the preamble is "superfluous." These guidelines leave a number of unanswered questions, which we must now look for answers:

1. Can a preamble "give life, meaning and vitality" to a claim if no term in the preamble is referenced in the body of the claim? The Court answers this question in the negative.
2. If only a single term from the preamble is used in the body of a claim, then do all of the terms in the entire preamble become incorporated as limitations? The Court also answers this question in the negative.
3. If a term from the preamble is referenced in the body of the claim, is that term limited to the actual disclosure in a manner similar to a means plus function, a "means for," clause or is it given broader definition and equivalence? The Court answers this question in the negative, but would look to the disclosure for a definition of such a term.
4. Although infringement is not an issue in claim interpretation, it is still relevant to ask, "Does a term from the preamble, which has been determined to be limiting, become a claim element, or does it remain simply part of the claim environment?" In other words, does a plaintiff have to prove that the term from the preamble is included in a defendant's apparatus or method or does the plaintiff merely have to prove that the term is present when defendant's apparatus or method is in use? In the present case, since many claims of the '702 patent include "a remote telephone," in the preamble, and no defendant is likely to also make a particular remote telephone, would all defendants automatically be excluded from being direct infringers?

- 2363 -
Under Reasons for Allowance for the '702 patent, the Patent Examiner stated "The following is an Examiner's Statement of Reasons for Allowance: the preamble of the claims was given patentable weight." The Examiner did not state any specifics, but just referred to the preamble generally. We must, therefore, apply normal rules of claim construction in order to determine what makes the preamble of each claim of patentable weight by determining which terms in the preamble of each claim are used in the body of that claim. We will consider the phrase "of patentable weight" to mean that at least some term of the preamble acts as a limitation on the claim.

Within the '702 patent, the term "hook flash" is used as a single word, as two words and as a hyphenated term. All of these will be considered equivalent. When actually quoting from the patent, the words will be quoted as actually used in the quotation and considered correct for our purposes. Otherwise, the term will be used as two words. Claims 20, 32 and 48 all use the term "hook flash" in the preamble and in the body of the claim. The term "hook flash" is, therefore, at least part of what makes the preamble for those claims of patentable weight, functioning as a limitation of those claims. The term "hook flash" does not appear in the body of Claims 1, 2, 3, 6, 7, 8, 9, 12 or 13. Moreover, the body of claims 20, 32 and 48 include the expression "an energy pulse received by the local telephone equipment having a frequency characteristic of the hook-flash signal." Emphasis added.

The term "local telephone equipment" appears in the preamble and the body of the claim in claims 1, 7, 13, 20, 32 and 48. Although the Court has not been asked to interpret that term, it does explain the Examiner's remarks with respect to the preamble of claims 1 and 7 and their dependent claims, as well as adds to the reasoning for claims 20, 32 and 48. Finally, with respect to Claim 18, the terms "limited access telephone" and "called party's telephone" appear in both the preamble and the body of the claim. The Court is thus in agreement with the Examiner with respect to the preamble of all claims being of patentable weight.

It is the position of Global that the disclosure of the term "hook flash" in the specification should be read into the term as used in the claims in which the term acts as a limitation. This would make a term from a preamble interpreted in a manner similar to that of a "means for" clause. In particular, Global asks the Court to include a specific numerical value of frequency taken from the specification into the claims for the term "hook flash." Global cites no authority for this interpretation or any compelling logic for such an interpretation. Just because a term in a preamble is used in the body of a claim does not act to limit that term, but only to limit the claim to that term. Even the expression "a frequency characteristic of the hook-flash signal" can hardly be so limited since dependent claims 21, 22, 33, 34, 49 and 50 all have numerical frequency limitations, which are less restrictive than "about 270 Hz." These are unasserted claims, claims no longer in the case, but they are still part of the patent. Claims 21, 33 and 49 include "wherein the frequency to be detected is between 100 and 300 Hz." Claims 22, 34 and 50 include "wherein the frequency to be detected is between 200 and 300 Hz." Claims 21 and 22 are dependent on Claim 20, claims 33 and 34 on Claim 32 and claims 49 and 50 on Claim 48.

Finally, there is "a heavy presumption that a claim term carries its ordinary and customary meaning."

c) Construction

In view of the foregoing, the Court concludes that:

The term "hook flash signal" means a temporary interruption of loop current at the remote telephone, for example, caused by briefly depressing and releasing the hook switch or rotary dial, consistent with an attempt to initiate a three-way call.

1968

a. "Horizontal Deflection Circuit"

For this term, IP requests the following definition: the circuit which causes the displayed image elements to be placed in position for each horizontal row thereof. Lexmark and Dell propose: a circuit which produces a continuously variable alteration of the path of a particle beam, as distinguished from address or pixel selection as might be applied to LCD type displays.
As is apparent, neither party's definition is grounded in the plain language of the claim, and neither provides convincing argument or support why its proposed language should supplant the plain meaning of the words used within this claim and those used in claim 1, upon which it depends. Therefore, we construe this term to mean a circuit that assists selective filling of a void at an identified particular position by deflecting an image element to a new position along a horizontal plane.

As is pertinent here, in its January 24, 2005 Claims Construction Order, the Court construed certain terms of Claim 1 as follows:

<table>
<thead>
<tr>
<th>Term</th>
<th>Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;controller&quot;</td>
<td>a device that interfaces between a host and nonvolatile memory.</td>
</tr>
<tr>
<td>&quot;host&quot;</td>
<td>interfaces, through the controller, with nonvolatile memory</td>
</tr>
</tbody>
</table>

The plaintiff contends that the term "host" means "a computer system having one or more computers." The defendants contend that the "host" is the "primary or controlling computer in the system." As used in the patents, the term "host" refers to the primary or controlling computer in a multi-computer system. As such, the court adopts the defendants' proposed definition.

Plaintiff's construction relies primarily on Figures 1, 7, and 8 in the patent specification, asserting that the host computer pictured therein is "connected to a network of bus controllers," thus justifying the importation of the term "network" into the definition of host computer. Pl. Reply at 19. As in its construction of "binary tree configuration," however, plaintiff's effort to insert terms that do not appear elsewhere in the patent is unavailing. Cf. Catalina Mktg., 289 F.3d at 807. Rather, the Figures support defendant's construction, since they establish that the "network" is better described as a "binary tree of bus controllers." See Phillips, 415 F.3d at 1316 ("The construction that stays true to the claim language and most naturally aligns with the patents description of the invention will be, in the end, the correct construction."). The specification further adds that the "host computer [ ] generates instructions . . . to control the operation of the system." '024 Patent at 3:35-38.

Plaintiff argues that this construction, by referring to the instructions to the bus controllers, imports a limitation from dependent Claim 3 into Claim 1 and thus runs afoul of the doctrine of claim differentiation. Pl. Reply at 20. Claim 3 reads "the binary tree computer system of claim 1 wherein each of said bus controllers further includes means for interpreting instructions received from the host computer." Under the doctrine of claim differentiation, limitations from a dependent claim are normally not read into the independent claim. See Phillips, 415 F.3d at 1315 ("[T]he presence of dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim."). Here, however, Claim 3 is adding further detail about the bus controllers, not imposing a particular limitation on the host computer. Moreover, independent Claim 7 confirms that the host computer sends instructions to the bus controllers by defining the patent invention as "a binary tree computer system for connection to and control by a host computer"
comprised of bus controllers in a binary tree configuration in which "each of said bus controllers includ[es] means for interpreting instructions received from the host computer." '024 Patent 8:11-12, 29-30. Thus, there is no doubt that Claim 7 does not treat the bus controllers as a dependent limitation, as plaintiff asserts. See Regents of the Univ. of Cal. v. DakoCytomation Cal., Inc., 517 F.3d 1364 (Fed. Cir. 2008) ("While it is true that dependent claims can aid in interpreting the scope of claims from which they depend, they are only an aid to interpretation and are not conclusive. Indeed, the presumption created by the doctrine of claim differentiation is not a hard and fast rule and will be overcome by a contrary construction dictated by the written description or prosecution history.") (internal quotations marks and citations omitted).

Nor does the defendant's construction, which emphasizes the connection between the binary tree and the host computer, rely improperly on the preamble. A preamble is generally construed as a limitation "if it recites essential structure or steps, or if it is 'necessary to give life, meaning, and vitality to the claim.'" Catalina Mktg. Int'l, Inc., 289 F.3d at 808(quoting Pitney Bowes, Inc. v. Hewlett-Packard Co., 182 F.3d 1298, 1305 (Fed. Cir. 1999). In Catalina Marketing, the Federal Circuit clearly found that the preamble of a patented invention, which referred to terminals located at "predesignated sites such as consumer stores," was not a limitation on the claim, since the patented invention did not depend on the location for the patent's significance or novelty and was not relied upon to distinguish prior art. Id. at 810. But that court also noted that where the preamble "is essential to understand limitations or terms in the claim body" or "when reciting additional structure or steps underscored as important by the specification," it may limit claim scope. Id. at 808. Here, the term "host computer" appears in both the preamble and the body of Claims 1, 3, and 7, and therefore reliance on the preamble does not unduly limit the scope of the claim language. See id. ([D]ependence on a particular disputed preamble phrase for antecedent basis may limit claim scope because it indicates a reliance on both the preamble and claim body to define the claimed invention.); Bell Commc'ns Research v. Vitalink Commc'ns Corp., 55 F.3d 615, 620 (Fed. Cir. 1995) ("[W]hen the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined.").

In light of the unambiguous claim language and support from the specification, the Court construes "host computer" to be a computer that is connected to and controls the binary tree of bus controllers.

1972

9. Host computer; host server; server; host

The above terms are found in various claims of all of the patents in suit. The defendants' proposed construction of each of the above terms is "a source of data for presentation to data terminal equipment." The plaintiff's proposed construction is "computer that sends data downstream." Upon consideration of the parties' arguments, the court adopts the plaintiff's proposed construction.

1973

1. "host computer network"

The term "host computer network" in claim 1 shall mean "a network having attached thereto one or more remote access servers providing command-response services to computers connecting to the network from remote locations."

1974

A. Host computing device

The parties' main point of contention with respect to this term is whether the disclosed "host computing device" is required to perform the comparison of the epidermal topographical patterns. Accu-Time argues broadly that the function of the host device is to "control[] communications" among devices, regardless of "whether the devices are physically separated and operably connected, or are physically within the same unit and operably connected." Accu-Time's Mem. at 9.
TMC's argument is by far the more persuasive. The specification discloses only one device that compares epidermal topographical patterns: the host computing device. The Abstract depicts a device that generates an epidermal topographical pattern and "transmit[s] [it] to a host computer for determining access privileges." '541 Patent, Abstract. n2 The same language is employed in the Field of Invention section. Id., Col. 1, II. 12-13. Similarly, the Summary of Invention states that "[e]ach terminal scans a predetermined epidermis and generates an epidermal topographical pattern which is transmitted to a host computing device. The host computing device compares the transmitted epidermal topographical pattern with the stored epidermal topographical patterns. If a match is found, the host computer reads the information associated with the stored epidermal topographical pattern and determines whether access or egress at the current time is permissible." Id., Col. 2, II. 28-36. Clearly, this describes a comparison function performed by the host and not some other optional component. In addition, the Description of Preferred Embodiments provides that "the scanner 12 reads a portion of an individual's epidermis and generates an epidermal topographical pattern which is transmitted to the host 20 for comparison." Id., Col. 3, II. 31-34. "When an epidermis is detected (S3), the epidermal topographical scanner 12 scans the epidermis (S4), generates a digital epidermal topographical pattern signal (S5) and transmits that to the host 20 (S6). The host 20 compares the transmitted pattern with epidermal topographical patterns stored in the database 60 (S7)." Id., Col. 3, II. 41-46. In the apparatus' alternative embodiment, "[t]he identification information, along with the identification code, and epidermal topographical pattern are transmitted to the host 20 (S9). The host 20 compares the transmitted information with the information in the database (S10)." Id., Col. 5, II. 10-14.

n2 At the hearing, Accu-Time argued that defendants' reference to the abstract is not permitted in determining the scope of the invention. However, as defendants correctly point out, this is not the case. See SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1342 (Fed. Cir. 2001).

n3 The definition provided for "host computer" in Webster's Unabridged Dictionary 924 (2d ed. 2001) is "the main computer in a network: controls or performs certain functions for other computers." A technical dictionary, the Oxford University Dictionary of Computing 229 (4th ed. 1996), defines "host computer" as "a computer that is attached to a network and provides services other than simply acting as a store-and-forward processor or communication switch." When questioned by the court at the hearing about this definition, Accu-Time's counsel agreed that the host computer must do more than simply route messages between or among devices; rather, it must do some processing. According to Accu-Time's counsel, the host "needs to initialize." The court understands this to mean that the host must be able to recognize the external devices to which it is connected in order to expedite intra-system communications. If Accu-Time's construction is correct, then the host device adds nothing of an exceptional nature to the operation of the system.

n3 The court is aware that the Federal Circuit has cautioned against overreliance on dictionaries. "Heavy reliance on the dictionary divorced from the intrinsic evidence risks transforming the meaning of the claim term to the artisan into the meaning of the term in the abstract, out of its particular context, which is the specification." Phillips, 415 F.3d at 1321. However, "[i]n some cases, the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges, and claim construction in such cases involves little more than the application of the widely accepted meaning of commonly understood words. . . . In such circumstances, general purpose dictionaries may be helpful." Id. at 1314 (internal citation omitted).

Accu-Time's last effort to bolster its argument resorts to prior art. Accu-Time notes that U.S. Patent No. 5,337,043 (the '043 Patent) discloses an access control system in which the comparison is performed by the processing device, rather than by the host device. Therefore, Accu-Time argues, one of ordinary skill in the art would recognize that the comparison could be
made by devices other than the host. While this may be true, Accu-Time does not identify any device or component disclosed in the '541 Patent other than the host that actually performs the comparison. Accordingly, the court adopts TMC's interpretation of this term as meaning "a processor or computer, connected to the data collection terminals through a network, that performs the comparison of the epidermal topographical pattern for a presented individual with the stored epidermal topographical patterns on behalf of a data collection terminal." n4, n5

n4 Defendants make a second convincing argument with regard to this element. They argue that the use of the word "host" in conjunction with the words "computing device" can only mean that the host performs some computing function. Defendants note that Claim 1 also describes a database that is "operatively associated" with the host. According to defendants, this necessarily means that the database is more than merely "in connection" with the host. Defendants construe the phrase "operatively associated with the host" to mean that the host accesses information stored in the database when activated.

n5 The parties agree that the court's claim construction applies to both the '541 Patent and the '455 Patent.

1975

B. "host device"

Claim One of both Patents claims "[a]n interface device for communication between a host device, which comprises drivers for input/output devices customary in a host device and a multi-purpose interface, and a data transmit/receive device . . . ." '399 Patent, col. 12:42-45 (emphasis added); '449 Patent, col. 11:46-49 (same). The Camera Manufacturers propose that "host device" be construed to mean "a general purpose computer that connects to and controls the operation of peripherals," CMs' Markman Br. at 9, while Papst proposes "a general purpose computer to which hardware devices may be attached, such as Personal Computers ("PCs") and other host computer systems as described in the patent written description, including drivers for input/output devices customary in a host device and a multi-purpose interface." Papst's Revised Appendix of Claim Constructions [Dkt. # 244, Ex. C] ("Papst's App.") at 2. Papst also objects to the phrase "controls the operation of peripherals" in the Camera Manufacturers' proposed definition. Neither Figure One nor Figure Two of the Patents shows a "host device;" the Figures only indicate where one would be connected to the invention.

The Patent Claims refer solely to a "host device," but the specification clarifies the nature of the intended host device. See '399 Patent, col. 1:9-11 ("The present invention relates to the transfer of data and in particular to interface devices for communication between a computer or host device and a data transmit/receive device . . . .") (emphasis added); '449 Patent, col. 1:13-15 (same). Thus, the "host device" is a computer, and the Court uses the terms interchangeably hereafter.

The specification identifies "common host devices which can be, for example, IBM PCs, IBM-compatible PCs, Commodore PCs, Apple computers or even workstations." '399 Patent, col. 4:31-33; '449 Patent, col. 3:34-36. The specification further requires the host device to have "a driver for an input/output device customary in a host device," such as, "drivers for hard disks, for graphics devices or for printer devices," of which the hard disk driver is the preferred embodiment. '399 Patent, col. 4:25-30, 34-36; '449 Patent, col. 3:29-34, 38-40. The Patents tout the advantage of attaching "host devices or computer systems" by means of the invention to a "device whose data is to be acquired." '399 Patent, col. 1:20-22; '449 Patent col. 1:21-23. Thus, the inventor intended his "host device" to include most computers -- PCs, Apples, workstations -- as long as they had a driver for a customary input/output device and a multi-purpose interface.

As the Camera Manufacturers suggest, there is little substantive difference between their construction of "host device" and that offered by Papst, although they argue that his definition is more clear and concise. It may be that the development of computers since the application for the '399 Patent makes it somewhat more complicated: the inventor specified customary drivers and a "multi-purpose interface" that had to be present in his "host device," intimating that not all computers of that time necessarily had such devices inside their chassis. See '399 Patent, col. 4:27-30 ("Drivers for input/output devices customary in a host device which are found in practically all host devices are, for example, drivers for hard disks, for
graphics devices or for printer devices.

The Court construes "host device" in the Claims of the Patents to mean "a general purpose computer that connects to and directs the operation of peripherals, including drivers for input/output devices customary in a host device and a multi-purpose interface.

As to the Camera Manufacturers' proposal that "host device" be defined as a computer that "controls the operation of peripherals," the Court finds that this aspect of a host device is critical to the ability of a host device to communicate through the invented interface device. That is, the host device must have internal drivers, i.e., software, to instruct hardware how to operate. As Papst acknowledged, drivers "are the software programs that are used by the computer[] to communicate with the hardware that's attached to the computer. So for each and every hardware device that you connect to a computer there has to be a driver to communicate with that hardware device." Tr. 1:5 (Papst). The specification explains that such drivers can instruct a hard drive (the preferred embodiment) that is internal to the computer, or such drivers can instruct a printer that is external to the computer. In all instances, the driver instructs the how and when of hardware operation and thus directs it. Further discussion of the element of "control" is found below in the construction of the term "driver."
involves the simultaneous transmission of information over separate paths.

T-Mobile responds that the only host interface mentioned in the specification is a direct parallel bus connection, and that the specification contains no disclosure of an indirect or serial interface. T-Mobile argues that there is no requirement that different claims must always be of different scope, although that is the usual case. In Tandon Corp. v. United States International Trade Comm'n, 831 F.2d 1017, 1023-24 (Fed. Cir. 1987) the court explained that the doctrine of claim differentiation means that different claims are presumed to be of different scope; however, the court pointed out that describing claim elements or limitations in different words does not invariably change the scope of the claim. The boundaries of patented inventions are set forth in the claims, construed in light of the description in the specification, as well as by the prior art and the prosecution history. Phillips v. AWH Corp. 415 F.3d 1303 (Fed. Cir. 2005) (enbanc).

T-Mobile points out that the other claims of the '079 patent contain other limitations affecting their scope; for example, each claim that contains the term "parallel bus interface" designates a particular type of parallel bus interface, a "PCMCIA parallel bus interface" (claims 2, 24, and 33). T-Mobile points out that the '079 patent itself disparages serial interfaces, referring to the "Background of the Invention" wherein the inventors state that:

A big drawback of the PDA systems being offered is the way they transfer data between a user's desktop unit, or other host, and the PDA. Known communication is by modem, by infrared communication, and by serial connection. These all require manipulation by a user, modulation on one or both ends of the communication path, and the like, which can be time-consuming, error-prone, and hardware extensive (expensive).

'079 patent, col. 1, lines 48-55. The specification further states:

It is very troublesome to have two or more sets of critical data, with differences that one must remember to correct at an appropriate time. This can cause unending grief if files are not correctly updated. At best, current PDAs must use a relatively slow compressed bus to download and upgrade files. Typically this is done through a serial port, using a linking application like Laplink.

Col. 2, lines 5-12. The '079 specification then explains that "what is needed is a small and inexpensive PDA that has a range of features that eliminate the above-described risks and problems," col. 2, lines 19-21, including low cost and small size, and states that:

A very important feature of the APDA in an aspect of the present invention is a direct parallel bus interface with a connector allowing the unit to be docked by plugging it into a docking bay in a host unit. Moreover, when the APDA is docked in the host, there needs to be a means to effectively disable the CPU in the APDA and to provide direct access to both the APDA software and data storage by the host CPU. This direct access would provide immediate ability to communicate in the fastest available fashion between the APDA and the host, and would also facilitate additional important features to be described below.

Col. 2, lines 30-40 (emphases added).

The district court correctly observed that the only host interface described in the specification is a direct parallel bus interface, and that the specification emphasizes the importance of a parallel connection in solving the problems of the previously used serial connection. See SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001) ("Where the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question.") Claims are construed in light of the specification, of which they are a part. See Phillips, 415 F.3d at 1315-16. Although claims need not be limited to the preferred embodiment when the invention is more broadly described, "neither do the claims enlarge what is patented beyond what the inventor has described as the invention." Netword, LLC v. Centraal Corp., 242 F.3d 1347, 1352 (Fed. Cir. 2001).

The specification does show a "serial" connection in its optional "expansion bus interface." That is the interface on the other side of the PDA, intended for connection to peripheral devices such as printers and fax machines. The specification states
that the expansion bus interface takes several forms, and if necessary can be attached to a host computer via a serial port:

In another embodiment, an undocked APDA can transfer data via the optional expansion bus 40 (FIG. 3) directly to a host. In the special case of a APDA user without access to a PCMCIA interface on his host (notebook or desk-top) computer, he or she can connect to a host via an auxiliary port on the host, such as a serial port, via the expansion bus interface.

Col. 12, lines 11-17. Claim 8 is specific to this aspect of the invention, by calling for a "digital assistant module as in claim 7, wherein said expansion bus interface is adapted to connect to a serial port of said host computer."

Unlike the "expansion bus," which is separately described as providing a connection to peripheral devices, the "host interface," which is described as providing a "connection to the host in docked mode," does not contain any suggestion that a serial connection could fulfill the purposes of the invention to improve the "time-consuming, error-prone, and hardware extensive" limitations associated with the serial connections of the prior art. Col. 1, lines 54-55. The description of a serial connection in the discussion of the expansion bus interface, and the lack of any such description in the discussion of the host interface, reinforce the interpretation of the host interface as requiring a parallel bus interface, for that is the only interface described for that purpose.

The specification characterizes the direct bus interface as a "very important feature" of the invention, stating that a "direct" connection is necessary to provide "direct" access, which allows for fast communication. Col. 2, lines 30-40. The specification explains, in its "Description of the Preferred Embodiment," that the "direct" connection between the host and PDA bus allows for the "automatic updating and cross-referencing of existing files and new files in both computers, under control of the host system, with the host having direct bus access to all memory systems." Col. 11, lines 53-56. Further, in the "Summary of the Invention" the inventor states:

A host interface means comprising a host interface bus structure, which may be configured as a PCMCIA bus interface, is connected to the microcontroller and to a first portion of a host interface connector at a surface of the enclosure, and the host interface means is configured to directly connect the microcontroller to a compatible bus structure of a host computer.

Col. 3, lines 16-22. And in discussing Figure 6, a block diagram of a preferred embodiment, the inventor emphasizes the "direct" path between the PDA and host:

When a APDA unit is docked, connector 14' in FIG. 6 comprises portion 14 shown in FIGS. 1B and 3 and a mating connector portion for engaging portion 14 in port 105 (FIG. 5). The engagement of the separate portions of the connector cause bus 26 in the APDA and bus 26' in the host to become directly connected. There is then a direct bus path between microcontroller 11 and host CPU 24 (FIG. 6).

Col. 10, lines 61-67.

The prosecution history supports the interpretation of "host interface" as a direct parallel bus interface. In prosecuting the first in this series of applications, the applicants explained that their invention overcame certain limitations of known PDA devices:

[A] big drawback of the PDA systems being offered is the way they transfer data between a user's desktop unit, or other host, and the PDA. Known communication is by modem, by infrared communication, and by serial communication. These all require manipulation by the user, modulation on one or both ends of the communication path, and the like, which can be time-consuming, error-prone, and hardware extensive (expensive).

Applicants have made it abundantly clear in their specification that this interface is a full-service bus, and that it exists to allow memory accesses and control between the host and the digital assistant, and have recited in the original claim that this bus was configured to directly connect the digital assistant's bus to a compatible bus of a host computer. The Examiner has rejected the claim on the basis of [the '023 prior art], which states "In the case of remote processing, the hand-held computer may be connected to a host computer 35 via the series interface connector . . . . Applicants, in their background section, as restated above, made it clear that this is a serious drawback of the existing art, one which the present invention is intended to overcome. The provision of a direct bus between the host and the digital assistant, including memory control signals, as
in applicants' invention, overcomes this serious limitation in the prior art. To more clearly distinguish, applicants have
amended claim 1 to decidedly narrow the scope of the claim, so it does not read on series connections, as in [the prior art].

Inpro argues that this prosecution history is of limited relevance, as it does not originate from the prosecution of the
application that led to the '079 patent and is largely focused on the particular claim limitations added to overcome a specific
reference. Inpro observes that the original claim in the parent application already contained the requirement of a "direct"
connection and that the applicants overcame the cited reference by adding "parallel bus connected between the local CPU
and a host interface connector at a surface of the enclosure" to the claim. T-Mobile responds that the addition of the "parallel
bus" requirement to the claim reinforced that this invention was directed to solving problems associated with the "serial
connections" of the prior art, and that the applicant explicitly excluded serial connections.

T-Mobile also cites the prosecution of the parent application, which contained claim language nearly identical to the "host
interface" of the '079 patent ("a host interface adapted for providing communication between the digital assistant and a host
computer"). Inpro, in a brief to the Board of Patent Appeals and Interferences, described the host interface as involving a
direct connection:

The invention is a means of providing a personal digital assistant module comprising an enclosure for enclosing and
supporting internal elements . . . A host interface means comprising a host interface bus structure, which may be
configured as a PDCMCIA bus interface, is connected to the microcontroller and to a first portion of a host interface
connector at a surface of the enclosure, and the host interface means is configured to directly connect the microcontroller to
a compatible bus structure of a host computer.

Appeal Brief in Case No. P249229FWC, at 5 (July 17, 1996) (emphasis added). Inpro responds that the entire argument in
that appeal was directed to whether a reference disclosed a PDA that negotiates synchronization of files in common with the
host upon initiation by the user, a requirement of each of the claims there presented, and that the brief had nothing to do
with the scope of the "host interface" in the '079 patent.

Although arguments in the prosecution of related applications should not receive undue weight, for claims and issues and
inventions vary from case to case, here the applicant was describing the broad technologic basis of these related
applications; the usage in each application is consistent with the district court's view of "host interface" as requiring "a
direct parallel bus interface." That interface excludes the serial connection of the prior art, and requires direct parallel
connection. The district court's interpretation of this term is correct, and is affirmed.

1977

2. "host mode"

HP asks the Court to construe this term as: "An operational state that facilitates communication with a particular host."
EMC proposes: "A mode, unique to a particular operating system, that specifies the manner in which an array controller
should communicate with a host computer that is running said operating system."

Although the meaning of "host mode" is unclear from the claim language alone, a "host mode entry," according to the
Court's construction of the preceding term, must be "data that governs the interactions between logical units and host
computing systems." Indeed, according to the claim, a "host mode entry" may indicate "if a particular logical unit should
communicate with a particular host computing system" and the host mode is predetermined.

For clarification, the Court must turn to the specification, which describes embodiments in which the host mode relates to
the host's operating system. For example, "unique host modes' [are] adapted to be employed uniquely to each host operating
system to which the logical unit . . . is coupled. These unique host modes permit the array controller to be adaptable to
handle different idiosyncrasies of particular host operating systems." 979:4/31-36. Although in one embodiment the host
mode field "corresponds to the name of the operating system running on the particular host," 979:7/37-38, the host mode
entry need not be limited to data concerning only a particular host or operating system. "For example, if a particular host is
found to operate more efficiently or more smoothly in a particular mode, then based on the host operating system type, [such information can be] stored in the configuration table." 979:6/45-51. That is, although host mode entries contain information related to idiosyncrasies of a particular host, nothing in the intrinsic evidence requires each host to have a distinct or unique idiosyncrasy or associated host mode entry. Groups of hosts could share the same idiosyncrasy or host mode entry. Thus, a host mode entry could contain information about a particular operating system or the "operating system type."

The specification does not limit host mode entries solely to information relating to operating systems or operating system types. For example, the configuration table may include a data field such as "any special host modes for the particular host adapter." 979:5/11-12. The "host's adapter connects to the array controller." 979:5/41-42. This adapter contains identification information of the host, which is stored in the configuration table. 979:5/42-45. In this way, access to of the host to the logical units can be controlled. Thus, "host mode" data are additional information about the host, such as any of its "idiosyncrasies," 979:6/42-51-and not only the host's operating system.

Accordingly, a "host mode entry" may be an entry of data documenting the particular or idiosyncratic characteristics or the operational state of a host or group of hosts. This is consistent with a dictionary definition of "mode" as an "operational state of a computer or a program." Landgraff Decl., Separate Appendix, vol. 7, p. 1219 (Microsoft Computer Dictionary). Such information may be used in accordance with the invention to facilitate communication with a particular host (part of HP's proposal) or to specify the manner in which an array controller should communicate with a host computer (part of EMC's proposal). It follows that the term "host mode" relates only to the state of the host, not the purpose or use of the "host mode" data. Indeed, HP concedes that a "mode" is an "operational state of a computer." HP's Opening Brief, p. 40.

Accordingly, the Court construes this term as "the particular or idiosyncratic operational state of a host or group of hosts."

1978

1. "host platform"

The parties dispute whether certain narrowing terms such as "bus controller," "CPU or host bus," and "electrically connected" are necessary to define "host platform." To support its construction, OPTi points to this court's prior construction of the term "host platform" in the '141 patent in OPTi v. NVIDIA, Inc., 2:04-cv-377, Dkt. No. 96 (TJW) (E.D. Texas). There, the Court agreed with OPTi that "host platform" means "a bus controller to which a CPU is connected by a CPU or host bus and to which peripheral devices are connected by a peripheral bus." Defendants argue that the "host platform" is "interface circuitry electrically coupled to peripherals and a CPU." Defendants contend that "electrically" connected is the ordinary meaning of coupled in the context of electrical circuitry and that it is no broader than the court's prior construction.

The focus of the LPC patents, as described in the abstract and the specification, is directed at interfacing a host to a peripheral device. '807, 3:21-23; '141, 3:24-26. The patent does not specifically mention the term "bus controller," but does reference an ISA controller that is not part of the "host platform." 7 The ISA controller, therefore, is also a bus controller. In all instances, save for one, when the term "host platform" appears in the detailed description, the term appears as "host platform interface circuitry." '807, 4:53-5:12; 6:53-7:64; 8:17-9:18; 9:19-11:31; 11:61-13:37. "Host platform interface circuitry 115 communicates address, data, interrupt request, and DMA request information to/from a peripheral device 130 via a bidirectional address-data bus..." '807, 4:58-60; '141, 4:62-64. These signal lines link the host platform to the peripheral devices across the interface. The host platform, therefore, is the interface circuitry that allows for these communications. The only time the term "host platform" does not appear as "host platform interface circuitry" is when it appears as "host platform interface device 831," '807, 12:57; '141, 12:64. Reference numeral 831, however, refers to a peripheral device such that the "host platform interface device" is attached to the host platform, but is not the host platform itself. '807, 12:14, 17, 23, 26, 33; '141, 12:21, 24, 30, 33, 40. The court, therefore, finds that "host platform" must include interface circuitry.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -
Defendants' attempt to read a requirement into the claims that the "host platform" is "electrically connected" to peripherals and a CPU is not persuasive. There is no support in the specification or the claims for an electrical connection. The terms "electrical," "electric," and "electronic" never even appear in the specification. Further, as discussed in the court's previous construction of "host platform," the "host platform" is connected to a CPU by a CPU or host bus and a peripheral device by a peripheral bus. NVIDIA, at 11-13.

Accordingly, the court adopts a modified version of its prior construction. The court defines "host platform" as "interface circuitry to which a CPU is connected by a CPU or host bus and to which peripheral devices are connected by a peripheral bus."

1979

1. host platform

OPTi contends that "host platform" is "a bus controller to which a CPU is connected by a CPU or host bus and to which peripheral devices are connected by a peripheral bus." nVidia contends that "host platform" is "a device or devices which include one or more CPUs, to which other devices (peripherals) are connected and that generally controls those devices." While using somewhat different language, the parties' proposed constructions are similar. The principal difference is whether the host platform is connected to a CPU (OPTi's construction) or whether a host platform must include a CPU (nVidia's construction).

To support its construction, nVidia first notes that in prior litigation, n1 OPTi recognized that the "host platform" included one or more CPUs. In addition, nVidia turns to Figure 1 of the 141 patent (shown below).

Based largely on Figure 1, nVidia asserts that the host platform interface circuit (115) is not the host platform. Instead, the host platform interface circuit forms the interface between the host platform and the peripheral devices. Thus, nVidia contends, the host platform interface circuit in Figure 1 is not the entire host system but is instead only a part of the host platform.

According to nVidia, the host system is the host side (105) in Figure 1 of the patent. See also 141 patent, Col. 4:59-62 ("FIG. 1 shows a host side 105 and a device side 110 of an interface 175. On the host side 105 is a host platform interface circuitry 115 coupled to CPU 120 via a CPU bus 125.").

OPTi responds by first noting that the statements by OPTi in prior litigation were made by prior OPTi counsel and that OPTi believes its prior position to have been in error. Consequently, OPTi advances what it believes to be the correct construction now. Further, OPTi notes that National Semiconductor and OPTi resolved their litigation before the Court in that case issued its claim construction opinion. Accordingly, there is no judicial estoppel. In this Court's view, claim construction is a matter of law and the Court will give OPTi's proposed construction the same consideration it provides to nVidia's proposed construction.

OPTi asserts that the intrinsic record supports its construction and also points to Figure 1 and citations in the 141 patent to support its position. OPTi contends that the CPU 120 is coupled to the host platform interface circuit and that, therefore, the
CPU and host platform must be distinct from one another.

To further support its argument, OPTi also relies on the problem the CISA patents sought to solve. The origin of the CISA patents was to design a new chipset interface so that the increasing demands of new bus architecture could be managed. Specifically, "the present invention, roughly described, is directed to an interface to be used between a host device and one or more peripheral devices." '141 patent, Col. 3:24-26.

The Court is persuaded that OPTi's construction is correct. In addition to the arguments raised by OPTi, the Court notes that the specification uses "host" and "host platform interface circuitry 115" interchangeably:

"Host platform interface circuitry 115 asserts CMD # synchronously with the rising edge of ATCLK. Host can also optionally inhibit its ISA MRD # /MWR # lines."

'141 patent, Col. 7:55-58 (emphasis added); see also Col. 9:52-54; Col. 10:1-5. Accordingly, the Court adopts OPTi's proposed construction of "host platform."

1980

B. Host Processor ('950 patent, claims 1, 8, 11, 13, 14)

PCTEL suggests the following construction of "host processor": "the CPU(s) of a computer such as a set top box, that processes digital representations(s) of signals, rather than including a digital signal processor dedicated to perform signal processing (including modulating and demodulating) in modem hardware." Agere proposes the following construction of the disputed phrase: "central processing unit of a host computer."

PCTEL's asserts that its proposed construction is accurate because a jury may believe that a computer is limited only to a "personal computer," and that devices that have names that do not include the word computer (e.g., set top box) are not computers. However, PCTEL fails to cite the disclosure of such devices in the claims, specification, or prosecution history. Agere relies upon the intrinsic record and the ordinary meaning of the term to support its construction. Agere states that its proposed construction is consistent with contemporaneous technical definitions of "host" as "[a] device, typically a personal computer, that will control the communications with attached peripherals." (Mills-Robertson Decl., Ex. 10 at AL 15385, The IEEE Standard Dictionary of Electrical and Electronics Terms (1996)). Agere also notes that the specification states that "[h]ost signal processing (HSP) modems reduce the cost of providing modem functions to a computer system by utilizing the processing power of the central processing unit (CPU) of a host computer. . . ." '950 patent, col. 12-17; '780 patent, col. 1:18-22.

Essentially, the proposed constructions of the parties are not significantly different. Although PCTEL objects to the use of the word "host," the Court agrees with Agere's conclusion that defining "host" as the "computer" or "host computer" comports with the ordinary meaning of the term. It also comports with the way in which the term is used in the patents. The specification states that "the computer system 100 includes a main or host processor 110" and that in the exemplary embodiment, "the computer 100 is an IBM compatible computer." '950 patent, col. 3:28-32; '780 patent col. 3:19-24.

Furthermore, the Court also agrees with Agere that PCTEL's inclusion of the phrase "including a specialized computer such as a set top box" is misplaced, as such language finds no support in the intrinsic evidence, prosecution history, or ordinary meaning of the term. Moreover, PCTEL's conclusion that a jury may believe that a computer is limited only to a "personal computer" is, at best, speculative.

Finally, PCTEL's proposed construction includes the phrase "rather than including a digital signal processor dedicated to perform signal processing (including modulating and demodulating) in modem hardware." The Court agrees with Agere that this language appears unnecessary as the host processor is part of the computer and not part of modem hardware.

Therefore, based on the ordinary meaning of the term and the intrinsic evidence, the Court construes "host processor" as the central processing unit of a host computer.
C. The '200 Patent

Next, defendants contend that the accused products do not infringe claims 1, 4, 5, 6, 8, 11 and 16 the '200 patent. The '200 patent discloses "an apparatus and method for utilizing multiple rendering pipes for a single 3-D display." Independent claim 1 of the '200 patent discloses a product with a "display" and independent claim 11 discloses a method for rendering an image for display; the other claims of the patent are dependent from claims 1 and 11. The parties raise all of the same arguments regarding the '200 patent they raised regarding the '327 patent with respect to its requirements for a display. In addition, defendants assert that none of their products infringe the '200 patent even when used in a system that contains a display because none contains a "host processor," which is required also by claims 1 and 11.

To establish whether any of the accused products infringe the '200 patent, the first step is to establish the meaning of the term "host processor." The parties appear to agree that the meaning of "host processor" is commonly understood. Defendants propose that it means "a processor that runs an application program and directs the rendering process." Dft.'s M. for Summ. J., dkt. # 45, p. 16. Plaintiff states that it means: "a processor for issuing high-level commands for graphics rendering." Pit's Supp. Resp. to Dft.'s M. for Summ. J., dkt. # 119, p. 12. Given the similarity of the proffered definitions, I turn to the language of the claims themselves to evaluate which most accurately reflects the meaning.

Claim 1 of the '200 patent discloses

A computer system comprising:

a plurality of rendering pipes for rendering pixels of an image, wherein each of the rendering pipes comprises a host processor having an application program issuing graphics commands, a geometry circuit coupled to the host processor for processing primitives, a rasterizer coupled to the geometry circuit for generating pixel data, a frame buffer coupled to the rasterizer which stores the pixel data, an interface coupled to the rasterizer that accepts requests from the transmission medium and outputs pixel data . . .

'200 pat., col. 7, Ins. 28-38 (emphasis added).

Claim 11 discloses,

In a computer system, a method of rendering a three-dimensional image for display comprising the computer-implemented steps of . . . executing an application program on a host processor which issues graphics commands; processing vertices by a geometry cir

Id., col. 8, Ins. 9-22 (emphasis added).

Next, the patent specification, describing one embodiment of the invention, describes the function of the host processor as follows: "A graphics application runs on the host processor and issues high-level commands and graphics data." Id., col. 3, Ins. 6-8. This is consistent with the function of the host processor described by both parties. Therefore, as used in the '200 patent, I find that a host processor is "a processor that runs a graphics program and issues high-level commands."

1. "host processor"

HP asks the Court to construe this term as "a processor that controls or accesses all or part of a user application network." EMC proposes: "a processor in a host computer that can issue read or write requests to the first and second storage media." HP argues that "the [parties'] only disagreement concerns whether or not the processor must reside in something called a
"host computer." Plaintiffs' and Counterclaim Defendants' Corrected Opening Claim Construction Brief on Key Terms ("HP's Opening Brief"), p. 6 n.4. As defined by the claim, a host processor is a processor that is capable of sending commands to a storage medium or requests for access that are received by a shadow set. HP's proposal adds a reference to a "user application network." EMC's proposed language adds the requirement that the host processor reside in a host computer.

According to HP, the dictionary meaning of "host processor" is "a processor that controls all or part of a user application network." HP's Opening Brief, p. 6; Declaration of Christopher D. Landgraff ("Landgraff Decl."), Separate Appendix, vol. 1, p. 0195. However, the claim language does not include reference to a "user application network" for the purposes of the claim would be, although it could be the claimed system as a whole. Instead, the claim language refers to commanding a storage medium and accessing a shadow set. Similarly, while the written description includes diagrams suggesting that a host processor may be part of a "host," the claim language does not include reference to a "host computer." The claim language simply has no location limitation, and while the word "host" may limit "processor," it need not do so by geography. Looking at all of the dictionary definitions provided by the parties, it is clear that a "host processor" is part of a network or system and that it controls or accesses other parts of the system. See id. The plain language of the claim indicates that "host processor" refers to a specific type of processor, one that sends commands to the memory aspects of the system. The claim language does not specify the physical location of the host processor.

Accordingly, the appropriate construction of the "host processor" as used in claim 1 is "a processor that can send a command to a storage medium or requests for access that are received by a shadow set."

1983

1. Host processor

The court adopts Judge Brewster's construction of "host processor" in the Gateway action. Accordingly, the court construes the term "host processor" to mean "a computer that communicates with one or more users to provide services such as transaction processing or database access."

1984

host program

Claim 1 contains the term "host program." Accolade contends that "host program" means "a set of instructions executed on the host computer." Citrix contends that the term means "an application program executed by the operating system of the host computer." The parties dispute whether the host program must be executed by an operating system.

The Court construes "host program" as "a set of instructions for execution by the host computer," substantially adopting Accolade's construction. "Program" has the commonly understood meaning of "a set of instructions" and is not given a special definition in the intrinsic evidence. "A set of instructions" conforms to the dictionary definition for "program," "A detailed and explicit set of directions for accomplishing some purpose, the set being expressed in some language suitable for input to a computer, or in machine language." McGRAW-HILL DICTIONARY OF SCIENTIFIC AND TECHNICAL TERMS 1680 (6th ed. 2003); see also THE AMERICAN HERITAGE SCIENCE DICTIONARY 504 (1st ed. 2005) ("A[n] organized system of instructions and data interpreted by a computer"). Furthermore, "host" modifies "program" in "host program," and the Court construes the modifying term "host" to mean "execution by the host computer." This is consistent with the specification, which states, "In FIG. 5, the virtual machine application 48 of FIG. 2 is illustrated in greater detail. This process will also be referred to as the 'host program[,][] since it runs on the host." Col. 10:12-14. The commonly understood meaning of "program" and the specification thus support the Court's construction.

Citrix argues that the host program must be executed by an operating system. However, no support in the intrinsic record exists for Citrix's proposed limitation. Citrix recites, "In FIG. 5, the virtual machine application 48 of FIG. 2 is illustrated in
greater detail. This process will also be referred to as the 'host program[']" since it runs on the host. The process 48 is an application program running on the computer system, e.g. on a Macintosh computer system, on a WINTEL computer system, on a workstation, etc." Defs.' Br. 27 (emphasis added by Citrix) (citing Col.10:12-17). However, this excerpt only states that the program runs on a "computer system," not necessarily an operating system. Also, even if the Court considered "Macintosh computer system" and "WINTEL computer system" as operating systems, "e.g." precedes such language rendering the systems examples rather than limiting references.

Citrix also cites, "In the process 42 of FIG. 2, an operating system of the host supports a 'system 44 extension' 46, a virtual machine application 48, and a Java Applet script 50. . . . The virtual machine application 48 is a computer program or 'process' running from a host computer system, such as computer system 14." Defs.' Br. 28 (citing Col. 7:4-30) (emphasis added by Citrix). While this excerpt refers to "an operating system of the host" that supports a computer program running from the host computer, it does not require that an operating system must execute the host program. Thus, the intrinsic record does not support limiting "host program" to being executed by an operating system. Accordingly, the Court construes "host program" as "a set of instructions for execution by the host computer."

A. Host Signal Processing (modem/communication system)

PCTEL asserts that this term does not require construction. Alternatively, PCTEL contends that the term means "an apparatus/system for transmitting and receiving signals that uses the CPU of a computer to process (including modulating and demodulating) digital representation(s) of the signals." Agere contends that the term means "a modem/communication system that utilizes the processing power of the central processing unit of a host computer to process signals rather than including a dedicated digital signal processor."

1. Preamble language

PCTEL argues that this term does not require construction because "host signal processing communication system" appears only in the preambles of claim 1 of both the '950 and '780 patents, and the term "host signal processing modem" appears only in the preambles of claims 13-15 of the '950 patent and claims 7-9 of the '780 patent. PCTEL asserts that claim 1 of the '950 and '780 patents define a structurally complete invention and therefore the preamble should not act as a limitation.

Agere responds that the term "host signal processing modem" appears in claim 3 of both patents, and therefore is not simply used as preamble language. Moreover, Agere argues that the intrinsic record reveals that these terms were necessary to define the invention of the '950 and 780 patents, and thus the preamble is properly deemed a part of the claim limitations.

"Whether to treat a preamble as a limitation is a determination 'resolved only on review of the entire[ ]' . . . patent to gain an understanding of what the inventors actually invented and intended to encompass by the claim." Catalina Mktg. Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002) (quoting Corning Glass Works v. Sumitomo Electric U.S.A., Inc., 868 F.2d 1251, 1257 (Fed. Cir. 1989). The Catalina court stated that "[i]n general, a preamble limits the invention . . . if it is 'necessary to give life, meaning and vitality' to the claim. . . . " Id. (citation omitted). "Moreover, clear reliance on the preamble during prosecution to distinguish the claimed invention from the prior art transforms the preamble into a claim limitation because such reliance indicates use of the preamble to define, in part, the claimed invention." Id. at 808. However, a preamble will not limit a claim where the body of the claim "describes a structurally complete invention such that deletion of the preamble . . . does not affect the structure . . . of the claimed invention." Id. at 809.

As an initial matter, the Court finds that "host signal processing modem" appears in claim 3 and, accordingly, is not simply used as preamble language. Further, it appears that the preamble has greater weight than PCTEL acknowledges. The prosecution history reveals that PCTEL clearly relied on the preamble language during the prosecution history. After the initial claims were rejected in light of prior art, the patentee wrote the PTO and stated that "[c]laim 1 distinguishes over Gross by reciting, 'A host signal processing communication system.'" (Mills-Robertson Decl., Ex. 7 at AL 014994.) The patentee also quoted the following specification language: "Host signal processing modems reduce the cost of providing modem functions to a computer system by utilizing the processing power of the central processing unit . . . of a host computer rather than including a dedicated signal processor . . . in modem hardware." (Mills-Robertson Decl., Ex. 7 at AL
Based on these statements to the PTO, it is clear that the patentee distinguished prior art based on the terms "host signal processing communication system" and "host signal processing modem." Thus, the Court disagrees with PCTEL that these terms are merely preamble language that do not require construction. n7 Rather, it appears that the preamble terms give "life, meaning, and vitality" to the claims.

n7 PCTEL's reliance on Intirtoo, Ltd. v. Texar Corp., 369 F.3d 1289, 1296 (Fed. Cir. 2004) is misplaced. In Intirtoo, the court refused to construe the preamble because the prosecution history distinguished the prior art based on the body of the claims, rather than on the preamble. Here, in contrast to Intirtoo, the patentee's reliance on the preamble to distinguish prior art is readily apparent. Furthermore, this conclusion remains unchanged even if, as PCTEL contends, the patentee also relied, at least in part, on limitations found in the body of the claims to distinguish prior art. See Bell Communication Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620 (Fed. Cir. 1995) ("[W]hen the claim drafter chooses to use both the preamble and the body to define the subject matter of the claimed invention, the invention so defined, and not some other, is the one the patent protects.") (emphasis added).

2. Construction

The parties central dispute surrounding the construction of these terms is whether the host signal processing modem/communication system can include a dedicated signal processor. Agere's proposed construction includes the phrase "rather than including a dedicated digital signal processor," and relies upon the specification and prosecution history for this limitation. Specifically, the specification of the '950/'780 patents states that "[h]ost signal processing (HSP) modems reduce the cost of providing modem functions to a computer by utilizing the processing power of the central processing unit (CPU) of a host computer rather than including a dedicated digital signal processor (DSP) in modem hardware." '950 patent, col. 1:13-17; '780 patent, col. 1:18-22. Similarly, the prosecution history of the '950 patent confirms that in order to obtain allowance of the claims, the patentee expressly distinguished the Gross patent by stating:

"Claim 1 distinguishes over Gross by reciting, "A host signal processing communication system." As indicated in Applicant's specification, "Host signal processing modems reduce the cost of providing modem functions to a computer system by utilizing the processing power of the central processing unit . . . of a host computer rather than including a dedicated signal processor . . . in modem hardware." []In contrast, Gross describes a system including a modem digital signal processor 20 . . . ."

(Mills-Robertson Decl., Ex. 7 at AL 14994.

Based on this language, the Court finds that the patentee clearly indicated that the claims do not cover systems that include digital signal processors in modem hardware. See Springs Window Fashions LP v. Novo Indus., L.P., 323 F.3d 989 (Fed Cir. 2003) (holding that a reasonable competitor could rely on unequivocal statements of disclaimer made during the prosecution history).

Finally, during oral argument, PCTEL argued that the "signals" being processed by the central processing unit are "communication signals transmitted by the communication system/modem." The Court agrees. Thus, the Court's construction of this term closely mirrors the explicit language used by the patentee in both the specification and the prosecution history, and is as follows: a modem/communication system that utilizes the processing power of the central processing unit of a host computer to process communication signals rather than including a dedicated digital signal processor.
The term "host system" is contained in claim 12 of the '646 patent.

The parties dispute the meaning of the term "host system" in claim 12 of the '646 patent. The parties first dispute whether a "host system" is a computer. The parties agree that a host system provides command sequences, but they further dispute whether the construction should specify the recipient of the "command sequence" produced by the host system.

PACid contends that claim 12 offers a broad meaning for "host system" that identifies the "I/O interface" as receiving the command sequence. Alternatively, "a system for providing command sequences"

Defendants respond that claim 12 requires a "host system" to identify the recipient of the command sequences and further argues that the patent is directed towards protecting information stored on a computer system. Referencing intrinsic and extrinsic evidence, Defendants contend that a person of ordinary skill in the art would read "host" to mean "a computer on a network." Regarding the plain language of claim 12 does not clarify the underlying meaning of "host," but the term's use throughout the patent as a whole supports Defendants' position that "host" is referring to a computer. The Federal Circuit has clearly stated that the written description "can provide guidance as to the meaning of the claims, thereby dictating the manner in which the claims are to be construed, even if the guidance is not provided in explicit definitional format." SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1344 (Fed. Cir. 2001). Thus, where as here, the patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning, he has defined that term "by implication." Vitronics, 90 F.3d at 1582; see also Hockerson-Halberstadt, Inc. v. Avia Group Intern., Inc., 222 F.3d 951, 955 (Fed. Cir. 2000). A definition by implication is provided for the claim term "host" in the context of the '646 and '612 patent. In particular, the Backgrounds of the Invention in each patent support a context in which "host" is used to explain the intricacies of a computer.

The '646 specification states that the patented technology protects information stored on a computer system or communicated over networks, '646 patent at 1:41-42, and the '612 specification particularly entitles that "with the introduction of the personal computer (PC), a migration to local computing through the use of centralized host/server systems began. Again, the conventional wisdom was that sensitive information could be protected by guarding against unauthorized access to the host/server system." 612 patent at 1:30-35. The '646 patent then links "host system" to a "computing system" that truncates the message digest and ultimately produces a symmetric and deterministic encryption key. '646 patent at 8:39-44. These passages all evidence an intrinsic representation of "host system" that aligns with a broad understanding of "computer." Since the patents-in-suit do not provide a special definition for the computer functioning as the "host" in claim 12, the Court sets forth its understanding of "computer" in light of the intrinsic record, as well as analysis provided by other courts as to a general definition of "computer." Claim 12 discloses that the I/O interface receives command sequences from the host system. Therefore, the patentee's instructions as to command sequences should be included in the construction of this term. Where the command sequences go, however, seems to be an ancillary to question of what is understood to be a computing system.

Defendants request that "host" be defined according to a dictionary definition that equates "host" to "the main computer in a system of computers" or "a computer containing data or programs that another computer can access by means of a modem or network." RESPONSE at 19 (citing AM. HERITAGE DICTIONARY 849 (4th ed. 2000) & MICROSOFT PRESS COMPUTER DICTIONARY 201 (2d ed. 1994)). Nonetheless, the meaning of computer to one of ordinary skill in the art is a recurring issue in patent infringement litigation, and therefore, it is useful to consider what other courts have emphasized.
in understanding computer functionality. The Federal Circuit has instructed that this claim term, like any other, should first be construed according to intrinsic evidence, but where such a record is not conclusive, the court understood "computer" to encompass "peripherals that are within a reasonable proximity to the CPU and it's main memory and directly connected to the CPU or the CPU circuit board." Pickholtz v. Rainbow Techs., 284 F.3d 1365, 1374 (Fed. Cir. 2002). In Pickholtz, the Federal Circuit implicitly disagreed with PACid's understanding of "host" or "computer" as being the broadest possible system, such as "any system needing an encryption key." Judge Lourie specifically noted, "[T]he term 'computer' cannot be so unbounded as to include all devices connected in any way to the CPU." Pickholtz, 284 F.3d at 1374.

Without a precise definition for "host system," in the '646 and '612 patent, the Court finds that the intrinsic record supports the implication that "host system" is synonymous with "computer." Extrinsic evidence is necessary to clarify the scope of the term and the Court adopts the dictionary definition of computer used previously in this district. See Soverain Software LLC v. Amazon.com Inc., No. 6:04-CV-14, 2005 U.S. Dist. LEXIS 46872, 2005 WL 6225276, at *9 (E.D. Tex. Apr. 7, 2005). Judge Davis consulted a technical dictionary to broadly define "computer" to mean "a functional unit that can perform substantial computation, including numerous arithmetic operations, or logic operations without human intervention." Id. (relying on IEEE STANDARD DICTIONARY OF ELEC. & ELECS. TERMS 192 (6th ed. 1996)). This understanding of "computer" is incorporated in the Court's construction of "host system" in this case. Accordingly, the disputed claim term is defined as "a computer that provides command sequences through an I/O interface."

2. "host system"

The parties dispute whether "host system" is synonymous with "host platform" or whether the "host platform" is part of the "host system." OPTi looks to this Court's construction of "host" in the NVIDIA case to support its proposal. There, the Court noted that "the specification uses "host" and "host platform interface circuitry 115" interchangeably. The court, however, found that "host" was synonymous with "host platform," not that "host system" was synonymous with "host platform."

--- Footnotes ---

8 NVIDIA, at 13 ("Host platform interface circuitry 115 asserts CMD # synchronously with the rising edge of ATCLK. Host can also optionally inhibit its ISA MRD #/MWR # lines." '141 7:55-58 (emphasis added); see also '141, 9:52-54, 10:1-5.).

--- End Footnotes ---

Defendants argue for an interpretation of "host system" that is broader than "synonymous with host platform." Defendants point to the specification where Fig. 1 is described as having a "host side" and refers to "system DRAM" which is not part of the host platform interface circuitry. '807, 8:20; '141, 8:23. Defendants further point to the prosecution history of the '807 patent. Claim 46 as filed in the original '807 application used the term "said host platform." Hsue Ex. 5, '807 Prosecution History, 9/4/97 Office Action at 4. Claim 46 depended from original claim 38, which used the term "host system." Id. The PTO Examiner objected to the term "said host platform" in Claim 46 as lacking proper antecedent basis. Id. Defendants contend that the Examiner's rejection is evidence that he did not equate the two terms. Furthermore, in response to the rejection, OPTi amended original claim 46 to replace the term "host platform" with "host system," Hsue Ex. 6, '807 Prosecution History, 2/4/98 Response at 17. Although improper antecedent basis is not necessarily indicative of the Examiner's interpretation of the term, the terms are different, and the court must construe the term as it appears in the patent. Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005); M.P.E.P. § 706.01 (objections are different from rejections and indicate a problem with a claim's form, not its substance).

The ordinary and customary meaning of a claim term "is the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention." Phillips, 415 F.3d at 1313. The plain meaning of the term "system" implies an aggregation of smaller parts, something that the term "platform" does not. Figure 1 of the LPC patents clearly shows a host side and a device side. Contained within the host side is the host platform interface circuitry, a CPU, a clock, an IRQ/DRQ generation circuit and multiple busses connecting different devices. '807, 4:53-5:12; '141, 4:57-16. The host side, therefore, is plainly different from the host platform. However, the term "host system" does not appear in the specification, but appears solely in the claims. Even if the patentee intended "host system" to be synonymous with "host
The claim language guides the court's conclusion of host system. "Host system" only appears in claim 1 of the '807 patent. The claimed "host system" does not communicate with components contained on the host side of the interface, but only with peripheral devices. See '807 patent, claim 1. Contrarily, the "host platform" explicitly communicates with the CPU and the IRQ/DRQ generation circuit, all of which exist on the host side of the interface. '807, 5:9-12, 10:60-65, 11:8-11, 11:23-28; '141, 5:13-16, 10:65-11:3, 11:13-17, 11:22-32. Where the "host platform" communicates with components on the host side and the "host system" only communicates with peripheral devices, "host system" and "host platform" cannot be the same. Similarly, Claim 18 of the '141 patent and its subsequent dependent claims do not claim any communications between the "host system" and the components contained on the host side. Claim 1 of the '807 patent and claim 18 of the '141 patent disclose a method of interfacing a host system, synonymous with the host side shown in Figure 1, with a peripheral device. The "host system" contains at least a host platform and a CPU, but may contain other devices. The court has construed "host platform" as requiring a connection to a CPU whereas the "host system" actually contains a CPU. Accordingly, the court construes "host system" to mean "at least a host platform and a CPU."

1988

3. Term 12 ('703 Patent, Claims 5, 15) 15

The term to be construed appears in claim 15 and claim 1, upon which claim 5 depends.

These two patent claims describe prepending a hostname to the URL for an embedded web page object. ('703 Patent, Claims 5, 15.) As described in the remaining steps of claim 15, in response "to a browser query to resolve the hostname," the IP address of a particular one of the "set of content servers distinct from the content provider server" is returned to the client's browser. (Id. Claim 15; accord id. Claim 5.) Thus, the hostname identifies a server on the Internet which the client's DNS server can resolve into an IP address so his or her browser can fetch the object. (See id. col.9 11.20-28.) The court's construction strikes a balance between Akamai's broad proposed construction and Limelight's narrow one, opting instead to include the functional limitations described in the claims rather than one specific to the current Internet name resolution system.

1989

"Housing" terms

The Court adopts Plaintiffs' construction and construes "housing" to mean "a cover or enclosure." Defendants propose that "housing" be construed to mean "the protective outer cover of the motion detector camera, which excludes any inserts or partitions contained within such protective outer cover." Defendants' construction contains unnecessary limitations. Defendants partially rely on Figure 7 to support their construction. Defendants seem to argue that because Figure 7 shows...
an outer housing and inside the housing a motion detector and a camera, the enclosures containing the motion detector and camera are not part of the housing and, therefore, "housing" must exclude any partitions or inserts contained within such "housing." Figure 7 is only one embodiment of the invention, and there is no explicit support in the specification for applying Defendants' limitation to the claim term. Defendants also cite prior art in which, according to Defendants, the housing is not considered to include anything within itself. However, Defendants fail to cite anything within the specification or prosecution history that would indicate the examiner or applicant defined or used "housing" in that manner.

The specification broadly describes the housing as "an enclosure for holding the various components of the camera." Col. 2:54-55. Accordingly, the Court construes "housing" as "a cover or enclosure."

**Housing**

In its briefing, Lantronix argued that "housing" is used according to its plain meaning and therefore does not require construction. Alternatively, if the Court does construe the term, Lantronix argued it should be construed according to its plain meaning: "a case or enclosure."

Digi argued "housing" should be construed as "cover that provides structural and protective support for the enclosed components." Digi contended the housing serves as both a cover and a structure for the enclosed components such as the electrical pins and socket connections. If this were not the case, Digi argued, "the claim language requirement that the connector contain at least two physical interface connection elements and electronic circuitry would contradict the 320 patent, which claimed the insertion of components inside the connector itself."

Further, Digi argued, the components must be attached to the connector's structural supporting unit (the housing) in order for them to be electrically connected and functional. Digi also relied on the 320 patent's prosecution history, which acknowledged that "a housing is required to provide a structure for the connector." See 320 patent prosecution history, Amendment and Response to Official Action, 4/30/1985, p. 5. Finally, Digi contended that Figure 1 and the 470 patent's prosecution history "show that the connector has its own separate housing to distinguish it from prior art where the functional circuitry was part of, and contained within, the computer housing."

During the hearing, the parties agreed to a compromise construction: "case or enclosure to cover and protect the connector's internal components." The Court agrees with the parties' agreed construction. As before, the Court rejects Digi's argument that the 320 patent was incorporated in any way into the 470 patent.

**2. The Claims Are Not Limited to a Portable Computer**

LPL would construe the claims of the invention as not being limited to a portable computer. LPL argues that limiting the invention to a portable computer improperly reads the preferred embodiment into the claims. Additionally, LPL contends that inserting the "portable computer" limitation into the claims would contradict the plain language of the asserted claims, none of which recite the term "portable computer." Moreover, LPL asserts that reading the "portable computer" limitation into the claims would violate the doctrine of claim differentiation, which holds that "[i]t is presumed to be a difference in meaning and scope when different words or phrases are used in separate claims." Comark Commc'ns, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998).

Defendants seek to limit the patents-in-suit to a portable computer. The crux of the Defendants' argument is that the patents describe and illustrate a portable computer and no other embodiment. As such, the portable computer is not the preferred embodiment, but is rather the only embodiment. Defendants reference numerous instances in which the patents describe or depict the invention as a portable computer including: the patents' titles, abstracts, summaries, and various places throughout the common specifications. n9
n9 Defendants note that at the conclusion of the specification, the inventors reference only a portable computer, thereby confirming that the invention is limited accordingly. '641 patent, 7:46-50.

Defendants also argue that the terms "housing" and "data processing device," as construed by them, link the claims to a portable computer. With respect to "housing," Defendants argue that, based on the prosecution history, "housing" should not be accorded its ordinary meaning. In this regard, Defendants submit that the inventors acted as lexicographers when, in response to an objection raised by the examiner, they explicitly defined "housing" in connection with a portable computer. Additionally, Defendants note that "portable computer" was specifically called out in the examiner's statement of reasons for allowance. Finally, Defendants assert that because "data processing device" is associated with the term "housing" in all of the asserted claims, it too is limited to a portable computer. n10

n10 Tatung also asserts that the ordinary and customary meaning of "data processing device" is a central processing unit of a computer.

The Special Master turns to an examination of the parties' arguments.

a. The Common Specification Is Not Limited to the Portable Computer Embodiment; Thus, the Claims Cannot Be So Limited

Claims are not necessarily limited to those embodiments disclosed in the specification, even if a patent describes only a single embodiment. See e.g., Phillips, 415 F.3d at 1323; Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004). The Phillips court said, "[t]hat is not just because section 112 of the Patent Act requires that the claims themselves set forth the limits of the patent grant, but also because persons of ordinary skill in the art rarely would confine their definitions of terms to the exact representations depicted in the embodiments." Phillips, 415 F.3d at 1323.

In Liebel-Flarsheim, the Federal Circuit overturned the district court which construed all of the asserted claims to require a pressure jacket even though none of those claims expressly recited a "pressure jacket." The Federal Circuit recognized that the "pressure-jacketed injector" embodiment was the only subject matter described in the specification; however, the court rejected the conclusion that the claims must therefore be limited to that embodiment. Liebel-Flarsheim, 358 F.3d at 905, 906. The Federal Circuit reiterated that the claims should be so limited only if the patentee has demonstrated a clear intention to limit the invention using "words or expressions of manifest exclusion or restriction." Id. at 906 (quoting Teleflex Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002)). Importantly, the Federal Circuit concluded that the standard is not met by the mere absence of any reference to alternative embodiments. See id. at 906, 907. Instead what is required is a clear exclusion of other embodiments, such as by distinguishing embodiments of the prior art. Id.

Accordingly, even assuming the patents-in-suit expressly teach only one embodiment, i.e., a portable computer, under both Phillips and Liebel-Flarsheim, the asserted claims should not be limited to that one embodiment. n11 As in Liebel-Flarsheim, the common specification of the patents-in-suit is replete with descriptions of the invention with respect to a single embodiment of a portable computer, including the abstract and title. At the same time, nothing in the common specification expressly precludes other embodiments or restricts the invention to only a portable computer. Id. The mere absence of a description of alternative embodiments in the common specification such as a flat screen monitor does not, in the Special Master's view, rise to the level of "words of manifest exclusion or restriction." n12 Thus, because: (1) the asserted claims do not specifically recite "portable computer"; and (2) the intrinsic record is silent regarding alternative embodiments and therefore contains no clear disavowal of other embodiments, the Special Master concludes the invention should not be limited to a "portable computer."
n11 LPL argues that other embodiments are disclosed and cites, for example, "[a]s a flat panel type display device 111, the LCD is widely used in portable computers and flat screen monitors." '641 patent, Col. 1:32-34. However, one skilled in the art would understand that statement as merely teaching that LCDs themselves are well known.

n12 In contrast, the inventors manifestly restricted the claims to "rear mountable" by arguing rear mounting advantages over the inferior front- and side-mounting disadvantages of the prior art.

b. Two Distinct Claim Groups Demonstrate that the Invention Encompassed More than Just a Portable Computer

Two distinct groups of claims were included with the originally-filed and subsequently-issued patents-in-suit. JA at Ex. G, JA00119-128; Ex H, JA 001057-1065. The first group of claims explicitly recite a "portable computer" (claims 1-34 of the '641 patent and claims 1-32 of the '718 patent); the second group of patented claims recite a rear-mountable flat-panel display device (claims 35-56 of the '641 patent and claims 33-41 of the '718 patent) without any limitation to a portable computer. The Special Master concludes that the distinct recitations in the first and second groups of claims make it apparent that the inventors intended different scope of coverage for those two groups.

Although not argued by the parties, in the Special Master's view, as an initial matter, "[t]he claims as filed are part of the specification, and may provide or contribute to compliance with § 112." Hyatt v. Boone, 146 F.3d 1348, 1352 (Fed. Cir. 1998). In the present case, both groups of claims were filed with the original applications associated with the '641 and '718 patents, thereby qualifying as part of the common specification. n13 The two groups of claims are unquestionably distinct: one set specific to a portable computer and one set specific to a flat panel display device and silent with respect to a portable computer. The second group of claims, which do not recite "portable computer," thus teach a non-portable-computer embodiment. In the Special Master's view, this demonstrates that the inventors understood that their inventions covered more than just a portable computer.

n13 Exceptions include claim 56 of the '641 patent and claims 39-41 of the '718 patent.

Additionally, different claims of a patent presumptively have different scope. Comark, 156 F.3d at 1187.

"As a general rule a limitation cannot be read into a claim to avoid infringement" Where ... the limitation sought to be "read into" a claim already appears in another claim, the rule is far more than "general." It is fixed. It is long and well established. It enjoys an immutable and universally applicable status comparatively rare among rules of law. Without it, the entire statutory and regulatory structure governing the drafting, submission, examination, allowance, and enforceability of claims would crumble.

D.M.I., Inc. v. Deere & Co., 755 F.2d 1570, 1574 (Fed. Cir. 1985) (citations omitted). The Special Master is of course mindful that claim differentiation may be overcome by an unequivocal disavowal of subject matter in the intrinsic evidence. See Kraft Foods, Inc. v. Int'l Trading Co., 203 F.3d 1362, 1367-68 (Fed. Cir. 2000) (finding the written description and prosecution history overcame any presumption arising from the doctrine of claim differentiation). That the common specification arguably teaches only a single embodiment does not in and of itself establish a clear disclaimer that would overcome the presumption. The result is, therefore, that the portable-computer limitation should not be read into the second group of claims.

In the Special Master's view, the prosecution history is consistent with the presumption of claim differentiation. Throughout the prosecution history, both the examiner and the inventors addressed each group of claims separately. For example, the examiner referred to a portable computer only when addressing the claims of group one (e.g. claims 1-34 of the '641 patent) and referred to flat-panel display device only when addressing the claims of group 2 (e.g., claims 35-43, 47-50, and 54-55 of
the '641 patent). n14 JA at Ex. G, JA00216-219, 312-315. Similarly, the inventors kept separate the patentability arguments regarding each of the two groups of claims. For instance, in the January 17, 2001 Amendment in response to the examiner's separate rejections of claims 1-34, and claims 35-43, 47-50, 54-55, the inventors characterized independent claim 1 as "drawn to a portable computer" and independent claim 35 as "drawn to a flat panel display device." See JA at Ex. G, JA00268 and JA00270. At no time did the inventors refer to a portable computer when arguing the patentability of the second group of claims.

--- Footnotes ---

n14 The examiner's reference to a portable computer in his statement of reasons for allowance of the '641 patent was, in the Special Master's view, merely a shorthand summary of the claimed invention, which included the first group of claims specifically directed to a portable computer. Moreover, the inventors' silence after the examiner's statement "cannot amount to a clear and unmistakable disavowal." Salazar v. Procter & Gamble Co. 414 F.3d 1342, 1345 (Fed. Cir. 2005).

Having stated the above, although the common specification may only describe the invention with respect to a portable computer, where the two distinct groups of claims were originally filed and granted together, the Special Master concludes that the inventors contemplated a broader scope for the invention than a portable computer, and did not clearly disavow embodiments other than a portable computer.

1992

20. a housing connectable to both a user's notebook or desktop computer

This phrase only appears in claim 13 of the '202 patent. The defendants contend that the phrase is indefinite because it is incomprehensible and the specification fails to provide meaning to this phrase. The court disagrees and finds that the phrase, read in the context of the whole patent, can be understood by one of ordinary skill in the art to refer to a connection to a flash memory module and to a user's computer. Accordingly, the defendants' indefiniteness argument is rejected and the phrase is construed to mean "a housing connectable to both a removable flash memory module and a user's notebook or desktop computer." The court incorporates by reference its definition of "connectable."

1993

18. a housing of a size to be held in the palm of a user's hands n8

The defendants contend that the phrase is indefinite because it has no discernible meaning in light of the prosecution history. The court disagrees and finds that the phrase, as written and in the context of the whole patent, can be understood by one of ordinary skill in the art. See In re Marosi, 710 F.2d 799 (Fed. Cir. 1983); Bancorp Services, L.L.C. v. Hartford Life Ins. Co., 359 F.3d 1367 (Fed. Cir. 2004). The phrase requires no construction and the court rejects the defendants' indefiniteness argument.

1994

A. "http," as used in claims 1, 9, and 10.
The parties agree that "http" is "a stateless communications protocol," but disagree on whether the claim term refers specifically to the HyperText Transfer Protocol. Accordingly, plaintiff offers the construction, "HyperText Transfer Protocol, a stateless communications protocol," and defendants offer the construction, "a stateless protocol that allows web users/clients and websites/servers to communicate with each other." The claim interpretation principle that is dispositive here is the patentee's ability to act as his own lexicographer in explicitly defining claim terms. The application of this principle to the '670 patent clearly compels the conclusion that "http" means "HyperText Transfer Protocol, a stateless communications protocol, which allows Web clients and Web servers to communicate."

It is well settled that a patentee may act as lexicographer, provided that he express a clear intent to define a claim term in the specification. See Sinorgchem Co. v. ITC, 511 F.3d 1132, 1136 (Fed. Cir. 2007). When such intent is manifest, the specification is essentially converted into a dictionary, written by the patentee, for the specific purpose of construing the disputed claim term. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). The definition supplied by the patentee is given deference by a court undertaking the task of construing claims, and ordinarily is dispositive of any claim construction dispute, absent justification to depart. See ASM Am., Inc. v. Genus, Inc., 401 F.3d 1340, 1344 (Fed. Cir. 2005).

In the '670 patent, the patentee has provided the following clear definition of the claim term "http" in the specification: "Web clients and Web servers communicate using a protocol called 'HyperText Transfer Protocol' (HTTP)." '670 Patent Specification col. 11. 53-55; see also id. col. 2 11. 36-39 ("In an embodiment of the invention, the server uses a hypertext transfer protocol (http') to communicate over the network with clients; such clients also communicate with the server using the hypertext transfer protocol."). Given that "http" is plainly an acronym for "HyperText Transfer Protocol," defendants' proposed construction--inclusive of any stateless Internet communication protocol--contravenes the patentee's express definition and accordingly finds no support in the intrinsic evidence. 16

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - - - - -
16 Tellingly, defendants explicitly recognize that "[t]he patentee provided an explicit definition of the term 'http'. See col. 1, Ins., 53-55 ('Web clients and Web servers communicate using a protocol called 'HyperText Transfer Protocol' (HTTP'))." Doc. 136 at 28 n. 19. - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - - - -

In addition, the patentee includes within his definition the fact that the protocol facilitates communication between Web clients and Web servers in either direction. Defining the claim term without these operative words would ignore an integral part of the definition as set forth in the specification. When the surrounding specification statements are considered, it becomes clear that the purpose of defining "http" was not only to identify the particular protocol, but also to emphasize how the protocol would be used in the invention. See Metabolite Labs., Inc. v. Lab. Corp. of Am. Holdings, 370 F.3d 1354, 1360 (Fed. Cir. 2004) ("In most cases, the best source for discerning the proper context of claim terms is the patent specification wherein the patent applicant describes the invention.").

In sum, where, as here, the patentee has explicitly defined a claim term in the specification, "the inventor's lexicography governs," Phillips, 415 F.3d at 1316. Accordingly, "http" is construed to mean "HyperText Transfer Protocol, a stateless communications protocol, which allows Web clients and Web servers to communicate."

1995

D. "http client," as used in claims 1, 9, and 10.

Closely related to "http server" is the disputed claim term "http client." The parties proposed constructions essentially match those offered for "http server," with the exception of substituting the word "requestor" for the word "provider." Accordingly, plaintiff proposes "a requestor of data using http" and defendants propose "a computer that communicates (i.e., requests HTML documents) with a server over a network by using the http protocol." As before, it is clear that the claim terms must be read consistently throughout the patent. Specifically, "http client" must be read in light of the previously determined
construction of "http server," see Chamberlain Group, Inc., 516 F.3d at 1337, particularly given the claim terms' close relationship in the '670 patent, see, e.g., '670 Patent Specification col. 4 11. 27-30 (defining "client" and "server" in relation to their complimentary roles). Given the foregoing discussion relating to the construction of "server" and "http server,"--and in light of the fact that "client" is specifically defined by the patentee as "refer[ring] to a computer's general role as a requestor of data (client)," Id. col. 4 11. 27-30-- the claim term "http client" must be defined as "a computer that requests data using HyperText Transfer Protocol."

1996

5. “HTTP-complaint device”
“HTTP-complaint device” is utilized in asserted claims 15-16 and 19 of the ‘335 Patent. The Plaintiff asserts that “HTTP-complaint device” does not need construction. Alternatively, if construed, the Plaintiff asserts that the proper construction is “a device that understands HTTP and whose behavior is affected by an HTTP request.” The Defendants assert that the terms should be construed as “a machine running an executable capable of storing, locating and returning Web pages in response to Web client requests.”

The Defendants assert the same construction for the terms “Web server” and “HTTP-complaint device.” The Defendants’ construction is based upon their assertion that the term does not appear in the specification and that the specification only discloses a Web server for performing the function described in the language surrounding the use of “HTTP-compliant device.” As such, the Defendants assert that “HTTP-compliant device” should be construed the same as “Web server” as that is the only corresponding device described and enabled in the specification. To hold otherwise, assert the Defendants, would result in a claim that is overbroad and invalid for not being described and enabled.

Regarding the maxim that claims should be construed to be valid, in Phillips the Federal Circuit guidance states that this maxim is limited “to cases in which ‘the court concludes, after applying all the available tools of claim construction, that the claim is still ambiguous.’” Phillips, 415 F.3d at 1327. The Court does not find that in light of the specification the term in question is ambiguous to one skilled in the art. Thus, the Defendants’ validity concerns should be more properly addressed with regard to validity motions.

The Defendants also assert that the more general construction proposed by the Plaintiff would be so broad as to even encompass a Web client. However, the claim language itself makes clear that this concern is not valid as there is substantial functional language regarding what happens at the HTTP-compliant device including the transferring of a request from the HTTP-compliant device to a page server, intercepting the request at the HTTP-compliant device, and concurrently processing other requests at the HTTP-compliant device.

The Defendants do however raise valid concerns over the Plaintiff’s definition raising additional interpretation questions with regard to the meaning of “understands HTTP” and “behavior affected by an HTTP request.” The Court agrees with the Defendants in this regard. The specification defines HTTP as “a communications protocol known as HyperText Transport Protocol (HTTP).” Col. 1:25-26. Mindful that not all terms in a claim need construction, the Court adopts a construction of “HTTP-compliant device” to mean “a device that is compliant with the communication protocol known as HyperText Transport Protocol (HTTP).”

1997

The Court is of the opinion that the findings and conclusions of the Magistrate Judge are correct. Therefore, the Court hereby adopts the Report of the United States Magistrate Judge as the findings and conclusions of this Court.
1998

3. Seven's renewed motion for judgment as a matter of law/motion for new trial.

After the verdict, Seven filed a renewed motion for judgment as a matter of law and a motion for new trial. That motion (# 385) is granted in part and denied in part. The court grants the motion insofar as it is related to claim 11 of the '192 patent. There is insufficient evidence to support a verdict that the accused products satisfy the limitation of "comprising one of an HTTP port and an SSL port." In a supplemental claim construction order, the court construed the term "HTTP port and SSL port" to mean "any port that is used to transfer information or communicate using Hyper Text Transfer Protocol (HTTP) and any port that is used to transfer information or communicate using Secure Sockets Layer (SSL) protocol." See Order Dkt. # 340. Despite Visto's arguments to the contrary, the evidence in this case is undisputed that the accused products do not use the HTTP or SSL protocols. In the words of Visto's expert, the term protocol means "the exact formatting, the syntax, and the semantics of the connection that's being made." (Tr. Transcript April 25, 2006, at 29:14-30:3.). Visto's expert conceded that the accused products use Seven's own protocol, rather than HTTP or SSL. Claim 11 requires a port that is used to transfer information or communicate using specific protocols. Viewing the evidence in the light most favorable to the jury's verdict, Visto has not met its burden to demonstrate infringement of claim 11 of the '192 patent. Seven's motion for judgment as a matter of law on this point is granted.

1999

C. "http server," as used in claims 1, 9, and 10.

The parties' proposed constructions for "http server" closely track their respective proposed constructions for "server," except here the definitions are tailored specifically to the http context. Plaintiff offers the construction "a provider of data that uses http," while defendants again offer a construction that makes reference to a computer, documents, and a communications protocol: "a computer that communicates (i.e., provides HTML documents that have been requested) with a client over a network by using the http protocol." Dispositive of the meaning of "http server" as used in the '670 patent is the claim construction principle that "a claim term should be construed consistently with its appearance in other places in the same claim or in other claims of the same patent." Rexnord Corp. v. Laitram Corp., 274 F.3d 1336, 1342 (Fed. Cir. 2001). This principle, applied here, points persuasively to the conclusion that "http server" must be defined as "a computer that provides data using HyperText Transfer Protocol."

It is axiomatic that a district court undertaking claim construction must read claims and claim terms consistently throughout the document. See Phillips, 415 F.3d at 1314. More specifically, the Federal Circuit held in Chamberlain Group, Inc. v. Lear Corp. that, although a single word ("code") was used in conjunction with two different modifiers ("binary" and "trinary"), the word "presumptively should carry the same meaning throughout the patent." 516 F.3d 1331, 1337 (Fed. Cir. 2008). Accordingly, Chamberlain Group, Inc. stands for the proposition that a claim term ordinarily retains its singular meaning throughout the patent whether it is used alone or whether it is used in conjunction with a modifier.

This rule concerning modifiers can be squarely applied in construing "http server." Both the object and the modifier in this claim term--that is, "http" and "server"--have been previously construed, and should retain their respective constructions when used jointly. Thus, "http server" is construed to mean "a computer that provides data using HyperText Transfer Protocol."

I. Processing Hub

\*\*Claim Term: "processing hub"

Alexsam's Proposal: the Court should adopt the definition provided in section V(5) of

IDT's Proposal: "a computer which provides front-end point of sale device management and message
the Humana Claim Construction processing for card authorizations Order (i.e., "a computer which provides front-end POS device management and message processing for card authorizations")

The Court construed this term in both the Humana and Datastream Markman orders. IDT asks the Court to revert to its construction in the Datastream Markman Order while Alexsam urges the Court to retain the construction adopted in the Humana Markman Order.

In the Datastream Order, the Court previously found that the '608 patent specification provided a definition of the "processing hub" as used in this invention. See Datastream Markman Order at 10. The Court, therefore, adopted the definition for this term as recited in the specification. Id. In the Humana Markman Order, the Court broadened the construction for "processing hub" by omitting "and activations," explaining that not all of the claims then asserted required activation. See Humana Markman Order at 15.

IDT argues that all of the claims now asserted require activation and the Court should revert to the Datastream order. The Court is not persuaded by this argument. Claim terms should have the same meaning across in all claims, mandating the Court keep the broadest possible definition. The Court does find that a processing hub could perform activations without performing authorizations. The Court construes the term to mean, "a computer which provides front-end point of sale device management and message processing for card authorizations or activations."

2001

Hue, lightness, and saturation color values

The Court construes this term to mean "computer-readable color data consisting of three numbers that represent the H value, L value, and S value (is the H, L, and S respectively) of a selected pixel." AVG proposed the following construction, "computer-readable data elements, each of which is indicative of a color's hue, lightness, and saturation." The Court disagrees because AVG's definition requires each "value" to have three components (one component for each of hue, lightness and saturation), and such requirement excludes the preferred embodiment. The claim clearly calls for "sets" of H, L and S color values, indicating that each of H, L and S has a separate value.

AVG agrees with Microsoft's definition of the individual terms of hue, lightness, and saturation, and the Court construes them as follows. "Hue" is "the attribute which determines whether the perceived color is red, yellow, green, blue or the like, and equivalents thereof." "Lightness" is "the brightness of an area judged relative to the brightness of a similarly illuminated area that appears to be white or highly transmitting, and equivalents thereof." "Saturation" is "the amounts of color and grayness in a hue that affect its vividness; that is, a hue with high saturation contains more color and less gray than a hue with a low saturation, and equivalents thereof."

2002

17. Hybrid access system

The term "hybrid access system" appears in claims 12 (by virtue of its dependency), 39, and 52 of the '121 patent. The plaintiff proposes a construction of "a device that provides active management of both upstream and downstream channels." The defendants propose "a common network management system that is separate and apart from upstream and downstream routers for controlling paths in both the upstream and downstream channels of hybrid interfaces." In accordance with the specification, the court defines a "hybrid access system" as "a system for managing upstream and downstream communications between a host computer and one or more remote clients."
2003

9. "displaying search results in hyper text markup language as a sequence of universal resource locators directed to the database entries" (claims 5 & 7)

Plaintiff argues that this term means "that when a search is performed, the search results include universal resource locators 'URLs' that point to entries in the database. 'Hyper text markup language' is a computer language used to specify the contents and format of a hypermedia document." Defendant proposes the following construction "displaying web search results in an HTML format that embeds the Web addresses linked to database entries."

Defendant's proposed construction functionally limits the computer network to the World Wide Web. The defendant's construction essentially construes an URL to mean a Web address. As discussed previously, the court does not limit the computer network in the claims of the '538 patent to the World Wide Web and does not require an URL to mean a Web address. The patent specification expressly states that the computer network in the claims is broader than the World Wide Web. 3:65-67. Consequently, the URL must be broader than a web address because the network is broader than the World Wide Web.

The court believes that it is not necessary to construe "hyper text markup language" because one of ordinary skill in the art knows what HTML means. Accordingly, the court construes "displaying search results in hyper text markup language as a sequence of universal resource locators directed to the database entries" to mean "displaying search results in hypertext markup language where the results are displayed as a sequence of universal resource locators directed to the database entries."

5. Hypertext linking reference ('461 patent, claims 49 and 53)

The parties dispute whether the phrase "hypertext linking reference" refers to the address associated with the keyword phrase (defendant's position) or to both the keyword phrase and the address associated with the keyword phrase (plaintiffs' position). Claim 49 of the '461 patent reads "said keyword phrase being associated with a hypertext linking reference." Substituting plaintiffs' proposed definition in claim 49 would produce the reading: "said keyword phrase being associated with said keyword phrase and an address." As this substitution illustrates, plaintiffs' proposed construction is nonsensical. It would result in the tautological construction that the keyword phrase would be associated with itself. Moreover, plaintiffs' proposed construction defies assertions the inventor made during the patent's prosecution. See Warner-Jenkinson, 520 U.S. at 30 (prosecution history is relevant if inventor considered particular interpretation during prosecution of patent and specifically disclaimed it); Vitronics, 90 F.3d at 1582-83. In particular, the prosecution history indicates that the inventor treated the phrase "hypertext linking reference" as synonymous with the uniform resource locator. See Aff. of Craig Smith, Exh. D, July 28, 1998 Resp. to Office Action, at 5 (remarking that "the hypertext linking reference, or URL, is fixed until the hypertext reference viewable by the user is deleted or changed") (emphasis added). Because of the prosecution history and plaintiffs' concession at the claim construction hearing that a uniform resource locator is the address, defendant's construction will be adopted. Accordingly, "hypertext linking reference" in claims 49 and 53 of the '461 patent means the address associated with the keyword phrase.

6. "Hyperlink": "A connection from one web resource to another." This term is not limited to a connection between two different web pages. No specific guidance in the intrinsic record is provided. Extrinsic evidence indicates that, in 1999, HTML was understood as providing a link between web resources (including images, video clips, sound bites, programs, and documents) and not simply web pages. (D.I. 387, ex. 139 at JA5362)
2006

2. Hyperlink (‘461 patent, claim 49 and ’505 patent, claims 15 and 19)

Plaintiffs argue that the word "hyperlink" should be construed as "a phrase, an address and information stored at each address." (Plaintiffs agreed at the claim construction hearing that "operations" may be removed from the definition they proposed in their brief.) Although defendant defined "hyperlink" as "an anchor, address and destination information" and plaintiffs defined it as "a phrase, address and information," the parties appeared to agree at the hearing that the dispute was one of nomenclature only. In fact, defendant admitted that the important point was that the term "hyperlink" be construed as having three components notwithstanding the labels on these components. Although I tend to prefer defendant's terminology, because the inventor did not use the words "anchor" or "destination information" in the patents, I will use plaintiffs' terminology (that is, a keyword phrase, an address and information stored at that address).

One final point needs to be addressed. Defendant argues that "hyperlink" includes the requirement that "upon selection of the anchor [keyword phrase] by a user, the computer directly and immediately accesses the address to retrieve the destination information and display it to the user." Plaintiffs argue that adopting a "direct and immediate" qualifier as part of the definition would limit the invention by, for example, allowing only one-click access rather than two-click access. Because the claims at issue do not limit the access as either direct or immediate, I will not read defendant's proposed limitations into the disputed claims. Accordingly, "hyperlink" in claim 49 of the ’461 patent and claims 15 and 19 of the ’505 patent means a keyword phrase, an address and information stored at that address.

2007

11. Hyperlink phrase (’505 patent, claims 15 and 19)

Defendant defines "hyperlink phrase" as equivalent to "keyword phrase" while plaintiffs define it as "an object name or phrase in text that may be highlighted." At the claim construction hearing, plaintiffs distinguished between "hyperlink phrase" and "keyword phrase" by arguing that a "keyword phrase" is a recognized text string before it is converted to a hyperlink phrase and a "hyperlink phrase" is a keyword phrase after it has been converted to hyperlink. However, plaintiffs concede that a keyword phrase is recognized in real time (in the context of defining the term "hypertext linking reference") and I have construed the claims to require that "hypertext linking reference" (the address) must also be established in real time. Therefore, in light of plaintiffs' concession and this court's construction, there is no meaningful distinction between "hyperlink phrase" and "keyword phrase." The conversion from a keyword phrase to a hyperlink occurs in real time, that is, as soon as the last word of the keyword phrase has been entered. Even a cursory reading of the ’505 patent specification reinforces this construction. See ’505 Patent, 3:5-13 ("A hyperlink phrase is related to a specific hyperlink site by an associated hyperlink address and usually is descriptive of the related site. . . . By selecting a specific hyperlink phrase, a user selects an associated hyperlink site and automatically displays the object stored at the selected site."). Accordingly, "hyperlink phrase" in claims 15 and 19 of the ’505 patent is equivalent to "keyword phrase," which is a recognized text string that serves as the hypertext link.

2008

"Hypertext pages " and "Hypertext links/links in a hypertext page"

"Hypertext pages" are "screen renderings referenced by or including hypertext links." "Hypertext links" or "links in a hypertext page" mean "a non-sequential web association which the user can use to navigate through related topics." Amazon argues that "hypertext pages" does not include pages that do not contain hypertext. This limitation is not supported by the claim language or specifications. Amazon's proposed construction of "hypertext links" is similar to that which the Court adopts, but is less straightforward.
"Hypertext transfer protocol"

"Hypertext transfer protocol" ("HTTP") is "the client/server protocol used to access information on the World Wide Web,"

The parties are in apparent agreement as to what HTTP is, but they disagree as to whether HTTP is limited to the version that existed at the time of the patent application or whether it includes future versions. On June 7, 1995, HTTP draft version 1.0 was in use; today, version 1.1 is used.

As used in this patent, HTTP is a generic term not limited to the version in use at the time the application was filed. This situation is different from that in Schering Corp. v. Amgen Inc., 222 F.3d 1347 (Fed. Cir. 2000). In Schering, the parties dispute over the claim term's meaning was essentially a dispute over the scope of what was claimed to have been discovered or invented. Id. Here, Soverain is not claiming to have invented HTTP, but only that the methods described use HTTP. There is no reason to think that one skilled in the art would think the claims were limited to only the then-current HTTP, especially since the then-current version was a "draft," which implies a subsequent version.

1. IEEE 802 compliant device (claims 1, 3-6)

Plaintiff's Construction: A device which complies with all standards set forth in IEEE 802, as those standards existed on May 27, 1997.

Defendant's Construction: Any device which is capable of transmitting or forwarding data packets in accord with any of the networking standards of IEEE 802.

The first dispute on this term is whether the device must be compliant with all standards set forth in IEEE 802 (as plaintiff says) or whether it is sufficient to comply with any IEEE 802 standard (as defendant says). Defendant's view borders on the nonsensical: how would one determine which standard was the relevant one? If it truly means "take your pick," how is that a meaningful limitation?

Also, defendant's view is not consistent with the natural reading of what it means to be compliant with a set of rules. For example, if an employer were to say that it was "Title VII compliant," this would not mean that the employer was compliant with just any part of the statute. If the employer was not discriminating on the basis of race but was discriminating on the basis of gender, the employer would not be "Title VII compliant." It may be that certain parts of the statute are inapplicable (for example, because all of the applicants for a job are members of a particular protected class), but that would not mean that the employer could pick and choose which portions of the law to follow, only that not all parts of the statute would be relevant in a particular situation. Similarly, if some standards of IEEE 802 have no application to the '042 patent, as defendant argues, this means only that those particular standards may be disregarded, not that compliance is established by any one standard.

The next question is which version or versions of the IEEE standards apply. There are three possibilities: (1) any version of the standards; (2) the standards that applied when the claims were amended to include this limitation; or (3) the standards that applied when the inventor filed the application for the '042 patent. This first option may be rejected quickly. An invention cannot comply with standards not yet in existence. Defendant argues that limiting the standards to a particular version could render the invention obsolete as the standards change. Defendant is correct, but that is not an argument for expanding the reach of a claim beyond what could have been anticipated by the inventor; it is an argument for not including as an element in a claim a set of standards that change over time. Defendant cites no authority to the contrary.

Defendant says also that it would be "illogical" to use the standards as they existed as of the date of the invention (1997) rather than the date the patent was amended to include "IEEE compliant" limitation (1999). To the extent that this is so, defendant may take that issue up with the Court of Appeals for the Federal Circuit, which has held that it is the date of the
invention and not the date of the amendment that controls for the purpose of claim construction. Phillips, 415 F.3d at 1313. I will adopt plaintiff's construction of this term: "a device which complies with all standards set forth in IEEE 802, as those standards existed on May 27, 1997."

The dispute surrounding the terms "IEEE 802 MAC header" and "MAC frame packets" is the same: whether a requirement to comply with IEEE standards means any standard from any date or whether it means all relevant standards as of the date of the invention. Because defendant advances no other arguments regarding these terms, I will adopt plaintiff's construction of "MAC frame packets" as "a connectionless Media Access Control frame packet, described in the IEEE 802.3, as that standard existed on May 27, 1997" and "an IEEE 802 MAC header" as a "Media Access Control header compliant with all IEEE 802 standards, as those standards existed on May 27, 1997."

The parties dispute the meaning of the phrase "I/O circuitry coupled to said I/O port, for providing processed video signal to said I/O port, and for accepting a processed video signal from said I/O port;"

The term "I/O circuitry" means circuitry that inputs and outputs data. Examples of such circuitry are the input and output FIFOs in Figure 2. The remainder of the disputed terms have already been construed.

The term "I/O device" is an abbreviation of the term "Input/Output device." All of the disputed claims directly or indirectly reference the term "I/O device." (Instrument No. 69, Exh D). The parties agree that the definition of "I/O device" includes "disk or other persistent storage device." Superspeed contends, however, that two additional limitations should be included in the definition of "I/O device," showing that the storage device must be "shared by multiple computer systems" and that those systems must be "in a network." (Instrument No. 69, at 15).

Claim 27 of the '226 Patent claims "each of a plurality of I/O devices connected to said network" and claim 15 of the '244 patent claims the same language. (226 Patent, at 28:17-18; '244 Patent, at 27:7) (emphasis added). Moreover, claim 1 of the '136 Patent claims "[a] method for coherently caching I/O devices available for shared access on a network." (136 Patent, at 26:33-34) (emphasis added). Although certain limitations in the claim language require the networking or sharing of I/O devices, networking or sharing is not inherent in the I/O devices themselves. In fact, the limitations of the claims relate to the utilization of I/O devices in a shared network, but do not explicitly describe networking or sharing as an intrinsic feature of an I/O device.

Because the claims explicitly state that the I/O devices are "connected to said network" or "available for shared access on a network," there is no need to define the term with an additional limitation stating that the storage device is "shared by multiple computer systems in a network." If the term "I/O device" were defined in such a way it would render the explicit limitations of the claims redundant or mere surplusage. See Texas Instruments v. United States ITC, 988 F.2d 1165, 1171 (Fed. Cir. 1993) (noting that a proposed construction would render the disputed claim language mere surplusage because "courts can neither broaden nor narrow claims to give the patentee something different than what he has set forth") (quoting Autogiro Co. of Am. v. United States, 384 F.2d 391, 396, 181 Ct. Cl. 55 (Ct. Cl. 1967). Without the additional limitation that the device is "shared by multiple computer systems in a network," the parties essentially agree that the term "I/O device" means "disk or other persistent storage device." Accordingly, the Court finds that the proper construction for the term "I/O device" is "disk or other persistent storage device"
b. "An I/O port for coupling said integrated circuit to memory means"

The parties dispute the term "an I/O port for coupling said integrated circuit to memory means." The parties generally agree that an "I/O port" is an interface on the integrated circuit through which input and output data may be transferred to and from the memory means. The court agrees and adopts this construction of I/O port.

The meaning of the terms "for coupling" and "memory means" is disputed. Broadcom asserts that the "for coupling" language requires that the I/O port couples, or electronically connects, the video processor integrated circuit to memory means that is external to the video processor chip. Broadcom then argues that because the dual-ported video random access memory (labeled VRAM 216 in Figure 2) is the only component external to the video processor chip disclosed in the patent that stores video data for the video processor chip, the meaning of the claim term "memory means" must be limited to a dual-ported video random access memory. In support of this argument, Broadcom cites the Federal Circuit case, Wang Labs, Inc. v. America Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999) for the proposition that if the only embodiment described in the specification is a particular protocol, then the claims are properly limited to that protocol. Wang Labs, Inc., 197 F.3d at 1383 (holding that term "frame" is limited to character-based frames and does not include bit-mapped frames).

The claim term "memory means" cannot be limited to the specific dual-mode VRAM that was used to describe the preferred embodiment, because the patentees did not claim "a dual mode VRAM." The patentee claimed a generic "memory means." It is undisputed that the term "memory means" is, and was at the time of the filing of the 201 patent, a term of art that is broadly defined as "memory or device where information can be stored and retrieved." Microsoft Computer Dictionary 285 (4th ed. 1999). Nothing in the specification compels a contrary or more limited construction. See Specialty Composites v. Cabot Corp., 845 F.2d 981, 987 (Fed. Cir. 1988) ("Where a specification does not require a limitation, that limitation should not be read from the specification into the claims").

In the Wang case cited by Broadcom, the issue for claim construction was whether the claim term "frames of information" covered both character-based and bit-mapped based protocols. The preferred embodiment was directed to character-based protocol systems, although the specification acknowledged that bit-mapped protocols were part of the prior art. The Federal Circuit found that the term "frame" as used in the context of the patent necessarily was limited to character-based protocols stating that "the specification would not be so understood by a person skilled in the field of the invention" to include protocols that were not specifically included in the specification. The Federal Circuit also noted the significant impact of the prosecution history on its finding. The prosecution history of the patent at issue in Wang demonstrated that the patentee specifically distinguished the scope of the patent from prior art references relating to bit-map protocols. This confirmed the courts reading that claim's scope included only character-based protocols and not bit-map protocols.

The court reads the Wang case as standing for the proposition that patent claims should not be construed to cover embodiments that are not supported by the specification and are contradicted by the prosecution history. Wang is distinguishable from the instant case. In this case there is no such limiting prosecution history, nor does the specification compel the conclusion that the patented claims required a specific type of memory means.

Therefore, the court finds that the term "memory means" is to be accorded its ordinary meaning and defined as memory or device where information can be stored and retrieved. It is clear, however, from the claim language indicating that the I/O port is "for coupling said integrated circuit to memory means" that this "memory means" must not be contained as part of the single integrated chip, but is located off-chip. See also col. 45:3-6, 49-61 (referring to port as a location of a component for receiving data from, or sending data to, another component). If the memory means were on-chip, there would be no need to be able to couple it by using an I/O port.

With respect to the functional phrase "for coupling," the court finds that this phrase indicates only that the I/O port must be capable of being connected to an off-chip memory means and not that it is actually connected to such memory means. See, e.g., EcoLab, Inc. v. Envirochem, Inc., 264 F.3d 1358, 1366 (Fed. Cir. 2001) (functional language "for ware and hard surface washing" of the non-means-plus-function element "a three-dimensional, solid, cast, substantially uniform alkaline detergent for ware and hard surface washing" required only that the recited detergent "be capable of ware and hard surface washing").
4. "I/O request"

HP asks the Court to construe this term as: "A directive to any operation, program, or device that transfers data to or from a computer." EMC proposes: "A request issued by a host computer, such as a read or write request, to transfer data."

Although the claim indicates that I/O requests are used to aggregate data in the memory means, the meaning of the term itself is not clear from the claim language alone. The specification clarifies that I/O requests are used both to write new data to the cache and disk device and to organize and distribute data to those structures. For example, "the host 10 issues I/O requests, such as reads and writes, to transfer data between memory 11 and the disk device 20 via the bus 30 and cache 40."

"Host 10 logical' I/O write requests store the new data in the cache 40, and the physical' I/O write requests transfer the data from the cache 40 to the disk drives." 602:3/62-64. "With striping, a host I/O request distributes the data to be transferred across the disk drives." 602:3/62-64. The subsequent portions of the written description describe how the computer system determines and attempts to minimize the number of required I/O requests. Thus, the specification indicates that I/O requests are issued from the host 10, and the computer system attempts to minimize the number of required requests.

A location limitation is not required for the purpose of construing the term. This is not a means plus function term, and the claim language does not include the location from which I/O requests are issued. Instead, the claim is directed toward organizing the memory of the system, and it does not identify the particular computer components that direct such organization. Definitions from dictionaries support this view. "I/O" is defined as the process of moving data between a computer system's main memory and an external device or interface such as a storage device, display, printer, or network connected to other computer systems. I/O is a collective term for reading or moving data into a computer system's memory, and writing, or moving data from a computer system's memory to another location.

Landgraff Decl., p. 0565. An "I/O request" is a "request by an application to read or write a specified amount of data." EMC's Response, Ex. A (Dictionary of Storage Networking Terminology). Just as in the claim language, nothing in the dictionary definitions limits which components of the computer system may contain such applications or issue such requests. In contrast, consistent with the definitions, the claim language indicates that I/O requests serve to organize data; that is, data are moved among the system's components regardless of the origin of the I/O request.

Accordingly, I/O requests are "commands, such as reads and writes, used to transfer data among various components or portions of the components of the computer system."

A. Claim Construction

On February 16, 2006, the Court held a claims-construction hearing in this matter. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The Court considered the '136 Patent and prosecution history, the parties' Markman briefs, the applicable law regarding, inter alia, claim construction, indefiniteness, and means-plus-function claims, and the argument of counsel. On May 25, 2006, this Court rendered a claims-construction order (Doc. # 292), which construed the terms as following:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Construed Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Debit Card&quot;</td>
<td>&quot;a prepaid card for exchange of value&quot;</td>
</tr>
<tr>
<td>n² &quot;ID information [stored on the debit card]&quot;</td>
<td>&quot;encrypted data, excluding the card number, stored on the debit card in the</td>
</tr>
</tbody>
</table>
"Terminal"  "a point-of-sale apparatus, which includes a central processing unit, a card reader, a keypad, and a communications interface"

"ID information [stored on the terminal]"  "data stored on the terminal in the form of merchant ID, store ID, or terminal ID"

"Stored thereon prior to the transaction"  "stored on the terminal prior to the consumer presenting the debit card to the merchant"

"Relates . . . in a predetermined manner"  "prior to a transaction, ID information stored on the debit card and ID information stored on a terminal are capable of being matched"

"Matching" and "Matched"  "determining whether ID information stored on the debit card and corresponding ID information stored on the terminal are equal or identical"

"Retrieving via the terminal"  "locating and returning, by means of the terminal, ID information and a card number stored on the debit card"

"Computer" and "Computer means"  "a data processing device"

"Transmitting to a computer"  "sending by means of a signal path to a computer"

"Validation" and "Valid"  "indication of whether the ID information stored on the debit card matches the corresponding ID information stored on the terminal"

"Computer means disposed remotely"  "a computer that is located apart from a terminal and connected to the terminal by a signal path"

"Card reader means"  "a device, included as part of a terminal, used for retrieving ID information from a debit card"

"Communication means function"  "transmitting the ID information stored on the debit card and the ID information stored on the terminal to the computer means"

"Communication means"  "a modem or a signal path"
A. Claim Construction

On February 16, 2006, the Court held a claims-construction hearing in this matter. See Markman v. Westview Instruments, Inc., 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). The Court considered the '136 Patent and prosecution history, the parties' Markman briefs, the applicable law regarding, inter alia, claim construction, indefiniteness, and means-plus-function claims, and the argument of counsel. On May 25, 2006, this Court rendered a claims-construction order (Doc. # 292), which construed the terms as following:

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Construed Meaning</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;Debit Card&quot;</td>
<td>&quot;a prepaid card for exchange of value&quot;</td>
</tr>
<tr>
<td>n2 &quot;ID information [stored on the debit card]&quot;</td>
<td>&quot;encrypted data, excluding the card number, stored on the debit card in the form of merchant ID, store ID, or terminal ID&quot;</td>
</tr>
<tr>
<td>&quot;Terminal&quot;</td>
<td>&quot;a point-of-sale apparatus, which includes a central processing unit, a card reader, a keypad, and a communications interface&quot;</td>
</tr>
<tr>
<td>&quot;ID information [stored on the terminal]&quot;</td>
<td>&quot;data stored on the terminal in the form of merchant ID, store ID, or terminal ID&quot;</td>

“Computer” and "Computer means" "a data processing device"

"Transmitting to a computer" "sending by means of a signal path to a computer"

"Validation" and "Valid" "indication of whether the ID information stored on the debit card matches the corresponding ID information stored on the terminal"

"Computer means disposed remotely" "a computer that is located apart from a terminal and connected to the terminal by a signal path"

"Card reader means" "a device, included as part of a terminal, used for retrieving ID information from a debit card"

"Communication means" "transmitting the ID information stored on the debit card and the ID information stored on the terminal to the computer means"

"Communication means" "a modem or a signal path"

"Selected from a group of ID information" (Claim 2) "chosen from one of the following ID information"

--- Footnotes ---

n2 "ID," as used throughout this opinion, in whatever context, is shorthand for "identification."

IP Address

Defendants n5 contend IP address should be defined as, "a fixed, unique, and unchanging identifier that has no internal structure to suggest network connection location information," and, as a compromise, Fenner submits that an IP address is "a fixed and unchanging identifier of a connection to the Internet represented by a series of numbers." Defendants maintain that an IP address must be "unique" and does not contain "internal structure to suggest network connection location information." In support of its second limitation, Defendants cite the claims, specification, and prosecution history.

--- Footnotes ---

n5 In discussing the '670 terms, the Court will refer to UTStarcom, Inc., Nortel Networks, Inc., Cisco Systems, Inc., and Alcatel USA, Inc, collectively as "Defendants."
Claims 1, 4, 6, and 14 provide for an IP address, "for identifying a mobile source of the data packet independently of the physical media over which the mobile source is communicating." One skilled in the art would understand that the IP address, as referenced in the claims, describes non-hierarchical addresses and the specification and prosecution history bear out that understanding.

During prosecution of the '670 patent's parent application, U.S. Patent No. 5,095,480 ("the '480 patent"), Fenner explicitly distinguished the prior art based on its use of hierarchical addressing. Using a telephone number as an example, Fenner explained that the area code identifies an "area of the country in which the receiver is located . . . the next three digits are an exchange that identify the switch to which a line to the receiver is connected . . . [and] the last four digits identify the line to the receiver." '480 Patent, File History at 143 (Amendment, 11/7/90 at 23). Thus, the prior art method relied on a hierarchical address made up of three sets of numbers that together identify a fixed physical location. By contrast, Fenner's method uses an address without such internal structure to identify a mobile source within a network, regardless of the physical location of that mobile source. The claim language cited above reflects this distinction, as does the specification. See 2:53-56, 4:40-47, 11:55-58, 17:35-38, 5:33-38, 6:9-13; 22:10-30.

As the prior art described a method of routing based on physical locations, a device moving from one physical location to another would be identified by a different code or address. 1:64-2:16. The IP address described in the '670 patent allows a mobile user to move within a network without changing its address. Accordingly, the address must be unique or its purpose within the invention is lost. Fenner argues that "unique" should not be read into the claims because it appears in Claims 4, 6, and 9, but does not appear in Claims 1 and 14. Defendants counter that the specification and prosecution history clearly require the IP address to be unique. See 2:40-42, 9:19-23, '480 File History at 144 (Amendment, 11/7/90 at 24). Reading the patent as a whole compels the conclusion that the IP address must be "unique."

Accordingly, the Court construes IP address to mean, "a fixed, unchanging, and unique identifier of a connection to the internet represented by a series of numbers that has no internal structure to suggest network connection location."

The parties dispute the meaning of "IP data session," as used in claim 1. NICE contends that the communication devices involved can be either IP (Internet Protocol) or non-IP telephony devices, and that in the preferred embodiment of the invention, "the IP multi-media session may also include one or more non-IP telephony devices," citing col. 3:52-56. Witness's construction would exclude the preferred embodiment, NICE contends, because non-IP telephones do not transmit or receive "data packets." Witness contends that the patent's specification and prosecution history support its construction, citing Figure 3 and '106 Pros. Hist., Resp. 6, Dec. 19, 2004. Further, Witness contends that NICE is attempting to redefine the claim term and to read "IP" out of "IP data session." The specification makes clear that all non-IP communications within the system are first "translated" into IP communications (or data packets), demonstrating, Witness contends, that its construction is correct.

The Court construes "IP data session" to mean "the plurality of data packet transmission between any two or more communication devices." Though the claimed invention clearly contemplates involving non-IP telephone devices, it also makes clear that the invention must convert those non-IP communications into IP communications.

If a telephony device 20 communicating through a PSTN 22 is contacted by IP telephone 12 to initiate the multimedia call and/or if telephony device 20 initiates the call . . . communication to and from telephony device 20 passes through a gateway 42, for example in order to translate regular PSTN 22 communication to IP-based communication.
Accordingly, the construction of "IP data session" should indicate that specifically IP-based communications are being transmitted.

7. ISA command information

OPTi offers a plain language construction for "ISA command information." OPTi asserts that "ISA command information" is "information correlating to one or more of the commands recognized in the Industry Standard Architecture bus standard." nVidia asserts that "ISA command information" means "the bits that identify at least SBHE # and one of MEMR #, MEMW #, IOR #, and IOW # signals and may also identify any other command signals as defined by the ISA specification."

As nVidia's construction improperly attempts to incorporate limitations from the preferred embodiment, it is rejected. There is nothing in the specification that would limit the construction of ISA commands in the manner nVidia suggests. nVidia implicitly admits this fact as it principally relies on statements made during prosecution to support its construction. However, a review of the prosecution history makes clear that the commands nVidia seeks incorporated into the construction of "ISA commands" are merely exemplars of ISA commands.

In contrast, the device of the present invention transmits commands that correlate to ISA commands such as those shown on pages 2-4 of the present application. . . . As shown in Table 2 of the present application, the low three bits of the MAD bus can convey information that correlates to at least the following ISA signals: SBHE #, MEMR #, MEMW #, IOR #, IOW #.

In direct contrast to nVidia's proposed construction, OPTi proposes a plain language construction consistent with the specification and the claims. The Court adopts OPTi's proposed construction. "ISA command information" means "information correlating to one or more of the commands recognized in the Industry Standard Architecture bus standard."

2020

I

Although Quanta characterizes the instant motion as a "motion for further construction of claim term 'ISA compatible computer,'" in essence, Quanta requests the court to reconsider its prior claim construction. But Quanta did not bother to follow Civ L R 7-9(a), which provides that "[n]o party may notice a motion for reconsideration without first obtaining leave of Court to file the motion." Because Quanta filed the present motion without first requesting leave of this court, the motion is properly denied on that ground.

Nonetheless, Quanta suggests that the court's claim construction order explicitly contemplated that Quanta would be able to file the instant motion. See Add Constr Mot at 2 ("At the Court's invitation, Quanta Defendants file this motion to ask the Court to further construe the term 'ISA-compatible computer' * * * as 'a computer having an ISA bus capable of handling ISA standard defined interrupts.'") (citing Order at 10). But Quanta misconstrues that order, which permitted the parties to apply for a further construction only to define particular interrupts that a computer must handle to be considered "ISA-compatible":

The Texas construction * * * is sufficient, at least for the time being. Nothing in this language excludes the possibility that some interrupts might not be used in a given computer. Plaintiff is free to argue that point to the jury. It may be that the parties' true dispute is not over an ISA-compatible computer's ability to handle interrupts, but rather over what interrupts must be defined for a computer to be dubbed 'ISA-compatible.' If so, the parties may apply to the court for a further construction of 'ISA-compatible computer.'
Order at 10:9-14. (emphasis added). The order says nothing about allowing the parties to move the court to add an "ISA bus" as another limitation in the claim, which is the "further construction" that Quanta presently seeks. Accordingly, the court did not in any way "invite" Quanta to file the present motion.

Even putting aside these procedural details, the motion itself appears frivolous and provides no basis for altering the court's prior construction. Quanta asserts that further construction is appropriate because Phillips v AWH Corp, 415 F3d 1303 (Fed Cir 2005), "changed the focus of claim construction." Add Constr Mot at 4. Quanta continues:

While Phillips did not change the general rule that the focus in construing claims remains on the intrinsic evidence, extrinsic evidence may be considered, particularly if the intrinsic evidence is not sufficient to provide a construction. When considering extrinsic evidence, expert opinion and technical treatises are on at least an equal footing with dictionary definitions.

Samsung used dictionary definitions almost exclusively in the Texas actions to defeat a construction of ISA compatible computer that referenced an ISA bus. Following Phillips, Samsung's arguments are no longer appropriate. Id at 4-5.

Quanta's argument is flawed in many ways. First, Phillips did not fundamentally change the principles of claim construction. Characterizing its previous decision in Vitronics Corp v Conceptronic, Inc, 90 F3d 1576 (Fed Cir 1996), the Phillips court stated "we did not attempt to provide a rigid algorithm for claim construction, but simply attempted to explain why, in general, certain types of evidence are more valuable than others. Today, we adhere to that approach and reaffirm the approach to claim construction outlined in that case, in Markman v Westview Instruments, Inc, 52 F3d 967, 979-81 (Fed Cir 1995) and in Innova/Pure Water, Inc v Safari Water Filtration Systems, Inc, 381 F3d 1111 (Fed Cir 2004)." Phillips, 415 F3d at 1324 (emphasis added) (citations altered).

More importantly, even if Phillips changed the focus of claim construction, those changes would not support the further construction that Quanta presently espouses. In determining whether an "ISA-compatible computer" necessarily included an "ISA bus," the Texas district court adopted Magistrate Judge Johnson's report and recommendation (R&R) in full. The R&R relied on intrinsic evidence to decide that the term "ISA-compatible computer" as used in the '273 patent did not require the additional limitation of an ISA bus:

Defendant Arima invites the court to adopt a construction that would specify that an ISA-compatible computer must include an ISA bus as one of its components. However, the court finds no legal justification for carrying its claim construction to that level of specificity. Such a narrow definition is not required either by the claims themselves or the intrinsic evidence. Defendant Arima argues that, although no mention of the ISA bus is made in the claims, it is clear from the specification that the only portion of the ISA-compatible computer that the patent is concerned with is the system of interrupts. Therefore, following Defendant Arima's logic, the ISA bus, as a main component of the commonly used system of interrupts described as a preferred embodiment in the specification, should be included in the definition. The court cannot give credence to this argument. Limitations to the claims should not be inferred from a preferred embodiment.

Doc # 321, Ex A (R&R) at 13-14 (emphasis added). Quanta's "further" construction, on the contrary, relies primarily on extrinsic evidence, Add Constr Mot at 6, and improperly attempts to limit the claim based on an "exemplary" embodiment in the specification, id at 5. Compare Teleflex, Inc v Ficosa North Am Corp, 299 F3d 1313, 1326 (Fed Cir 2002) ("[T]he claims must be read in view of the specification, but limitations from the specification are not to be read into the claims * * *" (citations omitted)); Phillips, 415 F3d at 1323. Accordingly, because the court's prior construction of "ISA-compatible computer" comports with the principles enunciated in Phillips -- unlike Quanta's proposed construction -- there is no reason to construe that term again.

Defendant Arima invites the court to adopt a construction that would specify that an ISA-compatible computer must include an ISA bus as one of its components. However, the court finds no legal justification for carrying its claim construction to that level of specificity. Such a narrow definition is not required either by the claims themselves or the intrinsic evidence. Defendant Arima argues that, although no mention of the ISA bus is made in the claims, it is clear from the specification that the only portion of the ISA-compatible computer that the patent is concerned with is the system of interrupts. Therefore, following Defendant Arima's logic, the ISA bus, as a main component of the commonly used system of interrupts described as a preferred embodiment in the specification, should be included in the definition. The court cannot give credence to this argument. Limitations to the claims should not be inferred from a preferred embodiment.

2021

C. Input Variable-Icon/Output Variable-Icon.

The court defines "input variable-icon" to mean a graphical image that represents a symbol whose value is entered into the system by the user for processing. The court construes "output variable-icon to mean a graphical image that represents a
The Court begins its analysis with the ordinary meaning of the term. The parties do not dispute the ordinary meaning of "identical" and agree that the ordinary meaning of "identical" refers to "being the same" or "having such close resemblance as to be essentially the same," as defined in Webster's New Collegiate Dictionary (1980), at 563. See Defendant's Claim Construction Brief at 9:13-15; Plaintiff's Opening Claim Construction Brief at 9:9-11. A claim term is to be given its ordinary meaning unless the patentee has explicitly redefined the term, or the term itself is so ambiguous it is incapable of being understood without reference to the specification. See Johnson Worldwide Assocs., Inc. v. Zebo Co., 175 F.3d 985, 990, 991 (Fed. Cir. 1999) ("A court must presume that the terms in the claim mean what they say, and, unless otherwise compelled, give full effect to the ordinary and accustomed meaning of claim terms."). The term "identical" as used throughout the '287 patent is ambiguous so that the Court must reference the specification in order to "determine how identical is identical." See Defendant's Claim Construction Brief at 9:25-10:1. As such, Dwin asks the Court to find that "identical" in the '287 claims means either:

1. Two video fields derived from the same film frame and are both even or both odd.
2. Two video fields derived from the same film frame.

The preamble of Claim 1 states "wherein at predetermined positions in the sequence a video field is identical to the video field preceded by it by the duration of a given number of video fields[,]" '287 patent at 8:7-9 (emphasis added). The parties dispute whether the term "identical" requires further definition beyond its ordinary meaning. At one point, Dwin agrees with Faroudja that the term "identical" should be given its ordinary meaning. See Defendant's Claim Construction Brief at 9:13-14. However, Dwin seems to also contend that the term "identical" as used throughout the '287 patent is ambiguous so that the Court must reference the specification in order to "determine how identical is identical." See Defendant's Claim Construction Brief at 9:25-10:1. As such, Dwin asks the Court to find that "identical" in the '287 claims means either:

- (1) two odd video fields or two even video fields derived from the same film frame or (2) identical, within a predetermined threshold, where the threshold is predetermined so that (a) when two video fields are both odd or both even and the two video fields are derived from a film frame compared to each other they are consistently found to be identical and (b) when an odd field and an even field derived from the same film frame are compared or when a field derived from one film frame is compared with a field from another film frame, they are consistently found not to be identical.

Defendant's Claim Construction Brief at 12:25-13:3. The Court finds no support for this loquacious limitation proposed by Dwin. Accordingly, the Court interprets "identical" in the preamble, and as used throughout the '287 patent claims, as not limited to these particular conditions. Such limitations are simply not warranted by the claim language itself.

The Court also considers whether the preamble gives contextual support for the proposed limitation. The Court finds that it does not. The preamble of claim 1 refers simply to identical video fields being found at predetermined positions in the sequence. See 8:7-8. Nothing in the preamble itself requires such a garrulous interpretation of identical.

The Court also finds that the specification is not inconsistent with the ordinary meaning of "identical," but rather provides an example illustrating where identical video fields may be found. Dwin alleges that because the specification indicates "identical" video fields occur where the fields are derived from the same film frame and are both even or both odd, reading this limitation into the claim term is supported, if not required. Although the specification provides an illustration of the term "identical," the term itself is not limited to that particular illustration when its ordinary meaning conveys a clear and accurate description.

Furthermore, the patentee has not used the term in such a way so as to deviate from its customary usage. There is nothing to indicate that the patentee sought to redefine "identical" in a manner that is inconsistent with its ordinary meaning. The Court
agrees with Faroudja that "the claim was drafted using the plain terminology" and recourse to the specification to redefine the term would be improper. See Claim Construction Hearing Transcript at 59:7-8; Enercon Gmbh v. International Trade Comm’n, 151 F.3d 1376, 1384-85 (Fed. Cir. 1998) (generic claim terms should not be limited to the example disclosed in the specification absent clear redefinition of the claim term by patentee); Envirotech Corp. v. Al George, Inc., 730 F.2d 753, 759 (Fed. Cir. 1984) ("words in a claim will be given their ordinary and accustomed meaning, unless it appears that the inventor used them differently." (Citation omitted.)).

As this Court well knows, a "lawyer may create a 'dispute' about any word, but there is nothing ambiguous or linguistically obscure about [the term] as used in the present claim" to justify turning to the specification for redefinition. Senmed v. Richard-Allan Med. Indust., Inc., 888 F.2d 815, 819 (Fed. Cir. 1989). Simply because parties dispute a term it does not follow that the term itself must be ambiguous. The Court declines to treat the claim language like a "nose of wax, which may be turned and twisted in any direction, by merely referring to the specification, so as to make it include something more than, or something different from, what its words express." White v. Dunbar, 119 U.S. 47, 51, 30 L. Ed. 303, 7 S. Ct. 72 (1886).

### Claim Term

<table>
<thead>
<tr>
<th>Plaintiff's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;identification code[s]&quot;</td>
<td>a code that unambiguously identifies each individual passenger and is associated with that passenger's destination floor</td>
</tr>
<tr>
<td>('861 Patent, claim 11)</td>
<td>('465 Patent, claim 1)</td>
</tr>
</tbody>
</table>

The dispute between the parties with respect to this term is whether the "identification code" must also include information about the passenger's destination floor. Plaintiff posits that the identification code need not necessarily identify a particular destination floor and relies on the fact that a floor terminal may include a "recognition device" that serves to recognize the identification code. The function of the recognition device is described in the specification as follows:

[T]he user carries the identification transmitter . . . and communicates an identification code to the recognition device . . . of the floor terminal . . . which identification code is recognized by the recognition device.

('465 Patent col. 8:9-14.) When the recognition device recognizes an identification code, it communicates to the computing unit an identification signal corresponding with the recognized identification code, whereby the computing unit then "assigns a predetermined destination floor to [the] identified passenger[.]" based on the identification signal. (Id. col. 8:15-19; id. col. 2:30-34.) Therefore, Plaintiff argues that it is actually the computing unit that assigns the destination floor to a particular identification code, and that the association between the passenger and the destination floor is not inherent in the "identification code" itself.

Defendants respond that a particular passenger is unambiguously identified with an "identification code" by way of a "user profile." Defendants cite to the following language in the specification describing "user profiles" generated by identification codes:

This user profile is unambiguously identifiable by way of an identification address. Exactly one identification code exists for each identification address. For example, an identification address is able to be exactly associated with an identification code when the identification address and identification code are identical.

('861 Patent, col. 6:61-67.) Defendants contend that based upon this generated user profile, an identification code unambiguously identifies both the individual passenger and the passenger's destination floor.

As no plain and ordinary meaning can be discerned from the claim itself, the Court will look to intrinsic evidence,
specifically the specification, in order to construe this claim. The Court finds that the cited language from the specification concerning "user profiles" indicates that an identification address is inherently associated with an identification code, such that it should be read as a claim limitation.

Furthermore, while Plaintiff's proposed construction may be technically accurate, Defendants' proposed construction comports with a common-sense reading of how the term "identification code" would be understood by a person skilled in the art, in that the identity of the passenger is irrelevant to the functioning of the elevator system unless the destination floor is also communicated. In other words, the only purpose of the recognition of the identity of the passenger is to determine the appropriate destination floor for the elevator, such that merely identifying the passenger is immaterial in terms of the functioning of the elevator system. See Lisle Corp. v. A.J. Mfg. Co., 398 F.3d 1306, 1313-14 (Fed. Cir. 2005) (rejecting plaintiff's "hyper-technical reading" of a claim limitation and instead relying on the specification to "attain a common-sense meaning of that claim limitation"). When read in the context of the entire Patents-in-Suit, including the specification, the Court concludes that the term "identification code" means "a code that identifies each individual passenger and is associated with that passenger's destination floor."

The Court also rejects Tomar's argument that "identification code" is defined as interleaving data pulses between priority pulses. Claim 1 includes the limitations involving interleaved data pulses, but such limitations are not included in claim 22. The doctrine of claim differentiation

is based on "the common sense notion that different words or phrases used in separate claims are presumed to indicate that the claims have different meanings and scope." Karlin Tech. Inc. v. Surgical Dynamics, Inc., 177 F.3d 968, 971-72 (Fed.Cir.1999). "To the extent that the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Tandon Corp. v. U.S. Intl Trade Comm'n, 831 F.2d 1017, 1023 (Fed.Cir.1987). Andersen Corp. v. Fiber Composites, LLC, 474 F.3d 1364, 1369-70 (Fed. Cir. 2007).

Applying this doctrine here, the Court finds that reading the limitation of interleaved data pulses into claim 22 would render the claim superfluous. This construction is supported in the section of the specification that entitled "Summary of the Invention" which distinguishes the method claim and the system claim. '113 Patent, 3:29-44. Further, nowhere in the specification is "identification code" defined as Tomar's suggests. Rather, identification code is referred to as a means to uniquely identify an optical emitter. Id. 3:43-44; 5:44-45.

"[C]laims of [a] patent must not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction.'" Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004)(citation omitted). In this case, numerous embodiments are described, and the claims and specification do not include such "words or expressions of manifest exclusion or restriction."

E. "Identification encoder."

1. The term "identification encoder" is a coined technical term which is ambiguous.

The Court confirms its tentative finding that the term "identification encoder" had no ordinary and customary meaning to one skilled in the art at the time of the invention. Mr. Weiss, Acacia's expert witness on the meaning of the term, testified that "identification encoder" had no ordinary meaning to one skilled in the art. (TR. 64:18-21.)

Since the term has no plain meaning, the Court looks to the patent specification to see if the patentee defined the apparatus. Unlike the "sequence encoder," the written description contains references to "identification encoder." Among others, the
written description contains the following references to unrelated preferred functions of the "identification encoder" occurring at various unspecified times in the transmission system:

1. The identification encoder 112 gives a unique identification code to items stored in a compressed data library (6:34-35);

2. Performs storage encoding (giving the item a unique identification code, optionally logging details about the item, called program notes, and assigning the item a popularity code) just prior to conversion of the item for transmission to reception system, at any item after starting the conversion process, or after storing the item in the compressed data library (6:34-42);

3. Preferably assigns: a unique identification code, a file address, a popularity code and input program notes (6:43-48);

4. Inputs digital signal to digital input receiver (6:62-64);

5. Inputs analog signal to analog-to-digital converter (7:6-8);

6. Passes previously compressed items directly to the compressed data library (7:36-41);

7. Allows entry of item notes and production credits (10:45-51);

8. Maps item addresses to item names as an alternative method of accessing items (10:52-53);

9. Operates a program which updates a master item database containing facts regarding items in the compressed data library system (10:56-59);

10. Generates a unique address code which makes access to the requested data possible (10:43-44).

As the Court stated in its July 12 Order, although some of the functions of the "identification encoder" are set out, there is no description of a structure which performs those functions. Apparatus claims cover what a device is, not what a device does. See Hewlett Packard Co. v. Bausch & Lomb, Inc., 909 F.2d 1464, 1468 (Fed. Cir. 1990). Figure 2a contains a block diagram designated "112" and labeled "IDENTIFICATION ENCODING PROCESS." A label entitled "Encoding Process" is more indicative of a method claim than it is of an apparatus claim. Indeed, the 992 patent, which is based on the same specification as the 702 patent, contains a method claim 41 which discloses identification encoding not as an apparatus, but as a step in a method:

41. A method of transmitting information to remote locations, the transmission method comprising the steps, performed by a transmission system, of:

- storing items having information in a source material library;
- retrieving the information in the items from the source material library;
- assigning a unique identification code to the retrieved information;
- placing the retrieved information into a predetermined format as formatted data;
- placing the formatted data into a sequence of addressable data blocks;
- compressing the formatted and sequenced data blocks;
- storing as a file, the compressed, formatted, and sequenced data blocks with the assigned unique identification code; and
- sending at least a portion of the file to one of the remote locations.

(992 24:54-25:5)
Notwithstanding the "process" label, based on the written description the Court finds that block "112" is a diagram of what
the patentee meant by "identification encoder." However, the references to block 112 in the specification do not assist the
Court in defining what an "identification encoder" is. All that the specification does is to describe what the "identification encoder" preferably must do. The specification does not disclose a circuit, a computer operating a software algorithm, or
other apparatus which performs the functions designated for the "identification encoder."

Under certain circumstances, it may be permissible to claim invention of an apparatus and include in the specification only a
block diagram along with a description of some of its functions. However, this method of claiming an apparatus is only
permissible if the device is a conventional one, such that a person of ordinary skill would readily understand what the device
is. Claiming an apparatus using only a block diagram with functional description is indefinite when the patentee names the
device using a coined term and the various functions could be performed by an indefinite variety of devices.

Acacia's expert witness, Mr. Weiss, testified:

Q. Does the 702 patent identify any single structure for identification encoder?
A. No, it does not.

Q. Does the 702 patent require any single structure for identification encoder?
A. Does it require? No, it does not.

(QR. 146:10-15.)

* * *

Q. Take a look at column 6, line 39 through 42. What else, if anything, would the hypothetical person of ordinary skill
have understood about the identification encoder from reading that portion of the specification?
A. . . . that the identification encoder could similarly be located at any of those places in the system.

(QR. 93:5-18.)

At one point, Mr. Weiss stated that the only non-optional function of the "identification encoder" was "assigning a unique
identification code." His stated assessment was based on the wording of the patent description. On the basis of Mr. Weiss'
opinion, Acacia contends that the only function to be included in the construction of "identification encoder" is assignment
of a unique identification code. The Court, however, must also include functions which may be worded as optional, but
which would render the invention inoperable were they not included. If the Court did not do so, the patent would have no
utility. Indeed, at another point in his testimony, Mr. Weiss disagreed with the "only non-optional function" analysis, stating
that one would have to list other functions of the "identification encoder." (QR. 291-293.)

The Court confirms its earlier conclusion that at the time of the invention, one of ordinary skill in the art would not
understand the scope or bounds of the structure of the term "identification encoder" when that term is read in light of the
specification, rendering the claim term "identification encoder" indefinite. In its July 12 Order, the Court defined the term
by using its nonspecific function-encoding an identification-and defined it as an apparatus for performing that function. The
Court now concludes that this functional definition is insufficient to comply with the requirement of definiteness. The Court
finds "identification encoder" indefinite and on that basis finds claims 1, 17 and 27 invalid. As with the "sequence encoder,"
the Court leaves for later consideration the affect of this finding on dependent claims.
8-12 and 18-10 recite the step of "requesting identification information from said prospective wagerers," while claims 24 to 26 recite the step of "requesting identification from said prospective wagerers." Gtech proposes that the term identification information means that it is "information that identifies a prospective wagerer, including an account number and a personal identification number." To the contrary, Lottotron submits that identification information should encompass a much broader definition, and thus, should mean "identification information, such as an identification number." Pursuant to the intrinsic evidence, the Court shall adopt Gtech's definition.

The Court finds substantial support from the "Summary of the Invention" section. It states that "the invention provides a lottery wagering system comprising . . . second voice responsive means (wagering VRU) . . . requesting subscriber wager information . . . including an account number, a personal account number, a personal identification number." Id., col. 2, ll. 2-28. The patent goes on to explain how the system requests identification number information, including an account number and personal identification number:

As shown in FIG. 3 in the Subscriber Identification And Game Selection process, the VRU plays a welcome message to the subscriber and requests their account number as depicted in FIG. 3a. In our example, the subscriber entered '123456789098', and the VRU responded with, "You entered 123, 456, 789, 098, press 1 to confirm, 2 to re-enter". The subscriber responded with a 1 and the VRU then played the message, "Enter your personal ID". The subscriber entered '12345' and the VRU responded with "You entered 123, 45, press 1 to confirm, 2 to re-enter". The subscriber responded by pressing '1' to confirm that the number was correct. The VRU stores the subscriber ID and PIN and immediately sends a transaction to the host to validated the subscriber.

Id., col.6, ll. 5-18. As indicated from these excerpts, the patent language clearly references identification information to include an account number and personal identification number. Despite the apparent references in the patent language, Lottotron argues that there is nothing in the subject claims themselves which requires the creation of an account, and nothing that requires the generation of a personal identification number. However, Lottotron ignores that in substantially all of the embodiments of the system, it requests identification information, including an account number and a personal identification number. In fact, no other embodiment that does not require the user to provide an account number and personal identification number is even suggested in the patent. Accordingly, as claim construction begins and ends in all cases with the actual words of the claim, it is appropriate for the Court to define the terms to be limited in this respect, and construe the terms identification information and identification to mean "information that identifies a prospective wagerer, including an account number and a personal identification number." See Renishaw PLC v. Marposs Societa' per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998) (citations omitted).

"identification information" and "address information"

The term "identification information" means specific information from the user communication device that identifies that specific device, its user and where the device is located, that is stored in the VPS and that is used by the VPS to determine if the data and voice communications received by the LAN or telephony server, respectively, are intended for the remote user and used by the VPS to route such data and voice communications to the remote user.

The term "address information" means a designation of the identity of the user communication device sufficient to indicate where the user communication device can be contacted. The information is typically a telephone number.

"Identification information" must have all of the following characteristics: (1) it must be "of said user communications device;" 131 (2) it must be received by and provided to the VPS from the user communications device; 132 (3) it must be used to determine if a communication from the LAN or PBX is intended for the remote user; 133 (4) it must be used by the VPS to "route" communications received by the LAN or PBX which are intended for the user communications device to the remote user communications device; 134 and (5) it must provide the identity of the remote user. 135 In sum, identification information identifies the remote user communications device and how the remote user's computer can be contacted by the VPS.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -
131 The PTO Notice of Allowability, Nov. 13, 1997, at 3 (Dx 2) stated: "the user communication device connects to the corporate office and provides identification information to the [VPS]."

132 '639 patent, col. 31, lines 40-42. 133 '639 patent, col. 34, lines 47-52. 134 '639 patent, col. 27, lines 28-34. 135 Bradner testimony, Tr. 911-15.

--- End Footnotes ---

The only example of identification information provided by the '639 patent is "caller ID" information in a description of "the preferred embodiment." 136 Mr. Bradner conceded that no other information is provided in the patent as to what is "identification information" although the patent allows that other types of identification information may be received. 137 The specification distinguishes "identification information" from "security data" 138 but does not preclude the possibility that security data could be included within identification information.

--- Footnotes ---

136 '639 patent, col. 18, lines 42-52; figs. 12 and 13.

137 '639 patent, col. 18, lines 50-52. 138 See, e.g., '639 patent, figures 12 & 13; col. 17, lines 43-52; col. 18, lines 11-18.

--- End Footnotes ---

Caller ID information may be sufficient for use as the identifier when the PSTN is the network between the VPS and the user communication device. But, if other networks are present, other identifiers would be necessary. 139 One with ordinary skill in the art would consider that "identification information" used in routing data in an IP network may include an IP address, 140 but, as Bradner conceded, cannot consist only of an IP address. 141 An IP address alone cannot meet the first and fifth criteria listed above and does not meet the third and fourth criteria with respect to voice communications. 142 Moreover, the '639 patent expressly claims an embodiment of the VPS that disconnects from the remote user and then reconnects to the remote user when the remote user receives a call at the office; 143 and IP address alone cannot be used to call the remote user and reestablish a connection between the remote user and the VPS. Significantly, the PTO distinguished prior art in which the "identification information" was an IP address, indicating that the examiner concluded that an IP address alone was not "identification information." 144

--- Footnotes ---

139 When discussing channels of communication, the specification refers to TCP/IP network protocol which a person with ordinary skill in the art would understand uses IP addresses as identifiers. Bradner testimony, Tr. 690-93; Witt testimony, Tr. 447; see '639 patent, col. 15, lines 30-34.

143 '639 patent, claims 11, 12, 13, col. 26, lines 61-66 to col. 27, lines 1-20; see also col. 22, lines 7-30.

144 Dx 2, PTO, Notice of Allowability, Nov. 13, 1997, at 4 (Slaughter).

--- End Footnotes ---

The term "address information" as used in claim 14 is similar to "identification information" found in claims 1 and 39. "Address information" refers to the identifier portion of identification information that indicates the identity of a user communications device sufficient to indicate where the user communications device can be contacted. Address information
received from the user communications device is stored or placed into the memory of the VPS. The VPS accesses or retrieves the stored address information from its memory to route communications received by either the LAN or the telephony server to the remote user communications device over the transmission media.

**2028**

3. First Identification Number

Both parties agree that this term refers to the "control number" used in the specification of the '909 patent. Fiala wishes to define "a first representation of said first identification number" as "something that represents or stands for the control number." (Pl. Brief at 30.) SVS argues that "first identification number" means "a control number which is uniquely associated with the metered account." (Def. Brief at 13.) Fiala has pointed out in its response that the parties "have proposed constructions for the term 'first identification number' that are similar if not identical…" (Pl. Resp. at 2.)

The dispute centers on the extent to which the first identification number must be "uniquely associated with the metered account." Fiala does not dispute this interpretation on its face, but objects on the basis that "uniquely associated" may be construed to mean that each account can correspond to only one control number. Fiala contends that the patent should be read to require that each control number can activate only one metered account. By implication, under Fiala's construction, one account could be associated with more than one control number, as long as each of these numbers is "uniquely associated" only with that account.

SVS cites to the preferred embodiments contained in the patent specification referring to a "unique" control number. U.S. Patent No. 5,918,909, Column 18:56-58, 20:39-41. To the extent that a "uniqueness" requirement exists in the preferred embodiments, it cannot be read to limit the plain language of claim 29. See Teleflex, 299 F.3d at 1326; Comark Communs. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998). Because both parties wish to incorporate the term "control number" from the specification, however, the context in which that term is used will be considered. Although the cited embodiments state that the control number is "unique," it is unclear whether the number is unique in that it is only associated with one account or whether it is unique because it is the only number associated with the account in question.

One of the embodiments cited by Defendant directly contradicts the latter interpretation: "A single company can manufacture the first card C and the package 30, and correlate, as, for example, by a correspondence table, the control number to the PIN P so that both numbers can be properly and uniquely associated with a metered account." Id., Column 19:9-13 (emphasis added). If an embodiment recommends that two different numbers can correspond so as to be "uniquely associated" with one account, "unique" cannot mean that there is only one number associated with a metered account. As a result, the characteristic of uniqueness taught by the '909 patent requires the control number to be associated with no more than one metered account.

Having reviewed the language of claim 12 in light of the specification, the court interprets the phrase "first identification number" to mean: "control number, associated with only one metered account."

**2029**

Second Identification Number

Both parties agree that "second identification number" refers to the "Personal Identification Number" ("PIN") as used in the specification. (See Pl. Brief at 37; Def. Brief at 16.) The disputed questions are whether this number must be "different from" the first identification number ("control number") and whether it must "independently provide… access to services and debiting of the metered account." In arguing that the PIN must be different from the control number, SVS cites the preferred embodiments:

Preferably, the PIN number P would be a very long sequence of digits and/or characters to ensure uniqueness and to inhibit guessing of the PIN number by a thief who otherwise could gain unauthorized access to the funds in the metered
account.

U.S. Patent No. 5,918,909, Column 5:25-34.

When the first card C has a PIN number P displayed thereon, it is desirable to obscure the PIN number P from view because any person knowing the PIN number P will have access to the metered account once the account has been activated.

Id. at Column 6:3-7.

For example, if a thief were able to collect the PIN numbers for several metered accounts before purchase activation of those accounts, the thief would simply have to wait until the card and package combination was purchased by an unsuspecting purchaser and the account was activated, and then the thief could surreptitiously drain the account of its funds by using its associated PIN to purchase goods and services.

Id. at Column 6:7-14.

Prior art methods of providing the metered account associated with a card's PIN involve the activation and crediting of the metered account before the card is distributed to a retail merchant for resale. However, a prior art scheme using such pre-activated accounts necessarily requires that such cards be stored under lock and key by the retail merchant until the moment the cards are sold because, if the cards are stolen or the PIN numbers surreptitiously discovered, the pre-activated metered accounts can be drained of funds. The method of the present invention avoids such problems by not activating the metered account until the time of purchase of the card.

Id. at Column 18:42-53. (Def. Resp. at 10) (emphasis in the original). These embodiments refer to the fact that the control number functions to activate the account, while the PIN provides access to the account after it has been activated. The described arrangement makes it advantageous that the two numbers be different: if one number could both activate and access a metered account, a thief's job would be easier. SVS therefore argues that the primary advantage of the '909 invention over the prior art - overcoming the problems associated with "hot cards" -- requires that the PIN be "different from" the control number.

Neither the specification nor the purpose of the '909 invention requires this result. In several instances, the specification states that the PIN is "preferably" different from the control number, implying that the claim itself is not so limited. See U.S. Patent No. 5,918,909, Column 19:4-8, 20: 42-45. Furthermore, claim 29 (on which claim 30 depends) refers to a first identification number which is "encoded … onto said data-encoded strip." Id., Column 24:63-64. This language indicates that, rather than being printed on the card, the control number is accessed only by mechanized reading of the data-encoded strip. Under this arrangement, surreptitious viewing of the PIN does not mean that a thief would gain knowledge of the control number, because there would be no way of knowing if the two were identical. Additionally, claim 29 speaks of activating the metered account through a "processing apparatus," implying that mere knowledge of the control number is not enough to activate the account. Id., Column 24:67-25:12. For these reasons, the court declines to interpret claim 30 to require that the PIN be different from the control number.

SVS claims that "second identification number" must be defined as "independently" providing access to the metered account. This argument appears to be based on the assertion that the PIN must be different from the control number. (Def. Brief at 16; see also Def. Reply at 11.) SVS argues, however, that the term means only that the second identification number is not dependent upon any other number or data in order to provide access to services and debiting the metered account. (Def. Reply at 11.) It is apparent from the language and context of claim 30 that providing access to the metered account is the purpose of the PIN; further clarification of the purpose is unnecessary. To the extent that the PIN may provide access "independent" of something besides the control number, claim 30 speaks for itself.

Both parties agree that the second identification number may be construed as "a personal identification number' (PIN') that 'is uniquely associated with the metered account, and provides access to services and debiting of the metered account." (Pl. Resp. at 11.) The court will construe the term accordingly. It is clear from the intrinsic evidence that "uniquely associated with a metered account" describes a relationship between the second identification number and metered account similar to that between the first identification number and metered account discussed above. Therefore, the court will similarly construe "uniquely associated with" in this context to mean "associated with only one."
Having reviewed the claim language, specification, and prosecution history, the court defines "a second identification number" as "a personal identification number, associated with only one metered account, which provides access to services and debiting of that metered account."

3. Claims 1 & 17 -- "Identification of a Position"

CIVIX argues that "position" should be given its ordinary meaning of "expression of a location." Defendants do not dispute this and, indeed, suggest the equivalent definition of "a location in space." However, CIVIX disputes Defendants' limitation that the "position" cannot be located with reference to coordinates outside of the geographic vicinity. Defendants contend that the phrase "identification of a position" means a coordinate pair uniquely defining a location relative to the positional coordinates as a reference. I am persuaded by Defendants' construction of this phrase.

The claims at issue state that the "identification of a position" is transmitted to the user. ('525 Patent, Claims 1 & 17). Within the claims, the phrase is, therefore, used as a noun rather than a verb. This supports Defendants' construction of this term as a thing specifying a position or location. Further, as noted earlier in this Order, the '525 patent and its prosecution history supports the limitation that positional coordinates uniquely define a geographic vicinity. Further, items of interest use the positional coordinates as a reference.

As I noted earlier, on October 2, 1996, the PTO rejected the thirty-seven claims pending in the '525 patent's application as indefinite under 35 U.S.C. § 112. (Office Action, CIV 0000214). In particular, the Examiner was concerned that the meaning of the term "identification of a position" was unclear. (Office Action, CIV 0000214). The Examiner presented applicants with a choice between relative positioning (i.e., positioning defined relative to a known point or points in the geographic vicinity) or absolute positioning (i.e., positioning defined in a universal manner, not relative to an arbitrary point in the geographical vicinity).

In response, on February 3, 1997, applicants amended the claims to specify the concept of relative positioning. For example, Claim 1 was amended to add the following emphasized phrase, "the transmitted portion including . . . identification of a position for each of the items of interest within the . . . geographic vicinity . . . relative to the positional coordinates and other items of interest within the vicinity . . . ." (Response, CIV 0000225) (emphasis denotes language added by amendment). In response to the amendments, the Examiner allowed each of the thirty-seven claims of the '525 patent. (Examiner's Statement of Reasons for Allowance, P 1.1, CIV 0000287). Accordingly, it is reasonable to infer that the '525 patent was issued because of the distinction of positions of items of interest defined in relative rather than absolute terms. For the above reasons, I adopt Defendants' interpretation of "identification of a position" as being coordinates defining a location using the positional coordinates of the vicinity as a reference.

2031

- "identification of a source" is construed consistently with its plain meaning as a "identification of a source." The Court declines to further interpret the phrase "identification of a source."

Lucent contends that this phrase should be given its plain English meaning, "evidence of identity of that part of a system from which messages are considered to originate." (D.I. 396 at 20).

Extreme contends that this phrase means "a fixed end user identifier, uniquely identifying the source of a data transmission, identifier assigned by a system administrator and that is independent for the end user system's physical and topological address, and that cannot be altered by the end user." (D.I. 395 at 27.)

Foundry contends that the term "source" means "a MAN name, which is a fixed end user name, that is a 32-bit MAN address, which is not an IP address, assigned by the MAN system that is independent from its physical and topological address."
The Court finds that Defendants impermissibly try to restrict the claim to the particular type of source used in the preferred embodiment. Further, the Court finds that Lucent has cited telecommunications dictionaries and dictionaries not published contemporaneously with the patent application. In the Court's view, telecommunications dictionaries may not accurately reflect the meaning of "source" to one skilled in the art in a data networking environment. Thus, the Court believes that the Court's construction is consistent with the plain language of the claim and the specification.

"identification of a destination" is construed consistently with its plain meaning as "identification of a destination." The Court declines to further interpret the phrase "identification of a destination."

Lucent contends that this phrase should be given its plain English meaning, and advances no specific construction. (D.I. 396 at 21.)

Extreme contends that this phrase means "a fixed end user identifier, uniquely identifying the destination of a data transmission, identifier assigned by a system administrator and that is independent for the end user system's physical and topological address, and that cannot be altered by the end user." (D.I. 395 at 27.)

Foundry contends that the term "destination means "a MAN name, which is a fixed end user name, that is a 32-bit MAN address, which is not an IP address, assigned by the MAN system that is independent from its physical and topological address." (D.I. 385 at 24.)

The Court finds that Defendants impermissibly try to restrict the claim to the particular type of destination used in the preferred embodiment. As Lucent has not proffered a specific construction of this term, in the Court's view, the Court's construction is consistent with the plain language of the claim and the specification.

5. "identified profile"

Disputed Term the technical database being structured to enable a plurality of access modes comprising name of publication, key word, and identified profile with migration capability between related records

Plaintiff's Construction data that identifies a given subject, such as a component or components

Defendant's Construction a list of one or more of the manufacturer, make and model numbers, including their synonyms

The parties dispute the meaning of "identified profile," which is used in Claim 8 as follows: "the technical database being structured to enable a plurality of access modes comprising name of publication, key word, and identified profile with migration capability between related records,..." ('806 Patent at 83:37-39.) Plaintiff contends that this claim term should be construed generally to mean data that identifies one or more components of a particular subject. In contrast, Defendant asserts that the claim imposes a limitation based specifically on the manufacturer, make and model of a particular aircraft. (Jt. Stmt. at 18-20.)

The patent specification indicates that a "profile" refers to a "component" (i.e., characteristic) or a set of components selected by the user to facilitate his or her search for information contained in the database. (Id. at 2:57-58; 31:3-5.) For instance, a user can set up the profile based on the specific make, model and serial number of an aircraft. (Id. at 2:48-49.) Alternatively, the user may customize a profile based on user-specific criteria other than the make and model of an aircraft. (Id. at 2:28, 3:312-13, 5:12-13.) This flexibility is illustrated in the preferred embodiment, which also envisions that the user may utilize an existing aircraft profile or customize a profile based on one or more data components. (Id. at 30:30-34, 30:42-44, 31:1-7.) Thus, while an "identified profile" may consist of an aircraft manufacturer, make and model number, such a profile is not limited, as Defendant suggests, exclusively to those particular criteria. Accordingly, the Court construes "identified profile" to mean "data that identifies a given subject, such as a component or components."
4. "identifier"

<table>
<thead>
<tr>
<th>Claim Language</th>
<th>FotoMedia's Proposed Construction</th>
<th>Defendants' Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;identifier&quot;</td>
<td>information for identifying image data</td>
<td>information uniquely identifying particular image data</td>
</tr>
</tbody>
</table>

The issue here is whether an identifier must uniquely identify an image. Defendants contend that if the identifier did not uniquely identify a particular image, it would not be able to perform its stated purpose. Defendants point to the specification wherein the patentee refers to the data in the Card Database and the data in the Image Database being "keyed by a unique identifier," and that "[t]he URL includes the Card Key that uniquely specifies that particular electronic postcard." '774 Patent, col. 5, ll. 32-52, col 12, ll. 51-55.

Fotomedia's argument is that the specification sufficiently discloses use of the same identifier for multiple cards. The Summary of the Invention states that "one or more displays may be assigned a unique identifier." '774 Patent, col. 2, ll 54-55. Further, the specification discloses that the data in both the Card Database and the Image Database are "keyed by a unique identifier." '774 Patent, col. 5 ll. 44-46. Fotomedia suggests that these are multiple images being keyed by the same identifier. This is not the case. The specification indicates that it is in fact the same postcard data that is stored in these two databases after the postcard is sent. '774 Patent, col. 5 ll. 32-33. Further, the specification goes on to explain that "this key [is] the information required for retrieving the electronic postcard data from the Card Database and Image Database." A non-unique card key would therefore fail in its utility by the patentee's own definition.

Therefore, "identifier" is "information uniquely identifying image data."

The one term at issue in this dispute is "identifier." Although this term appears in several of the asserted claims, the Court will focus on claim 2 as an example:

2. A system, comprising:

   a server;

   computer code for working in association with a network browser including a back button, a forward button, a refresh button, and a home button, and for displaying a plurality of identifiers in a portion of a graphical user interface separate from a window in which content associated with uniform resource locators (URLs) is displayed; and

   computer code for allowing a user to select, during use of the network browser, one of the identifiers in the portion of the graphical user interface separate from the window in which the content associated with the URLs is display, for correlating, after the selection, at least one of the URLs with the selected identifier in a manner that is based on the selected identifier which is distinct with respect to the at least one URL;

   wherein the user is allowed to manually enter the selected identifier which is distinct with respect to the at least one URL;

   wherein the identifiers and the at least one URL are stored on a user device with the network browser executable thereon; and

   the server being in communication with the user device via a network, the server for storing the identifiers;
wherein the identifiers and information associated with the identifiers are stored at both the user device and the server.

'625 patent at 5:27-54 (emphasis added).

THE PARTIES' ARGUMENTS

Google proposes that the term "identifier" be construed as "database entry which identifies a specific piece of intellectual property." It argues that this construction is consistent with the narrow interpretation of this term contained in the specifications of the '625 patent and with its parent application, the '941 application. Aloft counters that no construction is necessary because the plain meaning of the term "identifier" is easily understood. It argues that Google's proposed construction impermissibly reads a feature of the preferred embodiment into the claims as a limitation.

APPLICABLE LAW

I. General Claim Construction Principles

"It is a 'bedrock principle' of patent law that 'the claims of a patent define the invention to which the patentee is entitled the right to exclude.' Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (quoting Innova/Pure Water Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1115 (Fed. Cir. 2004)). In claim construction, courts examine the patent's intrinsic evidence to define the patented invention's scope. See id.; C.R. Bard, Inc. v. U.S. Surgical Corp., 588 F.3d 858, 861 (Fed. Cir. 2004); Bell Atl. Network Servs., Inc. v. Covad Communications Group, Inc., 262 F.3d 1258, 1267 (Fed. Cir. 2001). This intrinsic evidence includes the claims themselves, the specification, and the prosecution history. See Phillips, 415 F.3d at 1314; C.R. Bard, Inc., 388 F.3d at 861.

Claim construction analysis begins with the words of the claims themselves. Phillips, 415 F.3d at 1314. A term's context in the asserted claim can be very instructive. Id. Other asserted or unasserted claims can also aid in determining the claim's meaning because claim terms are typically used consistently throughout the patent. Id. Differences among the claim terms can also assist in understanding a term's meaning. Id. For example, when a dependent claim adds a limitation to an independent claim, it is presumed that the independent claim does not include the limitation. Id. at 1314-15.

Claims "must be read in view of the specification, of which they are a part." Id. (quoting Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995)). "[T]he specification 'is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.'" Id. (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)); Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002). The prosecution history is another tool to supply the proper context for claim construction because a patent applicant may also define a term in prosecuting the patent. Home Diagnostics, Inc., v. Lifescan, Inc., 381 F.3d 1352, 1356 (Fed. Cir. 2004) ("As in the case of the specification, a patent applicant may define a term in prosecuting a patent.").

Although extrinsic evidence can be useful, it is "less significant than the intrinsic record in determining 'the legally operative meaning of claim language.'" Phillips, 415 F.3d at 1317 (quoting C.R. Bard, Inc., 388 F.3d at 862). Technical dictionaries and treatises may help a court understand the underlying technology and the manner in which one skilled in the art might use claim terms, but technical dictionaries and treatises may provide definitions that are too broad or may not be indicative of how the term is used in the patent. Id. at 1318. Generally, extrinsic evidence is "less reliable than the patent and its prosecution history in determining how to read claim terms." Id.

II. Interpreting Terms in Light of the Specification

The dispute in this case involves the proper interpretation of a claim term with a broad meaning in ordinary use, but an arguably narrow meaning in the specification. In general, courts must impose a "heavy presumption" in favor of the ordinary meaning of claim terms, which can only be overcome by statements of "clear disclaimer" expressly indicating "manifest exclusion or restriction." Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 913 (Fed. Cir. 2004); Brookhill-Wilk 1, LLC v. Intuitive Surgical Inc., 334 F.3d 1294, 1301 (Fed. Cir. 2003); see also Phillips, 415 F.3d at 1312-13. However, this "heavy presumption" does not arise when the patentee acts as his own lexicographer and gives a claim term a different meaning than the term would otherwise possess. See Irdeto Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295, 1301(Fed. Cir. 2004); see also Nystrom v. TREX Co., 424 F.3d 1136, 1145 (Fed. Cir. 2005). In these situations, the inventor's lexicography governs. Phillips, 415 F.3d at 1316. A patentee can define a claim term either expressly, see Irdeto
Access, 383 F.3d at 1301, or implicitly, by consistently using a term in a particular way, see Nystrom, 424 F.3d at 1145. See also Bell Atl. Network Servs., Inc. v. Covad Commc’n Group, 262 F.3d 1258, 1271 (Fed. Cir. 2001) ("when a patentee uses a claim term throughout the entire patent specification, in a manner consistent with only a single meaning, he has defined that term 'by implication'"); ICU Med., Inc. v. Alaris Med. Sys., Inc., No. 2008-1077, 558 F.3d 1368, 2009 U.S. App. LEXIS 5271, 2009 WL 635630 at *3-4 (Fed. Cir. Mar. 13, 2009) (construing a term narrowly because every disclosed embodiment was consistent with the narrow construction, and the specification never suggested a broader interpretation). Although, consistent usage may define a term, particular embodiments and examples appearing in the specification should not be read into the claims. Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998); see also Phillips, 415 F.3d at 1323.

In Nystrom v. TREX Co., the parties disputed whether the term "board" is limited to only planks cut from a log, or whether the term could encompass planks made from any material. 424 F.3d at 1142. Because both parties agreed that the ordinary meaning of the term "board" is "a piece of sawed lumber," the Federal Circuit presumed that the narrower construction was appropriate. Id. at 1145-46. The Federal Circuit noted that the patentee consistently used the term board to refer to wood cut from a log, and that the specification framed the invention in the context of wooden decking materials. Id. at 1143. In addition, the prosecution history consistently used the term "board" to refer to wooden decking materials. Id. at 1144. Thus, the Court concluded that the presumption in favor of the ordinary meaning of the term "board" had not been rebutted. Id. at 1145-46. In fact, even if the ordinary meaning of "board" included non-wooden planks, the patentee had effectively defined "board" as "wooden plank." Id.

In Irdeto Access, Inc. v. Echostar Satellite Corp., the parties disputed whether the term "group" includes a group of all subscribers or whether it only includes subsets of all subscribers. 383 F.3d at 1300. The Federal Circuit found that the term "group" had no accepted meaning in the art, and thus neither party was entitled to a heavy presumption in favor of some ordinary meaning. Id. The Court began its analysis of the term "group" by analyzing the specification. Although it contained permissive language explaining that the claims should not be limited to the examples in the specification, the patent consistently used the term "group" to refer to subsets. Id. at 1301. Furthermore, during prosecution, the patentee disavowed any other meaning of the term "group" and "unequivocally directed the patent examiner, as well as the public, to the specification as the complete source of meaning for the disputed terms." Id. at 1303. Thus, the Federal Circuit found that the patentee had assigned the narrower meaning to the term. Id.

In Liebel-Flarsheim v. Medrad, Inc., the parties disputed whether the term "opening" referred to an aperture, or more narrowly, to an aperture in front of a pressure jacket. 358 F.3d at 905. Although the ordinary meaning of the term "opening" is simply an aperture, every embodiment of the invention described in the specification contained an opening in front of a pressure jacket. Id. Nonetheless, the Court cited statements in the specification which were inconsistent with the proposed narrow construction of "opening." In addition, the Court found this narrow construction inconsistent with the prosecution history because the patentee amended the claims of the patent to intentionally broaden the claims to cover products without pressure jackets. Id. at 909. The Court also found the broader construction inconsistent with the principle of claim differentiation. Id. at 910. Thus, the Federal Circuit interpreted the term broadly after determining that the patentee did not explicitly disclaim this broad scope, nor implicitly define the term narrowly through consistent use. Id. at 912; see also Acumed LLC v. Stryker Corp., 483 F.3d 800, 807 (Fed. Cir. 2007) (reaching a similar conclusion and emphasizing that the importance of not reading features of the preferred embodiment into claims as limitations).

DISCUSSION

The parties agree that the plain and ordinary meaning of the term "identifier" is something that identifies. The parties also agree that the patentee did not explicitly define the term "identifier" in the patent. Thus, unless the patentee has implicitly defined this term by using it in a consistent manner, the Court must presume that the plain and ordinary meaning governs. Liebel-Flarsheim Co., 358 F.3d at 913; Irdeto Access, Inc., 383 F.3d at 1301.

Google argues that the patentee has defined the term "identifier" because every embodiment described in the patent deals with intellectual property management. Nonetheless, while the specification only describes embodiments involving intellectual property identifiers, it contains several disclaimers explaining that these embodiments are merely exemplary and that the scope of the claims should not be limited by these examples. See '625 patent at 1:46-50, 1:51-52, 2:39-41, 4:57-60. In addition, the Abstract, Field and Background of the Invention, and Disclosure of the Invention sections of the '625 patent are not limited to intellectual property management. These sections broadly claim that the invention "relates to networking,
and more particularly to data networking interfaces." '625 patent at 1:14-15.

The claims themselves also support Aloft's broad interpretation of the term "identifier." Of the 23 claims listed in the '625 patent, only dependent claim 19 mentions intellectual property: "[a] system as recited in claim 2, wherein the information includes at least one of one or more of the URLs, the content, and information on intellectual property." '625 patent at 4:62-8:26. Because the only difference between claim 19 and claim 2 is that claim 19 is limited to the intellectual property context, the Court presumes that the term "identifier" is not inherently limited to the intellectual property context. Phillips, 415 F.3d at 1314.

Finally, the prosecution history supports Aloft's position. In an Office Action dated April 19, 2007, the Examiner relied on a version of Microsoft Internet Explorer as a basis for rejecting the pending claims. See April 19, 2007 Office Action, p. 2. In doing so, the Examiner argued that Internet Explorer's History function used "identifiers" equivalent to those described in the '625 patent. Because none of the examples of identifiers listed by the examiner identified specific pieces of intellectual property, it is clear that the examiner did not share Google's interpretation of the term "identifier."

1 Google argues that because Aloft claims priority back to the filing date of the '941 application, the Court's construction of the term "identifier" must be consistent with the invention actually disclosed in the '941 application. However, this argument relates to the appropriate priority date for the '625 patent. The most appropriate course of action is for the Court to construe the '625 patent as it issued. See Princeton Biochemicals, Inc. v. Beckman Instruments, Inc., No. 98-1525, 1999 U.S. App. LEXIS 19743, 1999 WL 641233 at *5 (Fed. Cir. Aug. 19, 1999) ("the subsequent filing of the CIP application ... counsels against applying the usual rule that the entire prosecution history, including parent and grandparent applications, be analyzed in interpreting a claim"); see, e.g., PowerOasis, Inc. v. T-Mobile USA, Inc., 522 F.3d 1299, 1306-09 (Fed. Cir. 2008) (affirming the District Court's decision to focus on the issued patent for claim construction purposes, and to then compare its construction to the disclosure of the original application for summary judgment purposes). If Google feels that the Court's construction is inconsistent with the '941 application, it may file an appropriate Motion challenging the claimed priority date of the '625 patent.

This case is distinguishable from the cases cited by Google.

Unlike Nystrom, the parties have not agreed that the plain and ordinary meaning of the term at issue is narrow. See 424 F.3d at 1145-46. Unlike Irdeto Access, the '625 patent does not direct the public to the specification as the "complete source of meaning" for the term "identifier." See 383 F.3d at 1300. In addition, whereas the intrinsic evidence in Nystrom supported a narrow construction because the specification narrowly framed the context of the invention, the intrinsic evidence of the '625 patent supports a broad construction of the term at issue. See 424 F.3d at 1143. For example, the '625 patent does not explicitly limit the claimed invention to the intellectual property context or claim that all of the benefits of the '625 patent are realized with regard to intellectual property management. See id. This case is also distinguishable from ICU Medical, Inc. v. Alaris Medical Systems, Inc., because in this case both the patent specification and prosecution history suggest a broad interpretation of the term at issue. See 2009 U.S. App. LEXIS 5271, 2009 WL 635630 at *3-4.

This case is similar to Liebel-Flarsheim: the patentee has not explicitly disclaimed the plain and ordinary meaning of the term identifier nor implicitly defined the term through consistent usage. The Court finds that Google's proposed construction impermissibly reads a feature of the preferred embodiment into the claims as a limitation. See Acumed LLC, 483 F.3d at 807. The Court further finds that because the plain and ordinary meaning of the term "identifier" is easily understood, no construction of this term is necessary.

2 Google argues that, under O2 Micro International Ltd. v. Beyond Innovation Technology Co., the Court must construe a term when the parties dispute the scope and meaning of claim language. See 521 F.3d 1351, 1362 (Fed. Cir. 2008). This Court has routinely rejected that argument. See Fenner Inv. Ltd. v. Microsoft Corp., No. 6:07-cv-8, 2008 U.S. Dist. LEXIS 65686, 2008 WL 3981838 at *3 (E.D. Tex. Aug. 22, 2008); Alcatel USA Sourcing, Inc. v. Microsoft Corp., No. 6:06-cv-499,

By rejecting Google's interpretation of the term "identifier," the Court, has resolved the parties' dispute and foreclosed any need for further construction. See O2 Micro International Ltd., 521 F.3d at 1362. The parties may not interpret the term in a manner that is inconsistent with this opinion. If Google later discovers that Aloft is presenting an inconsistent interpretation of the claims at issue, Google may object at that time. Until then, the Court sees no reason to construe a term that has a clear, easily understandable meaning.

B. "Identifier(s)"

The parties ask the Court to construe the term "identifier" or "identifiers" found in the '429 Patent, claims 1, 2, 6, 8, 23, 24, and 30, and in the '084 Patent, claim 1. In Vonage, the Court rejected Vonage's construction that would have limited the term to mean a VPI/VCI combination; the Court instead adopted Sprint's proposed construction, and construed the term "identifier" to mean data for routing information in a packet network. See 500 F. Supp. 2d at 1312-14. Sprint urges the same construction here. Big River argues that the term should be construed to mean data for routing user information in a packet network over a pre-provisioned virtual connection. Thus, Big River seeks to add language limiting the scope of the claimed invention to the use of pre-provisioned virtual connections (PPVCs). The Court rejects Big River's proposed limitation.

The Court first concludes that the language of the claims themselves does not support Big River's construction. Big River argues that because ATM technology uses virtual connections, the claims' references to the "interworking unit" necessarily refer also to virtual connections under the Court's construction of that term. The claims do not contain any language, however, indicating that those virtual connections must be pre-provisioned.

Once again, Big River relies primarily on the specification to support its proposed limitation. Big River does not point to any specific language in the specification defining or describing "identifier" with reference to PPVCs. Instead, Big River argues generally that the specification describes the claimed invention as requiring PPVCs. Specifically, Big River cites portions of the specification relating to the use of an ATM cross-connect system, and it notes that, according to the background of the specification, "connections through cross-connect systems must be pre-provisioned." ('301 Family at 1:28-29.) The specification makes clear, however, that the ATM cross-connect system represents only an exemplary embodiment of the invention. For instance, the background also states that "[s]ome ATM systems have used ATM cross-connects to provide virtual connections." ('301 Family at 1:22-23 (emphasis added).) The summary states that the system "could also include an ATM cross-connect system." ('301 Family at 2: 42-43 (emphasis added).) In reference to one drawing, the specification states: "FIG. 4 depicts virtual connections provided by the ATM cross connect system in a version of the invention, although numerous other techniques for providing virtual connections will be appreciated by one skilled in the art, and the invention contemplates any such system." ('301 Family at 8:61-65 (emphasis added).) Figure 1 is also described as showing a cross-connect system with PPVCs, but that figure also depicts only "a version of the present invention." ('301 Family at 3:36 (emphasis added).)

Thus, Big River has failed to identify any language in the specification that describes the invention generally, and not merely some embodiments, as requiring PPVCs. Nor has Big River adequately explained why the invention would require PPVCs even for versions not employing an ATM cross-connect system. Big River points to the invention's purpose, as stated in the specification, of allowing call-by-call switching without utilizing the switches' signaling and processing capabilities. (E.g., '301 Family at 2:64-67.) Big River has not shown, however, that fulfilling that purpose requires the use of PPVCs as the invention is described in the specification. The Court concludes that Big River has not shown that the
specification repeatedly or consistently describes the invention as a whole (and not merely in embodiments) as requiring the use of PPVCs, and that Big River has therefore failed to add a limitation to the otherwise-broad claim language under the Microsoft standard.

The Court also rejects Big River's argument based on the patent's prosecution history. In the cited excerpt, the applicant distinguished the prior reference as involving an ATM multiplexer that does not use signaling that identifies a selected virtual connection. That citation may support the idea that the present invention uses virtual connections; it does not support the limitation that those connections must be pre-provisioned, however.

Finally, Big River cites to deposition testimony by Sprint's expert in which the expert testified that "[t]his particular patent and in particular the written description describes preprovisioned connections," and that in "this patent family we're dealing with preprovisioned circuits" such as VCI/VPI pairs. It is clear from the specification, however, as noted above, that such a system represents only an exemplary embodiment of the claimed invention. Thus, the Court concludes that these isolated snippets from the expert's testimony is not sufficient to overcome the relevant evidence on this issue in the intrinsic record.

In its brief, Big River has attempted to divide its proposed addition to the definition of "identifier" into two separate concepts: the use of virtual connections and the requirement that those connections be pre-provisioned. The Court has rejected the insertion of the latter concept into this term. With respect to the former concept, Sprint does not dispute that virtual connections are used, a point confirmed by the summary of the specification. Big River has not explained, however, why the use of virtual connections in general should be included in this construction of "identifier". The use of virtual connections as a feature of ATM technology can be easily explained to the jury at trial. Therefore, the Court declines to incorporate that feature into the construction of this term.

For these reasons, the Court construes the term "identifier" to mean data for routing information in a packet network.

2036

i. "Identifier"

Beginning with the claim language itself, the claims do not indicate that the term "identifier" is limited to a VPI/VCI combination. In fact, Sprint correctly points out that the language of the claims identifies two key facts regarding the claimed "identifier": (1) it is part of a communication signal that includes user information in a packet format; and (2) it is used for routing the user information. Based on this information, Sprint urges the court to construe the claimed "identifier" to mean data for routing user information in a packet network.

Other claims of the patent are useful for understanding the ordinary meaning of claim terms. Phillips, 415 F.3d at 1314. Sprint points out that dependent claims 5, 14, 23, and 32 add the limitation that the identifier comprises an "asynchronous transfer mode [ATM] virtual identifier." It is undisputed that a person of ordinary skill in the art would understand this claim term to mean an ATM VPI/VCI pair. Thus, construing the claim term "identifier" in independent claims 1, 10, 19, and 28 to mean an ATM VPI/VCI pair would render dependent claims 5, 14, 23, and 32 duplicative of the independent claims on which they depend. This invokes the doctrine of claim differentiation. This doctrine is grounded in the notion that "[d]ifferences among claims can . . . be a useful guide in understanding the meaning of particular claim terms." Phillips, 415 F.3d at 1314. "[T]he presence of a dependent claim that adds a particular limitation gives rise to a presumption that the limitation in question is not present in the independent claim." Id.; see also Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380 (Fed. Cir. 2006) (doctrine of claim differentiation refers to the presumption that an independent claim should not be construed as requiring a limitation added by a dependent claim). This is because "reading an additional limitation from a dependent claim into an independent claim would not only make that additional limitation superfluous, it might render the dependent claim invalid." Curtiss-Wright Flow Control Corp., 438 F.3d at 1380. Here, the '294 Patent contains dependent claims which add the particular limitation urged by Vonage.

Consequently, a presumption arises that the "identifier" disclosed in claims 1, 10, 19, and 28 is not limited to an "asynchronous transfer mode virtual identifier," or an ATM VPI/VCI pair.

Vonage's argument that the court should construe the claim term "identifier" to mean an ATM VPI/VCI pair is based on
language contained in the specification. In addition to the overarching language concerning ATM technology discussed previously, Vonage points to language in the written description which discloses that VPI/VCI combinations are designated for the virtual connection. See ’294 Patent, col. 7, ll. 15-21; col. 9, ll. 12-29. In fact, the specification's references to VPI/VCI combinations are merely examples set forth as embodiments of the invention. The first reference to a VPI/VCI combination is contained in a portion of the written description describing Figure 2. It begins, "FIG. 2 depicts another embodiment of the invention." ’294 Patent, col. 5, at 41. In discussing the signaling received by the call/connection manager (CCM), the written description states as follows:

CCM 250 can select a virtual connection to the destination. The selection process can be accomplished through table look-ups. For example, a table could be used to translate a portion of the dialed number into a VPI. The VCI would be selected based on the available VCIs in the selected VPI. The VPI/VCI combination would correspond . . .

Id. col. 7, ll. 15-21 (emphasis added). The second discussion of VPI/VCI combinations is contained in a portion of the written description describing Figure 4, which is entitled the "ATM Cross-connect System." That portion of the written description states as follows:

FIG. 4 depicts virtual connections provided by the ATM cross connect system in a version of the invention, although numerous other techniques for providing virtual connections will be appreciated by one skilled in the art, and the invention contemplates any such system.

Id. col. 8, ll. 61-65 (emphasis added). The specification repeatedly states that drawings and the detailed descriptions of those drawings depict versions of the present invention. In fact, just prior to the claims themselves, the specification concludes as follows:

Those skilled in the art will appreciate that variations from the specific embodiments disclosed above are contemplated by the invention. The invention should not be restricted to the above embodiments, but should be measured by the following claims.

Id. col. 23, ll. 14-18.

With respect to the claim term "identifier," the court concludes that a person of skill in the art would understand the specification's reference to VPI/VCI combinations to be exemplary in nature, rather than defining the outer limits of the claim term. First, of course, the doctrine of claim differentiation gives rise to a presumption that the term is not limited to a VPI/VCI combination. Second, the references to VPI/VCI combinations in the written description fall far short of reflecting an intentional disclaimer, or disavowal, of the full scope of the claim. Instead, the written description's references to VPI/VCI combinations contain qualifiers such as the fact that Figures 2 and 4, and the related detailed descriptions, are only versions of the invention; the "[f]or example" language; the statement that numerous other techniques for providing virtual connections will be appreciated by one skilled in the art, and the invention contemplates any such system; and, finally, the statement that the invention should not be restricted to those embodiments, but instead should be measured by the claims, as the invention contemplates variations that would be recognized by one skilled in the art. Given the clarity of the language of the claim terms themselves, then, the court will not import this limitation from the specification into the claims. Instead, the court believes that a fair and accurate claim construction, which is based on the claim language itself, is the construction proposed by Sprint. As such, the court construes the claim term "identifier" to mean data for routing information in a packet network.

5. Identifier

The court adopts Judge Brewster's construction of "identifier" in the Gateway action. Accordingly, the court construes "identifier" to mean "a unique label that serves to distinctly identify each one of a plurality of input object types and, if any, each one of a plurality of group identifier types."
"Session Identifier" and "Authorization Identifier"

A "session identifier" is "a text string that identifies a session." Similarly, an "authorization identifier" is "a text string used in granting (access) rights." At the time of the '780 patent's application and issue, an identifier was understood to be "any text string used as a label." See Microsoft Press Computer Dictionary, at 205 (2d ed. 1994); Microsoft Press Computer Dictionary, at 243 (3d ed. 1997).

For both "session identifier" and "authorization identifier," Amazon proposes the construction, "a value with multiple fields whose cryptographic authentication indicates to an access-controlling server that the client identified in the session identifier is authorized to access the requested file." These constructions are too narrow and improperly import many of the limitations from the specifications and preferred embodiments into the claim language. Further, Amazon's proposed constructions do not distinguish a session identifier from an authorization identifier.

A. "peak value" and "lowest value"

In the Claim Construction Order, the Court construed sub-limitations (a)-(c) of claims 1 and 18 according to the construction proposed by the patent holder Elantech. See Claim Construction Order at 13-15. In relevant part, the Court construed "identify a...maxima" to mean "identify a...peak value" and "identify a minima" to mean "identify the lowest value." See id. Elantech argues that the construed sub-limitations (a)-(c) are met by identification of the traces with the peak (maximum) and lowest (minimum) values. Synaptics counters that the construed claims require identification of "specific" or "particular" measured capacitance values. Accordingly, methodology that does not somehow identify "particular measured values" cannot infringe.

At oral argument on October 5, 2007, Synaptics supported its reading of the terms by noting that the example method described in the '352 patent specification explicitly records the maxima and minimum measure capacitance values in a number of variables. See '352 patent at p. 22, col. 8 1. 52 - p. 23, col. 9 1. 14. However, standing alone, an embodiment disclosed in the specification does not limit the claims. Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004). Even when the specification describes only a single embodiment, the claims of the patent are not to be construed as restricted to that embodiment unless the patentee demonstrates a clear intention to limit the claim scope using "words or expressions of manifest exclusion or restriction." Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1327 (Fed. Cir. 2002). Absent clear statements of scope, courts must follow the language of the claims and not that of the written description provided by the specification. Id. at 1328.

The '352 patent specification states that the example embodiment is not meant to limit the invention. See '352 patent, p. 26, col. 16 ll. 6-12. Therefore, the example itself does not support Synaptics' view that the claim scope is limited to only cover methods that explicitly identify particular measured values corresponding to maxima and minima. See Teleflex, 299 F.3d at 1327.

In addition, Synaptics' reading of the construed claims would inappropriately limit their scope. The plain language of the claims reads on identifying maxima and minima. The claims neither mention nor require any sort of operation to be performed on capacitance values. Taken literally, Synaptics reading of the claims would allow a party to escape literal infringement by transforming the measured capacitance values (e.g. trivially multiplying the finger profile values by two) before identifying minima and maxima, because the identification steps would not use the literally measured capacitance values. There is no support for such a limited reading of the claims in the patent specification or intrinsic evidence.

The construed claims require identification of peak and lowest values, corresponding to maxima and minima, respectively. This step is satisfied by methodology that scans the finger profile to identify traces that contain the peak and lowest values.
Acknowledging the circularity of the dictionary definition of this term, namely, "establishing the identity of," the plaintiff proposes that this term be defined as "establishing the presence of." The defendant proposes that the term means "action by a human to inspect and label." Each party asserts that its definition is the ordinary meaning of the term.

Relying on the dictionary definition, as the meaning that would be attributed to the term by the skilled artisan, and providing additional clarity, I construe the term "identifying" to mean: "determining or establishing the presence or identity of."

3. "maps," "providing a map," "identifying anomalies"

KLA argues that "maps" include stored sensor or output signals, "providing a map" has an ordinary meaning-to provide a map, and "identifying anomalies" means an identification of anomalies by type. D.I. 338 at 19-22; D.I. 416 at 31-34. On the other hand, ADE argues that "map" means a visual display, "providing a map" means first forming a map for the entire wafer and then processing the stored detector output in a distinct step, and "identifying anomalies" means identification of the presence or absence of anomalies. D.I. 316 at 14-17; D.I. at 2-13.

Claim 36 of the '325 patent differs from claim 43 of the '325 patent in that claim 36 is directed to an "optical system" but claim 43 is directed to an "optical method." Both claims use the language, "maps," "providing a map," and identifying anomalies." This language, as it appears in claim 36, is reproduced below for purposes of representation:

a processor providing a plurality of maps by providing a map from said stored sensor output signals from each of the two or more sensors during the scan and comparing at least two of the maps for identifying anomalies

'325 at 18:41-47.

It is evident from reading the above quoted language that "maps" are provided from "stored sensor output signals" and compared to identify anomalies. This claim language is straightforward and supported by the written description. The inventors' description provides that "the processor 500 compares the data stored in memory at addresses represented by the map shown in FIG. 7A with the data stored in memory represented by the map shown in FIG. 7B." '325 at 7:67-8:3 This data, as represented by the maps shown in Figures 7A and 7B, reproduced below, is compared using logical OR and AND operators to construct the composited maps represented by Figures 7C, 7D, and 7E. '325 at 8:3-23. Clearly, the visual display or "maps" referred to in the '325 patent include the underlying stored data because "the processor 500 compares the data stored in memory…." Id. The visual display is merely a "representation" of the data. Id.

[SEE FIGURES 7A, 7B, 7C, 7D, 7E IN ORIGINAL]

Consistent with the inventors' written description and the plain meaning in the art of the words used in the claims, this court construes the word "maps" to include the underlying stored data that is displayed visually as in Figures 7A-7E of the '325 patent. Furthermore, "providing a map" is construed to mean that different "maps" may be generated by the processor. The phrase "identifying anomalies" as used in claims 36 and 43 is construed to mean identification of the presence or absence of anomalies on the surface of silicon wafers. '325 at 14:58-15:5. Had the inventors intended a different meaning for "identifying anomalies," such as "classifying anomalies," they could have drawn such a distinction in their claims as was done in the written description where it reads that:

The processor 500 constructs maps from the signals produced by the inspection channels. … The processor compares the maps from the inspection channels either in the analog domain or digitally, by performing logical operations on the data, e.g., AND, OR and XOR, in the manner described above, to detect anomalies. The processor forms composite maps, each
representing the detected anomalies by a single group of symmetrically disposed collector channels. The composite maps are then compared so that the processor may classify the anomalies as either a pattern defect or particulate contamination.

Id.

Having failed to use the term "classify" in the claims this court will not misconstrue the word "identify[]" as used in the claims to impart a meaning inapposite to that commonly understood in plain English and in the art to which the invention is directed. This court holds, therefore, that the phrase "identifying anomalies" means just that-to identify the presence or absence, as the case may be, of anomalies on the surface of a silicon wafer or similar article.

2042

3. identifying from among them a benchmark from which may be determined the beginning of each of such contributory frames and, thereby, the boundaries of such frames

In disputing the meaning of this phrase, Bellcore contends that the term "benchmark" means marker and the term "boundaries" means the beginnings or ends of certain portions of a frame. Bellcore contends that the transition from F1 to F2 framing bytes serves as the "benchmark." (D.I. 252 at 15).

FORE contends that this limitation means that (1) a benchmark must be determined for each instance of higher-level frames, (2) from the benchmark the first byte of each distinct and complete higher-level frame must be determined, and (3) from that first byte, the boundary of each distinct and complete higher-level contributory frame must be determined. (D.I. 253 at 3–4). FORE does not appear to disagree with Bellcore's definition of "benchmark." Additionally, FORE agrees that the term "boundaries" means the beginning or end of a frame, but disagrees to the extent that Bellcore construes this term to mean "certain other portions" of a frame, which FORE contends is vague.

It appears to the Court that the parties central disagreement concerning the meaning of this phrase is whether the frame boundaries "must" be determined as FORE contends or "may" be determined as Bellcore contends. Reading the claim language as a whole in light of the specification, the Court agrees with FORE that this element requires the beginning of each frame, and therefore the frame boundaries, to be determined from the benchmark. As the specification states, "It is essential to the proper recovery of the original SONET frames that the byte assembly be correctly synchronized and the boundaries of each frame be identified in the bit stream transmission in order that the reconstructed bytes will duplicate each of the bytes which were interleaved to produce that serial transmission signal." ( ’768 Patent, col. 1, lines 47–53 (emphasis added)). In the Court's view, accepting Bellcore's contention renders the requirement of identifying the benchmark a useless exercise. The very purpose of identifying the benchmark is to determine the "beginning byte" and the "boundary" of each contributory frame, and therefore, the Court cannot accept a construction of the phrase "may be" which would make this function optional. Accordingly, the Court concludes that this phrase requires that (1) a benchmark must be determined for each instance of higher-level frames, (2) from the benchmark the first byte of each distinct and complete higher-level frame must be determined, and (3) from that first byte, the boundary of each distinct and complete higher-level contributory frame must be determined.

2043

C. "Number-of-recording planes identifying information"

Plaintiff's construction: any information capable of indicating the number of recording layers

Defendants' construction: information intended for use in identifying the number of recording planes on the recording medium

The parties have two disputes with respect to this term. First, they dispute whether "number-of-recording planes identifying information" is limited to information whose purpose is to identify recording planes. Defendants argue that this limitation is
supported by the purpose of the patent, the language of the specification and the prosecution history.

Plaintiff disagrees, contending that the claim is broad enough to encompass any information that is capable of indicating the number of recording planes. The parties' second dispute is whether the "recording planes" should be defined as "recording layers," as plaintiff suggests. I already have rejected plaintiff's attempt to construe "recording planes" as "recording layers" and will not address this issue again.

With respect to the first dispute, I will adopt defendants' construction because it is supported by the patent specification and prosecution history. Claim 1 does not provide a clear meaning for "number-of-recording planes identifying information." However, in the specification, the inventors discuss shortcomings of the prior art, noting that "conventional management information does not include information that distinguishes [various] disc types," including "specific discs, single-sided discs, and double-sided discs." Id. at 1:24-27. During prosecution, the patentee's attorney explained that such information is useful because it allows a recording or reproducing device to determine whether it can "record or reproduce from another plane of the medium once it has finished with the current plane." Marshall Decl., Ex. C, dkt. 73, at 5. In explaining why he allowed an amendment to the '966 patent, the patent examiner explained that the number-of-planes identifying information identifies the "number of recording planes on the disk:"

none of the cited prior art shows or teaches an optical recording and reproducing apparatus comprising a disk having at least one recording plane wherein each recording plane includes a data recording region and a management region including the number of recording planes identifying the number of recording planes on the disk . . . .

Thus, according to the patent specification, a purpose of the '966 patent is to provide information in the management region of a recording medium that "determines the types of a recording medium," "the number of recording sides" and the "recording surface" of the medium. '966 patent, 2:8-13. To fulfill this purpose, claim 1 of the '966 patent requires two pieces of information in the management region of the disc: (1) number-of-planes identifying information, and (2) recording-plane-identifying information that uniquely identifies that recording plane. The number-of-planes identifying information is used to identify the total number of recording planes on the recording medium. This is illustrated in Figure 2 of the specification, which states that "The number-of-disc-sides identifier 2 represents whether the disc is a double-sided disc or a single-sided disc." Id., 6:20-30.

Therefore, in light of the purpose of the patent, defendants' construction makes sense. The inventors did not include information in the management region that may identify the number of recording planes; rather, they included information with the specific purpose of identifying the number of recording planes. Thus, I will adopt defendants' construction, with a slight modification, substituting "intended" with "purpose."

- Court's construction: information whose purpose is to identify the number of recording planes on the recording medium

- 2424 -
D. "Recording-plane identifying information that uniquely identifies that recording plane"

Plaintiff's construction: any information capable of identifying the recording layer

Defendants' construction: information intended for use in identifying the recording plane being reproduced

Similar to the previous dispute, the parties dispute whether "recording-plane identifying information that uniquely identifies that recording plane" is limited to information that the inventors intended for use in identifying the recording plane being used, or whether it includes any information capable of identifying the recording plane. Again, I am persuaded that defendants' proposed construction is more accurate in the context of the '966 patent.

"Recording-plane identifying information that uniquely identifies that recording plane" is illustrated in Figure 2 in the patent specification. Figure 2 uses an optical disc as an example and refers to the "recording-plane identifying information" as the "disc side identifier." The "disc side identifier 3 represents whether side A or side B of a double-sided disc is being reproduced." During the prosecution of the '966 patent, the patentee's attorneys explained that the purpose of the "recording-plane identifying information" was to identify uniquely to the player which side of the disc (or recording plane) was being reproduced:

Specifically, the specification clearly states that the medium according to the present invention has number of disc sides identifying information and recording side identifying information that represents the recording side. (See, e.g., Specification at 3, 4-5, 12-13, 15; Original Claims 2, 16; Original Abstract; and FIG. 2.) As illustrated in FIG. 2 and described in the Specification at 12-13, a number-of-disc-sides identifier 2 and a disc side identifier 3 are recorded in the application system region of a PVD table of the disk. It is clear that this information must be provided on each side of the disc. - i.e., each recording plane - in order for the disc side identifier 3 to serve its purpose of identifying which side is being recorded/reproduced. For example, the disc side identifier 3 for side A is set to 00H so that, when a reproducing device reads that disc side identifier 3, it can identify the side that it is reproducing as side A. Similarly, the disc side identifier 3 for side B is set to 01H so that, when a reproducing device reads that disc side identifier 3, it can identify the side that it is reproducing as side B.

Plaintiff points to no evidence suggesting that the "recording-plane identifying information" is anything other than the information whose purpose is to identify which recording plane is in use, as discussed in the specification and during the patent prosecution. On the other hand, defendants' construction is true to the claim language, which provides explicitly that the "recording-plane identifying information . . . uniquely identifies" the recording plane. Further, I agree with defendants that their construction will assist the finder of fact because it clarifies that this information is designed for the player to determine which recording plane it is reproducing. In other words, using the example in the patent, this information is used by the player to determine if the laser beam is directed at side A or side B or a double-sided disc.

Court's construction: information whose purpose is to identify the recording plane being reproduced

2046
g. Identifying which phenomena in the manufacturing plant are stochastic in nature

The parties agree on the meanings of the words "phenomena" and "stochastic" in the limitation "identifying which phenomena in the manufacturing plant are stochastic in nature." The central dispute appears to concern whether the limitation contains multiple steps. ITI maintains that the proper interpretation is noting observable facts or events that are random. Defendants' proffered construction includes two steps: as to those events or things that are selected to be observed in the manufacturing plant, determining which of them occur randomly. Though the Court is cognizant that the term
"which" indicates that certain phenomena will be identified from a group of phenomena, we do not believe that the claim language supports defendants' reading. Moreover, the specification does not support defendants' contention that this limitation involves two distinct steps. At the same time, ITI's definition overlooks some claim language. The proper construction is: determining which events or things in the manufacturing process occur randomly.

H. "Identity Data" as it relates to the Subscriber Client Computer and "Part Of Said Identity Data"

The parties disagree about what the term "identity data" identifies as it relates to the Subscriber Client Computer, as well as the meaning of the word "part." Thus, the Court must construe each term.

Defendants contend that the "identity data" at issue must uniquely identify the subscriber client computer, not the subscriber, because the claim language refers to identity data "of" the subscriber client computer. After considering the claim language and the specification, the Court again concludes that Defendants' are restrictively reading the word "of." The term is not limited, as Defendants have argued, to the identity data that uniquely identifies the subscriber client computer. When discussed in the '416 Patent, the identity data of the subscriber client computer is that identity data which is transmitted by the subscriber client computer and used by the invention to verify the identity of the subscriber. (See generally '416 Patent). Accordingly, the Court construes "Identity Data" as it relates to the Subscriber Client Computer to mean "data sufficient for the patented system to determine whether a person, organization, and/or computer is authentic and/or is entitled to assess said selected computer resources.

The Court will next consider whether "part of said identity data" should be construed to encompass the entirety of the identity data or whether it must refer only to a subset of the identity data. Plaintiff contends that nothing in the '416 patent or prosecution history precludes the invention from using only the hardware key's predetermined digital identification to authenticate a user. Plaintiff contends that, when the claims refer to the predetermined digital identification as being "part" of the identity data, the claims anticipate that the predetermined digital identification could be combined with other information, or could be sufficient on its own, to authenticate a subscriber. The specification, however, reveals that Plaintiff's position is inconsistent with the '416 Patent.

The '416 Patent discloses that the "identity data" needed to authenticate a subscriber depends upon the type of authentication scheme employed. The patent discloses that there can be one factor or two factor authentication. (Id. at col. 1, ll. 60-61). When using one factor authentication, the identity data is the subscriber's username and password. Id. When using two-factor authentication, the "identity data" includes the predetermined digital identification from the hardware key. (Id. at col. 1, ll. 61-63). Thus, the patent discloses that to successfully authenticate a subscriber under a one-factor scheme, that subscriber must correctly present a username and password, while successful authentication in a two-factor scheme requires the subscriber to present a username, password and the predetermined digital identification from a hardware key. Moreover, the patent never suggests the hardware key's predetermined digital identification alone could be enough to authenticate a subscriber. Rather, the specification makes clear that the optional hardware key is only used with two-factor authentication. (Id. at col. 1, ll. 58-67). In those instances where the hardware key is used for authentication, it is always in the context of two-factor identification. (See id. at col. 2, ll. 28-32, col. 3, ll. 45-47, col. 5, ll. 15-18, 50-55, col. 7, ll. 59-65, col. 13, ll. 44-46, col. 14, ll. 48-58, and col. 21, 45-49). Accordingly, the Court declines to construe "part of said identity data" as encompassing the entirety of the identity data, and instead construes it to mean "some, but not all, of the identity data of the subscriber client computer."

B. "creating a family of concentric indexed circles"

The parties contest the construction of the term "indexed":

<table>
<thead>
<tr>
<th>Plaintiff's Proposal</th>
<th>Defendants' Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>family of concentric indexed</td>
<td>creating a family of concentric circles</td>
</tr>
</tbody>
</table>

- 2426 -
circles: two or more circles with the same center point uniquely identified within each family  
circles: Bringing into existence two or more complete circles whose center is the same but whose points are located at different distances from that center, with each such circle numbered consecutively according to its relative distance from the boundary of the workpiece.

The Court concludes that Defendants' proposal is too narrow because it requires that the indexing be done by consecutive numbering, to the exclusion of letters or symbols. Plaintiff's construction is too broad because it does not convey that the indexing must be based upon a circle's location. At the Markman hearing, the Court circulated a tentative construction that was almost identical to the following construction, which it now adopts:

family of concentric indexed circles -- Two or more complete circles with the same center point but whose points are located at different distances from that center, with each such circle identified according to its position.

Plaintiff did not object to this construction. Defendants objected that the construction fails to specify that the indexing must be done according to a circle's location relative to the outer boundary of the workpiece and relative to other circles in the circle family. But this objection lacks support in the patent claim, specifications, or prosecution history.

--- Footnotes ---

4 The Court's tentative construction used the word "location" rather than "position." The Court has substituted "position" to make the construction more consistent with the prosecution history.

--- End Footnotes ---

1. Prosecution history

The prosecution history reveals that the patentee understood both that the index could be something other than a number and that the index would be related to a circle's location. The prosecution history does not, however, support Defendants' contention that the indexing must be done based upon the circle's position relative to the part boundary and to other circles.

The patentee stated to the patent examiner that "An index is a number or a symbol or expression to indicate a position in an arrangement . . . . [I]ndexing is a feature of an embodiment of the invention which provides the means for uniquely identifying each circle in each family of concentric circles." Trusso Decl., Exh. P., p.22 (emphasis added).

This definition of the term "index" by the patentee clearly encompasses the requirement of denoting a position, but it does not require that the position be determined relative to the outer boundary of the workpiece or other circles in the circle family.

2. The specification

Defendants point out that the patent's Sixth Preferred Embodiment describes an invention in which circles within a family are indexed by "numbering the circles from the outside in an ascending scale." ('013 patent 20:28-30). This language is consistent with the statement in the prosecution history that the circles must be numbered based on their position. This single embodiment alone does not, however, support the conclusion that numbering must be based on a circle's position relative to the part boundary or to other circles. See Phillips, 415 F.3d at 1323 ("[W]e have expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment.")

Defendants try to buttress the significance of this single embodiment by invoking the purpose of the invention claimed in the '013 patent. They argue that "[t]he point of indexing is to allow the identification of identically indexed circles in adjacent families so that they can be combined to form concentric isoloops. If index numbers were randomly assigned, as Surfware's proposed construction would permit, the 'isoloops' could be non-concentric and intersecting, which would yield a
bizarre tool path when blended according to the subsequent 'generating' step." Ds' Brief at 15. Defendants illustrate this argument in Figure B to Sherbrooke's declaration, which shows that "connecting circles that are merely 'uniquely identified' rather than numbered according to their relative position would allow isoloops to cross and would not ensure that the isoloops are nested as the '013 patent teaches and shows in Figure 22." Sherbrooke Decl. P 10. This argument has some force, as it is apparent that the purpose of the invention is to generate relatively efficient tool paths. But the Court has no way of judging whether the resulting tool paths would be truly "bizarre," as Defendants claim, or whether they would be consistent with the patent's purpose. (Plaintiff's expert, Dr. Potel, suggests that even if the resulting tool path would be inferior to the preferred embodiment, "persons of skill in the art would not understand such a method to be exempted from coverage by the claims as written." Potel Decl. II P 17.) Thus, the Court is in no position to conclude that this patent's purpose is inconsistent with the construction supported by the other relevant evidence.

For these reasons, the Court adopts the construction stated above.

E. '437 Patent Claim 21 - "an ignition system having the ability to diagnose the state of health of an igniter plug"

'154 Patent Claim 1 - "a diagnostic circuit responsive to the exciter and igniter plug detectors for reporting a failure of the igniter plug only when... the sparks are not being produced at the igniter plug, the diagnostic circuit including an output for reporting the state of the health of the ignition system"

'154 Patent Claim 1 - "an igniter plug detector for detecting whether the high energy pulses produce sparks at the igniter plug"

The Court construed these claims to mean that the diagnostic system must only detect an open circuit failure at the plug and need not detect all plug failures. Lucas Aerospace, Ltd. v. Unison Industries, L.P., 890 F. Supp. 329, 1995 WL 362387 at *12. Lucas now argues that the Court has construed these claims in a manner that does violence to the plain meaning of the claims. See D.I. 394 at 45-46. The Court rejects this suggestion and finds no error in its claim constructions. First, as stated in the Court's earlier opinion, Lucas's contention that the claims require detection of short circuit conditions at the plug would render both patents invalid for failure to disclose the invention adequately. See Lucas Aerospace, Ltd. v. Unison Industries, L.P., 890 F. Supp. 329, 1995 WL 362387 at *11. Second, with respect to both patents, what Lucas now wants to do is add a positive, or inclusive, limitation to the claims of the patent that is not found in the specification of either patent. As the Court noted previously, both the specification and the extrinsic evidence adduced at trial are consistent with the conclusion that the claim language does not require a device within the scope of the patent to detect all failures of the plug and that, consequently, a system that detects the open failure mode, or a system that determines sparks are not being produced by looking and asking the plug whether sparks are being produced, would fall within the purview of the patent.

Image means "a two dimensional representation of a scene, that depending on the context, may refer to the image to be displayed or to the image on the display device that is to be interleaved to recreate the image to be displayed."

2. The Term "Image" Means the Actual-Printed Image Excluding Registration Marks

The Court agrees with Defendants that the term "image" in Claim 29 should be construed to mean the actual printed image (i.e., a scene or picture) excluding registration marks. (Defs.' Proposed Findings of Fact, doc. no. 89, P 147.)

Defendants highlight that the stated purpose of the '577 Patent was to perform color registration without registration markers. They cite the "Background of the Investigation" section of the specification which states the primary goal of the
patent is, "to provide a system which is able to provide color-to-color registration based only upon scanning the image being printed" [and not any] "registration mark distinct from the image being printed." ('577 Patent specification at col.1, lines 36-45.) Thus, Defendants propose that the claim term "image" can only refer to a suitable area of the actual printed image or work (i.e. scene) to be printed. They claim that the "image" cannot include registration and reference marks printed outside of the boundaries of the actual printed work, because that functionality is specifically excluded from the '577 Patent.

The Court credits the declaration and testimony of HW "Buck" Crowley, an electrical engineer in the printing industry who has patented numerous inventions and products in the printing industry. As used in the '577 Patent and in Claim 29, one of ordinary skill in the art would understand the term "image" to mean a production image; that is, the actual image, such as the hand or flower depicted in Figure 2E of the '577 Patent, but not registration marks of any kind. (Defs.' Proposed Findings of Fact, doc. no. 89, P 138-140; Decl of HW Crowley, Appx. Ex. E.)

Moreover, the '577 Patent disavows the prior art's use of registration marks:

> U.S. Pat. No. 4,877,530, 9 issued to Jeffrey W. Sainio on Dec. 19, 1989, discloses a control system for adjusting the color-to-color registration of multi-color web-fed printing press system. In general, the device utilizes a registration mark distinct from the printed image to provide color-to-color registration. An optical scanner scans registration marks each associated with one color of the printed image. The optical scanner provides information to a control system which allows the control system to determine the spatial relationship of the registration marks and control the printing units of the printing press system such that registration of printed colors is corrected as necessary.

> The system of U.S. Pat. No. 4,877,530 is reliable and has proved highly useful for maintaining color-to-color registration of multi-color prints. However, the requirement of a registration mark distinct from the image being printed requires additional paper which is discarded and adds cost to the printing process. Additionally, there are certain types of printed materials which do not provide a convenient area for applying registration marks. Accordingly, it would be advantageous to provide a system which is able to provide color-to-color registration based solely on the image being printed.

('577 Patent Specification 1:20-45.)

9 The '530 patent is a prior-art issued to Jeffrey W. Sainio that discloses a color registration system that operates with registration marks. The description of how the '530 patent operates with marks is similar to how most prior-art marked registrations systems work, including the mRC System. (Defs.' Ex. 34)

The Federal Circuit has held that if "the specification makes clear that the invention does not include a particular feature, that feature is deemed to be outside the reach of the claims of the patent, even though the language of the claims, read without reference to the specification, might be considered broad enough to encompass the feature in question." SciMed Life Sys., Inc. v. Advanced Cardiovascular Sys., Inc., 242 F.3d 1337, 1341 (Fed. Cir. 2001). Moreover, the court has recently reiterated, "[w]here the general summary or description of the invention describes a feature of the invention . . . and criticizes other products . . . that lack that same feature, this operates as a clear disavowal of these other products. . . ." Edward Lifesciences LLC v. Cook Inc., 582 F.3d 1322, 1333 (Fed. Cir. 2009) (citing Astrazeneca AB v. Mut. Pharm. Co., 384 F.3d 1333, 1340 (Fed. Cir. 2004) (finding disavowal of resilient wires in the "background art" section of specification)).

When read in light of the specification and Background of the Invention section, Claim 29 covers a system that excludes any signals or data representative of registration marks. In the same breath, the specification praises the '530 patent as "reliable" and "highly useful" but then complains that the requirement of distinct registration marks requires additional discarded paper and adds cost. Moreover, the specification details that there are certain mediums that do not provide a convenient area for registration marks and where, theoretically, the '530 Patent method cannot operate.

Thus, the "Background of the Invention" section of the '577 Patent is clear that there are serious disadvantages of "registration marks" and that its one embodiment describes a system that bases its operation "upon an analysis of the color densities of a portion of a printed image, rather than registration marks or the dot locations of a printed image." (15:33-36.)

- 2429 -
Accordingly, the disavowal stems from the prior art's problematic use of registration marks distinct from the actual printed image or within the image, and the '577 Patent proposes to solve the problem. The preferred embodiment states that the invention solves all of the problems with prior-art. The disavowal and criticism of prior-art in this case is unmistakable. Consequently, this constitutes a legal disavowal of a registration system that operates within registration marks. 10 Where, "the specification may reveal an intentional disclaim, or disavowal, of claim scope by the inventor. . . . the inventor has dictated the correct claim scope, and the inventor's intention, as expressed in the specification, is regarded as dispositive." Phillips, 415 F.3d at 1316 (citing SciMed Life, 242 F.3d at 1341, 1343-44.; Timken Co. v. SKF U.S.A., Inc., 193 F. Supp. 2d 813, 818 (E.D. Pa. 2002) (Robreno, J.) (granting defendant's motion for summary judgment and relying upon specification language in holding that patent was limited by disavowal in summary of the invention section).

--- Footnotes ---

10 Quad/Tech argues there is no clear disavowal of markless registration control, but rather that the comments in the specification are directed to paper savings and merely point to why the markless functionality is the preferred embodiment. Quad/Tech relies primarily on two cases where the Federal Circuit discussed disavowal and found that "disparaging comments alone do not necessarily show a manifest or express disavowal of the criticized subject matter." Epistar Corp. v. Int'l Trade Com'n, 566 F.3d 1321, 1335-36 (Fed. Cir. 2009) (citing Ventana Med. Sys., Inc. v. Biogenex Labs., Inc., 473 F.3d 1173, 1180-81 (Fed. Cir. 2006)).

In Epistar, the court agreed with the ALJ that the background section only criticized the use of iridium-tin oxide ("ITO") as a front contact. Epistar, 566 F.3d at 1335. The court agreed with the ALJ that the disputed claim involved the use of ITO as a transparent window layer which "serves a distinct function in an LED [light emitting diode]." Id. For that reason, the court found that "this case does not present an instance where the inventor distinguishes an invention over prior art in an unmistakable disavowal of those prior art features." Id. at 1336. Here, no such distinction can be made. The '577 Patent describes several significant disadvantages from using the marked system. Quad/Tech now seeks to enjoin Defendants from selling a registration control system that operates solely with registration marks and cannot operate in markless mode.

In Ventana, the issue was the proper construction of the term "dispensing" in a patent claiming automated methods for staining microscope slides. Ventana, 473 F.3d at 1176. The district court construed "dispensing" to require "direct dispensing," because the embodiments in the specification involved direct dispensing. Id. at 1178. On appeal, the defendant argued that the specification, when read in its entirety, would lead to the "inescapable conclusion" that the heart of the invention involved "direct dispensing," and that the specification implicitly defined the term "dispensing" to mean "direct dispensing." The court disagreed, finding that the Background section of the patent in suit discussed different dispensing techniques, including a device that employed a "direct dispensing" technique. The court found that the defendant's argument could not be correct, because if it was, "the inventors have also disavowed coverage of 'direct dispensing,' which is the type of dispensing employed by the patent's preferred embodiment." Here, the '577 Patent does not reject a registration system that explicitly used registration marks. Thus, Ventana is distinguishable.

In the present case, the specification notes in the Background Section the benefits of a markless system and repeats its attributes. The inventors makes it clear that the attributes of the markless system are important in distinguishing the prior art. The prior art of the marked registration is clearly disparaged and disclaimed.

In sum, the Court finds that Epistar and Ventana are distinguishable because the present case involves much more than "general statements by the inventors indicating that the invention is intended to improve upon prior art . . . "Id. The present case is one like SafeTCare where the Court in construing the claims is "rely[ing] on the specification merely to understand what the patentee has claimed and disclaimed." SafeTCare Manufacturing, Inc. v. Tele-Made, Inc., 497 F.3d 1262, 1270 (Fed. Cir. 2007). The Court finds that the specification makes it clear that what was claimed was markless registration and what was disclaimed is the marked registration.

--- End Footnotes ---

Moreover, Quad/Tech's proposed construction ("the optical counterpart derived from a source" including "registration marks") contradicts the way the term "image" is used in the '577 Patent, is broader than the '577 Patent, relies on extrinsic sources and conflicts with the '577 Patent creators own admissions. Importantly, the '577 Patent inventors have described the '577 Patent as a "markless registration control system." In a sworn declaration in U.S. Patent No. 6,792,240 (240...
Patent), which is owned by QuadTech and invented by Jeffery Sainio, John Seymour and Randall Freeman, describe the '577 Patent: "The markless registration control system . . . described in U.S. Pat. No. [] 5,412,577 . . . use[s] the printed image itself as the source of registration." ('240 Patent specification 3:33-35.) Thus, Quad/tech and the patent inventors confirmed that the scope of the '577 Patent is a "markless registration control system."

In summary, after considering the relevant language of Claim 29, the ordinary and customary meaning of "image" and the written specification of the '577 Patent, the Court construes the term "image" in Claim 29 as: the actual printed image (i.e., a scene or picture) excluding registration marks. 11

--- Footnotes ---
11 As described supra, the Court need not construe any of the remaining claims in Claim 29.

--- End Footnotes ---

C. Whether the images must be still?

(Construction of category (3) terms: "image" and related terms)

St. Clair proposes that the term "image," as used, for example, in claim 16 of the '459 patent, does not require construction and means "image." Defendants, on the other hand, argue that "image" should be construed as "still picture." I agree with St. Clair that no construction is necessary, and certainly not a construction that would limit the claims to "still pictures."

Although the Court has not been asked in the prior cases to construe the claim term "image" (D.I. 259 at 31; Tr. at 149), in resolving other issues in the Canon Construction Judge Farnan wrote: "neither the specification nor the language of the claims imposes a still picture limitation on the patented invention and the specification expressly contemplates the camera's capability to take both still and motion pictures." 2004 U.S. Dist. LEXIS 17489, 2004 WL 1941340, at *7. I agree with Judge Farnan's reading of the claims and the specification. 11

--- Footnotes ---
11 Defendants insist that Judge Farnan's conclusion was reached pursuant to a now-obsolete legal framework, and that, post-Phillips, a court may not conclude that an embodiment is within the scope of a patent claim simply based on the absence of anything in the patent excluding that embodiment. I need not decide whether Defendants have correctly stated the law. Here, as will be explained, I find sufficient affirmative indications in the patent to conclude that the inventors included movie images within the scope of the asserted claims.

--- End Footnotes ---

It is true, as Defendants observe, that the word "'image' . . . is always used in its singular form in the asserted claims of the Patents-In-Suit." (D.I. 259 at 32) However, as St. Clair responds, the Federal Circuit "has repeatedly emphasized that an indefinite article 'a' or 'an' in patent parlance carries the meaning of 'one or more' in open-ended claims containing the transitional phrase 'comprising.'" Baldwin Graphic Sys., Inc. v. Siebert, Inc., 512 F.3d 1338, 1342 (Fed. Cir. 2008). Therefore, as St. Clair concludes, "the use of the term 'image' . . . in a singular form in the claim does not limit the claims to a single still image." (D.I. 283 at 36) The claim limitation "image" also includes multiple images as well as movie images that might contain other data (e.g., difference coding).

The specification contains several references to how the patented camera might be used to take movies. The specification references two movie compression schemes:

In the preferred embodiment of the present invention, the JPEG standard is the preferred algorithm chosen with the incorporation of the MPEG [Motion Picture Experts Group] standard or other similar standard in the future when available
commercially. An alternate embodiment of the present invention would be the incorporation of various proprietary compression algorithm standards such as DVI [Digital Video Interface].

'010 patent, col. 10 lines 23-29 (emphasis added). The specification also states: "a new international standard called MPEG is due to be announced in the 1991 time frame from the JPEG and should offer compression ratios of 275:1 and greater." '010 patent, col. 10 lines 20-23. A compression ratio of 275:1 is achieved only when processing movie images. (Tr. at 26 (describing plaintiff's expert's testimony); Tr. at 163 (defense counsel acknowledging JPEG does not go as high as 275:1 compression)) In light of these statements, excluding movie images from the claims would exclude a preferred embodiment, something which rarely occurs when claims are properly construed. See Chimie v. PPG Indus., Inc. 402 F.3d 1371, 1377 (Fed. Cir. 2005).

There is also much discussion in the specification about the ability of the disclosed "electronic still camera" to rapidly capture multiple images. The specification states that the camera circuitry of a preferred embodiment "allows for approximately 20 images to be captured in a one second period." '010 patent, col. 8 lines 18-19. The "object of this invention is to provide an electronic still camera device that can rapidly capture a series of images automatically as well as singularly." '010 patent, col. 2 lines 31-33. Defendants assert that, in 1990, one having ordinary skill in the art would understand that "rapid capture" of multiple still images involved a qualitatively different process than taking "full-motion video." Even assuming, however, Defendants are correct, no reason has been given for why a still camera capable of rapid capture could not also be capable of capturing "full-motion video." To the contrary, it appears that any electronic camera that can capture a single, still image is an electronic still camera, whether or not it can also perform "rapid capture" and/or capture "full-motion video." Nor have Defendants identified any portion of the claims, specification, or prosecution history suggesting that the patentees intended -- or one having ordinary skill in the art would understand them to have intended -- not to claim movie images as part of the asserted claims.

Defendants argue that construing "image" to include movie images would render the claims invalid under 35 U.S.C. § 112 for lack of adequate description, and would improperly permit Defendants to patent an invention they did not yet "possess" (since MPEG had not been introduced at the time the patent was granted). These arguments go to the validity of the patents, not claim construction. See Ampex Corp. v. Eastman Kodak Co., 460 F. Supp. 2d 541, 543 n.1 (D. Del. 2006) ("The validity of a claim is not an issue of claim construction . . . . I will not convert Defendants' claim construction argument into a motion for summary judgment."). In any event, Federal Circuit "case law allows for after-arising technology to be captured within the literal scope of valid claims that are drafted broadly enough." Innogenetics N.V. v. Abbott Labs., 512 F.3d 1363, 1371-72 (Fed. Cir. 2008).

Finally, both sides offered extrinsic evidence to support their contentions as to the import of the specification's references to MPEG and DVI. Unsurprisingly, the parties' experts do not agree with one another. Compare D.I. 260 Ex. 44 at P 16 (Plaintiff's expert, Gafford, opining that one of skill in art would read specification as suggesting inclusion of image file movie formats when available commercially) with D.I. 282 at 22 (explained that defense experts opine that one of skill in art would understand references to MPEG and DVI "as being illustrative of alternative compression algorithms" for still images, not movie images) (citing D.I. 284 Ex. O at P 4; id. Ex. Q at P 9). In reaching my conclusion, I have reviewed and considered this extrinsic evidence, but I have placed far greater weight on the intrinsic evidence in the record.

Accordingly, I agree with St. Clair that "image" and the related disputed claim terms are not limited to "still images" and do not require construction.

2053

1. "Image" (claims 1, 2, 21)

The parties take positions in the construction of "image" in the 182 patent similar to those they took in construction of the 377 patent. Cytyc argues for a narrow construction, "a digital representation obtained by scanning," while TriPath argues for a broad one, "a thing actually or seemingly reproducing another, such as the optical counterpart of an object produced by an optical device (a lens or mirror) or an electronic device." The debate here, however, differs from that surrounding the 377 patent in that the parties disagree only over the definition of "image" with respect to the second scan mentioned in claims 1(d) and (e), 2, and 21.
TriPath concedes that the term "first image" in claims 1(b), 2, and 21 means digital representation obtained by scanning. "First image" refers to the image captured during the initial low resolution scan of the slides described in the specification. 182 patent at col. 2, 11. 28-33. TriPath then contends that "second image", which is the image obtained by the camera during the high resolution scan, need not be a digital representation. This distinction between the first and second images is unsubstantiated.

If the first image is digital, it follows that the second must also be digital. Claim 1(b) reads "obtaining a first image." Similarly, claim 1(d) reads "obtaining a second image." Claim terms "are normally used consistently throughout the patent" Phillips, 415 F.3d at 1314, and "should be interpreted consistently", Digital Biometrics, Inc. v. Identix, Inc., 149 F.3d 1335, 1345 (Fed. Cir. 1998). There is no difference in the claim language here that would suggest a different meaning for the term "image." Furthermore, both the first and second image serve identical functions in the invention: to provide a representation of the specimen upon which the processor can perform a classification. If the second image were not also digital, it could not be processed by the device.

The language of the claims make clear that the "second image" must be a digital representation. The word "obtain" used in claim 1(d) means "to gain or attain possession." Webster's Third New International Dictionary 1559 (1986). This general definition finds support in the specification, which uses "obtain" and "capture" interchangeably to describe how the invention acquires an image that is capable of processing. 182 patent at col. 2, 11. 18, 20; col. 7, 1. 12. The broad definition that TriPath calls for includes images, such as those produced by looking through the lens of a microscope, that are not fixed in any tangible fashion. They exist only when viewed by the human eye. Such an image is not capable of being "obtained" or "captured", and thus cannot be classified by an image processor or a neurocomputer as called for in the claims and the specification.

TriPath argues that the images need not be obtained in digital form; that they could be captured in some other, non-electronic medium. It insists that the digital images described in the specification are merely the preferred embodiment, and should not be imported into the claims as a limitation. See Phillips, 415 F.3d at 1323. The question for a court is "whether a person of skill in the art would understand the embodiments to define the outer limits of the claim term or merely to be exemplary in nature." Id.

A person of ordinary skill would understand that the references to digital images in the specification are not just one possible variation of the invention, but its substantive boundary. The first reference to "images" in the Detailed Description of the Invention is in the description of the camera: "a camera for obtaining electronic images from the optical microscope." 182 patent at col. 3, 11. 30-33. The specification makes a point of noting that the images obtained by the camera are electronic or digital. Id. at col. 4, 11. 14-15; col. 2, 11. 25-33; col. 7, 11. 11-13. It is these electronic images that the device uses to perform the three scans. The patent describes no other images used for any other purpose.

The Summary of the Invention, which is not a preferred embodiment, but a concise description of the entire claimed invention as conceived at the time of filing, specifically mentions digital images and repeatedly refers to images that can be processed n7. Id. at col. 1, 1. 65 -- col. 2, 1. 55. Moreover, the word "image" appears one hundred sixty-one times in the patent. Each reference either implicitly or explicitly indicates that it is a digital representation. Although it is possible that the image of the specimen viewed through the lens of the optical microscope is not digital, there is no indication in the claims or written description that the device uses those images to perform the classifications described in the claims 1 and 21.

--- Footnotes ---

n7 The Summary of Invention "should, when set forth, be commensurate with the invention as claimed and any object recited should be that of the invention as claimed . . . The brief summary, if properly written to set out the exact nature, operation, and purpose of the invention, will be of material assistance in aiding ready understanding of the patent in future searches." Manual of Patent Examining Procedure, § 608.01(d)(2004).

--- End Footnotes ---

In defense of its proposed construction, TriPath contends that the patentee in no way disavowed a broad definition of
"image" during the prosecution. Cytyc points out in response that the applicant failed to reply when the patent examiner found the invention to be novel because "[the prior art] fail to disclose obtaining and displaying a second image by scanning." 182 File History at 169, 177(emphasis added).

TriPath is correct that the applicant had no duty to respond to the patent examiner's unilateral reasons for allowance, and thus disavowed nothing. See Salazar v. Procter & Gamble Co., 414 F.3d 1342, 1345 (2005)(holding that "an applicant's silence regarding statements made by the examiner during prosecution, without more, cannot amount to a clear and unmistakable disavowal' of claim scope.")(internal citations omitted) n8. However, the patent examiner's interpretation of the term "image" is not irrelevant to claim construction: "Statements about a claim term made by an examiner during prosecution of an application may be evidence of how one of skill in the art understood the term at the time the application was filed." Id. at 1347. The patent examiner's assumption that the image is obtained by scanning further supports the conclusion that one skilled in the art would understand the term "image" as used in claims 1, 2, and 21 to mean digital representation.

--- Footnotes ---

n8 Cytyc argues that Elkay Manufacturing Co. v. Ebco Manufacturing Co., 192 F.3d 973 (1999), applies here instead of Salazar. In Elkay, the patentee failed to respond to the Examiner's Statement of Reasons for Allowance in which the examiner explicitly approved a narrower set of claims than originally presented. Elkay then later argued for a broad claim construction that contradicted the claims as limited during prosecution. The court held that Elkay was estopped from arguing for a broad construction because he had disavowed it during prosecution. Elkay, 192 F.3d at 979.

Here, the examiner did not approve the 182 patent based on a narrow definition of "image". The examiner approved the 182 patent because it contained a second image, where the prior art contained only one. 182 File History at 177 (noting that "in the prior art of record, only one image is obtained"). Under Elkay, this record estops TriPath from arguing that the 182 patent claims only one image, but TriPath remains free to argue that the image is not necessarily obtained by scanning.

--- End Footnotes ---

Finally, returning to the claims themselves, the "usage of a term in one claim can often illuminate the meaning of the same term in other claims." Phillips, 415 F.3d at 1314. Although the claims at issue do not explicitly describe the images as digital, claim 11 does. Claim 11 reads, in relevant part:

A method of classifying objects in a cytological specimen; comprising the steps of:

a) obtaining a first digital representation of at least part of such cytological specimen;

b) storing such digital representation;

c) performing a first filtering operation to filter out images in such representation that are the approximate size of a malignant or premalignant cell or smaller to produce a second digital representation;

d) removing the images in such second representation from the images in such first representation to produce a third representation.

Id. at col. 15, 11. 13-24. (emphasis added). TriPath points out that the use of the term "digital representation" shows that the patent differentiates between "digital representation" and "image." Although true, this observation does not lead to the conclusion that an "image" cannot be digital. To the contrary, the language implies that the "image" must be digital. Claim 11(c), for example, states "to filter out images in such representation" (emphasis added). "Representation" logically refers to the "digital representation" in claim 11(b). Thus, the "image" must be a smaller part of the digital representation if it is to be "filtered out." The specification supports this reading when it describes "obtaining a first digital representation" followed by a "filtering operation to filter out images in the representation." 182 patent at col. 2, 11. 27-32.

In sum, taking a "claims up" approach, the term "image" as used in claims 1, 2, and 21 refers to a digital representation.
5. "Image" is construed to mean "the imitation of the external form of an object."

D. Ref. No. 81 "Ballot image," "image of the ballot," "image of each paper ballot," "image thereof."

These terms or phrases are recited in or referred to in Claims 13, 14, 16, 19, 33, and 47.

The Court has construed the term "imaging," "image," and "imaged" in Ref. No. 56 of the '944 Patent as follows: "Electronically capturing and reproducing images and data from a ballot in a pixilated or bitmapped format." The parties agree that the instant terms in Ref. No. 81 must be construed consistently with the Court's previous construction of variations of the term "image." The dispute here is whether the entire ballot must be imaged or only portions of the ballot must be imaged.

The specification teaches that "[o]nly the images of the [voter identifier] and mark space zones need be obtained and stored for tabulating and/or verifying voting by vote counter. Images of the [voter identifier] and mark space zones may be stored in any suitable electronic format . . . ." (Col. 15, ll. 21-25.) "The ballot reader produces a ballot image, whether of the entire ballot or only portions thereof selected in accordance with the applicable ballot template, that is preferably in a pixilated or bitmapped format, e.g., a TIFF or a BMP image, or other bitmapped format." (Col. 22, l. 65 to Col. 23, l. 2.)

The use of the term "a viewable" ballot has been discussed in Ref. No. 69 herein, and the Court found that there is no support for this term in the patent specification. Defendants' construction is supported by the specification language and intent.

Accordingly, the Court has construes the terms in Ref. No. 81 as follows:

An electronic representation of all or a portion of a paper ballot, including a representation of the jurisdiction identifier and at least one voting selection, which representation is stored in a pixilated or bitmapped format.

2. Displaying a map image with image coordinates corresponding to the geographic coordinates

The parties dispute nearly every term in this limitation. Specifically, they disagree on the meaning of "map image," "image coordinates, and "corresponding," as well as the meaning of the limitation as a whole. The court will address each of the parties' disputes.

Beginning with the term "map image," the plaintiff contends that the term means "a representation of a flood map, such as a FEMA flood map, stored as a grid of pixels." Based on the prosecution history, the defendants contend the phrase "map image with image coordinates" is limited to "a georeferenced raster map image."

With respect to the prosecution history, the plaintiff concedes that it surrendered vector maps during prosecution, yet asserts that the scope of the surrender is limited to vector maps. The court agrees. The court observes that dependent claim 5 requires a map image that is "a digital raster image." 326 patent, claim 5. Claim differentiation counsels a broader construction for independent claim 1 than for claim 5. The court therefore construes the term "map image" to mean "a representation of a flood map, such as a FEMA flood map, stored as a grid of pixels."

The next dispute involves the term "image coordinates." The plaintiff suggests that the term means "locations that define the
position of a point on an image." The defendants, building on their argument that the claim is limited to raster maps, contend that term "image coordinates" means "X, Y pixel locations (row, column intersections) that make up a raster image." The court has rejected that argument and therefore adopts the plaintiff's proposed construction of "image coordinates."

GO BACK

2057

2. "Image Data"

The third element of claim 64 recites the step of "providing an image store comprising storage for image data comprising pixel values of pixels defining an image."

Adobe interprets "image data" as "data representing the then-current state of the image being shown on the monitor, such that there is a one-to-one correspondence between pixels represented by the image data and the pixels that appear on the monitor." Quantel contends that "image data" is an electronic image stored in the image store where data can be found when needed.

Adobe's interpretation is supported by other recitations in claim 64. To wit, the fourth element of claim 64 recites that, in each processing operation, the processor retrieves image data from the store, processes the retrieved image data with brush data to combine the image and brush data, and then "stores the processed image data in said store in place of the image data used in the processing operation." Thus, it is clear that at every instant during a given stroke "image data" is data representing the current state of the image displayed on the screen that corresponds in a one-to-one relationship with the pixels on displayed on the screen.

At trial, Mr. Taylor testified that a person of ordinary skill in the art at the time of the '755 invention would have understood the term "image data" to mean data from which an image may be derived, in contrast to the term "displayed image," which such a person would have understood to mean the image appearing on the screen. Tr. at 53-53. Such extrinsic evidence, however, can never alter the meaning of a term where, as here, the claim language, on which the public has a right to rely, establishes the term's meaning. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996).

GO BACK

2058

b. "Image Display Device"

The next disputed term in claim 15 is "image display device." n3 IP argues that this term includes printers, whereas Lexmark and Dell contend that it encompasses only devices that display a video image on a screen. Both sides look to the prosecution history of the 780 patent to support their respective positions.

n3 IP considers the operative phrase to be only "display device," but there is no indication that a display device would display anything but an image. Accordingly, though our analysis would be the same if the term "image" were excluded, we will treat the operative phrase as consisting of the full "image display device."

During prosecution, Cooper sought to add a description of printers to the original specification, new claims that included printers, and a new figure. The original examiner more than once rejected the amendments as new matter. Cooper eventually petitioned the Commissioner for Patents to overrule the rejections, but the petition was dismissed because his request should have been directed to the Board of Patent Appeals and Interferences.

Cooper cancelled the relevant claims and figure and petitioned the Commissioner again. However, he did not remove all references to printers in the specification. This time, the Commissioner found the petition was moot because the "new
subject matters had either been deleted or cancelled by the petitioner." See S/N 07/355,461 Commissioner's Decision 1/24/94 at 1. Before the Commissioner issued this decision, Cooper filed a continuation application, which was assigned to a new examiner, who never officially withdrew the previous new matter rejections. Some of the terms the prior examiner found objectionable appear in the patent as issued. Lexmark and Dell argue that the rejections relating to printer terminology in the patent should exclude printers because the new matter rejections were never officially withdrawn. Although the prosecution history is less than pristine in this case, we disagree with Lexmark and Dell on its overall effect on this issue for several reasons.

First and foremost, Lexmark and Dell's argument would require us to ignore the references to printers within the specification, in essence writing them out of the patent entirely, which is not a proper exercise in circumstances such as these. See Purdue Pharma L.P. v. Boehringer Ingelheim GMBH, 237 F.3d 1359, 1364 (Fed. Cir. 2001) (refusing to limit claims to single-dose administrations of medication when specification made reference to both single and multiple doses). Second, the language of dependent claim 109 indicates that video monitors are but one kind of display device. n4 The doctrine of claim differentiation creates a presumption that each claim in a patent differs in scope from any other claim. See Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1187 (Fed. Cir. 1998). When applied in the context of dependent and independent claims, the doctrine generally leads to a conclusion that dependent claims are narrower than the claim on which they depend. Phillips, 415 F.3d at 1315. The presumption is extremely strong when the only meaningful difference between the independent and dependent claims is the limitation at issue, and one party is requesting that the limitation present in the dependent claim be imported into the independent claim. See Sunrace Roots Enterprise Co., Ltd. v. SRAM Corp., 336 F.3d 1298, 1303 (Fed. Cir. 2003). To construe the claims in another fashion would typically render the dependent claims superfluous, a result we must strive to avoid. See Comark, 156 F.3d at 1187. Here, the limitation that Lexmark and Dell contend to be omnipresent in the term "image display device" is the very limitation made explicit in claim 109. Thus, the presumption that "image display device" applies to devices other than video monitors weighs particularly heavily in favor of IP's construction.

Third, Lexmark and Dell's primary support for their argument comes from a definition of "display" n5 that states, in pertinent part:

1. A visible representation of information in words, numbers or drawings, as on the cathode-ray tube screen of a radar set, navigation system, or computer console.

2. The device on which the information is projected. Also known as display device.

Moreover, extrinsic evidence must be considered in the context of the intrinsic evidence. See id. at 1319. When so viewed,
the definition upon which Lexmark & Dell rely actually supports the conclusion that printers can be considered a "display device." The most natural reading of the definition reveals that the examples given are illustrative, not exhaustive. Printers, particularly laser printers, are capable of projecting a visible representation of information onto paper. Accordingly, we cannot agree with Lexmark and Dell that this definition excludes printers from its scope.

Lastly, in support of their argument, Lexmark and Dell rely on Dresser Indus., Inc. v. United States, 432 F.2d 787, 193 Ct. Cl. 140 (Ct. Cl. 1970), in which the patentee filed a § 312 amendment that redefined certain terms in a way that was inconsistent with the original specification. In that case, the court did not use the new language because it was clear that the amended text constituted new matter. Id. at 794. Here, by contrast, the history does not unequivocally indicate that a person of ordinary skill in the art would not have understood that the invention applied to printers.

Therefore, the court defines "image display device" as follows: a device for providing an image that may be viewed by a viewer. This construction will apply equally to the use of this term in claim 109 of the 780 patent.

2059

1. "Image server": "A computer server that stores image files and provides them, via the internet, to one or more web browsers." This construction is consistent with the specification: Figs. 1 and 2; col. 10, ll. 8-12; col. 11, ll. 8-12.

2060

c. "Pixel" and "Image Element"

The next two terms we must consider, "pixel" and "image element," are undeniably related, but the issue we need to decide is the extent of their similarity. IP differentiates between these two concepts; Lexmark and Dell ask that they be considered synonymous. n6 According to IP, "pixel" refers to the smallest complete element of an image, and it can be formed of subpixels that contribute to the formation of a complete element but that are not complete in themselves. IP urges a broader construction for "image element" as any element found within an image, including complete pixels, portions of pixels, and other elements of images that are not pixel-related. n7 Lexmark and Dell insist that "pixel" and "image element" are interchangeable. In their opinion, both terms refer to the smallest electronically coded part of an electronically coded input image. When the terms are used in the context of discussing a display device, Lexmark and Dell argue that they must mean the smallest addressable element of the display device.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - 

n6 In the joint claim construction chart, the parties also indicate that the meaning of the term "plurality" is disputed, but they offer no development of that issue. In light of the absence of a crystallized dispute, we offer no construction of that term.

n7 Examples could include the RGB components of a video signal or the yellow, cyan, and magenta components of a single pixel used in color laser printing.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

An examination of the intrinsic evidence reveals that IP has the better argument. For example, the specification of the 780 patent states that "voids in the image may be filled with all or a portion of a pixel," which is consistent with IP's position that pixels can be formed of subpixels. U.S. Patent No. 5,424,780, col. 4, Ins. 50-51; see also col. 5, Ins. 48-50 ("New pixels or pixels used for filling, substitution or replacement may be comprised of all or a portion of a pixel."). Examples could include the RGB components of a video signal or the yellow, cyan, and magenta components of a single pixel used in laser printing.

Although in many circumstances the patents use the terms interchangeably, that is not inconsistent with IP's proposed definitions, wherein all pixels are image elements, but not all image elements are pixels. Though the intrinsic evidence from
the 780 patent does not provide a great deal of illumination on these issues, the language of the 637 patent directly supports IP's position. The parties agree, and we concur, that the terms "image element" and "pixel" should be construed consistently as to both patents, so the guidance provided by the 637 patent clarifies the meaning of these terms in the 780 patent as well. Dependent claims 34, 51, 140, and 161 all have one limitation that states: "image elements are pixels." Here again, the doctrine of claim differentiation provides helpful guidance. See Comark, 156 F.3d at 1187. When applied to these four claims, the doctrine supports the conclusion that the image elements referenced in the independent claim are not always pixels, which indicates that they should not be treated as synonyms.

Furthermore, though the intrinsic evidence gives no indication that Cooper intended these terms to carry an idiosyncratic meaning, Lexmark and Dell's proposed definition adds in requirements that pixels and image elements must be an addressable element contained in electronically coded input image. They have not provided convincing support that these aspects are included in the ordinary and customary meaning of these terms, nor have they shown that Cooper intended to use these terms in an idiosyncratic way. See Phillips, 415 F.3d at 1312.

Therefore, we construe "pixel" to mean the smallest complete element of an image and "image element" to mean any element of an image, whether complete or not and whether pixel-related or not.

2061

ii. Image Element

The parties next dispute the meaning of "image element," as used in claims 15, 110, and 146 of the '780 patent, claims 1 and 107 of the '637 patent, and claims 4 and 10 of the '964 patent. Though the parties' interpretations vary, they concur that the Court should adopt a uniform meaning for the term.

IP defines "image element" as encompassing complete pixels, as well as sub pixels and other elements of images that are not pixel-related. It submits that although pixel is synonymous with image element, the reverse is not true, as an image element may refer to a sub-pixel or something altogether unrelated to a pixel. Sony, in contrast, urges the Court to adopt identical meanings for the terms pixel and image element, namely, the smallest part of an electronically coded picture image or the smallest addressable element in an electronic display.

The Court believes IP's definition more closely aligns with how a person of ordinary skill in the technology would understand the term "image element." Admittedly, in the context of the disputed claims, it is somewhat unclear whether the terms "pixel" and "image element" carry differing meanings. As Sony observes, the patentee appears to frequently use the two terms interchangeably. For example, Sony highlights two descriptions of figure seven in the '780 patent's specification. One describes the figure as depicting "a group of nine neighboring image elements." U.S. Patent No. 5,424,780, col. 3, lines 18-20. Another refers to the same figure as showing "a group of 9 pixels which are located on 3 scan lines of a raster." Id. at col. 7, lines 26-27. This example, however, is not necessarily inconsistent with IP's construction. As IP suggests, all pixels may be image elements, but not all image elements are necessarily pixels. Thus the fact that the patentee uses both terms to describe the items in the figure does not run counter to IP's position. Sony also argues that the patent directly equates the two terms when it describes "spatial resolution" as "the number of elements or pixels [that] make up an image." But again, this excerpt does not conclusively support Sony's position.

Moreover, the use of "image element" in unasserted claims clearly supports IP's interpretation. In the '637 patent, claim 127 repeatedly refers to the term "image elements." Claim 140 of that same patent discloses "The method of claim 127 wherein the image elements are pixels." As a dependent claim, claim 140 must be narrower in scope than claim 127. If the patent used image element and pixel interchangeably, it would violate the doctrine of claim differentiation by rendering claim 140 wholly superfluous. Furthermore, the patentee is entitled to a presumption that there is a difference in meaning and scope when different words are used in separate claims. See Tandon Corp. v. United States Int'l Trade Comm'n, 831 F.2d 1017, 1023 (Fed. Cir. 1987); see also Power Mosfet Techs., L.L.C. v. Siemens AG, 378 F.3d 1396, 1410 (Fed. Cir. 2004). In particular, where "the absence of such difference in meaning and scope would make a claim superfluous, the doctrine of claim differentiation states the presumption that the difference between claims is significant." Tandon Corp, 831 F.2d at 1023. Finally, the Court notes that IP's interpretation is in accord with the only dictionary definition submitted by the parties n2. The Court therefore accepts IP's definition of "image element" as encompassing complete pixels, as well as sub
pixels, and other elements of images that are not pixel related.

n2 Tech-Notes Glossary of Broadcast Terms' definition of "pixel" includes the following excerpts differentiating the terms pixel and image element:

Many unskilled people, and sometimes skilled people, incorrectly use pixel and image element interchangeably, or use pixel to refer to sub-parts. Unskilled people don't know any better and the skilled people know better but because the meaning is clear from the context do so anyway. Many dictionaries also get it wrong.

Image elements is a broader term than pixels and is also highly context sensitive. Image elements includes both complete pixels as well as those various sub-parts of pixels and other elements of images which are not pixel related such as DCI coefficients. For example, it is correct to say that the red part of an RGB pixel is an image element but it is not normally considered correct to refer to the red part as a pixel itself (although persons who are not skilled in the television industry often do).

When someone says a pixel is the smallest part of an image, that statement is incorrect if the image is made up of pixels having sub-parts, but is correct if the pixel is the smallest element ... Consequently one can say something like pixels and image elements are essentially the same when talking about technology when the pixel is the smallest part but can disagree that they are the same when talking about technology when the pixels s made up of sub-parts. This tends to confuse the hell out of unskilled people who can't pick up on the intended meaning from the context of the usage.

Tech-Notes Glossary of Broadcast Terms, at http://www.tech-notes.tv. No argument has been made that it is improper to consider this online dictionary definition, however the Court notes that even if it were to disregard this definition, the same outcome would be reached.

GO BACK

2062

With these commonly agreed definitions in mind, we turn to the term "image source." There is no dispute that, as a general matter, "real objects" -- those three dimensional solids we encounter in consensual reality -- may serve as "image sources" for an image-forming optical system. See id. at 33. An apple placed before a mirror gives rise to a virtual image, and thus, in one sense, may be considered an "image source." But this is not how the term "image source" is used in the claims of the '818 Patent; and it is axiomatic that proper claim construction begins, and frequently ends, with the claim language itself. See, e.g., Renishaw PLC v. Marposs Societa' Per Azioni, 158 F.3d 1243, 1248 (Fed. Cir. 1998); Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Furthermore, it is well-established that "a patentee is free to be his or her own lexicographer," provided the selected definition is made apparent in the patent specifications. Hormone Research Found., Inc. v. Genentech, Inc., 904 F.2d 1558, 1563 (Fed. Cir. 1990).

Claim One of the '818 Patent states that both the first and second image sources are "equipped and positioned to display" either a first or second image, which is then directed toward either the front or back of the beam splitter. Thus, only those "real objects" that are capable of generating images themselves may serve as "image sources" in the '818 Patent, for it is obvious that "real objects" like apples or baseballs do not generate or "display" images. As noted above, both sides agree that "images" are "reproductions" of objects, not the objects themselves.

While video monitors or projectors are certainly "real objects," they are distinguished by their specific ability to generate images -- what the '818 Patent defines as "screen-borne images" or "projection-based images as from a film-projector, a slide projector, or a video unit." See Detailed Description of the Invention, '818 Patent Specifications, Col. 7, Lines 24-25. Claim Nine, for example, explains that "the second image source is provided with a data stream containing three-dimensional image cues" from which it generates images. It is devices like video monitors and projectors that are so supplied with "data streams," from which they create "screen-borne" images.
Accordingly, the Court interprets the claim term "image source" in Patent '818 as denoting a device, such as a video monitor or projector, that can generate screen-borne images.

4. An image source attribute that specifies a web site traffic path analysis data location (First appearing in claim 1 at col. 12, ll. 52-53; and as used similarly in claims 8-11, 18-20, 22, 29-31)

Though characterized by the parties as a minor dispute, Websidestory and Netratings have not agreed to a construction of the term "an image source attribute that specifies a website traffic path analysis data location." See Joint Claims Construction Chart at 1. Websidestory contends the term should be construed as "the named location for the graphical element that specifies a website traffic path analysis data location." Joint Claims Construction Chart at 1. Netratings contends that the term should be construed to mean "a uniform resource locator of a location where website traffic path analysis data is sent to and received from and where the graphical element is stored." Joint Claims Construction Chart at 1.

The Court notes initially that a large part of this disputed phrase consists of the previously construed phrase "website traffic path analysis data." The Court also notes that the section of this disputed phrase which reads "that specifies a website traffic path analysis data location" is not ambiguous in light of the Court's previous construction of the term "website traffic path analysis data" and the ordinary and customary meaning of the words "specifies" and "location." The parties' primary dispute here centers on the meaning of "an image source attribute."

The parties agree that "an image source attribute" refers to the location of the graphical element, and both proposed constructions include the "location of the graphical element" as part of the definition. Netratings' proposed construction adds the language "a uniform resource locator of a location where website traffic path analysis data is sent to and received." Websidestory contends that Netratings' proposed construction improperly limits the scope of the claims, defies logic, and unnecessarily injects ambiguity into the claim. Netratings contends that the '479 Patent's claims and specification require the Court to adopt Netratings' proposed construction.

In support of their proposed constructions, both parties rely on the '479 Patent specification, and neither party cites to the claims. After reading the claims in light of this disputed phrase, the Court finds that the claims are of little help in construing "an image source attribute." The specification, on the other hand, does shed light on the meaning the phrase. Specifically, the description of the preferred embodiment section of the specification notes that, "[t]hose skilled in the art will understand that a graphical element such as an image on a web page must be specified by the location of an image source file, which the browser will request when it attempts to display the web page." Patent at col. 6, ll. 48-52. Thereafter, the specification states that a tagged web page "includes a graphical element that specifies an image source file . . . ." Patent at col. 6, ll. 54-56. After considering that language in the context of the '479 Patent's claims, the Court concludes that "an image source attribute" should be construed as "the named location for the graphical element."

The Court concludes that "an image source attribute" does not require reference to a uniform resource locator, or language describing a location where data is sent and received from. Netratings draws support for inclusion of uniform resource locator from the background section of the specification. However, uniform resource locator is used in the background section of the specification to describe the internet based analysis tools method which the '479 Patent intended to displace. Furthermore, as noted by Websidestory at oral argument, utilizing uniform resource locator could impermissibly limit the scope of the '479 Patent in regards to its use in conjunction with Intranets. Tr. at 39. The Court concludes that Netratings' proposed construction which includes language regarding a location where "data is sent to and received from" is not required by the claim language.

After considering the Patent, the parties' arguments, and the prosecution history, the Court adopts Websidestory's proposed construction of the term "an image source attribute that specifies a website traffic path analysis data location," and concludes that the acquired meaning of the term is "the named location for the graphical element that specifies a website traffic path analysis data location."
The source of disagreement is the definition of the word "image" as used in claim 18. Cytyc would limit the term to "digital representations presented to the cytologist on a display monitor." TriPath argues for a broader definition: "displaying a reproduction, such as an optical counterpart, of an object produced by an optical device (as a lens or mirror) or an electronic device."

Starting once again with the terms themselves, claim 18 claims "the step of presenting images of objects to a human corresponding to one or more of the identified locations." The word "presenting" suggests that there must be a mechanism for displaying the images to the human. This narrows the definition of "image" to representations that can be displayed by the claimed mechanisms. For example, mere objects sitting on a table viewed by the naked human eye are "images" because they are viewed through the lens of the eye, but they do not fit within claim 18 because they are not "presented." Thus, TriPath's proposed definition, which would include displays viewed by the naked eye, is overly broad.

Whether a person of ordinary skill in the art, however, would understand "images" to be limited only to digital representations is a harder question. The word "image" or "images" appears one hundred forty-five times in the patent. Of those references, only ten do not imply a digital display. Seven of these ten are used to describe the historical difficulties in processing Pap smear specimens. Id. at col. 1, 11. 43-64. The three remaining terms describe the image of the specimens on the slide as viewed through the microscope lens before a camera digitizes it. Id. at col. 13, 1. 34; col. 15, 1. 34.

Because of these three references, TriPath urges that "image" should be construed to include slides as viewed through a microscope as well as digital images. However, claim 18 does not contemplate such a construction. Claim 18 refers to images that are to be presented to a human. The camera digitizes the image immediately after focusing. Neither the claims nor the specification indicate that a human will view the slide through the microscope at any time before it is digitized.

Before limiting the definition of "image" to only digital representations, I must consider the possibility that a person of ordinary skill in the art in 1998, the year the patent application was filed, may have had a different understanding. In highly digitized 2005, it is easy to assume that all images would be digital, but it would be improper to construe the patent in the context of today's technology. See Phillips, 415 F.3d at 1313 ("a court construing a patent claim seeks to accord a claim the meaning it would have to a person of ordinary skill in the art at the time of the invention." (quoting Innova/Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 381 F.3d 1111, 1116 (2004))).

However, a survey of the prior art indicates that a person of ordinary skill in the art in 1998 would have understood the word "image" as used in claim 18 to refer to digital representations. The field of automated cytological screening relied extensively upon computer and digital technology for approximately forty years before the 377 patent application was filed. The first attempt at automated cytological screening occurred in the late 1950's. Nasseem Husain and Keith Watts, "Computerised Cell Scanners," Physics Bulletin 38, 198 (1988). Although largely unsuccessful, even this early system consisted of a scanner that attempted to digitize the image. Id. The three major precursors to the 377 patent, CYBEST, Vikers' Cytology Screening Apparatus, and LEYTAS, invented in the 1960s and 1970s, respectively, each included a computer to digitize images of the specimens and a monitor to display the images as the central components of their systems. See generally, Noboru Tanaka, et. al., "CYBEST Model 4", Analytical and Quantitative Cytology and Histology, Vol. 9, No. 5 (1987); Anneke M. J. Van Driel-Kulker & Johan S. Ploem, "The Use of LEYTAS in Analytical and Quantitative Cytology," IEEE Transactions on Biomedical Engineering, Vol. BME-29, No. 2 (1982).

This history, in addition to the use of "image" in the context of computers throughout the specification and the claims themselves lead to the conclusion that a person of ordinary skill in the field in 1998 would have understood "images" to be digital representations. Following logically, "images of objects" as used in claim 18 are digital representations on a display monitor.

GO BACK
1. Terms relating to images representing pages of a book.

The parties dispute the proper construction of the term "images representing pages of a book" used in claim 1 and the term "plurality of images . . . showing textual information" used in claims 7, 9, and 13. Harpo asserts that these terms require a digital image of the actual pages of a physical book (such as a digital photograph of the book's pages). Harpo's proposed construction is "digital representations of specified real pages of a physical book stored on a file server." Harpo Mem. in Supp. of Summ. J. at 13. ICR contends that the appropriate construction of the term is "a representation of the content of the actual pages of a book." ICR Resp. to Mot. for Summ. J. at 9.

In support of its proposed construction, Harpo argues that the specification of the '252 patent includes only one embodiment of the technology as applied to books: digital images of a physical book. Harpo Mem. in Supp. of Summ. J. at 13. Because the specification only includes one embodiment, Harpo argues, the claims should be construed to be restricted to that embodiment. Id. at 13-14.

Harpo is correct that claims must be read in the context of the specification. Phillips, 415 F.3d at 1315. However, the "particular embodiments appearing in a written description will not be used to limit claim language that has a broader effect." Innova, 381 F.3d at 1117. A claim is limited to the particular embodiment(s) in the specification only when "the intrinsic evidence shows that the patentee distinguished [it] from prior art on the basis of a particular embodiment, expressly disclaimed subject matter, or described a particular embodiment as important to the invention." Edwards Lifesciences LLC v. Cook, Inc., 582 F.3d 1322, 1329 (Fed. Cir. 2009) (citing CSS Fitness, Inc. v. Brunswick, Corp., 288 F.3d 1359, 1366-67 (Fed. Cir. 2002)).

Harpo cites SciMed Life Sys., Inc. v. Adv. Cardiovascular Sys., Inc., 242 F.3d 1337 (Fed. Cir. 2001), to support its view that ICR's claim should be limited to images of the actual pages of a physical book as referenced in the specification. In SciMed, the Federal Circuit affirmed the claim construction by the lower court, which had limited the patent to the embodiment described in the specification. In SciMed, however, the court found that the specification "expressly limits all embodiments of the claimed invention." The patent in this case includes no such express limitation.

Harpo also relies on Edwards Lifesciences LLC v. Cook Inc., 582 F.3d 1322 (Fed. Cir. 2009). In Edwards, an alleged infringer argued that a patent for grafts should be restricted to intraluminal grafts because those were the only grafts described in the specification. The court agreed. In doing so, however, it noted that "the specification consistently [used] the words 'graft' and 'intraluminal graft' interchangeably," the claim language itself supported that interpretation, and "the preferred embodiment [was] described in the specification as the invention itself." Id. at 1329-30. Those factors are not present here. The Court therefore follows Innova's guidance and declines to limit the claims to the preferred embodiment described in the specification.

The Court also notes that elsewhere in the specification, when discussing an embodiment involving an aspirin bottle for sale, the inventor stated that a "representation" of the bottle is not limited to a photograph of the product but could include a drawing made by a computer program. '252 patent, col. 3:17-22. This, as ICR argues, undermines Harpo's argument that the disputed claim language covers only an actual image of the pages of a physical book.

Claim 1 requires "images representing pages of a book." '252 patent, col. 7:44-53 (emphasis added). This language does not support the limitation Harpo seeks; the claim describes a "representation," a term that covers more ground than an image of actual pages of a physical book. The Court concludes that the proper construction of the phrase "images representing pages of a book" is not limited to photographs of the pages of a physical book. Rather, it includes any image that includes contents from a book's pages. The correct construction is "images that show content from the pages of a book."

Harpo similarly argues that the language "plurality of images . . . showing textual information . . . representative of contents of a book" in claims 7, 9 and 13 of the '252 patent requires a digital representation of text from specified real pages of a physical book. Harpo's argument on this language is even weaker than its argument regarding claim 1. The phrase does not support an interpretation that is limited to what would amount to a photograph of the actual pages of a physical book; this would read "textual information . . . representative of contents" out of the claim. The proper construction of the term is
Harpo also asserts that the language of claim 18, properly construed, requires images to be images of the actual pages of a physical book. Claim 18 states:

An apparatus comprising: a computer, providing limited pages of books that can be viewed over a publically available network, and including a connection to the network, and which receives information indicative of at least one desired page of a book over the connection to the network; and returns information indicative of only limited images of pages of the book based on said information; and wherein said computer limits a number of pages that can be displayed.

'252 Patent, col. 9:1-10. Harpo contends that the proper construction of the phrase "receives information indicative of at least one desired page of a book . . . and returns information indicative of only limited images of pages of the book based on said information" is "a request for a page image made over a network specifying a real page of a physical book." Harpo Mem. in Supp. of Summ. J. at 17. This would read the words "indicative of" out of the claim, which is inappropriate. "Information indicative of [a] page" cannot properly be limited to a digital image showing an actual physical page. The phrase is properly read as referring to "images that include content from ages of an actual book." The rest of the language of this portion of claim 18 is self-explanatory and does not require further construction.

A. Ref. No. 56 "Imaging," "Image," and "Imaged."

These terms and phrases are recited or referred to in Claims 1-3, 5, 7, 13, 18-20, 23, 30-32, 42-44, and 49.

Plaintiff contends that these terms should be construed as "electronically reproducing a reviewable representation (image, not just data) of an optically scanned region of a document or portion of a document." Defendants propose "capturing data from a ballot in a pixilated or bitmapped format."

This is a significant dispute between the parties and the arguments are multidimensional. Citing Honeywell Int'l, Inc., 341 F.3d at 1338-40, Defendants first argue that the above terms are not amenable to construction because they are indefinite and invalid under 35 U.S.C. § 112, P 2. "The definiteness requirement of § 112, P 2 focuses on whether the claims, as interpreted in view of the written description, adequately perform their function of notifying the public of the [scope of the] patentee's right to exclude." Id. at 1338 (quoting S3 Inc. v. nVIDIA Corp., 259 F.3d 1364, 1371-72 (Fed. Cir. 2001)) (alteration in original). "Because a claim is presumed to be valid, a claim is indefinite only if the 'claim is insolubly ambiguous, and no narrowing construction can properly be adopted.'" Id., 341 F.3d at 1338-39 (quoting Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001)). The Court does not find the terms "image," "imaging" or "imaged" to be insolubly ambiguous.

Defendants further argue that the terms "image" and "read" are used in an inconsistent manner. The Court acknowledges some overlap; however, a close look at the patent and specification language resolves the issue. Column 15, lines 2-4 provide that the ballot is "read/imaged and the voting information thereon is read/decoded." The specification described Figure 8 as comprising two separate paths -- one for imaging (320a) and one for reading (320b). In addition, in the above references, imaging is associated with decoding (i.e., read/imaged - read/decoded). 7 (Col. 15, ll. 2, 3.) In Figure 8, the ballots are passed through a reader (310). They either then proceed on the imaging path (320a) and are imaged and then decoded or on the reading path where they are passed through the reader and are read (320b). This demonstrates a clear difference between "image" and "read" and connects imaging to decoding. Moreover, decoding is used throughout the patent when discussing imaging. (See Col. 15, ll. 16-32; Col. 15, ll. 51-55; Claim 3; Claim 13; Claims 31, 33, 34, 36-38.) Defendants' invalidity argument is unavailing.

7 The Court does not agree with Defendants' argument concerning Claims 1, 5, and 29. "Read" and "image" are not used interchangeably in these claims.
The patent specification provides that the ballot imaging process described in Figure 8 at 320a "acquire[s] an image of the voting information." (Col. 15, ll. 16-18.) (Alteration added.) The specification provides that the images may be stored in a suitable electronic format including ".BMP,.TIFF, or .PDF or any other suitable format." (Col. 12, ll. 36-49.) This is consistent with the teaching in the '313 Patent that ":[t]he ballot reader produces a ballot image . . . that is preferably in a pixelated or bitmapped format, e.g., a TIFF or a BMP image, or other bitmapped format. Ballot images in such format may be produced directly by a commercially available office copier or scanner or may be converted to such format . . . ." ('313 Patent, Col. 22, l. 60-Col. 23, ll. 1-6.) As noted by Defendants, in the prosecution of the '313 Patent, Plaintiff distinguished it from a pending claim in another patent, "the Stewart Patent." (Defs. Ex. 6A at 31-42.) "Nothing in Stewart describes or suggests imaging a ballot or imaging a ballot in a pixelated or bitmapped format. Nothing is [sic] Stewart describes or suggests determining from an image a jurisdiction identifier and then selecting a template based thereon, or decoding voting selections from the image of the ballot." (Id. at 35.) This is evidence of Plaintiff's reliance on the pixelated and bitmapped formats and evidence that "imaging" includes a viewable electronic reproduction of the ballots.

--- Footnotes ---
8 The parties agree that the term "image" should be construed to mean the same in both the '944 and '313 Patents.

--- End Footnotes ---

In summary, Defendants' indefiniteness argument fails. Reading and imaging are two separate functions and are distinguishable as set out in Figure 8 and in the specification of the patent. And, as set forth above, there is support for use of the term "capturing" in the context of imaging and the ballot reader and for the need of an electronic reproduction of the ballot.

Accordingly, the Court construes the terms in Ref. No. 56 as: Electronically capturing and reproducing images and data from a ballot in a pixilated or bitmapped format.

--- Footnotes ---
35 The parties' disagreement concerning which delays are inherent and which merely arise from specific embodiments need not be resolved at this time because neither party has asked the Court to include any particular delay in its construction. Similarly, because even Agere's expert concedes that some delays are inherent, the Court need not determine the appropriateness of Broadcom's attempt to demonstrate the existence of inherent delays by reference to the '771 patent.

--- End Footnotes ---
This term is part of the recitation in claim 4 of the '846 patent of the write-through data storage mode, which the patentee defines in the specification as a simultaneous write operation to cache memory and main memory. See '846 Patent, Col. 30, ll. 37-42. The court defines the term "immediately stores said modified data in said primary memory" to mean "the CPU executes a write operation to main memory simultaneously with the writing of data to the cache memory."

In its claim construction, the Court concluded that the '628 Patent "was not intended to encompass an impedance matching network," without defining the term. (D.I. 154 at 3). However, a construction of the phrase "impedance matching network" is now required to resolve the instant motion.

MKS contends that an "impedance matching network" is "a lossless network placed between the power supply and the discharge to ensure maximum power transfer." (D.I. 179 at 1). In reply, Advanced Energy contends that an "impedance matching network" is "a collection of electrical components comprising capacitors and inductors that adjusts the impedance of a circuit." (D.I. 178 at 1). Advanced Energy contends that there is no single way to define the effect of "impedance matching network" on power, and therefore, a construction of the term should not include the effect an "impedance matching network" has on power transfer. (D.I. 178 at 5). Advanced Energy further contends that "a variance of up to ten percent 'off resonance' is acceptable for an "impedance matching network," and commercially, impedance matching networks may be operated deliberately off resonance to ensure effective power control. (D.I. 110 at 6-7).

With regard to this term, the parties' dispute centers on the characterization that an "impedance matching network," by definition, must seek to maximize power. The parties agree that an "impedance matching network" cannot be operated perfectly and at least ten percent 'off resonance' is considered acceptable for an "impedance matching network." (D.I. 111 at A330, D.I. 137 at 10). However, the parties cannot agree to what extent an "impedance matching network" may operate 'off resonance' and still be the type of "impedance matching network" the '628 Patent sought to exclude. MKS argues that the type of "impedance matching network," used in conjunction with a linear power supply and excluded by the '628 Patent, sought to maximize power and operate with as much resonance as possible. Advanced Energy argues that the construction offered by MKS is too narrow, and only encompasses one subset of the broader category of "impedance matching networks." Advanced Energy argues that the generic term "impedance matching network" includes all networks that allow a power supply to adapt to the dynamics of a load having complex (variable) impedance characteristics. Further, Advanced Energy argues that such an "impedance matching network" might be operated deliberately off resonance to ensure effective power control. (D.I. 110 at 6-7).

In construing the disputed phrase the Court has reviewed the claim language, patent specification, and prosecution history. (D.I. 111 at A9 col. 2 ln. 22-26, A12 col. 7 ln. 49-60, A13 col. 10 ln. 19-21, A121-22, 124, A169-70). The parties agree that the disputed term is not used in any of the claims and the specification does not contain a definition of the term. Based upon a review of the sources cited, the Court concludes that the term "impedance matching network" is used in the '628 Patent exclusively with reference to conventional linear power supply systems. (D.I. 111 at A9 col. 1 ln. 60-65 col. 2, ln. 23-25, col. 7 ln. 55-58, col. 10 ln. 13-12). Accordingly, the Court concludes that the patentee did not intend to exclude all "impedance matching networks" from the '628 Patent, but only those conventional "impedance matching networks" used with conventional linear power supplies. Therefore, the Court concludes that "impedance matching network" means "a lossless network placed between the power supply and the discharge to ensure maximum transfer."
suggests that this added phrase be defined to mean "making the resistance of the load equal to the internal resistance of the power supply and making the net reactance of the load and the power supply zero." (Id. at 20.)

Advanced contends that the Court's previous definition was appropriate and opposes any modification or clarification. Advanced contends that MKS's suggestion would require a perfect impedance matching network which is impossible and, in effect, no limitation on the MKS patents.

The Court concludes that its previous construction should be clarified, but the clarification does not require the level of specificity proposed by MKS. Clarified, the Court construes an "impedance matching network" to mean "a lossless network placed between the power supply and the discharge to ensure maximum power transfer by matching, although not perfectly, the impedance of the power supply and load."

2071

The "Implanted Region"

EMI states that the district court erred by equating "the implanted region" with "the source/drain region" at the stage of claim clause (b), EMI arguing that the source/drain region does not fully exist until after the heat activation step of clause (e). However, we observe that EMI's counsel as well as expert witnesses for both sides referred to this region as the source/drain region before as well as after heat activation. If there were technical error it is harmless, for there is no uncertainty as to the region of the transistor that was meant to be described.

In claim clause (d) the district court construed the phrases "implanted region" and "source/drain region" to mean "regions of opposite polarity as compared to the substrate surrounding them." This construction has not been challenged.

2072

1. "Improved Resolution"

In Claim 1 of the '594 Patent, the parties dispute the proper construction of the term "improved resolution" in the phrase "interpolation section responsive to groups of said samples to perform interpolation thereof to provide filtered samples having improved resolution." Defendant submits that "filtered samples having improved resolution" means "samples that are each represented by a larger number of bits than were the original samples generated by the sampling section." Plaintiff argues that "improved resolution" is not limited to improvements measured in numbers of bits. According to plaintiff, while bit improvements are specified in the preferred embodiment, "improved resolution" may also connote, among other things, reductions in distortions or noise. 5 Defendant does not contest the fact that reductions in distortion and noise are benefits of the process taught by the patent, but argues that these benefits are merely a side effect of the increase in bits of resolution and do not themselves constitute improved resolution.

5 Plaintiff also argues that defendant's reading of this limitation is inconsistent with the scope of the patent because the patent applies to analog as well as digital video, and analog samples are not expressed in terms of bits. The improved resolution, however, results from the process of converting analog signals into digital format. See Col. 4:50-67. Accordingly, while it is true that the patent "applies" to analog signals, the improvement in resolution that is the subject of the invention is properly measured in bits.

The patent specification is instructive in this regard. According to the specification, "the use of oversampling and interpolation to an increased number of bits of resolution is believed to be a novel feature in view of the unexpected result of reducing distortions occurring in the sampling and A-D conversion process." '594 Patent, Col. 4:63-67 (emphasis added).
This language strongly suggests that reductions in distortion are a central benefit, rather than merely a side effect, of the claimed invention. It also indicates, however, that reduction in distortion is a phenomenon distinct from, albeit complementary to, improvement in the number of bits of resolution. Accordingly, while it may be that the interpolation section provides filtered samples having not only improved resolution but also reduced distortion, the latter benefit is not, as plaintiff suggests, an inherent limitation of the claim. Adopting plaintiff's proposed construction would therefore have the effect of importing a limitation from the preferred embodiment into the claim itself, in violation of well-established rules of claim construction. See Electro Med. Sys. N.A. v. Cooper Life Sciences, 34 F.3d 1048, 1054 (Fed. Cir. 1994). The Court will thus adopt defendant's proposed construction.

2073

Claim 1 of the 948 patent is what is known as a Jepson claim, which includes (1) a preamble that sets forth all of the conventional elements of an invention and (2) a subsequent phrase describing the new or improved portion of the claimed invention. See Jepson v. Coleman, 314 F.2d 533, 50 C.C.P.A. 1051, 1963 Dec. Comm'r Pat. 304 (C.C.P.A. 1963); see also 37 C.F.R. § 1.75(e):

Where the nature of the case admits, as in the case of an improvement, any independent claim should contain in the following order: (1) a preamble comprising a general description of all the elements or steps of the claimed combination which are conventional or known, (2) a phrase such as "wherein the improvement comprises," and (3) those elements, steps and/or relationships which constitute that portion of the claimed combination which the applicant considers as the new or improved portion.

The United States Court of Appeals for the Federal Circuit has held that "Jepson claiming generally indicates intent to use the preamble to define the claimed invention, thereby limiting claim scope." Catalina Marketing Int'l, Inc. v. Coolsavings.com, Inc., 289 F.3d 801, 808 (Fed. Cir. 2002). The phrase "an improvement in a vehicle" is the preamble to the 948 claim.

Plaintiff argues that the phrase should be read to mean "a module combined with a vehicle to create an improvement to the vehicle." Defendants contend that "an improvement in a vehicle" means "a device that is incorporated in, and becomes a part of, a vehicle." The crux of the parties' dispute concerns whether or not the invention is intended to become a permanent fixture inside of the vehicle. Mr. Lundell has answered this question in the affirmative, recommending that the Court adopt the following construction: "a module that becomes part of a vehicle and is intended to remain part of the vehicle during use."

As Mr. Lundell notes, during the prosecution of a previous patent, which described an earlier version of the invention at issue here, Plaintiff distinguished that device from the prior art by noting that the prior art was "not an improvement in a vehicle, but a stationary piece of shop equipment." See Amendment After Final dated December 30, 1991, at 7 (Bates No. JBA 008689) (cited in Superchips' Claim Constr. Br. at 10). That statement had -- and has -- the effect of narrowing the range of claimed devices. Cf. Covad, 262 F.3d at 1273-74. The Court finds, therefore, that although the patented invention may, like any other automobile part, be removed after installation, the patent and prosecution history, when read together, contemplate that the invention will remain part of the vehicle once attached. Accordingly, the Court adopts Mr. Lundell's recommended construction and holds that "an improvement in a vehicle" means "a module that becomes part of a vehicle and is intended to remain part of the vehicle during use."

2074

A. "An improvement in a vehicle having a predetermined combination of operational elements for controlling vehicular operation... said predetermined combination of operational elements being defined in a fixed system having a bus..."
preamble comprising a general description of all the elements or steps of the claimed combination which are conventional or known, (2) A phrase such as 'wherein the improvement comprises,' and (3) Those elements, steps, and/or relationships which constitute the portion of the claimed-combination which the applicant considers as the new or improved portion." 37 C.F.R. § 1.75(e). The preamble separates the prior art from the inventive portion of the claim and constitutes a limitation for purposes of determining infringement. Id.

Hypertech's proposed construction defines "an improvement in a vehicle" to "refer[] to the fact that the patented apparatus is physically incorporated into the unchanging ('fixed') electronic control system of the vehicle to control . . . the vehicle while it is moving or stopped, but otherwise in normal operation. Personal computers and other programming equipment designed for use in a shop environment are specifically excluded from the definition of 'an improvement in a vehicle.'" (Dft.'s Claim Construction Statement at 5). The language of the preamble and its meaning is fairly straightforward, and the court declines to adopt Hypertech's invitation to include various limitations in the construction of the preamble.

The plain language of this term means the following: The invention is an improvement to a vehicle. That improvement includes a predetermined combination of operational elements. These operational elements control the vehicle according to at least one originally provided program. These operational elements define a fixed system that includes a bus. That bus includes a predetermined operable design for operation of the vehicle. The operational elements of the fixed system are controlled by an ECM, in accordance with an originally provided program. The ECM is coupled to the bus and is accessible to the outside at least for diagnostic purposes.

vi. Improving the apparent resolution of the image

The parties dispute the meaning of the following limitation found in both claims 15 and 146: "thereby improving the apparent resolution of the image without requiring an increase in the number of image elements originally making up the image." IPI's proposed construction for the phrase is: improving the original image to make it appear to have a higher resolution when displayed, without actually increasing the number of image elements originally making up the image, i.e., without increasing the number of elements in the image which is to be operated on by the claimed invention. In other words, under IPI's reasoning, the language "originally making up the image" refers to the signal that is originally input into the processing circuitry device. It argues that the invention has the ability to take an image from an input signal in a lower resolution and process that image in a manner that improves the resolution. Though no image elements are added to the image carried by the input signal, it maintains that the invention teaches that new image elements may be generated during processing of the signal in the device. Thus, the invention may include, but does not require, interpolation (i.e., inserting additional elements). IPI points out that adding new elements or replacing existing elements in an image that is subsequently displayed is a stated embodiment of the invention.

In contrast, Sony asserts that the limitation means to make the image which may be displayed appear as if it has more elements than it actually has, without adding further elements to that image, through interpolation or otherwise. Thus, it asserts that IPI is incorrect to the extent that it suggests that there can be an increase in the number of pixels of the image conveyed on the signal anytime up until the image is displayed. The patent defines "spatial resolution" as "the number of elements or pixels which are used to make up an image." U.S. Patent No. 5,424,780, col. 1, lines 22-24. Thus, Sony argues that "improving the apparent resolution" of the image means to make the image appear to have more image elements than it actually does, without increasing the actual resolution by adding elements to the image carried by the signal.

Sony likewise attempts to gather support from the prosecution history. In one of several relevant excerpts cited, Sony claims that Cooper was silent in response to, and therefore acquiesced in, the examiner's comments concerning how the King '478 patent did not anticipate or render obvious claims 1 through 25:

First, King does not improve the apparent resolution of the image without requiring an increase in the number of image elements originally making up the image as required by claims 1-25. Instead, King performs interpolation which generates new pixels. Therefore, there is an increase in the number of image elements originally making up the image.

Secondly, King does not alter the size or shape of [the] central element in order to provide information for the blank or
void areas as required by claims 26-41. Interpolation generates new pixels in blank or void areas. Interpolation does not change the size or shape of one or more pixels in order to provide information for a blank area. In the King reference the size of the matrix (containing pixel elements) has increased from a 7x5 to a 13x9. However, there is no direct relationship between the size of the matrix and the size or the shape of an individual pixel element.

Examiner's response to 11/29/99 communications during reexamination of the '780 patent at 16-17.

Sony likewise suggests that Cooper disclaimed de-interlacing techniques during prosecution when he distinguished the Birch '045 patent as follows:

As previously explained, Birch is not directed towards altering "voids" of the image; Birch merely substitutes one piece of modified information present at one time for another present at another time. In addition, the resolution of Birch remains unchanged over any scan conversion type device (i.e., in both the maximum of 480 lines of data will be perceived). At most it is believed that it could be said that Birch replaces the data with interpolated values for alternatives which it believes is more logical than the true value Y). Birch does not have or teach of filling any voids.

Finally, Sony invites the Court to consider a rebuttal report that Cooper submitted during the Dell litigation, which discusses the role - or lack thereof-of interpolation in the '780 and '637 patents. Though it is permissible for a Court to consider inventor testimony as one type of extrinsic evidence, see Phillips, 415 F.3d 1303, 2005 WL 1620331, at *10, it has only minimal probative value. See. e.g., E-Pass Technologies, Inc. v. 3COM Corp., 343 F.3d 1364, 1370 n.5 (Fed. Cir. 2003). The Court has reviewed the report but does not find it to tip the balance in favor of Sony's proffered construction.

Both parties make persuasive arguments in support of their respective positions. The Court agrees with Sony that the ordinary meaning of the term "apparent" suggests that the resolution is not actually improved, but only appears to be improved. Sony's interpretation, however, is directly at odds with language in the specification that clearly indicates that one method for filling voids is to generate new pixels. Bearing in mind the principles set forth in Phillips, the Court adopts IPI's interpretation, as it is truer to the claim language when read in light of the specification. Stating that the apparent resolution is improved "without requiring" more image elements does not preclude adding image elements as one way to increase apparent resolution, so long as other methods may also be used.

For example, the '780 patent states that "it is yet still another object of this invention to provide a means and method to improve the quality of an image by inspecting a plurality of neighboring elements to selectively generate new fill elements in response thereto." U.S. Patent No. 5,424,780, col. 2, lines 41-45. Similarly, the specification later reveals that "the video fill signal may be utilized to generate additional pixels in the video signal in response to 9, thus providing pixels to fill in the blank areas of the image." Id. at col. 5, lines 33-35.

Thus, the specification unambiguously provides that generating new pixels is one way in which the invention can fill voids in the image. In addition, the Court disagrees with Sony's contention that the inventor unequivocally disclaimed or limited the invention during prosecution in a manner that would exclude IPI's interpretation. In sum, the proper construction of "improving the apparent resolution" should be read as improving the original image to make it appear to have a higher resolution when displayed, without increasing the number of elements in the image carried on the signal originally input into the processing circuitry device.

2076

h. "Improving the Apparent Resolution of the Image Without Requiring an Increase in the Number of Image Elements Originally Making Up the Image"

For this term, which appears in claims 15 and 146 of the 780 patent, IPI proffers the following construction: improving the original image to make it appear to have a higher resolution when displayed without actually increasing the number of image elements originally making up the image. Lexmark and Dell contend that this term means improving the electronically coded input image to make it appear to have a higher resolution when displayed, but without actually
increasing the number of image elements making up the image (without interpolation).

Lexmark and Dell's proposed definition again relies heavily on the prosecution history of the 780 patent. During prosecution, the examiner made the following statement to which Cooper apparently acquiesced:

First, King does not improve the apparent resolution of the image without requiring an increase in the number of image elements originally making up the image as required by claims 1-25. Instead, King performs interpolation which generates new pixels. Therefore, there is an increase in the number of image elements originally making up the image.

S/N 90/005,484 O.A. 5/16/00 at 16. Lexmark and Dell contend that since Cooper acquiesced to this statement by the examiner, the phrase "without interpolation" must be included. The statements made by the examiner are not inconsistent with IP's proposed definition, which includes a limitation that there is no actual increase in the number of image elements displayed. Much as was the case with respect to the term "to select voids" in claim 15, Lexmark and Dell's definition seeks to specify a distinction implicitly contained in IP's definition. Accordingly, we accept IP's construction of this term.

In the Markman hearings, Defendant urged the Court to construe the word "providing" to mean "making the generated form available to the user." The Court rejected that construction and agreed with Plaintiff that the term "is an everyday word[] used in [its] ordinary, everyday sense and, thus, [it] need[s] no construction." Construction Order 1 at 31. Nevertheless, Defendant again urges the Court to define the word "providing" to mean "make available" in this instance. Using that definition, Defendant contends the XAP System does not meet this limitation because it only "makes available" the user information in a flat-file format rather than "in a format specified by the institution." In particular, Defendant argues that uploading the applicant information to a student-information system requires colleges to convert the flat-file format provided by the XAP System into a relational database format or a proprietary database format for use in the colleges' student-information systems. Defendant points to the expert opinion of Justin Tygar, Ph.D., to support Defendant's proposition that the XAP System does not provide information in a format specified by the institution.

Plaintiff, however, asserts it is entitled to summary judgment that the XAP System meets this limitation because the information the XAP System provides can be uploaded into a particular school's information system in a format selected by the school. Indeed, some of Defendant's own witnesses acknowledge the XAP System permits an institution to use Defendant's "Export Wizard" to choose a format that will allow it to upload information into its particular system. Def.'s Mem. in Supp. of Mot. for Summ. J., Shimanovsky Decl. P 4 (Export Wizard "is a point-and-click online tool, to be used by an authorized representative of a school or university in building a layout . . . [that] can be downloaded to the college's computer."); Pl.'s Reply, Monkress Decl., Ex. 4; Wagoner Dep. at 168 (a school can use Export Wizard to choose a format that will allow it to upload information).

This Court has construed the term "in a format specified by the institution" to mean "[t]he institution chooses from a third party one or more data formats that allow the institution to use the data without having to convert it." Construction Order 2. In his expert report, Dr. Tygar states "[t]he institution must access XAP's Control Center to create projects for retrieving the applicant data through Export Wizard." Pl.'s Mem. in Supp. of Mot. for Summ. J., Monkress Decl., Ex. 4; Tygar Expert Report at 63. Contrary to Defendant's arguments, the Court concludes Dr. Tygar's statement is, in fact, consistent with the Court's construction in that the institution accesses the XAP System's Export Wizard to choose a format suitable for uploading information without having to convert it and thereby specifies the format.

On this record, the Court concludes no genuine issue of material fact exists that Defendant's XAP System meets this limitation. Accordingly, the Court grants Plaintiff's Motion for Summary Judgment (# 371) as to this limitation of Claim 16.
The Court agrees with MEI and construes the term as "two or more plug electrodes are formed." Samsung argues that the phrase cannot be understood or construed. The claim language is awkward: "wherein said plug electrode is formed in a plural manner and said plug electrodes are connected respectively to both sides . . . ." '195 Patent col. 22:47-48. The grammatical error in the claim-at-issue does not cast its meaning into doubt so as to render it indefinite. The inventor's intent here is clear--plural means more than one. The intrinsic evidence shows multiple plug electrodes connected to a fuse portion. See '195 Patent Figs. 9g, 11e. Samsung fails to demonstrate that a person of ordinary skill in the art would not understand the claim as written.

Claim 1 of the '201 Patent states that the broadcasting and resolve functions are performed each in a time on the order of the logarithm of the number of processing elements . . .

Plaintiff construes the phrase here in issue as "each operation is performed in time based on the base 2 logarithm (log2) of the total number of nodes in a tree or subtree multiplied by the time required to broadcast from a parent to a child node and the time required to determine the result data between a parent and its child nodes." Pl. Br. at 16. Defendant's construction is "the broadcasting operation is performed in one clock cycle, multiplied by the base 2 logarithm of the number of processing elements in the binary tree; the priority is determined in two clock cycles, multiplied by the base 2 logarithm of the number of processing elements in the binary tree." Def. Br. at 14. According to defendant, "broadcasting" takes one clock cycle, and priority determination (or "resolve") takes 2 cycles (one for comparison and one to propagate the result to the next level). Thus, according to defendant, each operation is performed in the time that it takes to broadcast or resolve at each level multiplied by the number of levels in the tree. The time at each level is one clock cycle for broadcasting, and two for the priority determination. Def. Reply at 14.

Plaintiff's construction is flawed to the extent it suggests that "each operation" occurs in a time that is based on both the broadcast and priority determinations functions, omitting the words "each" and "respectively." See Def. Br. at 15. The parties are nevertheless essentially in agreement except for defendant's inclusion of a specific number of clock cycles, which plaintiff asserts contradicts the specific claim language of "on the order of." Pl. Reply at 12. The patent specification indicates, with respect to the broadcast function, that "data may be broadcast to all the [processing elements] of the array with a delay of only one cycle for each level of the array . . . . Since a processor instruction cycle typically requires over twenty clock cycles, there is sufficient time in one processor instruction cycle to broadcast data to all the [processing elements]." '201 Patent at 19:35-37, 42-45.

As the patent specification indicates, a single processor instruction cycle typically requires more than twenty clock cycles, '201 Patent at 19:42-43, but the patent was intended to ensure that the I/O device "communicate data and queries from the root processing element to all other . . . processing elements in one processor instruction cycle," id. at 5:11-14. According to the prosecution history, the applicants' original claim language specified that each of the functions would take "less than an average processor instruction cycle." '201 Patent Prosecution History, Def. Br., Ex. F, at FGC 408. The USPTO rejected that language because of the inherent ambiguity of the word "average," id. at FGC 829, and the applicants further amended the claim language to specify "each in a time." Thus, the time in which each function can be performed is calculated by
multiplying the number of levels in the binary tree by the time required for the broadcast or priority determination at each level.

With respect to the resolve function, the patent specification states: "[T]he entire resolve operation can be performed in the time it takes a number offered by a [processing element] to be clocked through the comparator plus the propagation time through the tree of one clock cycle per level. If the number offered is only a byte and the processor array only has ten levels, . . . the entire resolve operation can be completed in less than twenty-clock cycles which is less than the average processor instruction cycle." '201 Patent at 21:67-22:7. Plaintiff argues that this is the preferred embodiment using the example of only a byte, with the implication that if the number were larger than a byte, the time would exceed one clock cycle. See tr., 08/20/09, at 74, 99. Yet, while the preferred embodiment here specifies a ten-level binary tree, see '201 Patent at 19:39-40, it in no way indicates that the speed at each level would vary based on the size of the number offered for processing. To the contrary, in the same section of the specification, the patent clearly states: "Advantageously, there is a delay of only a single clock cycle in performing the comparison at each level in the binary tree . . . ." '201 Patent at 21:63-65. Hence, the comparison requires only one clock cycle. The report and resolve function, or determining a priority, thus takes one cycle for the comparison and one clock cycle per level to propagate the date back up the binary tree, for a total of two clock cycles, multiplied by the number of levels in the tree.

At the Markman hearing, counsel for defendants conceded that the specification indicated that the functions were capable of being performed in that time, not that they must be performed in that time. See tr., 09/21/09, at 105-06. Accordingly, the Court's construction of the disputed term is that "the broadcasting operation is capable of being performed in one clock cycle, multiplied by the base 2 logarithm of the number of processing elements in the binary tree; the priority is capable of being determined in two clock cycles, multiplied by the base 2 logarithm of the number of processing elements in the binary tree."

2081

8. "in accordance with" the "command" or "message." The command or message makes the bonus available. The claims do not require that the bonus is paid "automatically" or without any subsequent withdrawal steps upon receipt of the pay command.

2082

B. Claim 12

As stated in the mediation report, the only dispute as to Claim 12 is whether the 10Base-T MAU claimed there must meet the requirements of the proposed standards of IEEE supplement (P802.31/D10) for LANs. 4 Plaintiff. Mem., App. F at 4. The claim discloses a "10Base-T MAU comprising an AUI port in accordance with proposed standards of IEEE supplement (P802.31/D10) for LANs . . . ." '183 Patent at 8:35-37.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

- 2453 -
4 The parties also renew the arguments with respect to "auto-engage means" that were raised in their discussion of the term in Claim 6. The court construes that term to be the same in all relevant respects to the term in Claim 6 and interprets it accordingly.

Seeq urges the court to interpret the claim such that the MAU must meet the referenced IEEE standards, and Level One argues that only the AUI port claims to be in accordance with those standards.

Viewing the claim in isolation, the court would agree with plaintiff's reading that only the AUI port claims to be in accordance with the IEEE proposed standards. However, the specification, beginning with the second line of the abstract, states that the disclosed 10Base-T MAU will "meet[] or exceed[]" the proposed standards of the IEEE supplement (P802.31/D10) for LANs. See also '183 Patent at 2:17-19. Accordingly, the court concludes that both the MAU and the AUI port of Claim 12 must meet the referenced IEEE standards.

5 This construction of MAU holds true for the MAU disclosed in Claim 6 as well. This does not mean though, as defendant would have it, that any discussion of a twisted pair MAU in the proposed standard is automatically incorporated into the definition of the term.

2083

C. "In-Band Telecommunications Signaling" and "Out-of-Band Telecommunications Signaling"

Claim 38 of the '572 patent recites the term "in-band telecommunications signaling." Sprint contends that this is a term of art that should be construed to mean signaling that is sent on the same channel as that used for voice or data, whereas Vonage contends that it should be construed to mean signaling transmitted on the actual communications path. This claim also recites the term "out-of-band telecommunications signaling." Again, Sprint contends that this is a term of art which should be construed to mean signaling that is sent on a distinct channel from that used for voice or data, whereas Vonage contends that it should be construed to mean signaling message that is not transmitted on the actual communications path. The crux of the parties' dispute is whether characterization of signaling as in-band or out-of-band is determined by whether that signaling is transmitted on the same or separate channels (Sprint) or by whether it is transmitted on the same or separate communication paths (Vonage).

Vonage relies on language included in the specification which addresses the nature of in-band and out-of-band signaling, as follows:

As is known in the art, in-band signaling is typically used in many user to network connections, such as the local loop. This is because only one connection or link is typically provided to the user premises and thus, the signaling must be placed on the actual communications path. The initial network switch typically removes the signaling from the communications path and transfers it to an out-of-band signaling system. The current invention is fully operational in this context. Although the switch may receive the signaling initially, it will only route the signaling to the CCP for processing. Even if in-band signaling is used within the network, the switches could remove signaling from the communications path and route it to the CCP for processing in accord with the present invention.

'572 Patent at 7:50-63. Sprint, on the other hand, relies on Vonage's experts' understanding of the terms "in-band" and "out-of-band." Frank Koperda, Vonage's invalidity expert, stated in his expert report that "in-band' signaling is the exchange of signaling information . . . within the same channel that the telephone call itself is using" and that "'out-of-band' signaling is telecommunication signaling that is done on a channel that is dedicated for the purpose and separate from the channels used for the telephone call." Also, Joel M. Halpern, Vonage's noninfringement expert, testified in his deposition that out-of-
band signaling "has to be in a separate band, a separate recognizable channel."

The evidence from Vonage's experts clearly views the teens "in-band" and "out-of-band" as being distinguished with respect to a channel, which leads the court to believe that these might be terms of art, as Sprint contends. In an attempt to understand the distinction between a "channel" and a "communications path," the court has consulted a technical dictionary to determine the meanings of the relevant terms as they would have been understood by a person of ordinary skill in the art at the time of the invention. "In-band signaling" means "[s]ignaling made up of tones which pass within the voice frequency band and are carried along the same circuit as the talk path that is being established by the signals." Harry Newton, Newton's Telecom Dictionary 537 (7th ed. 1994). "Path" means "[t]he route a telecommunications signal follows." Id. at 773. "Out-of-band signaling" means "[s]ignaling that is separated from the channel carrying the information -- the voice, data, video, etc." Id. at 756. "Channel" means "a voice-grade transmission facility with defined frequency response, gain, and bandwidth. Also a path of communication, either electrical or electromagnetic, between two or more points." Id. at 217.

The common and ordinary meanings of these words can be harmonized with the excerpt from the specification. In discussing "in-band signaling," the specification explains that only one connection or link is typically provided to the user premises and therefore the signaling "must be placed on the actual communications path." '572 Patent at 7:52-53. The initial network switch typically removes the signaling from the communications path." Id. at 7:55-56. The specification further explains that even if in-band signaling is used within the network, the switches "could remove signaling from the communications path." Id. at 7:60-61. The technical definition of in-band signaling refers to the "talk path," and the term "path" means the route a telecommunications signal follows. With respect to the claim term "in-band," then, the intrinsic record establishes that its meaning is defined with respect to the communications path. There is no suggestion in the intrinsic record that it should be defined in terms of a channel. Consequently, the court must discount the expert opinions that are at odds with this intrinsic evidence. Accordingly, the court construes the claim term "in-band telecommunications signal" to mean signaling that is sent on the same communications path as that used for voice and/or data.

The specification does not, however, indicate that the claim term "out-of-band telecommunications signaling" must necessarily be construed as the counterpart to in-band telecommunications signaling. The specification sheds light on the meaning of the claim term "out-of-band telecommunication system," in that the network switch removes the "signaling from the communications path and transfers it to an out-of-band system." Certainly, this indicates that out-of-band means removing the signaling from the communications path. This is not inconsistent with what appears from the record to be the generally accepted meaning of the term within the telecommunications industry, which is that out-of-band signaling is signaling that is separated from the channel carrying the voice and/or data. And, defining out-of-band signaling in terms of a separate channel is also consistent with Vonage's experts' apparent understanding of this term. Thus, the court is persuaded that "out-of-band" signaling is indeed a term of art defined in terms of the channel, as suggested by Sprint. Accordingly, the court construes the claim term "out-of-band telecommunications signaling" to mean signaling that is sent on a separate channel from that used for voice and/or data.

1 The court recognizes the seeming incongruity in construing "in-band signaling" in terms of the communications path while construing "out-of-band signaling" in terms of a separate channel. But, this actually comports with the commonly understood meanings of those terms, as illustrated by the dictionary definitions set forth above. Moreover, the distinction is attributable to the "communications path" language included in the specification with respect to "in-band" signaling. In the absence of that language in the specification, the court would be inclined to construe both of the terms in light of the "channel" distinction.

3. "in circuit" (1[c], 11[b])

(i) Claim Construction

The Court has considered all of the testimony regarding interpretation of the term "in circuit." More so than with the
interpretation of other claim terms heretofore addressed, the parties' discussion of the claim term "in circuit" requires application of Phillips v. AWH Corp., 415 F.3d 1303, 1312 (Fed. Cir. 2005) (en banc). n27 "It is a 'bedrock principle' of patent law that 'the claims of a patent define the invention to which the patentee is entitled the right to exclude.'" Id. at 1312 (citation omitted). "The words of a claim 'are generally given their ordinary and customary meaning'" where "the ordinary and customary meaning of a claim term is the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention . . . .'" Id. Intrinsic evidence, such as the specification and the prosecution history, is key to an interpretation of claim terms, with the specification playing a slightly more important role than the prosecution history. Id. at 1315-17. However, a court should avoid reading limitations from the specification into the claim. Id. at 1323. In particular, the Federal Circuit has "expressly rejected the contention that if a patent describes only a single embodiment, the claims of the patent must be construed as being limited to that embodiment." Id. at 1323.

n27 Phillips was decided after the trial in this case concluded and after the parties submitted their briefs.

--- End Footnotes ---

Extrinsic evidence, such as dictionaries, treatises, and expert testimony has a more limited role than intrinsic evidence in claim interpretation. Id. at 1317-18. The parties submitted more extrinsic evidence regarding the interpretation of the term "in circuit" than with regard to any other claim term at issue in this case. Although extrinsic evidence in the form of expert testimony can be useful . . . to provide background on the technology at issue, to explain how an invention works, to ensure that the court's understanding of the technical aspects of the patent is consistent with that of a person of skill in the art, or to establish that a particular term in the patent or the prior art has a particular meaning in the pertinent field . . . conclusory, unsupported assertions by experts as to the definition of a claim term are not useful to a court. Similarly, a court should discount any expert testimony "that is clearly at odds with the claim construction mandated by the claims themselves, the written description, and the prosecution history . . . ."

Id. at 1318 (citation omitted) (emphasis added).

Claim 1 of the '903 Patent describes the first portion of the selection monitor "being connected in circuit with the vend producing means when the vend switch means are actuated." '903 Patent col. 8, lines 35-40. At trial, Mr. Kesner, Mars' expert witness, suggested that for two elements to be in circuit, a direct connection must exist between those elements. Therefore, Mars argues that this claim language requires that the product selection switch be located between the selection monitor and the vend producing means, as drawn in Figure 1, so that the first portion and vend producing means are not in circuit when the switch is not actuated. Dr. Morley, Coinco's expert witness, expressed his belief that elements in circuit shared a common completed current, and that the definition of "in circuit" had nothing to do with a direct connection between those elements. Consistent with this definition, Coinco argues that the claim language includes the situation where the vend producing means is between the selection monitor and the product selection switch.

The Court applies Phillips to determine the weight of the various sources submitted by the parties for interpretation of the term "in circuit." Therefore, the Court first considers the ordinary meaning of the language within the claims at issue. Claim 1 refers to an output signal which "establishes a circuit condition that initiates a vend operation." '903 Patent col. 8, lines 52-54. This provides evidence that the word "circuit," as used in the '903 Patent's description of the relationship between the selection monitor, selection switch, and vend producing means, refers to the flow of current.

Phillips also places strong weight on intrinsic evidence, such as the specification and prosecution history. The specification refers to "selection switches 12, 14, 16, and 18 which are connected in series, and when one of them is actuated it completes a circuit through an associated vending device 20, 22, 24, and 26." '903 Patent col. 2, lines 40-44 (emphasis added); see also '903 Patent col. 3, lines 40-46. Additionally, the specification explains that "line 62 determines that one of the vend selection switches 12, 14, 16, and 18 has been actuated . . . when a circuit has been completed through an associated one of the vend control devices 20, 22, 24, and 26 . . . ." '903 Patent col. 3, lines 29-36 (emphasis added). The specification thus provides further evidence that the requirement for an "in circuit" connection between elements refers to the ability for current to flow through all those elements.
The prosecution history contains further evidence that "in circuit" refers to the completion of a possible electrical circuit via a group of named structures through which electricity may flow. The examiner's remarks explain that:

Claim 1 also requires that the first portion be connected in circuit with the vend producing means when the vend switch means are actuated. This refers to the first portion of the circuit 58 which is the portion connected in circuit with the vend producing solenoid means when the operator actuates the associated vend switch. This establishes a circuit through the said first portion of the circuit 58 so that the second portion is actuated to operate . . . .

(Def's Ex. 471, at 47. (emphasis added)) In this case, the examiner clearly interpreted the term "in circuit" of claim 1 to refer to an action which permits the second portion to become actuated. This cannot occur unless current flows through the first portion.

Thus, following Phillips' holding regarding the importance of evidence intrinsic to the patent, the language of claim 1 itself, the specification, and the prosecution history all speak of the selection monitor and the vend producing means as "in circuit" only when current may flow between them.

Some of the trial testimony regarding the meaning of "in circuit" appeared to revolve around a discussion of "in circuit" as a defined term within the field of electrical engineering. (See, e.g., Tr. vol. 29, 151; Tr. vol. 33, 14-15.) The Court has considered this testimony and, in light of Phillips, rejects this extrinsic evidence. Although extrinsic evidence has value, Phillips holds that courts must look primarily to the intrinsic evidence to interpret claim terms. Therefore, a court need not look for supporting documentation outside of the '903 Patent if the patent itself and its prosecution history provide information necessary to properly construe a term. Additionally, Phillips also explains that single embodiments, like Figure 1, do not cause additional limitations to be read into the claim terms. Phillips, 415 F.3d at 1323. As a result, the words "in circuit" in claim 1 of the '903 Patent have not acquired the meaning that Mars urges.

Claim 11 describes "a control monitor circuit having an input control portion connected in circuit with the product selection switch and energized by actuating said product selection switch." '903 Patent col. 9, lines 64-67. Generally, the same terms in a patent should have the same meaning. Phillips, 415 F.3d at 1314. The language of claim 1, the specification, and the prosecution history all make clear that "in circuit" within claim 1 refers to the fact that current must be able to pass through all of the three named elements: the first portion, the input control portion, and the vend producing means. However, in claim 11, the term "in circuit" only refers to the selection monitor's input control portion and the product selection switch, without describing the vend producing means. Claim 11 also specifically requires that the unactuated selection switch be "in circuit" with the selection monitor at a time when current cannot flow. Because of the language used to describe these elements in claim 11, the Court agrees with Coinco, and finds no requirement that the use of "in circuit" within claim 11 places any limitation on the location of the vend producing means. The product selection switch and the selection monitor are "in circuit" here because electrical current could flow between the two of them if one chose to apply electrical current to the switch itself.

--- Footnotes ---
n28 As used in the patent, the "first portion" and the "input control portion" both appear to refer to the same element.
--- End Footnotes ---

F. "In Communication With the Personal Information Provider" (‘245 Patent)

This term appears in independent claims 1, 2, 7, and 8 of the ‘245 patent. CashEdge asserts that "in communication with the personal information provider" should be construed to mean "the client computer communicates with the personal information provider." Yodlee asserts that no construction is necessary and that CashEdge's construction is redundant, in response to which CashEdge asks the Court to accept its construction to prevent Yodlee from taking a contrary position later in the case. The Court agrees with Yodlee that CashEdge's construction is redundant. The plain language of the claim is substantively identical to CashEdge's proposed construction, making it clear that the client computer communicates with the
The Court therefore declines to construe this phrase. The Court construes the phrase "in data communication with" as used in Claim 4 of the '720 Patent, as follows:

a reception system connected to subscriber selectable receiving stations such that data can be transferred between the devices in real time.

EMC contends that the term "in parallel with," as used in the first command, means concurrently with. HP maintains that the term is vague. The plain and ordinary meaning of the term "parallel" is marked by likeness or correspondence esp. in time, direction, course, tendency, or development: similar, analogous, or interdependent in line followed: tending toward the same point or result[.]

Webster's Third International Dictionary, 1637 (1981). Nothing in that plain meaning nor in the claim language renders the term "in parallel with" vague or indefinite in the context of the subject patent. Indeed, the claim language clearly states that, in response to a first command, the second data storage facility is attached "in parallel with" the first in order to establish a mirrored copy of the data in the second data storage system. Given the objective of the subject attachment, it would be obvious to one skilled in the art that the phrase "in parallel with" means that the two data storage devices are attached together so that they correspond to one another in time, i.e. they are attached such that a mirroring relationship is created whereby changes made to the data in the second storage facility are made concurrently with changes to the data in the first storage facility. See '497 Patent, Col. 17, In 56 - Col. 18, In. 5. Thus, the phrase "in parallel with", as used in Claim 1 of the '497 Patent, describes the result of the attachment of the two data storage devices rather than the attachment itself.

Although that construction may not be obvious from a cursory review of the claim terms, because one of ordinary skill in the art would likely understand such use of the disputed term, the phrase "in parallel with" is not "insolubly ambiguous" and HP has not met its weighty burden of proving that a claim term is vague or indefinite. In accordance with the claim language and the Specification, therefore, the term "in parallel with" will be construed to mean that the two data storage systems are attached to correspond to one another in time such that a mirroring relationship is established whereby the two data storage facilities receive data from the first application concurrently.

Although used in a different context, that construction is also consistent with this Court's construction of the disputed claim term "concurrently" in the '347 and '792 Patents.
9. "In Relation to the Credit Value"

The plaintiff argues that this term does not need further construction. In the alternative, the plaintiff proposes "having a relationship to the credit value." The defendant proposes "having a one-to-one correspondence or other desired relationship to the credit value."

The defendant argues that the specification describes a numerical relationship between cash value and credit value. See '116 patent, 4:37-41. Although the specification describes such a relationship, the court is not persuaded that this claim term needs construction. This term may be understood according to its plain and ordinary meaning. No further construction is necessary.
Claims 1, 7, 11, and 14 refer to various computers acting "in response to" requests. NCI argues that this phrase means "to take some action in reply to or in reaction to the request." NCI's arguments are based on the ordinary meaning of the words. Microsoft counters that the phrase should mean that the response occurs "as a direct result of" or is "directly caused by" the request. Microsoft argues further that "in response to" cannot be unlimited in time, cannot cover breaks in causation, and that NCI's construction would eliminate the Claims' requirement of what performs the response. NCI responds that Microsoft is improperly adding time and event limitations from the specification.

The ordinary meaning of the words in the claim is clear; no further interpretation is necessary. "In response to" means to take some action in reply to or in reaction to the request. Nothing in the specification or prosecution history limits the meaning of this phrase, and it is immaterial whether the response occurs immediately after the request or whether there is a time gap or intervening events prior to the response. To add limitations of time and singular causation would be to improperly import limitations from the specification. Toro Co. v. White Consol. Indus. Inc., 199 F.3d 1295, 1301 (Fed. Cir. 1999).

The parties dispute the term "in response to a query command," which appears repeatedly in the context of the phrase "determining [a join table definition] in response to a query command." Because the parties do not dispute the meaning of "a query command," the specific issue is the meaning of "in response to." Defendants assert "in response to" should be construed to mean "after receiving." Plaintiff contends this term is entitled to its ordinary meaning, and that the ordinary meaning of "in response to" is "in response to." The Court relies on the plain and ordinary meaning of "in response to." See Interactive Gift Express, Inc. v. CompuServe Inc., 256 F.3d 1323, 1331 (Fed. Cir. 2001) (where claim language is clear on its face "then our consideration of the rest of the intrinsic evidence is restricted to determining if a deviation from the clear language of the claims is specified"). Neither the specification nor prosecution history provides a different meaning for "in response to" or indicates Plaintiff used the term with a meaning other than its ordinary meaning. As Plaintiff argues, "in response to," in the context of the claims, means the join table definition must be responsive to the query command. Defendants agree that "in response to" includes a causation requirement, but Defendants' construction consists of only a temporal requirement. (Defs.' Opp'n to Pl.'s Opening, at 20:22-24.) Under Defendants' construction, it does not matter what the resulting join table definition is, as long as the join table definition comes after the query command.

In addition, the Court agrees with Plaintiff that Defendants' construction limits the claim by requiring the entire query command to be received before the system can begin processing the query command. Nothing in the intrinsic evidence limits "in response to a query command" in this manner. Indeed, the specification describes the use of "queues" and "streaming" for parallel query processing, and indicates that data may be in the form of "data streams." Col. 9, lines 10-12, Col. 14, lines 33-37.

Therefore, the Court finds "in response to a query command" is entitled to its ordinary meaning.

The '386 Patent

The administrative law judge held that the claim term, "circuit interrupter coupled to the actuator assembly, the circuit interrupter being configured to disconnect the first conductive path from the second conductive path in response to the actuator signal in the reset state" did not require construction and could be analyzed according to its plain meaning. The administrative law judge noted, however, that the circuit interrupter need only trip in response to an actuator signal generated by a fault in the reset state; it need not trip in response to a wiring state detection signal in the reset state.
On review, the Commission mostly agreed with the administrative law judge, though it noted that the claimed circuit interrupter had to be configured to trip in response to the actuator signal in the reset state. Since the asserted claim requires the actuator assembly to generate an actuator signal in response to the wiring state detection signal, it follows that generation of a wiring state detection signal ultimately causes the circuit interrupter to trip when in the reset state. Commission Op. 2009 ITC LEXIS 525 at *23. The specification teaches that a wiring state detection signal is generated when the device is properly wired. Accordingly, under the Commission's interpretation of the claim the patented device must be configured to trip in response to a signal that the device is properly wired. Id. In so holding, the Commission acknowledged that such a claim requirement was not perfectly logical, and may have been the result of a claim drafting error. Id. Under the Commission's construction, the devices at issue were found not to infringe.

On appeal, P&S challenges the Commission's interpretation by arguing that the claim does not require the device be configured to provide a wiring state detection signal in both the tripped and reset states. According to P&S, the relevant claim limitations are satisfied by a device configured to provide a fault detection signal in the reset state, even if it is not configured to provide a wiring state detection signal in the reset state. As P&S admits, a device configured in this way would never trip in response to a wiring state detection signal in the reset state, because no such triggering signal would be generated in that state. Rather, it would only trip in response to a fault detection signal in the reset state. P&S argues that the claim as drafted is perfectly logical, and that the Commission's reinterpretation and characterization to the contrary merely betray a misunderstanding of the claim language.

We disagree. The plain language of claim 1 of the '386 patent requires that the circuit interrupter be configured to trip in response to an actuator signal in the reset state. The wiring state detection circuit and the actuator assembly claim elements do not contain limitations as to the circuit state. These components of the device must therefore generate their respective signals at least once, without regard to the state of the device (i.e., reset or tripped). Construing this limitation to require generation of an actuator signal without respect to the state of the device does not conflict with any other limitations of the claim. For instance, if a wiring state detection signal is generated in the reset state, then it will trigger an actuator signal, which will then trip the device. If such a signal is generated in the tripped state, it will again trigger the actuator signal. The actuator signal will not engage the circuit interrupter, of course, because the device is already tripped.

P&S's objection to the Commission's construction primarily relies on a statement in the specification that the wiring state detection circuit operates when the line terminal is powered and the appliance is properly wired, and not when it is improperly wired. See '386 patent col.12 ll.27-30. P&S argues that it makes no sense to require a miswiring protection device be configured to trip a properly wired appliance and not an improperly wired appliance. The plain language of the claims, however, does not allow for an exception to this consequence, and the intrinsic evidence of record supports the Commission's construction. The specification contemplates embodiments in which the wiring state detection signal trips the device in the reset state only once, until a fuse or resistor is burned out. See id. col.7 l.59-col.8 l.15.

P&S's claim differentiation argument, which relies on a comparison to claim 9, is also unavailing. Claim 9 requires that the device generate a wiring state detection signal during the transition between the tripped state and the reset state, in response to the user pressing the reset button. Id. col.15 ll.29-62. Under the plain language of claim 9, this signal may be generated while the device is completing the transition between states, and thus before it has entered the reset state. This limitation in claim 9 is not present in the claim asserted here, claim 1. Claim 1 is broader. It reads on a device configured to generate a wiring state detection signal in both the tripped and reset states. Moreover, just like asserted claim 1, claim 9 requires the device to trip in response to a wiring state detection signal in the reset state. See id. col.15 ll.45-60. The problem of the device tripping when properly wired therefore affects claim 9 and claim 1 alike.

The argument that the transition term of the claim is open-ended likewise does P&S no good. Even though the device may include additional wiring state detection circuits that generate signals only in the tripped state, it must still contain at least one wiring state protection circuit that generates a signal at least once when power is applied, without respect to the state of the device. If the accused products do not contain such a circuit, as the Commission found, then they do not infringe. See Warner-Jenkinson Co., 520 U.S. at 29. We see no error in the Commission's findings on this point.

2093

B. Defendant's Motion for Summary Judgment of Invalidity of the '621 Patent and Plaintiff's Motion for Summary
Judgment of No Invalidity of the '621 Patent

Claim 1 of the '621 patent recites the claim limitation of "a controller connected to said switching member and to a third winding of said transformer, for generating said control signal in response to the output of said power supply." ('621 patent, col. 10, 11. 45-48)

Defendant asserts that the '621 patent is invalid because each of the asserted claims is not enabled by the specification. More specifically, defendant argues that the claim limitation "in response to the output of said power supply" is not enabled by the specification. The validity dispute is essentially a dispute regarding claim construction.

The parties agree as to the essence of the invention described in the specification of the '621 patent. The patent discloses a switching power supply. As described by the patent,

it is especially preferred for the power supply to include a transformer having first, second and third windings, wherein the voltage component is provided to the first winding and wherein the second winding defines the output of the power supply. A switching member is connected to the first winding for permitting and preventing the flow of current through the first winding. The switch member is operable in response to a control signal. A control member generates the control signal in response to the output of the power supply and is connected to the third winding. ('621 patent, col. 2, 11. 38-47) The following is a simplified diagram of figure 5 of the '621 patent that illustrates the invention described in the specification.

GET DRAWING SHEET 4 OF 6

Defendant argues that the claim requires the controller to operate in response to the output of the power supply (i.e., the second winding) but the specification enables a controller operating in response to the feedback winding (i.e., the third winding). Plaintiff asserts that the third winding is representative or reflective of the second winding and, thus, the controller is responding to the second winding.

Defendant's argument is buttressed by the fact that in the parent application to the '621 patent the examiner rejected similar claim language in a different claim based on lack of enablement. Claim 8 in the parent application claimed, in relevant part, "a reference current generator for generating a reference current signal in response to the output of said power supply." (D.I. 103 at 383609) The examiner rejected claim 8 "under 35 U.S.C. § 112, first paragraph, as the disclosure is enabling only for claims limited to a reference current generator responsive to the voltage across the third transformer winding." (Id. at 383641) The patentee responded to the rejection stating, "applicant has amended claim 8 to now reflect that the reference current generator generates a reference current signal in response to a signal reflective of the output of the power supply. Such language could include the third winding or some other winding. The examiner's objection is believed to be overcome." (Id. at 383659) (emphasis added) Thus, claim 8 in the '621 patent states, in relevant part, "a reference current generator for generating a reference current signal in response to a signal reflective of the output of said power supply." ('621 patent, col. 11, ll. 16-18) Claims 1 and 13 (the asserted independent claims) were not rejected by the examiner nor amended by plaintiff based on this enablement issue.

The parties have each proposed a claim construction that, if adopted, is dispositive of the issue of enablement. 1 The court has reviewed the patent and determined that the proper construction of the phrase "a controller ... generating said control signal in response to the output of said power supply" means "the controller generates the control signal based a direct reaction from the second winding."

--- Footnotes ---

1 Plaintiff argues that the claim limitation "generating said control signal in response to the output of said power supply" means "that the control signal is generated based on a signal, such as voltage, that is representative of the output of the power supply." Defendant asserts that "in response to the output of said power supply" means "in response to the output of the second winding; does not include a signal reflective or representative of the output of the second winding."

--- End Footnotes ---
This claim construction is in accord with the prosecution history of claim 8. Plaintiff argues that "all the applicants did by amending claim 8 was make express the meaning of the claim term 'in response to the output of the power supply' that was already known to one of ordinary skill in the art -- the control signals are generated in response to a signal reflective of the output of the power supply." (D.I. 116 at 28) The court disagrees. The patentee indicated during prosecution what the plain language makes clear - adding the words "reflective of" to the claim was necessary to coincide with the specification.

Furthermore, plaintiff has failed to cite any evidence that one of ordinary skill in the art would understand that in the asserted claims the control signals are generated in response to a signal reflective of the output of the power supply. 2 In the absence of facts set forth in detail in an affidavit by a knowledgeable affiant, plaintiff has failed to carry its burden of proof. See Barmag Barmer, 731 F.2d at 835-36 (internal citation omitted).

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

2 Although not cited in the claim construction papers or the summary judgment briefs, the court did locate the expert report of Professor James K. Roberge. (D.I. 106, Ex. 21) The expert report of Professor Roberge simply reiterates the attorney argument presented by plaintiff in the briefing papers. The expert report does not provide any guidance for the court with respect to what one of ordinary skill in the art would understand "in response to the output of the power supply" to mean.

- - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

While it is not clear why the examiner did not reject claims 1 and 13 on the same basis as claim 8 (or why the patentee did not amend each of the claims pursuant to the enablement rejection), the court finds claims 1 and 13 are not enabled by the specification. The claims require the controller to directly respond to the second winding. The specification, however, only enables a controller that responds to the third winding.

For the reasons stated above, defendant's motion for summary judgment of invalidity of claims 1, 2, 12, 13, 23 and 24 (D.I. 100) is granted. Plaintiff's motion for summary judgment of no invalidity of the '621 patent (D.I. 107) is denied.

2094

Elster argues that the district court's claim construction is not in accordance with the plain and ordinary meaning of "in response to." Specifically, Elster contends that the claim should be construed to cover a controller that generates a control signal in reaction to the output of the power supply, i.e., an indirect reaction to the output of the second winding, as reflected in the output of the third winding. Elster contends that an indirect response by the third winding to the second winding of the transformer is enabled by the specification. Schlumberger points out that even if the claim is construed to include an indirect and a direct response to the second winding, the written description must enable both. Schlumberger contends that under this construction, the summary judgment for invalidity was appropriate because the claim covers the third winding's direct response to the second winding, and the written description fails to enable such a direct response.

Claim 1 of the '621 patent provides:

1. A power supply for use in apparatus for electronically measuring or distributing electrical energy, said electrical energy defining an input voltage, said power supply comprising:

   a transformer comprising first and second windings, wherein said input voltage is provided to said first winding so that current flows through said first winding, wherein said second winding defines the output of said power supply;

   a switching member connected to said first winding, for permitting and preventing the flow of current through said first winding, wherein said switching member is operable in response to a control signal;

   a controller connected to said switching member and to a third winding of said transformer, for generating said control signal in response to the output of said power supply; and
a voltage blocking clamp, connected to said transformer and said switching member, wherein said input voltage is applied to said voltage blocking clamp, for limiting and blocking the voltage applied to said transformer, said voltage blocking clamp comprising first and second transistors and biasing means connected to said first and second transistors, wherein said biasing means biases said first and second transistors so that the voltage provided by said voltage blocking clamp does not exceed a desired level.

'621 patent, col. 10, ll. 31-58 (emphases added). The claim recites that the "controller connected . . . to a third winding" of the transformer responds "to the output of said power supply." Id. at col. 10, ll. 45-48. The claim also recites that "the output of said power supply" is defined by the second winding. Id. at col. 10, ll. 35-39. Therefore, in order to have the controller respond to the output of the power supply, the signal in the third winding must be responsive to the signal in the second winding. The district court appeared to recognize this principle by construing the claim limitation "in response to" to require the third winding directly respond to the second winding. However, this claim construction is unduly restrictive because the claim encompasses any response-either direct or indirect-by the third winding to the second winding. Nonetheless, claims 1 and 13 are not enabled because the written description fails to teach any response between the third and second windings.

10. "in response to a user selecting one of the entries' universal resource locator" (claims 5 & 7)

Plaintiff argues that this term means "that information is presented to the user after the user selects one of the search results displayed as a result of the search." Defendant proposes that the term should be construed to mean "in response to a user selecting one of the embedded web addresses." This is another instance in which the defendant asks the court to limit the computer network to the World Wide Web by requiring an URL to be limited to a Web address. That argument previously was rejected.

The construction proposed by the plaintiff is consistent with the record. The court construes "in response to a user selecting one of the entries' universal resource locator" to mean that information is presented to the user after the user selects one of the search results displayed as a result of the search."

5. "in response to the stored compressed, digitized data"

Claim 14 provides:

in response to the stored compressed, digitized data, transmitting a representation of the at least one item at a real-time rate to at least one of a plurality of subscriber receiving stations coupled to the local distribution system

The parties dispute the proper construction of the phrase transmitting "in response to the stored compressed, digitized data" as that phrase is used in Claim 14 of the '863 patent.

The word "responsive" has a plain and ordinary meaning, namely, "answering." See Webster's New Twentieth Century Dictionary, 1543 (2d ed. 1983). In the field communications field, a responsive action is one which replies to a transaction generated by a request. IEEE 100: The Authoritative Dictionary of IEEE Standards Terms, 976 (7th ed. 2000). Thus, the word "responsive" is commonly understood to describe both a "cause-effect" relationship between two events and a timing relationship between them.

4 In the "cause-effect" relationship, a second event is "responsive" to a first event if the first event causes the second event to happen. In the "timing" relationship, the second event is "responsive" if the second event happens after the first event. The Court finds that these two concepts are not mutually exclusive.
The Court finds that one of skill in the relevant art reading the patent documents would give the phrase "in response to the stored compressed data" in its plain and ordinary meaning. Accordingly, the transmitting step is caused by the storing of the compressed, digitized data and is commenced after the storing of the compressed, digitized data. 5

5 Although it is not explicitly stated as a step, because the information which is stored is the same information which is being transmitted (albeit at a real-time rate), a step of retrieving the information from the place where it is being stored is necessary before the information can be transmitted.

With respect to the timing concept included in the definition of "in response to," the parties dispute whether the responsive "transmitting" step may take place while the information is being stored in the local distribution system, or must the "transmitting" step wait to commence after the storing step has been completed. In the December 14 Order, the Court held that a step, which acts as an antecedent for a subsequent step, must commence before the succeeding step commences, and it must finish before the succeeding step can finish. However, the succeeding step can start while the antecedent step is in process. (See December 14 Order at Section IA2.) The Court gives this same interpretation to Claim 14 and finds that the responsive transmitting step can start before the antecedent storing step has been completed.

The Court construes the phrase transmitting "in response to the stored compressed, digitized data" as follows:

transmitting a representation of the at least one item which is initiated by the commencement of storing compressed, digitized data or by the completion of storing compressed, digitized data.

7. "each controlled rectifier being turned on and off in synchronization with the voltage waveform across a primary winding" (’190, ’083, and ’702 patents)

* * *

SynQor argues that, contrary to the Defendants’ assertions, the terms "synchronous rectifier" and "controlled rectifier" are not synonymous. SynQor argues that the term "synchronous rectifier" may refer to a device that contains a controlled rectifier plus other things, such as a body diode that is part of the structure of the synchronous rectifier. SynQor argues that the specification describes a MOSFET "synchronous rectifier" composed of a "controlled rectifier" (e.g. a transistor) and an "uncontrolled rectifier" (e.g. a diode). See ’190 patent, 6:27-29. SynQor argues that other types of synchronous rectifiers do not include an uncontrolled rectifier. SynQor also argues that the claim language clearly indicates that the inventor did not use the terms "synchronous rectifier" and "controlled rectifier" synonymously. SynQor also argues that its proposed construction follows the same logic as the agreed upon construction for the term "uncontrolled rectifier." Defendants argue that the clarity of the claim language is such that no construction is necessary other than to note that the rectifiers required by the claim are "synchronous rectifiers." Defendants argue that the language of the claims makes it clear that there cited rectifiers are "synchronous rectifiers." Moreover, the specifications of the patents-in-suit repeatedly use the term "synchronous rectifiers" to describe the exact types of rectifiers recited in the claims. Defendants argue that the term "controlled rectifier" on its face is not limited to a "semiconductor" device and there is no language in the specification that would limit the concept of a "controlled rectifier" only to a semiconductor device. Further, Defendants argue that SynQor improperly injects "fact findings" into the proposed construction that is inconsistent with the specification and the claims. Defendants argue that while there are no references equating a MOSFET to a "controlled rectifier," there are many references discussing "MOSFET synchronous rectifiers."

The specification uses the terms "synchronous rectifier," "controlled rectifier," and "uncontrolled rectifier." In contrast, the claims only use the terms "controlled rectifier" and "uncontrolled rectifier." Defendants admitted during oral argument that a "controlled rectifier" is not always a "synchronous rectifier." Rather, Defendants essentially argue that in the context of the
claims and specificationthat the rectifiers as claimed are "synchronous rectifiers." The Court rejects this argument. The Court has consistently held that when the claims and specification use different terms, that those different terms should normally not be given the same meaning. While there are portions of the specification that indicate a relationship between controlled rectifiers and synchronous rectifiers, the Court will not equate the two terms when the claims expressly require "controlled rectifiers." Further, in certain dependent claims, such as claim 5, the "controlled rectifier" is a "voltage controlled field effect transistor," which is not necessarily a synchronous rectifier.

The claims and the specification contrast "controlled" and "uncontrolled" rectifiers. In general, a diode is an uncontrolled device. In contrast, a "controlled rectifier" is a type of active device, represented by a transistor. The background of the invention states that diodes are sometimes replaced with transistors called synchronous rectifiers, which "are typically power MOSFETs for converters switching in the 100 kHz and higher range." See '190 patent, 1:42-47. The specification provides that "the schematical drawings of Q3 and Q4 depict the need for a controlled rectifier (e.g. a transistor) and an uncontrolled rectifier (e.g. a diode) connected in parallel." Id. at 6:25-27. Thus, both in the specification and dependent claims, a controlled rectifier is represented by a "transistor." However, the specification repeatedly references a MOSFET with a synchronous rectifier. Id. at 1:45-46; 6:24-25; 12:24-26; 13:25-26; 16:8-10. While a MOSFET synchronous rectifier might be a controlled rectifier in some instances, the Court is hesitant to equate a MOSFET to a controlled rectifier in its construction when the specification treats a MOSFET as a synchronous rectifier and when SynQor ardently opposes equating a controlled rectifier with a synchronous rectifier. The parties agreed that the term "uncontrolled rectifier" means "diode (including MOSFET body diode) or other passive device used as a rectifier." The Court will adopt a similar construction for the term "controlled rectifier" as the parties did for the term "uncontrolled rectifier." Thus, the Court construes the term "controlled rectifier" to mean "transistor or other active device used as a rectifier."

Regarding the entire phrase, consistent with previous terms and for the same reasons, the Court rejects SynQor's attempt to add "during normal operation" to this term when there is no basis for it in the claims or the specification. The phrase requires the controlled rectifiers to act in synchronization with the voltage waveform across a primary winding. In general, the dictionary definition of synchronization means to occur at the same time, to operate in unison, or to cause to agree in time of occurrence. Synchronization, as used in the claims, implies that the controlled rectifiers are turned on and off at the same time as a change of the voltage waveform, not a change from one voltage stage to another. SynQor attempts to add "approximately" in its construction for the term without support in the specification, and thus the Court denies such an attempt. However, the Court notes that one of ordinary skill in the art would not view "synchronization" to mean "at exactly the same time." The Court also rejects Defendants' insertions of the limitations "each time" and "voltage state" as unnecessary limitations not based on the specification or the claims. Both parties recognize that the controlled rectifiers can be turned from onto off and from off to on. Thus, the Court construes the term "each controlled rectifier being turned on and off in synchronization with the voltage waveform across a primary winding" to mean "each controlled rectifier being turned from on to off or from off to on at the same time as a change of the voltage waveform across a primary winding."

C. "Based Upon The Order Of The List," "Based Upon The Desired Order," and "In The Desired Order."

Parties dispute the meaning of the above three terms. Essentially, Blockbuster argues that these three terms are interchangeable in the context of the patents in suit. The first term appeared in claim 14 of the '381 patent which recited in pertinent part (col. 13:64-14:17):

14. A computer-implemented method for renting movies to customers, the method comprising:

- providing electronic digital information that causes one or more attributes of movies to be displayed;

- establishing, in electronic digital form, from electronic digital information received over the Internet, a movie rental queue associated with a customer comprising an ordered list indicating two or more movies for renting to the customer;

- causing to be delivered to the customer up to a specified number of movies based upon the order of the list, wherein the customer is not required to return the movies within a specified time associated with delivery;
in response to one or more delivery criteria being satisfied, selecting another movie based upon the order of the list and causing the selected movie to be delivered to the customer.

The second and third terms were used in claims 4 and 5 of the '450 patent (col. 14:64-15:19):

4. A method as recited in claim 1, wherein

the one or more item selection criteria indicates a desired order for the one or more items that a customer desires to rent, the step of providing to the customer up to a specified number of the one or more items indicated by the one or more item selection criteria includes providing to the customer up to a specified number of the one or more criteria in the desired order indicated by the item selection criteria; and

the step of providing to the customer one or more other items indicated by the one or more item selection criteria includes providing to the customer one or more other items indicated by the one or more selection criteria in the desired order indicated by the one or more item selection criteria.

5. A method as recited in claim 4, further comprising if a particular item from the one or more items indicated by the one or more item selection criteria is not available, then providing another item from the one or more items based upon the desired order indicated by the one or more item selection criteria.

Here, Netflix proposes that "based upon the order of the list" should, mean "so as to provide the next-available movie in the order specified by the list." Blockbuster proposes that the same term should mean "in the same sequence as that of the 'ordered list' referred to earlier in the claim." As to "based upon/in the desired order," Blockbuster argues that both terms should have the same meaning, "in the same sequence in which any person wants the items to be provided." Netflix proposes that "based upon the desired order" should mean "so as to provide' the next-available movie in the rental sequence specified by the customer," and that "in the desired order" should mean "in the rental sequence specified by the customer."

The question of whether or not the order in the "list" is the customer's order has already been addressed. As stated above, it may be the customer's order but need not be so restricted. The real dispute is over the meaning of "in" versus "based upon." Had the inventors chosen to do so, they could have used the same term, either "in" or "based upon," in both claims. They did not. The use of two different terms in close proximity gives rise to the inference that two different meanings were intended for the two different terms. Bancorp Serv., L.L.C. v. Hartford Life Ins., 359 F.3d 1367, 1373 (Fed. Cir. 2004). Looking to commonly-understood meanings, "based upon" allows some deviation from the exact, specified order, while "in" requires that the order must be followed. This inference could possibly be defeated, of course, by showing evidence to the contrary. Blockbuster fails to do so.

The use of the terms in the claims is instructive. Claim 4 of the '450 patent recited "the step of providing to the customer one or more other items indicated by the one or more item selection criteria includes providing to the customer one or more other items indicated by the one or more selection criteria in the desired order indicated by the one or more item selection criteria" (col. 15:8-12). Claim 5 depended from claim 4, and recited "further comprising if a particular item from the one or more items indicated by the one or more item selection criteria is not available, then providing another item from the one or more items based upon the desired order indicated by the one or more item selection criteria" (col. 15:13-18). Here, if the first item on the customer's list was unavailable, the system would select another item from the list. When the provider chooses an item "based upon" the order of the list, the provider does not necessarily follow the list's precise order.

Indeed, if "based upon" and "in" were given the same meaning in these two claims, the provider would have no way to continue renting items to the customer until the first item on the list were available. This reflects the reality that the provider cannot rent what it does not currently have. The specification also supports this construction. The '381 patent stated "[c]ustomers may specify priorities for the items indicated by the item selection criteria. Thus, if a particular customer's first choice is not available, or already rented, then the item having the next highest priority can be rented to the particular customer" (col. 11:18-23). Blockbuster's argument under the written-description requirement of 35 U.S.C. 112, P 1 fails because of this. Blockbuster argues that the specification teaches no other criteria for selecting movies other than those that the customer selected. The above statement shows that this is not the case. The specification explicitly contemplated considering the availability of items before renting them and does not exclude the use of other factors.
The requirement that "based upon" necessarily means the next-available item, however, is without support. Reading this limitation into the definition would render claim 5 redundant because the concept of sending the next-available item was specifically recited. Accordingly, this order holds that "based upon the order of the list" allows for some deviation from the exact order of the list. "Based upon" need not be strictly based on availability; it could be based on other factors. *In the desired order* refers to the precise order the customer selected, while "based upon the desired order" allows for some deviation from the desired order that need not be solely based on availability.

---

2099

1. Inaudible (Claim 1)

Plaintiff Arbitron proposes that the Court adopt the Random House dictionary definition of the term "inaudible" as being "incapable of being heard." Ipsos points to the background section of the patent to argue that the inventors understood inaudible to mean below 40 Hz or in the range of -50 to -60 db. It further points to an amendment filed with the USPTO during prosecution to argue this narrow understanding of the term by the inventors during prosecution. Arbitron contends that the same amendment included definitions of "audibility" and "inaudible," and explained to the examiner that a sound can be inaudible based either on the frequency, the signal level or when it is masked by other sounds. The Court concludes, however, that by listing a range in their specification, the inventors have defined the scope of this term.

The Court therefore construes "inaudible" as "a sound signal that is too faint, meaning that it is approximately 50dB to 60dB below the level of its accompanying sound signals or a sound signal whose frequency is outside the range of audible frequencies, meaning that it is approximately below 40 Hz."

---

2100

Although Tomar did not provide the Court proposed constructions for "includes" or "identification code", its arguments with respect to these terms appears to be an attempt to limit the '113 patent to a preferred embodiment. The Court finds, however, that Tomar has failed to demonstrate that the '113 patent should be construed so narrowly.

First, the Court notes that the Federal Circuit has provided a specific construction to the word "includes", and that such construction will be applied in this case:

As a patent law term of art, "includes" means "comprising." See, Amgen Inc. v. Hoechst Marion Roussel, Inc., 314 F.3d 1313, 1344-45 (Fed.Cir.2003); Hewlett-Packard Co. v. Repeat-O-Type Stencil Mfg. Corp., Inc., 123 F.3d 1445, 1451 (Fed.Cir.1997). Neither includes, nor comprising, forecloses additional elements that need not satisfy the stated claim limitations.

SanDisk Corp. v. Memorex Products, Inc. 415 F.3d 1278, 1284 (Fed. Cir. 2005). Thus, use of the word "includes" in the claim language does not support Tomar's narrow construction.

---

2101

C. "memory includes an audio recorder" / "said memory including an audio recorder mounted in said housing"

Claim 4 of the "783 patent states in part, "wherein said memory includes an audio recorder in said housing for recording sounds." Likewise, claim 77 contains the following limitation: "said memory including an audio recorder mounted in said housing." Both parties chose to construe the full term "said memory including an audio recorder mounted in said housing" in claim 77, but the shorter term "memory includes an audio recorder" in claim 4. For "said memory including an audio recorder mounted in said housing," Minerva argues that no construction is necessary, or alternatively, the term means "the memory is linked to a device within the housing for recording sounds." The defendants contend that this term means "the
memory contains a device for recording sounds that is attached to the housing." Minerva's proposed definition of "memory includes an audio recorder" is "the memory contains instructions for recording audio." The defendants assert that this term means "the memory contains a device for recording audio." The written description provides no definition of "includes" or "audio recorder," and its usage of "memory" appears to be consistent with that word's plain and ordinary meaning.

The proposed constructions differ regarding whether the audio recorder is a physical device or software instructions and whether the audio recorder is located in the memory or in the housing. The defendants argue that the plain and ordinary meaning of the term "includes" is "contains." See Merriam-Webster's Collegiate Dictionary 588 (10th ed. 1998). Thus, according to the defendants, the memory must contain the audio recording device. But the dictionary also defines "include" as "to take in or comprise as a part of a whole or group." Merriam-Webster's Collegiate Dictionary 629 (11th ed. 2006).

In contrast, Minerva contends that, according to one of skill in the art, it would make no sense to have memory—a storage medium for data—contain a separate device. See Phillips, 415 F.3d at 1312-13. Therefore, Minerva wishes to define "audio recorder" as either a set of instructions or a separate physical device linked to memory.

Defining "includes" as "contains" does not make sense, because the audio recorder would have to be contained in the memory as well as in the housing. Likewise, there is no support for defining "audio recorder" as memory instructions in claim 4, but in claim 77, defining it as a physical device. The court perceives no meaningful difference between the disputed terms in claim 4 and 77. Thus, the court defines the terms "memory includes an audio recorder in said housing" and "memory including an audio recorder mounted in said housing" to mean "the memory comprises an associated device in the housing for recording sounds."

The parties dispute the meaning of the term "includes" in the phrase "a scrambled television program signal that includes an identification code" of claim 8. IPPV contends that "includes" requires that the identification code be part of the transmitted program signal and that the identification code not overlap, in time or space, the video signal portion of the program signal. Echostar, on the other hand, argues that "includes" requires the identification code to be part of the video signal, and as such, in order to not disturb the viewable portion of the signal, it must be placed in the vertical retrace interval.

In support of its position, IPPV refers the court to the plain meaning of "include," which is to take as a part or member. IPPV argues that its proposed construction is supported by this plain meaning and is consistent with the specification, which states that "the codes [including the identification code] are preferably included in the vertical retrace interval of the video portion of the program signal," and that "during the vertical retrace interval, various equalizing and synchronization pulses are provided, and it is in this interval that the scramble and program ID codes are preferably combined with the transmitted program signal." (emphasis added). IPPV contends that the inventors' use of the term "preferably" makes clear that while the retrace interval may be the best location, there are other options.

Echostar counters by referring the court to Figures 1, 3 and 4 of the specification. It points out that in each of these figures, the identification code is placed in the vertical retrace interval of the video signal. Echostar therefore contends that claim 8 requires that the identification code be placed in the interval.

After reviewing the parties contentions and the specification, the court finds that claim 8 does not require that the identification code be placed in the vertical retrace interval. The plain language of the claim makes clear that the program signal, and not the specific video signal, includes the identification code. Moreover, the inventors' use of the term "preferably" in describing the placement of the code shows that the inventors favored the vertical retrace interval, but that there were other less advantageous alternatives. This preference explains why the figures included in the patent place the code in the interval. The preference and the figures, however, do not justify a limitation of the plain language of the claim. Thus, the court will construe "includes" to require that the identification code be part of the transmitted program signal, but the court will not limit the location of the code within the program signal to the retrace interval.
5. Includes Relationship/Excludes Relationship/Removes Relationship/Requires Choice Relationship/Optional Relationship

The parties have grouped these terms together. The dispute is whether the "relationship" language requires a construction which imposes a "left-hand side" and "right-hand side" limitation to the terms. Trilogy contends that the term "includes relationship" means "a classification in which a second set of one or more elements is included when all members of a first set of one or more elements exist in a configuration." Selectica contends that the term "includes relationship" means "a relationship that causes the elements on the right-hand side of the relationship to be included in the configuration when all elements of the left-hand side of the relationship are already included."

In discussing the relationship terms, the patents state "[a] relationship relates a first set of parts with a second set of parts."

651 patent, col. 2, 11. 13-14. The patents also state:

Preferably, the part relationships are: included, excluded, removed, and requires choice. An included part is included automatically. A part is excluded from the configuration when its inclusion would result in an invalid configuration. A part may be removed when another part is added. Thus, when a first part exists in the configuration and a second part is added, the first part is removed from the configuration. The requires choice relationship is used to allow a set of choices to be made from a group of parts.

'651 patent, col. 2, 11. 23-31. For essentially the reasons discussed previously, the court adopts the following constructions of these terms:

"includes relationship" means "a relationship that causes the elements on the right-hand side of the relationship to be included in the configuration when all elements of the left-hand side of the relationship are already included;"

"excludes relationship" means "a relationship that causes the elements of the right-hand side of the relationship to be excluded when all elements of the left-hand side are already included;"

"requires choice relationship" means "a relationship in which a number of elements must be chosen from a second set of elements on the right-hand side of the relationship when all elements of the left-hand side are already included;"

"removed relationship" means "a relationship that causes the elements of the right-hand side of the relationship to be removed when all elements of the left-hand side are already included;" and

"optional relationship" means "a relationship in which a number of elements may be chosen from a second set of elements on the right-hand side of the relationship when all elements of the left-hand side are already included."

Claim Element 11d

including a web page at the web site having customized information from the first user point for users at the second user point

The parties disagree on the meaning of the above-stated language.

Dell argued that the ordinary meaning should suffice. Lucent proposed: "the web site includes a web page containing a subset of the managed information that is assembled to suit the needs or preferences of users at the second user Internet point." The court concludes that no construction of this claim term is required.
2. "Inclusion" and "three-dimensional inclusion" Claims 1-5.

This term is used in each of the five claims of the '742 patent. An exemplar use in Claim 1, stating in part, with the disputed term in bold: "each of said sub-layers having three-dimensional inclusions in a semiconductor material. . . ."

Nichia argues that the proper term to construe is actually "three-dimensional inclusion" and offers the definition "islands of indium arsenide grown using three-dimensional nucleation and then buried by a different material." The specification discloses inclusions made from semiconductor materials other than indium arsenide ("InAs"). In addition, Claim 4 specifically states that the inclusions are made of InAs, while Claim 1 merely discloses the need for inclusions. Reading Claim 1 to require the inclusions to be made of InAs would render Claim 4 unnecessary. At the hearing Nichia agreed that the inclusions need not be made from InAs. Tr. at p. 50, l. 14 - p. 51, l. 25.

Seoul suggested that "inclusion" should be construed to mean "a crystal or a fragment of a crystal found within another crystal." This is somewhat broad, implying that an inclusion could be of any material.

The "Summary Of The Invention" starts off with "one of the layers comprises three-dimensional inclusions in a semiconductor material . . . ." '742 Patent, col. 2, l. 66-67. The patentees distinguished prior art, including U.S. Pat. No. 4,802,181 to Iwata which used etching and subsequent deposition to create quantum boxes and U.S. Pat. No. 4,751,194 to Cibert et al which disclosed ion-implantation and lithographic masking techniques to form quantum boxes, by stating that the inclusions were grown in the material and not inserted later. Pl. Br., Ex. 5 (Prosecution File History), Examiner's First Office Action at 3-4; Response to First Office Action at 4-5. The patentee distinguished the references on the basis that the inclusions are formed "during the semiconductor crystal growth" Id. at 5.

The only growth process discussed in the specification is three-dimensional nucleation. Col. 6, l. 37-39. Seoul contends that the specification discloses the two-dimensional growth mode as a route to the formation of inclusions. Tr. at p. 41, l. 2-9; See col. 5, l. 18-20. However, that part of the specification describes only the growth of the first monolayer of atoms. The specification then goes on to discuss a transition to a three-dimensional growth mode beginning with the second monolayer of atoms. Col. 5, l. 21-25; l. 38-40. The three-dimensional growth mode can be accomplished via different synthetic routes, such as molecular beam epitaxy, chemical vapor deposition and vapor phase epitaxy. See col. 6, l. 38-40. The fact that different techniques may be used to deposit the material that makes up the layers does not change the fact that the physical formation of the inclusions is by three-dimensional growth process.

While the parties argued about the use of "island" in any definition, the word is used a number of times within the specification. Col. 4, l. 62; col. 5, l. 25; col. 5, l. 26; col. 5, l. 28; col. 5, l. 29. It does not necessarily convey a "flat region" as argued by Seoul. Tr. at p. 63, l. 22-23 (testimony of Seoul's expert Dr. Streetman). The "Description of the Preferred Embodiments" disclosed a hemispherical shape. Col. 4, l.62 - 63 ("the inclusions 8 of InAs form islands substantially of a semi-spherical cap shape"). Further, use of the term "island" to convey three-dimensional features is consistent with the extrinsic evidence. Def. Resp., Doc. # 53, Ex. 10, J-Y Marzin, III-V Semiconductor Strained-Layer Superlattices, in Physics, Fabrication, and Application of Multilayered Structures 215, 220 (Dhez & Weisbuch eds., 1988) ("the growth process can switch from bidimensional to three-dimensional: this process results in the formation of 3D islands"); see also Def. Resp., Doc. # 53, Ex. 2, Dieter Bimberg, Marius Grundmann, and Nikolai Ledentsov, Quantum Dot Heterostructures 43 (1999) (illustrating a pyramid and prism shapes). The court will therefore construe, the term "inclusion" as follows:

"inclusion" and "three-dimensional inclusion" mean "island of semiconductor material grown by three-dimensional nucleation buried in a layer of a different semiconductor material that has a larger bandgap."

"Three-dimensional nucleation" is a process where structures form and grow in three-dimensions, but does not include two-dimensional flat layer-by-layer growth.
The word "incrementally" is used by Roxio in Claims 1, 4, 17, and 20 of its '686 Patent. The relevant language of Claims One and Seventeen is similar; both claim "A method [system] of incrementally storing data on a compact disc . . . ." ('686 Patent, col. 18, ll 65-66; col. 19, ll. 60-61). Claims Four and Twenty specify that "wherein said at least one packet is recorded in a form compatible with the Orange Book specification for linking packets recorded incrementally." ('686 Patent, cot. 19, ll. 28-30; col. 20, ll. 31-34).

Each party's proposed claim construction of "Incrementally" is as follows:

<table>
<thead>
<tr>
<th>Optima's Proposed Claim</th>
<th>Roxio's Proposed Claim</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>&quot;Incrementally&quot;</strong></td>
<td>Information Written to a CD</td>
</tr>
<tr>
<td></td>
<td>In several distinct writing</td>
</tr>
<tr>
<td></td>
<td>actions (e.g., at different</td>
</tr>
<tr>
<td></td>
<td>times, or on different</td>
</tr>
<tr>
<td></td>
<td>recorders).</td>
</tr>
</tbody>
</table>

The parties' dispute over the term "incrementally" is centered on whether the construction must be limited to a method of recording CDs using "packets" or not. Optima urges that packets necessarily are a part of incremental writing (Pl.'s Opening Markman Brief, p. 15-17); however, Roxio contends that the term should not be so limited. (Roxio's Opening Claim Construction Brief, p. 18-19).

The Court finds that Roxio did not act as its own lexicographer with respect to the term "incrementally." Therefore, the Court begins its analysis with a presumption that the term has its full ordinary or accustomed meaning. K-2 Corp. v. Salomon S.A., 191 F.3d 1356, 1362-63 (Fed. Cir. 1999); see Brookhill-Wilk 1, LLC v. Intuitive Surgical, Inc., 334 F.3d 1294, 1298 (Fed. Cir. 2003) ("In the absence of an express intent to impart a novel meaning to the claim terms, the words are presumed to take on the ordinary and customary meanings attributed to them by those of ordinary skill in the art.")

When engaged in claim construction analysis, the Court is free to consider extrinsic evidence to educate itself about the term and relevant technology. Karlin Tech. v. Surgical Dynamics, 177 F.3d 968, 971 (Fed. Cir. 1999).

The ordinary meaning of "incremental" is "the process of increasing in number; size, quantity, or extent." AMERICAN HERITAGE DICTIONARY OF THE ENGLISH LANGUAGE (4th ed. 2000). The customary meaning of the term, however, can be found in § 5.2 of the Orange Book, 8 which states:

> Recording the disc in several distinct writing actions (e.g., at different times, on different recorders) is defined as Incremental Writing. In case of Incremental Writing the linking rules must be taken into account.

(ORANGE BOOK § 5.2.)

8 The "Orange Book" is a common reference to a publication entitled "Recordable Compact Disc System," Part II CD-WO, Version 2.0, System Description, January 1994. N.V. Philips and Sony Corp. Optima and Roxio both cite to § 5.2 of the Orange Book to support their proposed claim construction. (Pl. Opening Markman Brief, p. 15-17; Roxio's Opening Claim Construction Brief, p. 18-19.)

Thus, it is clear under the Orange Book definition that the linking rules must be taken into account when using Incremental Writing. Therefore, the Court refers to § 5.2.3 of the Orange Book, entitled "Data Linking," which states, among other things, that "[e]ach Data Track must contain minimum one Packet with User Data." ORANGE BOOK § 5.2.3.

The Court finds the ordinary meaning of "incremental" inapposite because it does not address the technical nature of the
The Court finds that the customary meaning of the term, as provided by the Orange Book, is proper. Optima's proposed construction, "Information written to a CD in one or more distinct writing actions using packets," thus comports with the term's customary meaning and is adopted by the Court as the correct construction.

9 The Court notes that both parties have submitted extensive expert reports to aid the Court in construing the terms at issue in this action. These reports were considered but not relied on by the Court in deciding the instant motion because the ordinary or customary definition of the terms at issue were found in dictionaries and other treatises. See Texas Digital Systems Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202-03 (2002) (explaining that dictionaries, encyclopedias; and treatises are more reliable sources of information with respect to the meaning of terms than expert testimony, which is "colored by the motives of the parties" and "inspired by litigation"). The Court acknowledges that experts views may be helpful; the Court simply did not have to do that level of analysis on the present record.

2107 3. "Independent" is construed to mean "performed by a computer algorithm(s) at least partially distinct from the algorithm(s) for computing the collective mass information, and where the computation of spiculation information is performed separately from the computation of the collective mass information."
3. "Independent communication"

SercoNet contends that "independent communication" should be construed as "communication among a pair of devices that does not effect nor preclude the communication of any other communicating pair of devices." NetGear contends the term should be construed as "capable of communicating with adjacent cells by means of different types of frames and protocols." An example of such communication, according to NetGear, is "if cell B is connected to cells A and C, cell B uses one type of frame and protocol to communicate with cell A, and a different type of frame and protocol to communicate with cell C." The parties' proposed constructions make clear that the real dispute is the meaning of the term "independent."

This term is used in claims 1-6 and 21 of the '360 patent, claim 1 of the '510 patent, and claims 18 and 36 of the '280 patent. Starting with the claim language, claim 1 of the '360 patent refers to communication channels that allow "mutually independent communication in either or both directions and comprising at least two electrical conductors, . . . " Claim 1 of the '510 patent describes communicating pairs, "each of said at least one communicating pair is operative to engage in said communication bidirectionally and independently of the communication of any other of said at least one communicating pair." Claim 36 of the '280 patent describes communication links in which the first communication link "carried data independent of said second communication link."

Reading the plain language of these claims, independent communication denotes a communication between each pair, in which such a communication operates irrespective of communications between any other communicating pair. However, the claim does not really define "independent." The language of the claims does not focus on how an invention may achieve independent communication. Rather, the claim language focuses on what it means to communicate independently. The claim language, therefore, supports SercoNet's construction of "independent communication," as NetGear's construction focuses on the means by which such communication is achieved.

Turning to the claim specification, the '280 patent notes that communication between SICs of a communicating pair is independent of the communication between SICs of any other communicating pair, in that these communications neither preclude nor affect one another in any way. See '280 patent at 4:40-45. The specification, therefore, explicitly defines the term according to SercoNet's construction. It also states that the SIC network can support two "independent communication routes simultaneously, provided different segments are used . . . for example, SIC 800 can communicate with SIC 802 while SIC 804 simultaneously communicates different data with SIC 806." The '360 patent also references communications between "adjacent PSICs in either or both directions independent of a simultaneous communication between another pair of adjacent PSICs." See '360 patent abstract; see also '360 patent at 6:28-30.

NetGear relies on part of the '510 specification which discusses differences between the circular topology defined in the invention and prior art ring topology. One difference is in framing. The ring uses the same frame structure throughout all communication links, and all cells must recognize the same framing. In the present invention, however, "each communication link (between any two connected SICs) is totally independent from all other network communication. Hence, a first SIC can communicate with a second SIC using one type of frame structure and protocol, while the same first SIC can communicate with a third SIC using a different type of frame structure and protocol."

This discussion, however, occurs in the context of discussing multiple differences between one type of topology of the invention -- the circular topology -- from the Token Ring topology of the prior art. It is not clear that using different types of frame structure and protocol is the only way of implementing independent communication. And again, this part of the specification is giving an example of how such communication can be implemented, rather than defining what it is. Finally, there is no real clarification in the specification as to what "frame structures" and "protocols" are, and construing the term with such words would not lend any clarification to the construction.

NetGear also relies on the patent prosecution history in support of its construction, noting that the inventor maintained that each communication link in the invention can be totally independent from any other and that "cell B can communicate with connected cell A using one type of frame and protocol, while its communication with cell C may use a different type of frame and protocol." See Parry Decl. Ex. 1 at 5. This construction has problems for the reasons discussed above. In addition, patent prosecution history is less important and less reliable in claim construction than the specification. See Phillips, 415 F.3d at 1317.
In sum, and for all the reasons set forth above, the court adopts SercoNet's proposed construction of "independent communication" and construes the term "independent communication" as: "communication among a pair of devices that does not effect nor preclude the communication of any other communicating pair of devices."

10. Independent forward and return channels; upstream channel that is independent of the downstream channel; independent upstream channel

The above terms are found in various claims of the '774, '121, and '845 patents. The plaintiff's proposed construction of each term is "the downstream channel is different from the upstream channel, either in the same or a different medium." The defendants propose "forward (downstream) and return (upstream) channels which are not contingent upon one another that connect to an interface allowing for multiple types of physical media to be used on the return (upstream) channel." The court has considered the parties' arguments and adopts the plaintiff's proposed construction. The specification and prosecution history do not require the channels to use different media.

The clauses at issue in claims 61 and 67 relate to the interface's ability to perform functions "independent of" the connected application program. Claim 61 has two contested clauses: "means, independent of the one computer-related application, for forming link data linking a portion of the audio data to at least one of the recognised words independently of the one computer-related application;" and "means, independent of the one computer-related application, for updating position identifiers in response to changes in positions of the recognised words within the one computer-related application." '273 Patent col.29 ll.38-41, 48-51. Claim 64 (on which claim 67 depends) has the clause: "means, independent of the computer-related application, for determining positions of the recognised words in the computer-related application." '273 Patent col.30 ll.7-9. The district court construed "independent of" to mean essentially "isolated." Janicke Report P 56-60. According to this interpretation, the claimed interface cannot receive any information back from the application. Rather, it must keep track of the positions of words in the application without ever obtaining position data from the application.

This interpretation of the claims is not correct. Instead, the claim term "independent of" means that the interface must maintain its own position data, in its own data structures, but still have the ability to receive positional information from the application. Once again the district court went astray by taking the prosecution history out of context. As discussed earlier, AllVoice distinguished its invention during prosecution from an older software application program called Digital Dictate: "However, in contrast to the claimed invention, the 'Microsoft Word' version of Digital Dictate reviewed in the Seybold Reports 1 itself fails to include any feature that determines the positions of recognized words. Instead of including these features within its system, Digital Dictate depends on the bookmarking feature inherent to Microsoft Word, the application program targeted to receive speech input." Janicke Report P 55 (emphases in original). The district court read this passage as a disavowal of any interface ability to receive information from the application program for use in maintaining position data.

To the contrary, this passage merely requires that the AllVoice interface include a feature that "determines [the] positions of the recognized words," "within its own system." Id. This distinction does not bar the interface from receiving any information from the application. As long as the interface maintains its own internal data structure to keep track of the positions of words, neither the prosecution history nor the claim language prevents the interface from using information from the application to maintain that data structure.
Thus, the district court proceeded to assess indefiniteness with an unduly narrow claim construction. This narrow reading of the "independent of" requirement in claims 61 and 67 led to a finding that the specification did not contain structure corresponding to that narrow claimed function. With a proper reading of the claim term, however, the specification does contain adequate structure. Figure 2 and its associated description in columns 5, 6, and 7 of the patent show that memory maintains the position data separately from the application. Specifically, memory 20 stores the link data 25 (the position data stored by the interface 12) separately from the current document 26 maintained by the text processor 13. ‘273 Patent col.5 ll.44-62.

GET DRAWING SHEET 2 OF 17.

Because neither the claim language nor the prosecution history requires more, the record shows that the district court erred in finding claims 61 and 67 indefinite on the basis of the "independent of" language.

2112

n. "external clock is operative at a frequency independent of a clock frequency of said oscillator"

The plaintiffs propose "a change in the frequency of the oscillator (claims 6-9) or the variable speed clock (claim 10) does not affect the frequency of the external clock." The defendants propose "an external clock wherein a change in the frequency of one of the external clock or oscillator does not affect the frequency of the other (claim 6)."

The Court construes the term to mean "an external clock wherein a change in the frequency of either the external clock or oscillator does not affect the frequency of the other."

GO BACK

2113

m. "second clock independent of said ring oscillator . . . system clock" and "second clock independent of the ring oscillator system clock"

The plaintiffs propose "a change in the frequency of the ring oscillator does not affect the frequency of the second clock." The defendants propose "a second clock wherein a change in the frequency of one of the second clock or the ring oscillator system clock does not affect the frequency of the other." The dispute is whether the term "independent" means "one-way independence" or "two-way independence."

The plaintiffs argue that the specification only refers to one-way independence because it describes the situation where the I/O clock has a fixed speed while the CPU clock has a variable speed. According to the plaintiffs, there is no discussion about the situation where the I/O clock speed can be modified without affecting the CPU clock speed; the specification only states that varying the CPU clock speed would not affect the I/O clock speed.

The defendants argue that the plaintiffs' construction would conflict with the purpose of the invention of having a first clock function independently from the second clock. According to the defendants, the specification describes the first and second clock as functioning independently from one another.

The defendants have the better argument. One of ordinary skill in the art would understand the term "independence" to mean "two-way independence." Accordingly, the Court construes the term to mean "a second clock wherein a change in the frequency of either the second clock or ring oscillator system clock does not affect the frequency of the other."

2114

ii. Independent processes
Plaintiff contends that "independent processes" means "devices external to the computer." Sun proposes that the term should be construed as "processes under the control of distinct (separate) state machines." Apple contends that the terms means "a group of coordinated devices (i.e. tasks) under the control of peripheral controllers, where the devices in the groups generate interrupts. Each group is independent of each other group."

With respect to the parties' positions, they appear to agree that "independent processes" is a special term to which no ordinary meaning attaches. As a result, the parties each resort to the specification for guidance. The parties also appear to agree that the independent processes are external to the computer.

The Gobeli patent states that "the interrupt handler should be capable of overseeing such devices . . . Each of these independent device subsystems should be viewed as an external process' with its own unique context." Gobeli patent, Col. 4, 11.67 -- Col. 5, 11. 4. Further, the patentee states "the combined motion of each subsystem is viewed as a process . . ." Id. at Col. 6, 11. 23-24. "The motion of each subsystem is, in effect, an external process." Id. at Col. 11., 11. 58-60. Thus, the Gobeli patent explains that independent processes are not solely limited to devices, but could also be device subsystems.

Sun's proposed construction parrots the claim term itself and includes the additional limitation of a "state machine." The Court rejects any "state machine" limitation. Certain claims of the Gobeli patent expressly mention a "state machine" limitation; however, Claim 11 does not. Moreover, although Sun asserts that the only embodiment in the Gobeli patent is a state machine interrupt handler, the specification suggests that an interrupt handler is not always equivalent to a state machine. See Gobeli patent, Col. 11, 11. 60-62 ('the interrupt handler services two external processes, each of which requires a separate state machine."") Id. at Col. 11, 11. 60-62.

Apple includes in its definition the limitation that the devices must be controlled by a "peripheral controller." Just as with Sun's construction, this is an example of the preferred embodiment. The Court finds that peripheral controllers and state machines are additional limitations related to the preferred embodiment and therefore refuses to incorporate them into the claims. See Comark Communications, Inc. v. Harris Corp., 156 F.3d 1182, 1186 (Fed. Cir. 1998)(cautioning against reading limitations from preferred embodiment into claims).

Accordingly, the Court finds that "independent processes" are "the part of the devices or device subsystems external to the computer that independently generate interrupts."

"the user can request viewpoint motion and point of interest motion independently"

Claim 52 of the '785 Patent contains the term "the user can request viewpoint motion and point of interest motion independently." IPI contends the term means "the user can request viewpoint motion and/or point of interest motion separately or simultaneously." Google contends the term means "the user can request viewpoint motion and point of interest motion separately and simultaneously." The parties dispute whether both requests must occur separately and simultaneously.

IPI argues that its proposed construction is supported by the specification, which states that "[u]ser input means can include one or more 'user input devices' that provide signals based on actions of a user, such as a keyboard or a mouse." '785 Patent, col. 5:57-60 (emphasis added). The specification goes on to describe how the signals are requested:

Signals from user input means can request motion of the viewpoint and motion of the POI. If the user can request viewpoint and POI motion separately and can request both types of motion simultaneously, the user input means is structured so that the user can request viewpoint motion and POI motion "independently."

'785 Patent, col. 8:5-10. IPI interprets this to mean that "the user could request viewpoint motion, point of interest motion, or viewpoint motion and point of interest motion." IPI's Opening Brief, at 24. Thus, the specification teaches that the user can request viewpoint motion and point of interest motion "independently" of each other. Google counters that IPI's proposed construction "disowns" the invention described in the specification by changing "and" to "and/or" and "or," and IPI's attempt to expand the reach of the claim limitation is simply unsupported. Google's proposed construction requires that
the user be able to request both viewpoint motion and point of interest motion separately as well as simultaneously. IPI asserts that it "is at a loss for how a claim element whose plain meaning requires that a request for motion independently must also occur simultaneously." IPI's Reply Brief, at 8-9.

It appears the parties are saying the same thing in different words. The parties only get into a semantic dispute, especially in regard to inclusion of "simultaneously" in the constructions, because the specification uses "independently" in a somewhat garbled description. In view of the specification and the claim language, it is clear that the user can request viewpoint motion and point of interest motion separately, simultaneously, or separately and simultaneously. However, neither the specification nor the claim language require that the user request viewpoint motion and point of interest motion separately and simultaneously.

The plain and ordinary meaning of "independently" as used in the claim language is "individually." The specification, particularly in view of the example given of using one hand to request point of interest motion and the other hand to request viewpoint motion (i.e., individually), is consistent with this meaning. See '785 Patent, col. 8:11-14. Thus, the Court construes the term "the user can request viewpoint motion and point of interest motion independently" to mean "the user can individually request viewpoint motion and point of interest motion." Although the Court finds that it is not necessary to include any reference to "separately" and "simultaneously" in the term's construction, it has nevertheless resolved the parties' dispute in accordance with O2 Micro International Ltd. v. Beyond Innovation Technology Co., 521 F.3d 1351 (Fed. Cir. 2008). To the extent that this claim term arises at trial, the Court instructs the parties to tailor their trial arguments to conform with this Order.

D. "Independently connected electrically" (claim 5)

Claim 5 teaches that each gate electrode segment is "independently connected electrically" to the bus. The parties dispute whether this language discloses that the gate electrode segments cannot connect to each other. AMD proposes the following construction of the phrase "independently connected electrically": "A gate segment is 'independently connected electrically' if it has its own connection or can connect without having to go through another gate segment." According to AMD, claim 5 imposes no limitation on whether the gate electrode segments can connect to each other, in addition to being connected to the bus. Samsung's proffered construction is: "Each gate electrode segment is connected through a separate electrical path that is not shared by any other gate electrode segment." Under Samsung's construction, each gate electrode segment must connect to the Vcc bus through a connection that is not shared with any other gate electrode segment.

The Court agrees with Samsung that the phrase "independently connected electrically" in claim 5 means that the gate electrode connects to the Vcc bus and not with any other gate electrode. AMD's construction is inconsistent with the innovation disclosed in claim 5. The specification explains that in a preferred embodiment of claim 5, the independent gate electrodes have "separate" connections with the bus so that the gate electrodes are "insulate[d]" from one another." 5:11-25. One advantage of this structure is that if a defect (i.e. a short) occurs between the bus and a single gate electrode, the defect is isolated. 5:33-43. The defect causes of the loss of an individual gate segment, but insulation prevents the short from spreading to the rest of the capacitor. Id.

Samsung points out that AMD's construction permits the connections illustrated in the following diagram, where the dashed line is a direct connection between the gate electrode and the bus, and the solid line represents a second connection, through another gate electrode. Samsung Opp. Br. at 29. Samsung explains that electrical current follows all paths simultaneously. Hassoun Decl. P 41. If, as AMD proposes, a gate electrode can have two connections to the bus (i.e. one that is direct and one that is through a second gate electrode), current will flow through both connections at once. In the foregoing diagram, current will necessarily flow through the direct connection (the dashed line) and the second gate electrode (the solid line). As a result, the first gate electrode will not be insulated and will not have an "independent" connection to the bus. If the direct connection shorts, the defect will not be isolated. AMD's construction is not viable because it allows for a construction that precludes the preferred embodiment of claim 5.

[SEE DIAGRAM IN ORIGINAL]
AMD objects that the phrase "connected through a separate electrical path" (emphasis added) in Samsung's construction incorrectly permits only a single electrical path between the gate electrode and the bus. AMD points out that nothing in claim 5 precludes multiple connections between the bus and gate. (Applying this embodiment to the foregoing diagram, AMD argues that there could be several dashed lines between the Vcc bus and the gate, where there is now only one dashed line.) The Court agrees that nothing the claim language or specification imposes a limitation of a single direct connection. Accordingly, the Court adopts Samsung's construction, modified as follows: "Each gate electrode segment is connected through a separate electrical path, or paths, that are not shared by any other gate electrode segment."

H. Independently modifiable copy

Visto proposes that the term "independently modifiable copy" means "a copy of a workspace element capable of being modified independent of the workspace element. The copy does not have to be an exact copy." Seven contends that the term means "a copy of a workspace element stored on a global server that has content capable of being modified independently of any modification to the content of the workspace element."

This term appears throughout the patents. Visto supports its proposed definition, particularly the last sentence, by pointing to language in the specification of the '708 patent which suggests that the copy of the workspace element may be in a different format: "The system includes a first store for storing a first workspace element in a first format [and] a second store for storing a second workspace element which is an independently modifiable copy of the first workspace element in a second format." '708 Patent, Abstract. As noted above, the '708 patent describes a global translator for maintaining data consistency when data are stored in two locations in different formats. Although the data may be stored in a different format in different locations, Visto's proposed definition appears to suggest a broader meaning of copy than the claim language supports. The court has reviewed carefully the cited portion of the specification and therefore defines the term "independently modifiable copy" to mean "a copy of a workspace element capable of being modified independent of the workspace element. The copy of the workspace element does not have to be in the same format as the workspace element."

III. "[A] layer acts independently of other content within a particular HTML document"

The phrase "a layer acts independently of other content within a particular HTML document" is not found in any claim but remains critical to defining the scope of the patents in suit because it defines an embodiment of a "Window Object." The term "Window Object" ("window object") appears in every independent claim of the '493, '563, and '882 Patents. "A window object is a Module or a Layer." E.g. '493 Patent col. 5, l. 64. A "Layer" ("layer") is defined in identical glossaries found in the '493, '563, and '882 Patents as follows:

A Layer is a WWW browser content display section produced within a content manifestation environment (CME) including, but not limited to, any object within an HTML document that may be scaled, dragged, or otherwise operated upon such as an IMG object, a SPAN object, a DIV object, a form element, etc. and which may be associated with program logic such as within a script, etc. A layer has its own properties including, but not limited to, a name, etc. within an HTML rendition model such as those defined by DHTML standards. Additionally, a layer acts independently of other content within a particular HTML document.

A. The Special Master's Recommended Construction
According to the Special Master, "a layer acts independently of other content within a particular HTML document" means that the activity associated with a layer, such as moving or resizing, does not depend on other content within a particular HTML document." (R&R at 139-40.) The Special Master's recommended construction was built upon an extensive analysis which included the following steps: (1) construing the term "window object" according to the claim language and specifications of the '493, '563, and '882 Patents; (2) describing the relevant technical background of a "layer" in the context of HTML and DHTML standards; (3) defining the attributes of a layer within the context of the specifications of the patents in suit; and (4) analyzing the source code disclosed in the '493 Patent in order to determine how certain embodiments of the claimed invention would operate in light of the requirement that a layer act independently of other content in the same HTML document. (Id. at 90-137.)

After framing the term "window object" in the context of the claim language of the patents in suit, the Special Master turned to their specifications. (See id. at 90-97 (construing the term "window object" according to claim 1 of the '493, '563, and '882 Patents).) Based on the identical glossaries found in the specifications of the '493, '563, and '882 Patents, the Special Master defined a "window object" as a "Module or Layer." (Id. at 98 (citing '493 Patent col. 5, l. 64; CCS Fitness, 228 F.3d at 1366).) Combining the teachings of the specifications with the requirements of the claim language of the patents in suit, the Special Master determined that, at the least, DMOs and TMOS were layers which had to "act independently of other content." Next, the Special Master, construed the term "layer."

As an initial matter, the Special Master established that the patentees' glossary definition of the term "layer" would control. (R&R at 99.) What remained was to resolve the parties' dispute over exactly how the glossary definition was to be interpreted. In analyzing the definition of the term "layer," the Special Master noted that a "layer" can be placed in the context of "HTML" and have properties as defined by "DHTML standards." (Id. at 99-100.) According to the Special Master, associating the properties of a "layer" with DHTML allows a window object to: (1) execute scripts that allow for their "dynamic" modification and (2) be acted upon without necessarily impacting other portions of a content manifestation environment. 14 (Id. at 111; see also id. at 106-11 (citations omitted).) Having provided a technical overview of HTML and DHTML, as they relate to the patents in suit, the Special Master turned to the specifications of the '493, '563, and '882 Patents to analyze the characteristics of a "layer." (See id. at 100-11 (discussing the HTML and DHTML standards which informed his recommended construction).)

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

13 HTML and DHTML are programming languages used to develop web pages. In combination with other programs including JavaScript, HTML and DHTML can be used to create the windowed content manifestation environment claimed by the patents in suit.

14 "Dynamic" modification includes but is not limited to user actions such as moving, resizing, closing and minimizing window objects within their content manifestation environments. In the context of the patents in suit, the patentees claim that dynamic modification can be done without triggering a "refresh." In essence, DHTML contributes to the ability of a user to manipulate a window object without causing the content manifestation to be reloaded or redrawn.

- - - - - - - - - - - - - - End Footnotes - - - - - - - - - - - - - -

In order to construe the disputed phrase, "a layer acts independently of other content within a particular HTML document," the Special Master first determined the acts a layer was capable of performing and then determined the scope of the term "independently" as intended by the patents in suit. According to the Special Master, the claim language and specifications of the patents in suit clearly indicate that the acts of a "layer" include: (1) scaling; (2) dragging; (3) resizing; (4) minimizing; (5) maximizing; (6) being made to pop up; (7) being closed; and (8) manifesting and refreshing content such as text, video or sound. (Id. at 114-15.) However, the Special Master indicated that it was unclear as to whether or not the acts of a layer included "refreshing or reloading content." (Id. at 115-17.) Next, upon consideration of the relevant intrinsic evidence and the acts a "layer" is capable of performing, the Special Master noted that "the word 'independent' in the context in which it is used appears to mean just that -- 'not dependent.'" (Id. at 117.) Accordingly, the Special Master determined that "the phrase 'a layer acts independently of other content' merely connotes that the acts of a layer are not subject to control by other content, or do not require or rely on other content." (Id.) Next, the Special Master determined whether DMOs and TMOS "acted independently" as contemplated by the patents in suit.
The Special Master pointed out that there was little dispute over the behavior of DMODs which could be "moved independently ('freely') within the browser CME, i.e., without constraint by other content." (Id. at 118.) However, the truly debatable issue was whether TMODs "acted independently." (Id.) As the Special Master pointed out, the parties agreed that "tiled" means "arranged to be adjacent and non-overlapping" (Id. at 119.) In light of the patents in suit, the Special Master proceeded to find that, as a verb, "tile" would be understood as follows by one skilled in the art: "'[i]n an environment with multiple windows, to rearrange and resize all open windows so that they appear fully on the screen without any overlap.'" (Id. (citation omitted.).) In laymen's terms, window objects that remain tiled could be adjacent to each other but could not be placed or positioned so that they overlap each other. The next step was to determine the behavior of TMODs when they were moved.

15 Once again, in this context, "independently" means "not subject to control by other content, or . . . not requir[ing] or rely[ing] on other content." (R&R at 118.)

The Special Master concluded that, according to the specifications of the patents in suit, TMODs can be defined "'much like a tiled type window provided within an operating system environment,'" such as "'Microsoft Windows.'" (Id. at 119-20 (citing '493 Patent col. 6, ll. 25-26, col. 9, ll. 1-6, col. 11, ll. 26-35.) This is significant because of the way in which windows could be "tiled" in Microsoft Windows. (Id. at 120.) Specifically, "in the Microsoft Windows environment, tiled windows may be tiled or untiled by the user, and also dragged about the screen." (Id. (citation omitted.).) This led the Special Master to find that the specifications of the patents in suit did not "require or even suggest" that TMODs snap into predetermined rows and columns. (Id.) In essence TMODs could only behave as tiled windows in the Microsoft Windows operating system, if they were to "act independently of other content," since snapping would require that the movement of a window object be constrained by other content such as position information or other window objects in the same content manifestation environment. The Special Master then reinforced his conclusion by analyzing the specifications of the patents in suit.

16 The Special Master detailed how windows were tiled in the Microsoft Windows Operating System as follows:

There seems to be no dispute over how Microsoft Windows worked at the time of invention. Mr. Goodman, for example, has explained that "'[i]n Microsoft Windows you can place your cursor on a blank portion of the task bar (the bar with the 'Start' button), right click, and select 'Tile Windows Vertically.' If you run Excel, Word, and Adobe Acrobat applications, and select 'Tile Windows Vertically,' you will end up with a screen * * * showing Excel, Word, and Adobe Acrobat windows tiled across the screen. You can drag and resize any window independently of anything else on the screen." Goodman CC Decl. at P 26. That is, in the Microsoft Windows environment, tiled windows may be tiled or untiled by the user, and also dragged about the screen.

(R&R at 120.)

17 The Special Master defined the term "snapping" as follows:

Although the parties do not explicitly say what "snapping" is, they appear to have a common understanding of that term, namely, that automatic alignment into rows and columns, or at least with respect to other tiled elements, when moved or resized so that all of the elements remain tiled. None of the references at hand define "snapping" per se; nevertheless, it seems clear that "snapping" perhaps implies the existence of an invisible "table" or grid arrangement into which window objects are forced to avoid overlap with other windows when dragged about and imprecisely dropped by user. The MICROSOFT COMPUTER DICTIONARY (4th ed. 1999) defines "drag-and-drop" as a verb:

2. [T]o perform operations in a graphical user interface by dragging objects on the screen with the mouse. For example, to delete a document, a user can drag the document icon across the screen and drop it on the trashcan icon (Macintosh OS) or in the Recycle Bin (Windows).
Indeed, this comports with Simple's understanding of the term as applied to TMODs. "According to Simple, '[b]y definition, tiled window objects cannot be 'freely moved' independently of other window objects,' but rather "snap" into a column and row of a table of window objects,' which sometimes"causes other window objects in a 'column' to be moved." (Id. at 86-87 (quoting Defs.' Mem. of Law in Supp. of Summ. J. on Claim Construction (Dkt. No. 365), at 23).)

The Special Master found that according to the specifications of the '493, '563, and '882 Patents, one need only conclude that TMODs are "arranged in table fashion," [but] not that [they] . . . are actually arranged in a table or grid." (Id. at 122.) The Special Master reviewed the relevant portions of the specification, the relevant figures, such as Figure 2A of the '493 and '882 Patents, supra at 22, the relevant source code, such as the "module_draw.js" and "positioning_function.js" files, and questioned Simple's expert witness as to how the patents in suit specifically showed how TMODs could be made to snap into a grid formation. (Id. at 120-30.) Taking the foregoing evidence into account, the Special Master found that, at best, the ability of TMODs to snap was only implied. However, there was no direct indication or proof of this on the record. (Id. at 120-30.) Accordingly, the Special Master found that:

Overall, . . . the specification does not per se disclose or require "snapping" by TMODs, whether in the glossary, description, figures or code. The specification only provides inferences, at best. Nor has Simple pointed to anything in the prosecution histories of the patents-in-suit that requires TMODs to "snap." In short, the glossary's requirement that a "layer" "act independently * * *" is not inconsistent with the specification's disclosure of TMODs.

(Id. at 130.) Since the Court has already discussed the Special Master's proposed construction of the term "content," it will not do so again. Building upon his analysis of the term content, the Special Master concluded that "[t]he phrase 'a layer acts independently of other content within a particular HTML document' means that the activity associated with a layer, such as moving or resizing, does not depend on other content within a particular HTML document." (Id. at 139-40.) The parties however, disagree, and propose their own constructions.

B. The Parties' Objections

CA's "proposed construction would require the acts of the window object neither be affected by nor affect other content." (CA's Claim Construction Objections at 1.) Simple, for its part, attacks the Special Master's definition on various fronts. First, Simple asserts that the Special Master improperly imported a limitation from the specification into a claim term by incorporating the glossary definition of a "layer" into his construction of the term "window object." (Simple's Claim Construction Objections at 2.) Simple further contends that the Special Master improperly excluded a preferred embodiment of the claimed subject matter, TMODS, by (1) incorrectly broadening the definition of the term "content" and then (2) requiring that "the activity associated with a layer, such as moving or resizing, . . . not depend on other content within a particular HTML document." (Id. at 6 (emphasis added).) In addition, Simple asserts that the Special Master failed to consider the acts of refreshing or reloading in reaching his determination. (Id. at 13.)

C. Analysis

Since the parties have not objected to the Special Master's interpretation of "a particular HTML document" the Court need only interpret the phrase "a layer acts independently of other content." Defining exactly what a "layer" is and how it may "act" form the crux of the matter. The Court's analysis of the phrase "a layer acts independently of other content within a particular HTML document" will entail the following steps: (1) defining the terms "window object" and "layer"; (2) identifying the "acts" which can be performed by or upon a "layer"; (3) defining the term "independently" in the context of the patents in suit; (4) defining the phrase "a layer acts independently of other content"; and (5) addressing the parties' objections and arguments.

1. The Patentees' Glossary Definitions of "window object" and "layer" Control

Federal Circuit precedent and the intrinsic evidence before the Court require that: (1) a "window object" be defined as a "Module or a Layer," and similarly (2) a "layer" be defined according to the glossaries in the '493, '563, and '882 Patents. Phillips, 415 F.3d at 1316; CCS Fitness, Inc., 288 F.3d at 1366; Durel Corp., 256 F.3d at 1303-04; Sinorgchem, 511 F.3d at
The glossaries of the patents in suit fit well within the boundaries of instances where the Federal Circuit has found that a patentee's own lexicography will determine the meaning of a disputed term. For example, in Sinorgchem, the patent specification in question stated that a "controlled amount" of protic material is an amount up to that which inhibits the reaction of aniline with nitrobenzene, e.g., up to about 4% H[2]O based on the volume of the reaction mixture when aniline is utilized as the solvent. 511 F.3d at 1136 (emphasis added). According to the Federal Circuit, setting the term apart in quotation marks and following it with the word "is" was enough to "clearly, deliberately, and precisely . . . [define] the term 'controlled amount' of protic material as 'an amount up to that which inhibits . . . , e.g., up to about 4%' . . ." and require that the patentee be bound to this definition. Id. (emphasis and bracketed text added). Similarly, in Abraxis Bioscience, Inc., the Federal Circuit found that the patentee's lexicography trumped ordinary usage because a patent specification clearly defined the term "edetate" in the following passage: "By the term 'edetate' we mean ethylenediaminetetraacetic acid (EDTA) and derivatives thereof . . . ." 467 F.3d at 1376 (citation omitted).

In the case at bar, the answer is obvious. The patentees have gone so far as to use a glossary to clearly define a window object as a "Module or a Layer" and then provide a separate definition for the term "layer." E.g., '493 Patent col. 5, l. 64 - col. 6, l. 8. This level of clarity goes well beyond the quotation marks and the term "is" used in Sinorgchem. Accordingly, a window object must act as either a layer or module would. Having established that a window object is a "module or a layer," and that a "layer" will be understood as defined by the patentees' glossary, the Court will further inform its interpretation of the term "layer."

2. Identifying the "acts" of a "layer"

In order to construe the disputed phrase "a layer acts independently," the Court must first identify the qualities and "acts" of a "layer." In order to define the acts of a "layer," the Court will first identify exactly which "window objects" and embodiments fall under the scope of the term "layer." According to the specifications of the patents in suit, a layer can refer to a DMOD, TMOD, "Fixed Layer," or "Content Manifestation Layer" used to display information within a content manifestation environment in accordance with the patents in suit. See, e.g., '493 Patent col. 5, l. 65 - col. 6, l. 8, col. 6, l. 22-36. "Layers," as understood by the patents in suit, include DMODs and TMODs because a "Module" is simply a "layer" with a control section and content display section. E.g., '493 Patent col. 6, l. 13-21. Accordingly, the acts and properties of a "module" fall under the ambit of the term "layer." (See generally Markman Tr. at 74:3-15.) Consequently, a "layer" can, among other things, be: (1) scaled; (2) dragged; (3) minimized; (4) maximized; (5) restored; (6) made to-pop up; (7) display content; or (8) made to display content or host a module based on user or module operations. E.g., '493 Patent col. 5, l. 65 - col. 6, l. 8, col. 6, l. 27-30, col. 10, l. 33-51, col. 26, l. 41-47. Having listed the acts of a layer, the Court will construe the term "independently" in the context of those actions.

3. "[I]ndependently" Cannot Be Interpreted in an Absolute Sense Because Actions in One Window Object Can Impact Other Window Objects in a Content Manifestation Environment

The intrinsic evidence before the Court makes it clear that a layer can be impacted by or affect other window objects, but need not have a "global" impact on every other element in a content manifestation environment provided in accordance with the '493, '563, and '882 Patents. Any definition of "acts independently" can not require absolute autonomy on the part of all layers at all times since: (1) actions in one window object can cause a new layer to "pop-up"; (2) actions in one window object can lead directly to the display of information in another layer; and (3) certain layers are used to display information not destined for other window objects in a content manifestation environment. E.g., '493 Patent col. 6, l. 27-30, col. 10, l. 33-52. For example, one embodiment of a "layer" is a "Content Manifestation Layer or CML." E.g., '493 Patent col. 6, l. 32-36. CMLs can be made to "pop-up" "based on operations occurring within another Module" in the same content manifestation environment, such as when a user clicks on a link or scrolls her mouse over a certain portion of an active module. See id. Another embodiment of a layer is a "Fixed layer or FL," which is a "static, always visible" layer used to display information not destined for other window objects within the same content manifestation environment. '493 Patent
col.6, ll. 27-32, col. 10, ll. 33-52. For example, a FL, as described by the patents in suit, could possibly be made to display flight schedules, weather reports or other travel related information if a user were to scroll over the "BOOK A FLIGHT" link in item 203, the "TRAVEL" module, in Figure 2B, supra at 17. Accordingly, it is clear that one layer can be impacted by acts performed in another window object.

The specifications of the patents in suit also point out that when a module control is acted upon, it "need not have a global effect on the entirety of the CME in which [a] module . . . is displayed." E.g., '493 Patent col. 8, ll. 46-48. Accordingly, the Court recognizes that a user can minimize, maximize, close, restore, scroll through, or request a help screen from one window object without affecting every other window object in a CME. The Court also recognizes that a user can move, minimize, maximize, resize, or otherwise perform the acts of a layer, without being constrained by or depending on other "content" in the same HTML document. Having identified the functions and properties of a layer according to the specifications of the '493, '563, and '882 Patents, the Court will define the phrase "a layer acts independently of other content within a particular HTML document."

4. "[A] layer acts independently of other content within a particular HTML document" Defined

The Court adopts the Special Master's recommendation and finds that the phrase "a layer acts independently of other content within a particular HTML document' means that the activity associated with a layer, such as moving or resizing, does not depend on other content within a particular HTML document." (R&R at 139-40.) This definition is consistent with the Court's finding that the acts of a layer can be performed regardless of the other content within a particular HTML document but may have an impact upon other content or window objects within a particular HTML document. (See also id. at 117 (stating "the phrase 'a layer acts independently of other content' merely connotes that the acts of a layer are not subject to control by other content, or do not require or rely on other content.").) 18 In short, the Special Master's recommended construction is fully supported by the evidence before the Court. Having defined the relevant phrase, the Court will address the parties' objections and arguments below.

--- Footnotes ---

18 The Court also agrees with the Special Master's interpretation of the claim language and specifications of the '493, '563, and '882 Patents as to the acts which a layer can perform. These acts, as previously mentioned, include: (1) scaling; (2) dragging; (3) resizing; (4) minimizing; (5) maximizing; (6) being made to pop up; (7) being closed; (8) manifesting content such as text; and (9) playing sound. (R&R at 114-15.)

--- End Footnotes ---

5. CA's Argument Is Inconsistent with the Specifications of Patents in Suit

CA's assertion that the "acts of . . . [a] window object neither be affected by nor affect other content" is inconsistent with the specifications of the patents in suit. In light of the fact that the specifications of the '493, '563, and '882 Patents establish that a layer can be made to display content, host another window object or even pop-up based on user actions or merely because other window objects are active within a content manifestation environment, it is clear that a window object is affected by other content. E.g., '493 Patent col. 5, l. 65 - col. 6, l. 8., col. 6, ll. 27-36, col. 9, ll. 39-43, col. 10, ll. 33-51, col. 26, ll. 41-47. However, it is critical to note that one can move, resize, scroll through, close, or otherwise act upon a layer regardless of the other content within a particular HTML document. In short, though a layer can be impacted by user actions upon other window objects in the same content manifestation environment, the acts of a layer cannot be constrained by other content in an HTML document. Having addressed CA's objection, the Court turns to the various issues raised by Simple.

6. The Special Master Correctly Applied the Glossary Definition of the Term Window Object as Required By the Specifications of Each Patent in Suit

Simple's argument that the Special Master improperly imported a limitation from the specification into a claim term by incorporating the glossary definition of a "layer" into his construction of the term "window object" is without merit. (See Simple's Claim Construction Objections at 2.) The '493, '563, and '882 Patents contain identical glossaries. Each glossary states that "[a] window object is a Module or a Layer." E.g., '493 Patent col.5 l. 64. Additionally, a "module" is merely a "layer" with a control section and an associated content display section that can host other window objects. E.g., '493 Patent
7. The Term "Layer" Should Be Given the Same Meaning Regardless of Whether or Not It Is Capitalized

Simple's argument that the Court should ascribe a different definition to "Layer" when it is not capitalized finds no support in the intrinsic evidence before the Court. (See Simple's Claim Construction Objections at 2.) In fact, the patentees' glossary informs its definition of the term "Layer" by referring to it in an un-capitalized format. Specifically, the glossary provides that:

A Layer is a WWW browser content display section produced within a content manifestation environment (CME) including, but not limited to, any object within an HTML document that may be scaled, dragged, or otherwise operated upon such as an IMG object, a SPAN object, a DIV object, a form element, etc. and which may be associated with program logic such as within a script, etc. A layer has its own properties including, but not limited to, a name, etc. within an HTML rendition model such as those defined by DHTML standards. Additionally, a layer acts independently of other content within a particular HTML document.

E.g., '493 Patent col. 5, l. 65 - col. 6, l. 8 (emphasis added to identify each time the term "layer" is used). The Court finds it implausible that the patentees would choose to refer to a different meaning of the term "layer" in the very paragraph they were using to define the term. Indeed, the intrinsic evidence before the Court critically undermines Simple's argument. In short, the patentees have defined the term "layer" in a glossary within the patents in suit and this lexicography will govern.

If the Court were to apply Simple's rationale, one of ordinary skill in the art would be forced to guess whether the patentees meant for the term "layer" to have its specially defined meaning or its ordinary meaning in the art. For example, the capitalized term "Layer" is used four times in the specification of the '493 Patent. '493 Patent col. 5, ll. 64-66 ("A window object is a Module or a Layer. . . . A Layer is a WWW browser content display section"), col. 6, ll. 30-31 ("A Fixed Layer or FL is a layer having the same behavior as a FSR."); col. 6, l. 32 ("A Content Manifestation Layer or CML is a pop-up type layer much like a pop-up dialog box that can manifest . . . . "). The un-capitalized term "layer" is used 19 times, five of which correlate to instances where the term "layer" is used to help define other terms within the glossary of the '493 Patent. See, e.g., '493 Patent col. 5, l. 65 - col. 6, l. 8 (quoted supra, at 50). As shown below, the glossary entry for the term "module" also contains a reference to the un-capitalized term "layer."

A Module (also referred to herein as a Window Module) is a layer having (1) a control section, and (2) a related content display section which may be manifested within a CME. A module may be recursively referenced in that a particular module provided in accordance with the present invention may include other modules. In other words, the present invention makes it possible to have window objects within window objects.

E.g., '493 Patent col. 6, ll. 13-21 (emphasis added). This pattern of usage is consistent with the '563 and '882 Patents as well. Needless to say, the Court will once again decline Simple's request to add uncertainty to the art of claim construction.

8. Since TMODs Are Not Explicitly Disclosed and Contradict the Unambiguous Language of the Patents in Suit, Certain Unproven Aspects of Their Behavior May Be Excluded when Determining the Scope of Patent Claim Language

Simple asserts that the Special Master's interpretation of "acts independently" excludes the embodiment shown above in Figure 2A, supra at 22, featuring TMODs. According to Simple, TMODs must "snap into a column and row of a table of window objects." (Highly Confidential Expert Report of Richard A. Belgard (Dkt. No. 366) ("HC Belgard Expert Report"), at ex. 36 P 101.) Simple's expert witness also asserted that this snapping action may cause "other window objects in a 'column' to be moved" so as to keep a tiled appearance. (Id.) However, in light of this expert report and the specifications of the patents in suit, the Court sees no way in which a window object can remain tiled and act independently of other content in the same HTML document. Moreover, even if it were necessary for a TMOD to remain "tiled," the Court, like the Special Master, finds no express proof of this behavior in the record. The Court provides its rationale below.
When patent specifications disclose multiple embodiments, claims may be interpreted to exclude embodiments which are "inconsistent with unambiguous language in the patent's specification or prosecution history." Sinorgchem, 511 F.3d at 1138 (citing Telemac Cellular Corp. v. Topp Telecom, Inc., 247 F.3d 1316, 1326 (Fed. Cir. 2001); N. Am. Container, Inc. v. Plastipak Packaging, Inc., 415 F.3d 1335, 1347 (Fed. Cir. 2005)); see also Wang Lab., Inc. v. Am. Online, Inc., 197 F.3d 1377, 1383 (Fed. Cir. 1999) (the designation of a particular embodiment as "preferred" does not of itself broaden the claims beyond their support in the specification). Though the Court acknowledges that "[a] patent claim should be construed to encompass at least one disclosed embodiment in the written description portion of the patent specification," it is undeniable that the patents in suit fail to disclose TMODs that remain tiled. See Sinorgchem, 511 F.3d at 1138 (citing Johns Hopkins Univ. v. CellPro, Inc., 152 F.3d 1342, 1355 (Fed. Cir. 1998)) (emphasis added). Moreover, the Court has already construed the disputed claim terms to encompass a content manifestation environment featuring DMODs, one of the preferred embodiments described in the '493, '563, and '882 Patents.

The Federal Circuit's recent decision in Sinorgchem is highly analogous to the case at bar. At issue in Sinorgchem, was the definition of the term "controlled amount" as it pertained to the quantity of "protic material" necessary to inhibit a reaction of aniline with nitrobenzene. Id. at 1136. According to the patent at issue in Sinorgchem, a "controlled amount' of protic material is an amount up to that which inhibits the reaction of aniline with nitrobenzene, e.g., up to about 4% H[2]O based on the volume of the reaction mixture when aniline is utilized as the solvent." Id. (quotations omitted). In a ruling that was vacated and remanded by the Federal Circuit, the United States International Trade Commission held this definition was not controlling for two reasons, the most relevant being that it was countered by an example of a "preferred" embodiment. However, the preferred embodiment was actually one of many disclosed "preferred" examples in two related patent specifications. The example in question related to a reaction of "aniline, nitrobenzene" and another compound under specified conditions, but failed to explicitly disclose the amount of water necessary to facilitate said reaction. Id. at 1139. Due to this omission, one of ordinary skill in the art would have to perform a calculation to determine the proper amount of water used in the reaction. Id. The Federal Circuit reasoned that this inadequately described embodiment was inconsistent with the unambiguously defined term "controlled amount" and could thus be excluded from the scope of the claimed invention.

Simple's interpretation of how TMODs act is not directly shown or taught by the '493, '563, or '882 Patents and would run counter to the consistently stated definition of the terms "content" and "layer." Accordingly, the embodiment of a content manifestation environment featuring TMODs that remain "tiled" is inconsistent with the unambiguous language of the patents in suit and may be excluded when determining the claim scope of the patents in suit. Indeed, an analysis of the relevant intrinsic evidence and Simple's expert testimony only reinforces this finding.

The term "layer" can refer to both TMODs and DMODs.

SPECIAL MASTER PETERSON: Now, let's look at this definition of layer: '… a layer acts independently of other content …. 'A layer may be either a DMOD or a TMOD, right, or include a TMOD or a DMOD?

THE WITNESS [Mr. Richard A. Belgard, Simple's expert witness]: Well, actually a layer is the primitive of DHTML that a TMOD or a DMOD can be constructed of.

SPECIAL MASTER PETERSON: All right. Point being that a layer can refer to both?

THE WITNESS: Correct.

Markman Tr. at 74:3-15; see also, e.g., '493 Patent col. 6 ll 13-26. Moreover, the specifications of the patents in suit distinguish DMODs from TMODs by stating that, a TMOD must be "tiled" while a DMOD must be draggable and freely movable. See, e.g., '493 Patent, col. 6, ll. 21-26, col. 10, ll. 17-32. Yet, there is no mention that TMODs must remain tiled after they are moved. In fact, the specifications of the patents in suit make no reference to modules that "snap" into a pre-aligned grid to remain tiled at all times. Moreover, as Mr. Belgard admits, the patents in suit fail to disclose the programming source code necessary to create an executable embodiment of the claimed subject matter featuring TMODs that remain "tiled." (Markman Tr. at 71:14 - 73:25, 83:24 - 84:11.) Indeed, for TMODs such as those described by Simple to exist, they would potentially have to be repositioned every time they were moved so as to remain adjacent while not overlapping other window objects. Yet, there is no express showing that the source code disclosed in the '493 Patent will

- 2486 -
even perform this repositioning, as evinced by the following excerpt from the Markman hearing.

Q. [Questions posed by Mr Fram, CA's attorney, on cross examination] Before, you said there were missing parts of the code?

A. [Answers provided by Mr. Belgard] Yes.

Q. And some of that missing parts of the code affects, as you understood it, the parts of the code concerning the TMODs that we were looking at; isn't that right?

A. Well, it concerns both. It concerns positioning of the window objects on the screen.

Q. So when something is moving one way or the other positioning, that's what -- that's part of the code that's missing?

A. Yes, some of that code is missing.

(Id. at 83:24 -84:11.) In fact, a detailed analysis of the source code referred to by Mr. Belgard, Simple's expert witness, merely hints that repositioning may occur. E.g., '493 Patent cols. 41-48, 53-58; see also Markman Tr. at 71:10-14 ("[T]his is the outer JavaScript that draws the modules on the screen or helps to draw the modules on the screen, and it calls ancillary routines throughout. It's not -- It would be nice if it was fully contained here, but it's not." 19) As Mr. Belgard, Simple's expert, admits, there are certain JavaScript functions and "routines" which are not disclosed by the '493 Patent but are necessary to position TMODs in a tiled format. (Markman Tr. at 71:10-14.) In short, there is nothing on the record which expressly shows that TMODs must remain tiled or snap into a grid of rows and columns when moved, as suggested by Simple.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

19 In the testimony excerpt above, Mr. Belgard is referring to the JavaScript source code that is used to "draw modules" as they appear in the claimed content manifestation environment. (See Markman Tr. at 71:10-14.) However, as Belgard points out, the JavaScript included in the specification of the '493 Patent is incomplete because it does not disclose the source code necessary to implement TMODs that remain tiled.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The assumption that TMODs snap into place would directly contradict the definition of a layer which must act independently of other "content" in a particular HTML document. The '493, '563, and '882 Patents all state that "content" includes the positioning information of a window object. Ensuring that a TMOD did not overlap but remained adjacent to another window object would require that the act of moving one layer be constrained by the position information of another window object. In the case at bar, just as in Sinorgchem, an inadequately disclosed "preferred" embodiment must be excluded from the scope of a claimed invention. In sum, TMODs which remain tiled are not fully disclosed and run counter to repeated and clearly stated language found throughout the patents in suit.

Even assuming that the TMODs disclosed in the '493, '563, and '882 Patents could "snap" into position after being moved, this would contradict the definition of a layer which must act "independently of other content within a particular HTML document." Indeed, other window objects would potentially have to be repositioned and the layer being moved would be constrained to snap into a specific location since something that is always "tiled" can be adjacent to but may not overlap other window objects. If TMODs were to snap, the independent acts of a layer would be limited to refreshing since resizing, minimizing, moving and maximizing functions would all be constrained by an invisible grid or the placement of other window objects. (HC Belgard Expert Report P 104.) However, the intrinsic evidence makes it clear that a layer can do more than be refreshed. In fact, the Special Master correctly points out that "the patentees consistently described refreshing content as something unnecessary and something that the layers did not cause." (R&R at 115.) In sum, Simple's argument that the Special Master's construction of the phrase "a layer acts independently of other content" is incorrect because it excludes a preferred embodiment of the patents in suit and is inconsistent with the evidence before the Court.

D. The Court's Ruling on the Phrase "a layer acts independently of other content"
Having considered the intrinsic evidence, Markman hearing transcripts, expert witness reports and technical dictionaries associated with the ‘493, ’563, and ’882 Patents, in addition to the parties' objections and counter arguments, the Court concludes that the phrase "a layer acts independently of other content within a particular HTML document" means that the acts of a layer can be performed regardless of the other content within a particular HTML document but may have an impact upon other content or window objects within a particular HTML document. Accordingly, the Court adopts the Special Master's recommended construction of "a layer acts independently of other content within a particular HTML document" and interprets the phrase, as he does, to mean "that the activity associated with a layer, such as moving or resizing, does not depend on other content within a particular HTML document." (R&R at 139-40.) In sum, for a layer to act independently, its acts cannot be constricted by other content in an HTML document.

4. "at least one of said signal processors . . ."

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Plaintiff's Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;at least one of said signal processors in said plurality operates independently of other signal processors&quot;</td>
<td>one (1) or more of the signal processors of said plurality of signal processors executes instructions autonomously from another one of said signal processors</td>
</tr>
</tbody>
</table>

Claim 11

<table>
<thead>
<tr>
<th>Claim Term</th>
<th>Defendants' Proposal</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;at least one of said signal processors in said plurality operates independently of other signal processors&quot;</td>
<td>at least one signal processor can operate without being interrupted by any of the two or more other signal processors</td>
</tr>
</tbody>
</table>

The parties dispute whether this term requires the presence of two or more signal processors or three or more signal processors. Saxon argues that because the term uses the word "plurality," the claim only requires two or more signal processors. See, e.g., Dayco Prods., Inc. v. Total Containment, Inc., 258 F.3d 1317, 1327-28 (Fed. Cir. 2001) ("'plurality,' when used in a claim refers to two or more items, absent some indication to the contrary"). Saxon argues that "[t]he actual claim language requires two or more signal processors, with one of the two or more signal processors operating independently of one or more signal processors." Defendants argue that the plain language of the term requires three or more signal processors.

Saxon's argument focuses on the word "plurality," and ignores the other limitations in the claim. While the term does recite a "plurality" of signal processors, it also states that at least one signal processor must operate independently of other signal processors. This is an undeniable "indication to the contrary," id., that, at a minimum, the claim requires one signal processor to operate independently of two signal processors. Thus, the "plurality" referred to in the term must consist of three or more signal processors. The Court adopts Defendants' proposed construction.

2120

Circuitry Operable Independently of the Operation of Said Memory Array

- 2488 -
The Court adopts ST's proposed construction and construes "circuitry operable independently of the operation of said memory array" as "circuitry whose operation is not contingent upon operation of the memory array." The Court holds that ST's proposal most clearly represents the meaning as understood by one of ordinary skill in the art. Moreover, the Court declines Motorola's proposed construction 7 for two reasons. First, the proposed limitation "located on the same chip as the memory array" appears redundant of the immediately preceding claim language "a plurality of on-chip transistors comprising." '092 Patent, 50:7-8. Second, Motorola’s proposed word "asynchronously" would interject the requirement that the components work in relation to one another. The patent discusses independent operation, and the Court finds no cause to interject asynchronous or synchronous requirements.

--- Footnotes ---

7 Motorola's proposed construction is: "circuitry operable asynchronously from the memory array and located on the same chip as the memory array."

--- End Footnotes ---

b. "independently modifiable copy"

Visto contends that Judge Ward's construction of the term "independently modifiable copy" should be adopted. According to Judge Ward, the term "independently modifiable copy" means "[a] copy of a workspace element capable of being modified independent of the workspace element. The copy of the workspace element does not have to be in the same format as the workspace element." While Sproqit proposes a construction different from that of Judge Ward, it does not dispute the accuracy of his construction. Instead, Sproqit's main argument is that, even if the copy of the workspace element does not have to be in the same format as the workspace element, the copy is otherwise an exact copy of the workspace element. Visto argues to the contrary, even though Judge Ward expressed concern with that very argument. See Ward Order at 16-17 (rejecting Visto's claim that a copy does not have to be an exact copy).

The patents at issue do not explicitly define the term "copy." However, as pointed out by Sproqit, the specifications for the '192 and '131 patents do give context to the word, stating that

In independently modifiable copy of the workspace data 185, referred to herein as workspace data 123, is stored on the global server 120 for easy access by a user from the remote terminal 105. Being a copy, the workspace data includes independently modifiable copies of each workspace element in workspace data and an independently modifiable copy of version information 255 . . , referred to herein as version information.

'192 patent, col. 3; '131 patent, col. 3 (emphasis added). The '708 specification contains similar language. See '708 patent, col. 3 ("[T]he workspace data 120 includes an independently modifiable copy of each workspace element in the selected portions of the workspace data 136 and 116 and an independently-modifiable copy of each corresponding version information 255 . . and 150.") (emphasis added). If a "copy" of workspace data must contain each workspace element making up the workspace data, then it logically follows that a "copy" of a workspace element must contain each subpart making up the workspace element -- in other words, a copy must replicate all the information that comprises the workspace element.

Visto contends still that there is support for its position in the specification for the '708 patent. However, as discussed above, the specification for the '708 patent should not be used to construe the claims of the '192 and '131 patents, at least with respect to new matter contained in the '708 specification. Visto relies on that part of the '708 specification that constitutes new matter. As noted above, the '708 patent addresses translation across different formats, thus potentially adding a new dimension to "copy" not addressed by the '192 and '131 patents.

Even if the Court could consider the new matter in the '708 specification, Visto's argument is not convincing. The part of the '708 specification on which Visto relies states as follows:
FIG. 6 illustrates an example bookmark workspace element in the global format. The global translator 122 incorporates all the information needed by both formats (Format A and Format B) to create the Global Format. For example, if a bookmark in Format A needs elements X, Y and Z and a bookmark in Format B needs elements W, X and Y, the global translator 122 incorporates elements W, X, Y and Z to create a bookmark in the Global Format. Further, the global translator 122 incorporates the information which is needed by the synchronization means such as the last modified date. Accordingly, a bookmark in the Global Format includes a user identification (ID) 605, an entry ID 610, a parent ID 615, a folder ID flag 620, a name 625, a description 630, the Uniform Resource Locator (URL) 635, the position 640, a deleted ID flag 645, a last modified date 650, a created date 655 and a separation ID flag 660.

"708 patent, col. 8.

According to Visto, the above statement "clearly illustrates that an independently modifiable copy of a workspace element need not include the same fields of the original workspace element." Op. Br. at 9. The problem for Visto is that the statement above concerns differences due to different formats. In other words, as argued by Sproqit, there may be differences between the copy and the original workspace element because the applications have different formats, but, if the applications are the same, then the copy should be a complete copy of the original workspace element.

Accordingly, for the '192 and '131 patents, the Court adopts the following construction for the term "independently modifiable copy": A copy of a workspace element capable of being modified independent of the workspace element. A copy of a workspace element is a complete replication of all the information comprising the workspace element.

For the '708 patent, the Court adopts the following construction: A copy of a workspace element capable of being modified independent of the workspace element. A copy of a workspace element is a complete replication of all the information comprising the workspace element unless the copy and workspace element are in different formats. In that case, there may be some differences between the copy and workspace element, but those differences are due to formatting only.

(3) "Index"

EMC contends that an "index" is an organized collection of information, e.g. tables, lists, hierarchical structures or directories. HP responds that, to the contrary, "index" means a single data structure that contains indicators about predetermined data elements and that the indices located on the respective data storage systems must be simultaneously maintained. HP also asserts, with respect to Claim 10 of the '792 Patent, that the four indicators described therein must be contained within "an index." As illustrated by the parties respective definitions, there are four primary disputes with respect to the claim term "index:"

(1) whether the data storage systems must "simultaneously maintain" their respective indices,

(2) whether each data storage system can contain more than one index,

(3) whether an index must be a "single data structure," and

(4) whether, in Claim 10 of the '792 Patent, the four described indicators must be contained within "an index."

The parties do not, however, dispute that an index can take multiple forms such as tables, lists or directories.

(a) "Simultaneously Maintained"

While the parties do not dispute that both the local and remote data storage systems must "maintain" an index, HP contends that those indices must be "simultaneously maintained". One need look no farther than the claim language to discredit that contention. Indeed, Claim 1 of the '347 Patent states, in relevant part,
said first data storage system enabling transfer of said data to said second data storage system, concurrently with said data received from said host computer, so as to nearly simultaneously maintain a concurrent copy of data stored on said first data storage system and on said second data storage system wherein both said first and said second data storage systems maintain an index . . . .

'347 Patent, Col. 8, ll. 60-66 (emphasis added). The phrase "simultaneously maintain" refers only to the copies of data stored on each data storage system and not to the respective indices. Although a requirement that the indices be simultaneously maintained makes sense in light of the purposes of the invention, i.e. efficient error recovery, neither the claim language, nor the Specification nor the prosecution history limits the term "index" to one that is simultaneously maintained on both systems.

(b) Whether There Can Be More Than One Index

EMC contends that the term "an index" denotes at least one index but could include more than one. Although HP does not dispute that the disclosed invention may contain more than one index, it contends that there may be only one index which contains the requisite indicators providing an indication of the validity of a predetermined data element. Claim 1 of the '347 Patent states, in relevant part,

wherein both said first and said second data storage systems maintain an index, said index including at least a first indicator . . . and at least a second indicator providing an indication of whether [a] predetermined data element . . . is valid.

'347 Patent, Col. 8, ln. 65 - Col. 9, ln. 5 (emphasis added). Similarly, other claims in the '347 and '792 Patents as well as the respective patent specifications refer to the required indices as "an index."

The Federal Circuit Court of Appeals has consistently emphasized that "the indefinite articles 'a' or 'an', when used in a patent claim, mean 'one or more' in claims containing open-ended transitional phrases such as 'comprising'.” Crystal Semiconductor Corp. v. Tritch Microelectronics Int'l, Inc., 246 F.3d 1336, 1347 (Fed. Cir. 2001). Thus, the claim limitation "a" requires a construction of "at least one." Id. 6

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

6 In Crystal Semiconductor, the disputed claim contained the transitional phrase "having", which the Court found does not necessarily convey the same open-ended meaning as the phrase "comprising" but the Court construed that claim as being open-ended and found that the phrase "a capacitator having . . . a first conductive layer disposed over a portion of" meant "disposed over at least one portion." Id. at 1348.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Here, Claim 1 of the '347 patent includes the transitional phrase "comprising," meaning, as the Federal Circuit has made clear, that it is an open-ended claim. Because nothing in the Specification or the prosecution history indicates a clear intent to limit the term "an index" to only one index, the disputed claims will be construed to include at least one index, said index having the requisite indicators which provide an indication of the validity of a predetermined data element.

(c) Whether "An Index" Must Be a Single Data Structure

EMC contends that "an index" can include multiple data structures as illustrated by the language of the Specification of the '347 Patent and Figures 2 and 3 therein. HP, on the other hand, claims that "an index" means at least one data structure, i.e. one table, one list or one directory, that contains the required indicators. 7

- - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

7 It is noted that in its post-Markman claim construction memorandum, HP admits, in the section entitled "Said Predetermined Data Element", that "an index" can consist of multiple tables combined together.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -
The plain and ordinary meaning of the term "index", that would be relevant in the context of the subject patents, is "something that serves as a pointer or indicator." Webster's Third International Dictionary, 1148 (1981). Accordingly, "an index" does not require that it consist of a single data structure.

Moreover, the language of the '347 Patent supports EMC's contention that "an index" can consist of multiple data structures. Claim 1, for example, discloses a first and second data storage system that

maintain an index, said index including at least a first indicator providing an indication of whether a predetermined data element stored on said first data storage system is valid, and at least a second indicator providing an indication of whether said predetermined data element stored on said second data storage system is valid.

'347 Patent, Col. 8, ln. 66 - Col. 9, ln. 5. Although one might, initially, presume that "an index" refers to one data structure including both required indicators, further perusal of the claim language weakens that presumption. For example, dependent Claim 8 discloses the system of Claim 5 (a dependent claim to Claim 1) wherein,

said maintained index [the index referred to in Claims 1 and 5] includes at least a list of data which must be copied from said first data storage storage [sic] to said second data storage system and, a list of data storage device storage locations for which a format command is pending and for which an invalid track exists.

'347 Patent, Col. 9, ll. 32-37 (emphasis added). Because claim terms must be construed similarly throughout the subject patent, the language of dependent Claim 8 illustrates that the term "an index" can refer to more than one data structure, i.e. at least two lists. Consequently, in Claim 1, "an index" including at least a first and at least a second indicator could be comprised of two separate structures each of which contains at least one of the required indicators.

The Specification of the '347 Patent also indicates that "an index" can be comprised of multiple data structures when it states, in relevant part,

[a]ccordingly . . . data integrity must be maintained by maintaining an index or list of various criteria including a list of data which has not been mirrored or copied, data storage locations for which a reformat operation is pending, a list of invalid data storage device locations or tracks, whether a given device is ready, or whether a device is write-disabled.

'347 Patent, Col. 7, ll. 21-28 (emphasis added). The term "include" means "to place, list, or rate as a part or component of a whole or of a larger group, class, or aggregate." Webster's Third International Dictionary, 1143 (1981). Thus, the Specification illustrates that "an index," in the context of the subject patent, can refer to more than one data structure, i.e. it may refer to at least two lists.

(d) Whether the four indicators disclosed in Claim 10 of the '792 patent must be contained within an index

HP asserts that, with respect to Claim 10 of the '792 patent, the four described indicators must be contained within "an index." The claim language, however, requires no such thing. While Claim 1 of the '792 Patent clearly discloses a "system" which maintains "an index" including at least four indicators, nothing in Claim 10, a method claim, requires the four indicators described therein to be contained within an index.

As HP aptly points out, the Specification of the '792 Patent states that the present system "maintains a list or index." Similarly, the PTO's statement of reasons for allowance of the '792 Patent provides that the applicant's instant claims set forth a system comprised of, inter alia, a first and second data storage system wherein the first data storage system controls the copying of data to the second data storage system by "maintaining an index" which includes at least four indicators. Notwithstanding the well-established premise that one cannot import limitations from the specification or prosecution history into the ordinary claim terms (unless one of the previously described specific circumstances exists), neither of the cited statements limits the terms of Claim 10 (a method claim) so as to require an index. Indeed, in utilizing the term "index," as the above-quoted portions illustrate, the Specification and the PTO specifically refer to the system described in the '792 Patent, e.g., Claim 1, and not to any of the methods disclosed therein. Because the language of Claim 10 does not require that the subject indicators be contained in an index and because neither the Specification nor the prosecution history implicitly or explicitly refute that omission, no index is required.
(e) Conclusions: "An Index"

For the foregoing reasons, the term "an index" as used in the subject patent claims will be construed to mean an organized collection of information which may be contained in one or more data structures, including but not limited to tables, lists or directories, which contains the requisite indicators providing an indication about the validity of predetermined data elements. Because the terms "a" or "an," in the context of patent claim language, mean at least one, the subject patents will be construed to include at least one index having the characteristics described above. For purposes of illustration, an index containing at least a first and second validity indicator could therefore include two lists, each containing one of the respective validity indicators. Moreover, the invention might include a second index, containing two different validity indicators comprised of two tables, each containing one of the respective validity indicators. Finally, there is no requirement for "an index" in Claim 10 of the '792 Patent.

C. Index of Refraction (Independent Claim 5; Dependent Claims 4, 21, 26)

The court finds the term "index of refraction" to mean "the ratio of the speed of light in a vacuum to the speed of light in a medium: the fraction, v<sub>vacuum</sub>/v<sub>medium</sub>";

There appears to be little dispute over the meaning of this term. Defendants adopt this fraction but wish to ensure that the term is used contextually to refer to the specific material referenced in a particular claim. However, Plaintiffs do not dispute the fact that the core, cladding, and air gap have different indices of refraction and the court will adopt the most straightforward reading of "index of refraction." 4

4 "Index of refraction" is not construed in Laser Peripherals.

With respect to the phrase "index parameter" the parties dispute whether the parameter is limited to a "transaction counter."

The phrase "index parameter" is not used in the "Detailed Description of the Invention." In the Claims, the inventor used the phrases "index parameter" and "index value" interchangeably, 3 and used the phrase "index value" in the written description. Therefore, the Court examines the inventor's definition of "index value" to define "index parameter."

3 See e.g., Claim 44: "The method of claim 40 wherein said second device also contains an index parameter, and comprising the further steps of: (a) selecting the larger index parameter of the two devices, (b) using said larger index value to secure said transaction, and (c) both of said devices incrementing and storing said larger index value for use in subsequent transactions.

A person of ordinary skill in the art at the time of the invention would understand that the phrase "index value" refers to a value which can perform the function of indexing. Transaction counting produces a value which can be used for indexing. However, the "Summary of the Invention" clearly states that the "index value" claimed in the invention is not limited to a transaction counter.
The present invention can be used in connection with a client and server using such a protocol. To perform a transaction with the client, the server obtains the client's current transaction counter (or another key index value).

The "Detailed Description of the Invention" discloses an embodiment where the value used for indexing is not limited to a transaction counter:

FIG. 3 shows an exemplary server-side process compatible with the exemplary client-side process of FIG. 2. Prior to commencing the process of FIG. 3, the server obtains the client's counter value C (typically by receiving C from the client device via a digital I/O interface), which is used as a key index. (In this exemplary embodiment, a transaction counter is used as a key index, but alternate embodiments can use a different value or representation of the key index.)

("902 Patent, Col. 6:54-61.)

Accordingly, the Court construes the phrase "index parameter" to mean: a parameter used to derive another value. For purposes of the process disclosed in Claim 1, a transaction counter can be used as an "index parameter." However, an "index parameter" is not limited to a transaction counter.

3. Tunnel Table, Indexed by Tunnel Identifiers, Used to Identify an Entry in a Connection Table

Lastly, Starent argues that summary judgment is appropriate because the ST products do not include a tunnel table which is indexed by tunnel identifiers and used to identify an entry in a connection table. Once again, our conclusion that the ST products do not use tunnel identifiers disposes of this issue because the ST products cannot have a tunnel table indexed by tunnel identifiers if the ST products do not have tunnel identifiers.

However, assuming, arguendo, that the ST products do use tunnel identifiers, we must determine whether the ST products have tunnel tables which are indexed by tunnel identifiers and used to identify entries in a connection table. The key phrase disputed by the parties is "indexed by tunnel identifiers." UTStarcom asserts that "indexed by tunnel identifiers" simply means that the entries in the tunnel table are identified and accessed using information derived from the tunnel identifiers. Starent asserts that "indexed by tunnel identifiers" means that each tunnel identifier is used to access an entry in the tunnel table directly.

Starent identifies specific references in the specification and prosecution history to support its proposed claim construction. Specifically, the specification states that the "PDSN uses the key (e.g., the GRE key) to do a direct look-up of the appropriate tunnel to the mobile node." (Def. St., Tab 2, '905 patent, col. 4, ll. 54-56.) During prosecution, UTStarcom specifically distinguished its claims from the prior art on the grounds that the tunnel table was indexed directly by tunnel identifiers. For example, UTStarcom argued:

While the present invention involves a fast lookup using the tunnel identifier to directly access the tunnel table, which is indexed by tunnel identifiers, Magret teaches an approach that involves the extra overhead of an additional tunnel header . . .

. . . Magret thus does not anticipate the direct-table-access approach of the present invention.

(Def. St., Tab 3, Prosecution History, February 15, 2006 Response to August 15, 2005 Final Office Action and January 10, 2006 Advisory Action at 19-20 (FH-0096-97).) In a later Office Action Response, UTStarcom argued:

nowhere does Verma disclose the foreign agent using that tunnel ID to directly access a tunnel table that is indexed by tunnel IDs, thereby identify an entry in a connection table, and forward the data over the connection identified by that connection-table entry. Simply using a term such as "differentiate" is not enough

(Def. St., Tab 3, Prosecution History, July 25, 2006 Response to March 15, 2006 Office Action at 17 (FH-0044).)
UTStarcom argues that the above cited passages do not rise to the level of being clear disavowals or expressions of manifest exclusion so as to warrant limiting the claim scope because the above cited passages represent only one of several ways in which UTStarcom distinguished each piece of prior art. We do not see the merits in this argument. Distinguishing prior art based on several grounds does not, in any way, minimize the limiting effect of each distinct argument. In fact, the more arguments a patentee asserts for distinguishing a specific piece of prior art, the greater the limiting effect of those arguments will be on the claim scope.

7 In its LR 56.1 Response, UTStarcom asserted that it "did not merely distinguish the independent claims in the simple manner set forth above. More precisely, UTStarcom distinguished Magret . . . in six different ways." (Pl. Res. P 61.) In regard to the Verma prior art, UTStarcom asserted that it "did not distinguish the independent claims from the prior art in the simple manner set forth above. The reference at issue in the response above was the Verma patent, which UTStarcom distinguished on multiple grounds." (Pl. P 66.)

Furthermore, during prosecution, UTStarcom also specifically distinguished hashing from using tunnel identifiers directly. In describing the prior art Leung reference, UTStarcom stated: "the FA will typically carry out a 'hash function,' where the inputs to the hash function are the mobile node's home address and HA address, and the output is an index into a table of PPP connections." (Def. St., Tab 3, Prosecution History, April 29, 2005 Response to January 11, 2005 Office Action at 16 (FH-0167).) UTStarcom went on to distinguish Leung from the claims by stating:

Claim 1, in contrast, is directed to a method where the tunnel identifier . . . perhaps just a simple integer, is merely extracted from packets sent from the HA to the FA, intended for the mobile node, and used directly to identify the correct connection to the mobile node, without the FA needing to extract both the home address and the HA address, and then perform a computation, before finally looking up the correct connection. As such, with the method of claim 1, the connection to the mobile node can be identified more quickly (i.e., a "PDSN Fast Tunnel Lookup").

(Id. at 17 (FH-0168).) This argument put forth by UTStarcom during prosecution clearly shows its intent to distinguish hashing from directly using tunnel identifiers to determine the connection. UTStarcom clearly intended the claims of the '905 patent to use tunnel identifiers directly to determine the correct connections to the mobile node. This limitation is consistent with the purpose of the '905 patent. As stated in the above passage, the '905 patent is titled "PDSN Fast Tunnel Lookup" and using tunnel identifiers directly allows for the "connection to the mobile node [to] be identified more quickly." (Id.)

UTStarcom argues that this reference to hashing in the prosecution history did not distinguish or exclude all use of "hashing" from the claimed invention because it arose as background to a discussion about the use of tunnel identifiers which was related to the "tunnel identifier" amendment that UTStarcom later withdrew. We find this argument unpersuasive. Based on a plain reading of the above mentioned passages from the prosecution history, it is clear that UTStarcom was distinguishing the hashing function from the direct use of tunnel identifiers in the claims. Furthermore, the subsequent withdrawal of the "tunnel identifier" amendment did not act to nullify this distinction. First, as we explained in our claim construction of "tunnel identifier," the withdrawal of the amendment did not nullify any disclaimers UTStarcom made as part of the original amendment because UTStarcom did not attempt to reclaim the disclaimed scope after the withdrawal was made. Second, even if the withdrawal had the effect of nullifying any disclaimer made as part of the original amendment, it still did not nullify the limitation distinguishing hashing from the direct use of tunnel identifiers because the "tunnel identifier" amendment pertained to a distinct and separate element of the claim. In other words, the withdrawal would only nullify those parts of the arguments that were specifically directed at the amendment that was later withdrawn; the withdrawal would not nullify the entire Office Action Response.

UTStarcom relies on the Authoritative Dictionary of IEEE Standard Terms and Dr. Olivier's declaration to support its proposed claim construction. Dr. Olivier's declaration regarding the claim construction of the term "indexed by tunnel identifiers" is a conclusory assertion which is unsupported by any intrinsic or extrinsic evidence. As such, we cannot give any weight to his declaration. The IEEE dictionary definition is probative but is afforded less weight than the intrinsic evidence in the claim construction analysis. Given the multiple references to direct look-up in the specification and
prosecution history, we construe the term "indexed by tunnel identifiers" to mean that each tunnel identifier is used to access an entry in the tunnel table directly.

It is undisputed that in the ST products, the address fields are entered into a hash function to find a data structure corresponding to the call. (Def. St. P 76; Olivier Decl. P 32.) Therefore, the question of literal infringement reduces to a question of claim construction. MyMail, Ltd. v. America Online, Inc., 476 F.3d 1372, 1378 (Fed. Cir. 2007). Under our claim construction of "indexed by tunnel identifiers," there is no question that the ST products do not meet the claim limitation of using the tunnel identifiers directly to access entries in the tunnel table.

UTStarcom has failed to raise any genuine issue of material fact as to whether the ST products directly use tunnel identifiers to access entries in a tunnel table leading us to conclude that the ST products do not contain this limitation. As such, the ST products do not contain every claim limitation found in the disputed claims of the '905 patent. It is therefore determined that the ST products do not infringe the '905 patent and summary judgment should accordingly be granted.

2126

16. "Indexed Memory Sized and Structured to Store Cash Values for a Multitude of Consumer Accounts"

The plaintiff argues that this term does not need further construction. In the alternative, the plaintiff proposes "electronic memory sized and configured to store cash values for a multitude of consumer accounts." The defendant proposes "a computer memory associated with an index. The index includes a listing of keywords and/or associated data that point to a location of more comprehensive information within the computer memory. The computer memory is sized and configured to store cash values for a multitude of consumer accounts."

Unlike the previous term, this term requires construction. The plaintiff's proposal reads out the requirement that the memory be indexed. The court therefore defines this term to mean "a computer memory associated with an index that is sized and configured to store cash values for a multitude of consumer accounts."

2127

3. "multiplying, modulo said modulus, said value in said accumulator by a positive integer power of said digital quantity, said integer power being indicated by said symbol"

The Preamble to Claim 1 discloses a method for cryptographically processing a "message" using a "private key including a secret exponent and an associated modulus." In step (a), a "digital quantity" representative of at least a portion of the "message" is obtained. 3 In step (c) 4, a positive integer power of the "digital quantity" is loaded into an accumulator. In step (b), the "secret exponent" of the private key is transformed into an "expanded representation" of itself, which includes a sequence of "symbols, each symbol representing a modular multiplication." Step (d) operates on each "symbol in at least a portion of the expanded representation." The step (d) operation on each "symbol" is divided into two 5 sub-steps: (d)(i), a "multiplying" sub-step; and (d)(ii), an "updating" sub-step. The "multiplying" and "updating" sub-steps are accomplished by executing microprocessor instructions as disclosed in (d)(iii).

Footnotes

3 The provision in step (a) that "said digital quantity to be cryptographically processed using an asymmetric cryptographic protocol involving a private key including a secret exponent and an associated modulus" is not a limitation on the step. This language simply expresses the intended result of the process. See Texas Instruments Inc. v. U.S. Int'l Trade Commission, 988 F.2d 1165, 1172 (Fed. Cir. 1993). 4 In tracing the method, the Court goes from step (a) to step (c) because step (b) operated on the private key disclosed in the Preamble and does not operate on the "digital quantity" disclosed in step (a). 5 Step (d) is enumerated with three subparagraphs. However, there are only two sub-steps, namely (d)(i) and (d)(ii). Subparagraph (d)(iii) limits how (d)(i) and (d)(ii) are performed.
In the "multiplying" sub-step (d)(i), a modular multiplication is performed. This sub-step contains the following limitation: "said integer power being indicated by said symbol." The parties dispute whether "indicated by" should be defined to mean "determined by" or whether it should be defined to mean "directly determined by."

The inclusion of the adverb "directly" (meaning immediately) in the construction would connote that the literal operation of the exponent must be followed. The method is not limited to literal operation of the exponent. Claim 1 discloses a cryptographic algorithm in which the exponent itself represents an algorithm. As explained in the following description of an embodiment, the exponent could be a pointer to another value:

It will also be understood by one skilled in the art that various combinations of the variations discussed here can be used in connection with the invention. For example and without limitation, the operation-based encoding schemes may be combined with the bit windowing techniques using k-ary modular exponentiation where each nonzero exponent digit could represent a power of x, while zero digits could represent squaring operations. For example, as stated above, a "1" digit denotes simple multiplication of the result accumulator by the value x (i.e. by exponentiation of x to the power 1). Similarly, a "2" digit (if used) denotes multiplication x 2 mod n, and so forth. In one embodiment of the invention, a table of pointers may be employed to indicate the value of the bit. For example, the first entry (offset zero) could be a pointer to the result accumulator R (for squaring operations), the entry at offset 1 could point to x (i.e., x 1), the entry at offset 2 (if used) could point to the precomputed value x 2 mod n, and the entry at offset 3 (if used) could point to the precomputed value x 3 mod n. The powers of x may be precomputed at the beginning of the modular exponentiation operation; even so, the performance benefit obtained by reducing the number of multiplication operations during the modular exponentiation generally more than compensates for the precomputation time. Note that x 0 (equivalent to multiplication by 1) is not used; all steps involve multiplication with a number larger than 1 because "0" digits in the encoding represent multiplication by R.

('442 Patent, Col. 7:66-8:23.)

Furthermore, an independent claim should not be interpreted in a way that is inconsistent with a claim which depends from it. Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995). Claim 2, which depends from Claim 1 discloses two types of "symbols," one of which is not directly used, but uses "a previously stored positive integer power." Thus, a construction of "indicated by" which requires "direct determination" of the integer power by the symbol arguably would invalidate Claim 2.

Therefore, in the claim element, "multiplying, modulo said modulus, said value in said accumulator by a positive integer power of said digital quantity, said integer power being indicated by said symbol," the Court construes the phrase "indicated by" to mean: directly or indirectly determined by.

4. Indicates.

The court construes the term "indicates" to mean "signifies."

10. "Said input voice command indicating a desired movement." The voice command input to the system by the surgeon indicates a desired movement of the surgical instrument.

4. "Indicating an operating status of a defibrillator" means "providing a visible or audible alert of whether the defibrillator is capable of treating a patient and possibly other indications of operational status."
Three substantially identical claims of the 374 Patent require the invention to "indicat[e] an operational status of an external defibrillator" by "indicating the operational status of the defibrillator. . . ." 374 Patent Claims 42, 44, 67 (emphasis added). Because the claims use the article "an" before "operational status," they suggest that the defibrillator need only indicate one of many possible operational statuses. See Elkay Mfg. Co. v. Ebco Mfg. Co., 192 F.3d 973, 977 (Fed. Cir. 1999). Defibtech contends that the indication of operational status is limited to "information about whether the defibrillator can be used to treat a patient." Philips' preferred construction is not clear to the court. Philips may be asserting that any indication of information on the operational status of the defibrillator would satisfy the claims, or it may contend that although the claims require an indication of whether the defibrillator can be used to treat a patient, the defibrillator may reveal additional operational statuses as well. The court adopts the latter construction.

The claim language supports a more expansive interpretation of "operational status" than Defibtech's construction, as does the written description. The inventors noted that a defibrillator should "indicat[e] not only . . . whether it will operate at all, but also verify that the defibrillator meets its established specifications." 374 Patent at 1:63-65. Thus, the invention suggests that the defibrillator must indicate whether it will operate, and may also indicate other operational statuses. Later, the patent discloses that those operating statuses are not limited to those that would indicate when the defibrillator is capable of treating a patient. The failure of any of numerous self-tests requires "an indication of an inoperable status or error status. . . ." 374 Patent at 7:8-9 (emphasis added). One suggested test is the "Stuck Button self-test" that verifies whether any of the defibrillator buttons are stuck in a closed position. 374 Patent at 13:49-53. Although a stuck button would result in a "Not OK" indicator display, id., this would not necessarily mean that the defibrillator is incapable of treating a patient. As to other self-tests, while many of them check defibrillator functionality, some also assess calibration. E.g., 374 Patent at 9:2, 9:25. It is thus possible for a self-test to indicate that the defibrillator is functional but not properly calibrated. See 374 Patent at 2:3-7 (noting importance of defibrillator calibration). Moreover, the inventors envisioned a status indicator that would allow the defibrillator to display these more complex assessments of operational status. 374 Patent at 5:41-6:10 (describing an indicator with a "separately addressable portion" indicating power and functionality in addition to a "fail-safe OK' symbol").

While the invention is not limited to displaying whether it is capable of treating a patient, it must at least provide such an indication. A defibrillator that did not display this information would not serve the purpose of the invention. Philips admits as much in stating that the "patent expressly teaches the need for a defibrillator to provide an operator with an indication of (1) whether it will operate and (2) whether the defibrillator meets its established specifications." Philips' Opening Br. at 19 (citing 364 Patent at 1:56-64) (emphasis added). Thus, the court construes these claims to require "providing a visible or audible alert of whether the defibrillator is capable of treating a patient and possibly other indications of operational status."

Claim Element 17

indicating in the computer readable data file at least one implementation operation required for the implementation of the selected choice in the computer system during manufacturing of the computer system.

The parties disagree on the meaning of the above-stated language. Dell argued that the ordinary meaning of the above-stated language should suffice. Lucent, however, proposed the following: "a complete, working computer that includes not only the computer, but also any software (including an operating system) and peripheral devices that are necessary to make the computer function."

The court construes the above-stated claim term as follows:

"indicating in the computer system readable data file at least one operation required for the implementation of hardware components and software programs on a computer system including, but not limited to, installation programs, hard-disk-drive formatting operations, testing operations and other similar operations."
6. "Indicating Signal"

Term
"indicating signal"

VIA & Intel's-Proposal
This term is indefinite. To the extent the Court opts to provide a construction, Intel and VIA offer the following alternative to CCCC's proposal: "a signal that triggers the actions of placing the generated second address together with the SNOOP signal on the second bus, receiving data from a second data storage location mapped to the generated second address, and transmitting the received data to a requesting bus master via a first bus."

CCCC's Proposal
"A signal that results when an address in a first address space has been mapped to an address in a second address space."

Via has separately moved for summary judgment that the patent is invalid for indefiniteness. It asserts, inter alia, that the term "indicating signal" cannot be construed because, aside from the claims, there is no other description of the "indicating signal" in the patent. This section addresses both Via's motion for summary judgment and the construction, if one is possible, of "indicating signal."

The term "indicating signal" appears as part of the first mapping means in the asserted claim as follows:

first mapping means coupled to said first bus for mapping first addresses within the first address space to second addresses within the second address space, for asserting an indicating signal and for generating one of said second addresses in response to one of said first addresses transmitted on said first bus from one of said first plurality of bus masters, said first mapping means also generating a SNOOP signal of a state indicating when a generated second address is mapped to one of said particular subset of the second data storage locations.

'369 patent at 13:15-14:6 (emphasis added). The parties have agreed that "indicating signal" is part of a means-plus-function claim, thus the corresponding structure must be identified to construe this term. A challenge to a claim containing a means-plus-function limitation as lacking structural support requires a finding, by a clear and convincing evidence, that the specification lacks disclosure of structure sufficient to be understood by one skilled in the art as being adequate to perform the recited function. Intell. Prop. Dev., Inc. v. UA-Columbia Cablevision of Westchester, Inc., 336 F.3d 1308, 1319 (Fed. Cir. 2003); see also Allvoice Computing, F.3d at 1347, 2007 U.S. App. LEXIS 23949, 2007 WL 2963933, *3. Where a means-plus-function claim is not "amenable to construction," it is invalid as indefinite under 35 U.S.C. § 112 P 2. Exxon Research & Eng'g Co. v. United States, 265 F.3d 1371, 1375 (Fed. Cir. 2001).

The indicating signal must satisfy requirements set forth in the claims. First, it has to be asserted by the mapping means. Second, the bus interface means has to respond to this signal as described in the last paragraph of claim 1. '369 patent at 14:3-8 ("bus interface means connected to said first and second buses for responding to the first indicating signal when said on of said first plurality of bus masters is reading data . . .").

The first step to identifying which signal is the claimed "indicating signal" is determining which structure corresponds to the "mapping means" because pursuant to the claim language, the indicating signal is asserted by the mapping means. '369 patent at 13:16-19 ("first mapping means coupled to said first bus . . . for asserting an indicating signal . . ."). As discussed above, the structure that corresponds to the mapping means for asserting the indicating signal is the mapping circuit or, in the preferred embodiment, the V-F translation circuit or address generator.
In its motion for summary judgment, Via challenges the asserted claim as indefinite because, it argues, it is not clear what the "indicating signal" refers to. As set forth in the claims, however, the indicating signal indicates a request which then initiates a sequence of steps related to arbitration and control that results in placing the translated address onto the second bus. See '369 patent at 14:3-12.

Via further contends that based on CCCC's proposed construction ("A signal that results when an address in a first address space has been mapped to an address in a second address space"), any number of the following signals discussed in the patent could be the indicating signal: the SNOOP signal, the V-LREQ request signal, the EN4 enable signal, the LOC_AS local address strobe signal, the L-FREQ request signal, the EN6 enable signal, the BT block transfer indicating signal. However, of the candidate signals suggested by Via, only SNOOP, BT, and V-LREQ are asserted by the V-F translation circuit.

Of the signals asserted by the V-F translation circuit, SNOOP could not be the indicating signal because the claim specifically distinguishes between SNOOP and indicating signal. The claim states that one of the responses to an indicating signal is "placing the generated second address and SNOOP signal on the second bus." '369 patent at 14:5-7. Because the SNOOP signal is placed in response to the indicating signal, these signals cannot be the same. The BT signal also cannot be the indicating signal because the BT signal only applies when VMEbus wishes to perform a block transfer wherein it read or write accesses a variable number of up to 256 data bytes at successive addresses on Futurebus, thus limiting it to a specific application. See '369 patent at 6:18-25.

It is suggested by both experts that V-LREQ may be the indicating signal. Indeed, this signal satisfies all the requirements that an indicating signal must have. It is asserted by the mapping circuit, it is understood to indicate a request to the VMEbus arbitration and control circuit, which then initiates a sequence of steps related to arbitration and control. The bus interface subsequently responds to this signal. This V-LREQ signal is shown in the patent figures as starting a cascade of commands that occur to place the translated address on the second bus. See Fig. 2. Thus, the court construes "indicating signal" as the "V-LREQ request signal" which is a signal that requests control of the first bus. See '369 patent at 5:5-28 ("V-F translation circuit 18 determines whether the VME address bus has been addressed to a corresponding Futurebus address, and if so, transmits a request signal V-LREQ to VMEbus arbitration and control circuit 38.").

8. "Indicating the occurrence of the second game trigger condition if one of the allotted numbers matches the selected random number"

Aristocrat and IGT have two disputes over the construction of the limiting language "indicating the occurrence of the second game trigger condition if one of the allotted numbers matches the selected random number." First, the parties disagree as to whether two numbers can "match" when one is less than the other. Second, they dispute whether "indicating the occurrence" of the second game trigger condition must be displayed to the user, and when that indication must occur. The parties propose the following constructions:

<table>
<thead>
<tr>
<th>Term or Language Requiring Construction</th>
<th>Aristocrat's Proposed Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>indicating the occurrence of the second game trigger condition if one of the allotted numbers matches the selected random number</td>
<td>indicating the occurrence of the second game trigger condition if one of the allotted numbers matches the selected random number</td>
</tr>
<tr>
<td>Term or Language Requiring Construction</td>
<td>IGT's Proposed Construction</td>
</tr>
<tr>
<td>indicating the occurrence of the second game trigger condition if one of the allotted numbers matches the selected random number</td>
<td>If one of the allotted numbers is identical to the selected random number, alerting the</td>
</tr>
</tbody>
</table>
numbers matches the selected random number player during the first main game that a second game will appear after the first game is complete. This indication is different from and precedes the appearance and display of the second game.

a. "match"

IGT contends that one of the allotted numbers has to be identical to the selected random number in order for an indication of the second game trigger condition to occur. In other words, the numbers have to be identical. Since the court has construed "allotting a plurality of numbers" to include allotting the numbers represented by the player value, the dispute regarding the term "match" has little significance. Accordingly, even if the court were here to adopt IGT's construction, the embodiment at issue would still be covered by the claim language under the court's above construction.

Nonetheless, Aristocrat's contention that "match" does not mean "identical" based upon a dictionary definition of "match" as "a suitable pairing of persons or objects" is not persuasive. Reply CC at 14 (citing MERRIAM WEBSTER'S DICTIONARY, 334 (1995)). Numbers do not "match" in the same way as a shirt and jacket might. In the context of the claimed invention, it would be nonsensical to say that two numbers "matched" merely because they were "suitably paired." The court therefore concludes that two numbers "match" under the claim language when they are "identical."

b. "indicating the occurrence of the second game trigger condition"

IGT also argues that "indicating the occurrence of the second game trigger condition" cannot be an internal action within the software. IGT CC at 21. That is, the occurrence of the trigger condition must be indicated to the player. IGT cites a section of the specification which describes how the player is notified when the second-game trigger condition is satisfied:

Preferably, when a jackpot game is triggered, all players are alerted by a jackpot bell that a possible grand jackpot is about to be played for. This is done so that all players share in the experience of a jackpot win. Anecdotal evidence of players watching feature games being played in Australian casinos suggests that the drawing power of such games is immense.

Players are alerted by the jackpot bell instantaneously at any point during a game, but the feature game at will not appear until the current game (including base game features) are completed.

'215 Patent at 7:41-51. Aristocrat responds by citing the "Summary of the Invention" section of the specification which states that the "function of triggering a feature jackpot game may either be performed by a central feature game controller or may be performed within each console in the system." Id. at 4:4-7.

The portion of the specification cited by Aristocrat deals with whether the triggering calculation is done centrally in the game-machine network, or on the particular machine. It does not suggest that the occurrence of the second game trigger is not indicated to the player. On the other hand, the section of the specification that IGT cites from the preferred embodiments explains the purpose of indicating the occurrence of the second game trigger--attracting the attention of players. Therefore, it follows that the "indicating the occurrence" as used in the claim means indicating to the player.

2134

A. Literal Infringement Under the "Indicating" Step

In order to literally infringe, IGT's accused devices must perform every step of the claimed method. Muniauction, Inc. v. Thomson Corp., 532 F.3d 1318, 1328 (Fed. Cir. 2008). According to this court's claim construction, the patent requires that when the second-game trigger condition is met, the player is alerted "during the first main game that a second game will appear after the first game is complete. This indication is different from and precedes the appearance and display of the
second game." Claim Construction Order 24. IGT argues that this construction imposes two requirements on the indication to the player that a second game will appear: first, that the indication must appear during the first main game; and second, that the indicated second game must appear after the first game is complete. IGT moves for summary judgment of non-infringement on the basis that the accused device can meet one, but not both, of these claim requirements.

In support of this claim, IGT offers the declaration of Richard Michaelson who testifies to the behavior of the accused gaming machines. Decl. of Richard Michaelson ISO IGT's Mot. for Summ. J. Non-Infringement PP 2-5 ("Michaelson Decl."). The declaration attaches as Exhibit 1 a video and audio recording depicting the play associated with various outcomes of a "Fort Knox" game. Id. Michaelson states that he operated the gaming machine in the recording on May 19, 2009, at IGT's offices. Id. P 2. The video shows an electronic video screen depicting five columns of three symbols which spin like reels when the player touches the "spin" button. Id. at Exhibit 1 at time 0:09. When a player wins access to the "Fort Knox" bonus game, vault doors close across the screen from each side. Id. at time 0:16. "YOU ARE NOW ENTERING FORT KNOX!" appears in text on the screen and is spoken by a male voice. Id. at time 0:19. No notification to the player that he or she has won access to the Fort Knox bonus game appears before the closing of the vault doors. After a few seconds the vault doors part, revealing a grid of safes from which the player chooses, and which choice apparently determines the progressive prize the player wins. Id. at time 0:21-0:58. The video depicts a variety of outcomes, including whether the player has or has not won the base game and whether the player has obtained or did not obtain a Fort Knox bonus. Michaelson Decl. P 4 (describing the game outcomes in the video at particular time markers). Although the video itself only displays the play of the "Fort Knox" game, Michaelson states that "[e]ach game with a Ft. Knox, Party Time, Jackpot Hunter, or Wheelionaire bonus distributed by IGT operates similarly to the Ft. Knox game play described above and shown in the Exhibit 1 recording, in that the first indication to the player that a bonus round of any of those four kinds will appear is when the bonus round does appear and is displayed." Id. P 5.

Aristocrat first contends that Michaelson does not provide any basis for his personal knowledge for the allegation that the "recording accurately shows the operation of the [base and bonus game] as they appear, display, and play during gambling by casino patrons on IGT gaming machines programmed with the Ft. Knox bonus." Pl.'s Opp. to Mot. for Summ. J. of Non-Infringement re: "Indicating" Step 2 ("Indicating Opp."). Aristocrat also suggests that the video is of an emulator as opposed to a functioning gaming machine. Id. In Michaelson's supplemental declaration in support of IGT's reply, he states that "[t]he video and audio recording attached as Exhibit 1 to my declaration . . . shows operation of a gaming machine, not an emulator. The gaming machine was programmed with the actual code that is executed in gaming machines used in casinos." Suppl. Michaelson Decl. re: "Indicating" Step P 2 ("Suppl. Michaelson Decl."). Michaelson also states in his deposition that he is a staff engineer in IGT's legal department. Ex. A to Decl. of Robert Blanch ISO Aristocrat's Opp. 6:16-22. IGT also points out that neither Aristocrat nor Crevelt contends that the depicted game play is not representative of that which appears in casinos. IGT's Reply re: Summ. J. Based on "Indicating" Step 1 (hereinafter "Indicating Reply"). Although it is not entirely clear the personal knowledge basis on which Michaelson describes the software and devices at issue, he does state that he has personal knowledge, and Aristocrat provides no basis to doubt that assertion.

On the basis of the video, IGT contends that it cannot infringe. If the completion of the first main game occurs before the closing of the vault doors, which are the first notice to the player that a second game will appear, then no indication has been made to the player "during the first main game," and IGT does not infringe. On the other hand, if the completion of the first main game occurs after the closing of the vault doors, that completion must still occur before the second game begins, because the patent elsewhere requires that the second game "appear[] after completion of said first main game." '215 Patent at 9:12-13; '603 Patent at 8:38-39. According to IGT, no possible completion point for the first main game exists after the vault doors close but before the second game begins. Thus, argues IGT, the accused Fort Knox device cannot infringe, and IGT is entitled to summary judgment on that basis.

At the motion hearing, Aristocrat argued that summary judgment should be denied because the specific temporal limitation in this court's construction of the "indicating" step requiring that the indication appear "during the first main game" is incorrect and perhaps unintended. Aristocrat pointed out that, in the court's order on Aristocrat's motion for leave to move for reconsideration, the court's reasoning focused on the requirement that the indication precede the appearance of the second game, not whether the indication must be during the first main game. Aristocrat additionally argued that the claims and specification did not offer any support for requiring that the indication be "during" the first main game. The parties have not previously focused on the question of whether there could be some intervening period of time between the first and second games. As a result, the court's previous orders have not considered an indication appearing during the first main game and an indication appearing before the second game begins as having any significant difference.
IGT argues that the specification supports a "during" limitation. In a preferred embodiment, the specification states that "[p]layers are alerted by the jackpot bell instantaneously at any point during a game, but the feature game will not appear until the current game (including base game features) are completed." '215 Patent at 7:48-51 (emphasis added). As articulated in the court's order on Aristocrat's motion for clarification, the requirement that the indication appear before the second game arises primarily out of the claim language. Clarification Order 2-3. In contrast, there does not appear to be any specific basis in the claim language for requiring that the indication appear during the first main game. Furthermore, the cited portion of the preferred embodiment, as the court stated in its claim construction order, explains the purpose of indicating the occurrence of the second-game trigger: to attract attention of players. See Claim Construction Order 19. But attracting other players only requires that the indication appear before the second game starts; it is not critical that the first game still be in progress. Requiring the indication to occur during the first game would be improperly importing a limitation from the specification into the claim. Phillips v. AWH Corp., 415 F.3d 1303, 1323 (Fec. Cir. 2005). The court concludes therefore that the indication need not appear during the first main game. The court will clarifies its previous claim construction as follows:

<table>
<thead>
<tr>
<th>Disputed Language</th>
<th>Court's Construction</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;indicating the occurrence of the second game trigger condition if one of the allotted numbers matches the selected random number.&quot;</td>
<td>If one of the allotted numbers is identical to the selected random number, alerting the player that a second game will appear after the first game is complete. This indication is different from and precedes the appearance and display of the second game.</td>
</tr>
</tbody>
</table>

Aristocrat argues that the computer code run by the accused devices includes routines that satisfy the "indicating" step. In his declaration, Aristocrat's expert, Dwight Crevelt, states that "there are routines in the Fort Knox and Party Time! [games] that ring a bell and then play an introductory animation if one of the allotted numbers matches the selected random number." Decl. of Dwight Crevelt ISO "Indicating" Opp. P 9 (hereinafter "Crevelt Decl."). Crevelt also states that "an introductory screen indicating that the bonus round is about to start is displayed on the display screen . . . ." Id. P 10. Although Crevelt does not identify it as such, based on the court's review of the video of the Fort Knox game, the introductory screen referred to appears to be the sequence in which the vault doors close over the screen and the text "YOU ARE NOW ENTERING FORT KNOX" appears on screen. Indeed, the language used -- "You are now entering" -- implies that the player is not yet in Fort Knox, but only entering it. This vault screen and the text overlay therefore raise a genuine issue of material fact as to whether the IGT machines indicate to the player that a second-game trigger condition has been satisfied.

Aristocrat also contends that code exists to ring a bell when the second-game trigger condition is satisfied. Crevelt Decl. P 9. For the various games at issue, the parties dispute whether the bell sound begins simultaneously or before the animation introducing the second game. The ringing of a bell may satisfy the "indicating" step based upon the facts submitted, and, therefore, Aristocrat has raised a triable issue of fact with respect to the "indicating" step.

ii. Writeable Semiconductor Memory

Plaintiffs further argue that their accused systems do not meet the additional limitation of claim 5 where the remote object indicates "its ability to receive and store transmitted data by the existence of writable semiconductor memory within said object." Plaintiffs contend that TransCore fails to demonstrate the existence of a signal by their accused devices indicating the presence of a writeable semiconductor memory. TransCore responds that Plaintiffs misconstrue claim 5 since the claim does not require an additional signal indicating the presence of a writeable semiconductor memory, but only that said semiconductor memory exists within the tag.

Claim 5 reads:
The system for identifying, for writing data into and reading data out of remote objects of claim 4 further characterized by said remote object indicating to said interrogator its ability to receive and store transmitted data by the existence of writable semiconductor memory within said object.

'807 Patent 10:35-40. The plain and ordinary meaning of the claim supports that the remote object indicates its ability to perform the functions stated through or "by the existence of writable semiconductor memory," not, as Plaintiffs contend, that the remote object signals to the interrogator "the presence of writable semiconductor memory." A review of the patent specification supports this finding, where no instance of a remote object signaling to an interrogator that it has writable semiconductor memory within the remote object can be found. This Court, therefore, rejects Plaintiffs' argument regarding Claim 5. In addition, for separate reasons already discussed, because this Court already finds a genuine issue of material fact regarding Claim 4, and Claim 4 depends upon Claim 5, the Court also DENIES TransCore's motion for summary judgment of Claim 5.

GO BACK

2136

8. indication (Claims 29, 32, 34)

As with other limitations related to means plus function limitations, defendants argue that an "indication" must limited to the output of the supporting structure defined for the related "indication means." As discussed above, this is just another way to argue that a term should be limited to its disclosed embodiments. Electro Med. Sys., S.A. v. Cooper Life Sciences, Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994) ("[A]lthough the specifications may well indicate that certain embodiments are preferred, particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments.").

The specification clearly discloses multiple ways of indicating to the audience member whether the audience member's usage of the device has been in accordance with the predetermined usage criterion. '276 patent, 7:33-38. Therefore, plaintiff's proposed construction is adopted by the Court. "Indication" means "a communication to the audience member." GO BACK

2137

G. Indication of a respective resolution level

Although the Plaintiff did not construe the phrase "indication of a respective resolution level" in its opening brief, the Plaintiff, in its Reply, took issue with the Defendants' suggestion that this phrase be construed to mean "data specifying the amount of detail per unit area corresponding to a level of resolution in the hierarchical structure of data blocks." Skyline now offers instead the following broad construction: "something that indicates, points out, or signifies a respective resolution level."

The first step of the method claimed in Claim 1 is for part of what I will refer to as "the system" to receive from the renderer "one or more coordinates in the terrain along with indication of a respective resolution level." (col. 16, 11. 32-34) That part of the system is then able to "provide the renderer with a first data block which includes data corresponding to the one or more coordinates, from a local memory" and if that first block "is not at the indicated resolution level," the system downloads more data blocks corresponding to the coordinates. (col. 16, 11. 39-44) In Claim 12, it is the "processor which receives one or more specified coordinates along with indication of a respective resolution level from a renderer [and then] provides the renderer with a first data block . . . and downloads . . . one or more data blocks . . . if the first block is not from the indicated level." (col. 18, 11. 21-30) The specification describes how preferably the "renderer determines the exact blocks needed and calls for them using their (x, y) coordinates and their resolution level." (col. 14, 11. 10-12) All of these references suggest that "indication of a respective resolution level simply means the renderer indicates (to the processor) or identifies the particular resolution level or the particular level of the hierarchical database of the data required.

At the Markman hearing, the parties agreed with this construction except that Skyline questioned whether it is necessary to bring the concept of hierarchical structure into this definition. (Transcript, p. 66) Upon reflection, I find that it is
unnecessary to include hierarchical database within the construction of this term because it is already agreed that the database is organized hierarchically by resolution level.

Construction: (indication of respective resolution level) the identification of the particular resolution level of the data required

5. "Indication of the condition of the defibrillator" does not require indication of the status of the electrodes.

Similar to the 374 Patent claims described in the previous subsection, two claims of the 059 Patent require that the invention "provide[e] an indication of the condition of the defibrillator" (Claim 1), and "determine a condition of the defibrillator" (Claim 9). The parties raise two disputes. The first is a reprise of their dispute over "operational status" in the 374 Patent. Defibtech argues that the indicated "condition" is limited to whether the defibrillator is operable. The second dispute is whether, as Defibtech argues, the operability of the defibrillator electrodes is a condition that the defibrillator must indicate.

The court resolves the first dispute in the same manner it resolved the similar dispute over the "operational status" indication in the 374 Patent. The indication of "condition" must at least include whether the defibrillator can be used to treat a patient, but is not limited to this indication. Like the 374 Patent, the 059 Patent claims require "an" indication of condition (Claim 1) or "a condition" (Claim 9), and thus suggest that more than one condition or indication is possible. Although the 374 Patent and 059 Patent do not have a common written description, the 059 Patent similarly discloses statuses other than a binary operable/inoperable status. Compare 059 Patent at 3:47, 3:50, 4:3, 4:29, 4:43-44 (describing operable/inoperable indication) with 059 Patent at 5:39-40 (describing a "fault indicator" without requiring operable/inoperable indication), 5:62-64 (same), 6:65-67 (describing a test result indicator without requiring operable/inoperable indication), 8:33-35 (same). Thus, the defibrillator must at least indicate whether the defibrillator is operable, but may disclose other "conditions" as well.

As to the second dispute, the written description does not support a requirement that the "condition" include the condition of the defibrillator electrodes. Defibtech correctly notes that the 059 Patent focuses on testing the condition of the electrodes rather than other portions of the defibrillator. E.g., 059 Patent at 1:8-9 ("This invention relates generally to a method and apparatus for testing medical electrode systems"); 1:56-59 ("What is needed, therefore, is a defibrillator system providing an indication of the condition of the defibrillator and defibrillator electrodes"). The claims, however, never use the term "electrode." The parties' dispute is much like their dispute over the meaning of "through conductors" in the same patent. See supra Part III.B.2. As in that dispute, the court must reject Defibtech's limiting construction.

The court cannot accept Defibtech's construction because the 059 Patent expressly describes how its indicator can disclose the condition of non-electrode components of the defibrillator system. The 059 Patent discloses tests of conditions arising in components other than the electrodes. It teaches that an "inoperable" indication "could mean that there is a problem with the electrodes, the conductive gel on the electrodes, the electrode interface, and/or the defibrillator circuit itself." 059 Patent at 4:32-34. The indicator can thus disclose information about the defibrillator separate from the electrodes. If a user receives an inoperable indication, she can "replace the electrodes . . . and run the test again," and she will know from the result of the second test whether the problem was in the electrodes or in the remainder of the defibrillator system. 059 Patent at 4:35-39. The written description thus does not require the indication of electrode "condition," and the court therefore construes these claims in accordance with their broad language. "Indication of the condition of the defibrillator" means "indication of whether the defibrillator is capable of treating a patient, and possibly other defibrillator statuses."

K. "Providing an Indication of the Detection of a Virus from Said Searching Step"

Finally, the parties dispute the meaning of the phrase "providing an indication of the detection of a virus from said searching step." '776 Patent, col. 18, Ins. 53-54, which comprises the second step of the method claimed in Claim 18. Defendant contends that this phrase means that "the computer provides an alert to the user if a virus has been detected during the
searching step." JCCS, Appx. A, at 18 (term 69). Plaintiff counters that this step merely requires "indicating the detection of a virus, not necessarily to the user." Id. The Court adopts defendant's construction.

Plaintiff does not explain how the plain meaning of the word "indication" contemplates an alert to anything other than a human user; the alert is meaningless otherwise. Further, because it is the destination computer which on its own initiates the transfer of data under the terms of the patent claims, the only relevant user to be alerted is the user of the destination computer system on which the claimed invention is operating. The specification confirms this reading. See '776 Patent, col. 4, lns. 16-19 (emphasis added) ("If a virus signature is detected by the string search routine, the user is alerted at step 36, typically by an appropriate warning message displayed on the computer system monitor."); id., col. 7, lns. 3-6 (emphasis added) ("The virus detection function informs the user that a virus has been detected and gives the user the option to cancel the transfer by setting the VirusDetectedFlag."). Accordingly, the Court adopts defendant's proposed construction of this phrase.

2140

3."indication signal"

3Com proposes "a signal that indicates a subsequent action, such as an interrupt." Doc # 81 (05-0098) at 7. Realtek proposes "a signal that is not an interrupt but may be used by the host system to generate an interrupt." Id. The dispute revolves around what the indication signal indicates.

In order to evaluate the parties' proposed constructions, it is useful first to understand "interrupt." In the context of computer technology, an interrupt is a "signal to a computer that stops the execution of running program so that another action can be performed." American Heritage Dictionary of the English Language (4th ed 2000). It is clear from the specification of the '459 patent that the patentee used the term interrupt in this manner. See '459 patent at 1:49-54. With this ordinary meaning in mind, the court turns to the language of the claims.

Realtek argues that claim five shows that "the indication signal cannot be the interrupt signal; otherwise, the interrupt signal of claim five would have no meaning." Doc # 333 (03-2177) at 18. Claim five reads:

The apparatus of claim 1, wherein the network interface logic includes:

control means for generating an interrupt signal to the host processor responsive to the indication signal and posting status information which may be used by the host processor as feedback for optimizing the threshold value.

'459 patent at 43:31-38. This language shows that the indication signal and interrupt signal are different things. Nothing about this language, however, excludes the possibility that the indication signal and interrupt signal could both be interrupts. Accordingly, the court rejects Realtek's proposed construction.

3Com proposes "a signal that indicates a subsequent action, such as an interrupt." Doc # 81 (05-0098) at 7. The intrinsic evidence shows not only that the indication signal heralds the arrival of a subsequent action, but that this action is an interrupt. Claims five and twenty-two recite "generating an interrupt signal to the host processor responsive to the indication signal." '459 patent at 43:34-46; 44:46-69. Claim thirty-four includes an "indication signal, which reduces host processor interrupt latency." Id at 45:62-63. Claim forty-four, fifty and fifty-two recite "generating an interrupt signal to the host processor, responsive to the early transfer indication signal, which reduces host processor interrupt latency." Id at 47:35-38; 48:31-34. In addition, the specification discloses that it is "desirable to provide a network adapter with an optimized indication signal * * * which reduces interrupt latency." Id at 2:22-25.

Intrinsic evidence demonstrates a sole purpose for the indication signal: indicating the arrival of a subsequent interrupt. Accordingly, the court adopts the construction "a signal that indicates a subsequent interrupt."
1. The term "INDICATIONS" (claim 1) means something that represents the physiological parameters. Such a representation can be in the form of a number, a word, a symbol, or any other marker with established meaning.

Claim 13 of the 720 patent depends from independent claim 12. Both claims are reproduced below, with the pertinent claim terms emphasized:

12 A water control system for bathing, comprising:

an open container for holding water for bathing;

a heater element for heating said water;

a temperature sensor for monitoring the temperature of the water in said container;

a control panel positioned adjacent said container for controlling the temperature of said water;

a microprocessor electrically coupled to said control panel, said microprocessor programmable by a user via said control panel to control the operation of said heater element, said microprocessor also being capable of diagnosing failures in said water control system and providing an output signal to the control panel indicative of a source of the failures.

13 A system as in claim 12, wherein said microprocessor comprises an 8-bit CMOS device.

In its opinion accompanying the order granting the preliminary injunction, the district court construed the phrase "diagnosing failures in said water control system" to mean "displaying error codes when there is a failure in the water control system." The district court also construed the phrase "indicative of a source of the failures" to require that "the system be capable of displaying multiple error codes dependent on the source of the failures, such as, for example, heater not heating, pump not operating, lack of water flow, or a microcomputer failure."

As this appeal arises from the grant of a preliminary injunction, we recognize that the district court's claim construction may evolve with greater understanding of the dispute. Although we agree generally with the district court's claim construction, we suggest the following clarifications subject, of course, to the district court's plenary consideration during subsequent proceedings.

First, it would seem that the phrase "diagnosing failures" connotes the process of detecting the causes or symptoms of failures in the water control system. Second, the phrase "indicative of a source" connotes the ability to indicate where in the water control system the failures might be occurring. The minor differences between our claim construction and the district court's, however, are not sufficient to convince us that the district court abused its discretion in granting a preliminary injunction.

Dr. Tehrani argues that the term "indicative of" is broader than the term "representing" and means "suggestive." Hamilton points out, however, that the patent uses the terms "indicative of" and "representing" interchangeably and argues that they must be construed to mean the same thing. Thus, while claim 1 refers to digital output data "indicative of required ventilation and optimum frequency for a next breath of a patient," the summary of the invention refers to input data.
"representing the amount and optimum frequency of ventilation required for the next breath," '268 patent, col. 2, ll. 5-7, and the detailed description of the preferred embodiment refers to the signals "representing the total ventilation and the frequency of breathing," id., col. 3, ll. 63-64. Moreover, while claim 16 refers to data "indicative of" the levels of carbon dioxide and oxygen, the lung elastance factor, the air viscosity factor, and the barometric pressure, other portions of the patent refer to the same data as "representing" those factors. Id., col. 1, l. 68, to col. 2, l. 2; col. 7, ll. 58-60. We agree with Hamilton that the intrinsic evidence indicates that the patentee meant for those two terms to be interchangeable and to carry the same meaning within the claims.

We agree with Hamilton that the intrinsic evidence indicates that the patentee meant for those two terms to be interchangeable and to carry the same meaning within the claims.

8. Displays images indicative of said thoroughfares

The third subpart of claim 5 reads:

a display, connected to said processor, wherein said display displays images indicative of said thoroughfares and displays the names of each thoroughfare in a selected one of said sets of thoroughfares.

The disputed phrase is underlined. Defendant contends that aside from the terms "display" and "thoroughfare," this phrase needs no construction. On the other hand, plaintiff again seeks to characterize the thoroughfares as those "in the geography surrounding the vehicle." As explained in section F.5, I decline to add this limitation to the claim. I do agree with plaintiff, however, that the words "indicative of" are unnecessary. Accordingly, I construe "displays images indicative of said thoroughfares" as "shows the thoroughfares."

2. "Sensed signals indicative of ... generator electrical power output"

It is helpful to see the disputed phrase in context, along with the preceding paragraph of the claim:

sensing means, for sensing generator speed and generator electrical power output and for providing sensed signals indicative thereof;

a variable speed wind turbine controller, responsive to the sensed signals indicative of generator speed and generator electrical power output, for providing a generator torque command signal for commanding maneuvers of the generator speed according to a function defining generator speed versus generator electrical power output which maneuvers tend to cause the wind turbine to operate substantially on the wind turbine power coefficient versus velocity ratio optimum performance curve substantially at the peak thereof;

In construing the phrase, "signals indicative of ... generator electrical power output," the question is whether it include signals from which generator power can be calculated or whether signals "indicative" of speed and power are signals of actual, measured speed and actual, measured power.

The fourth limitation of claim 1 discloses a "sensing means, for sensing generator speed and generator electrical power output and for providing sensed signals indicative thereof." I understand this "sensing means" to be the sensed signals to which the phrase in element five refers when it discloses a controller responsive to the sensed signals indicative of generator speed and generator electrical power output."

The word "indicative" in preceding element four makes it clear that the signals would convey the amount of power sensed. Contrary to plaintiff's suggestion, this reading does not render the phrase "indicative of" superfluous; instead, the phrase is used to signify the content of the sensed signals.

This construction is consistent with the meaning of "indicative" as it is used in other portions of claims. In each instance, indicative is used to signify what information a particular signal relays. E.g., '736 Pat., col. 10, lines 21-24 ("a difference
signal having a magnitude indicative of the difference in magnitudes between the generator speed reference signal and the generator sensed speed signal"; lines 44-46 ("an additional sensor for sensing turbine rotor speed for providing a sensed signal indicative thereof"); col. 11, lines 14-16 ("a calculated wind speed signal indicative of effective full-disc wind speed"); col. 12 lines 2-5 ("a velocity ratio signal having a magnitude indicative of the ratio of the magnitudes of the rotor tip speed and wind speed signal"). In addition, the construction is consistent with the use of the word "indicative" in the claim specification. E.g., "737 Pat., col. 2, lines 15-18 ("[a] difference signal indicative of the difference between the speed reference signal and the sensed generator speed signal"); col. 3, lines 60-63 ("a calculated wind speed signal indicative of effective full-disc speed"); lines 64-66 ("a velocity ratio signal having a magnitude indicative of the ratio of the magnitudes of the rotor speed and calculated wind speed signals"). It is presumed that "the same terms appearing in different portions of the claims should be given the same meaning." Fin Control Systems Pty, Ltd. v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001) and that words are used consistently in the claim language and the specification, Autogiro Co. of Am. v. United States, 384 F.2d 391, 397, 181 Ct. Cl. 55 ("words must be used in the same way in both the claims and the specification").

C. '073 Patent Claim 17 - "a sensor incorporated into said inductive device"

The Court construed this language to mean "any inductive device incorporating a sensor 'providing a diagnostic signal having electrical characteristics that represent the electrical and magnetic events occurring at the gap of the ignitor plug during the period of energy transfer to spark across a gap of the ignitor plug' that is placed in the ignition system in accordance with the requirements of the claim." Lucas Aerospace, Ltd. v. Unison Industries, L.P., 890 F. Supp. 329, 1995 WL 362387 at *12. In reaching this conclusion, the Court rejected Lucas's argument that the patent specification limits the phrase "said inductive device" to saturable core inductors. See id. at *7 Lucas now abandons this argument and contends that the Court erred in its claim constructions not because the sensor required by claim 17 must be a saturable core inductor, but because the sensor in claim 17 must be "the same inductor that is creating the 'sequence' described in claim 1." D.I. 394 at 28. Because, Lucas concludes, "claim 17 does not refer to a saturable core inductor" but instead refers to the inductor that creates the sequence of events described in claim 1, the Court's claim differentiation analysis, see Lucas Aerospace, Ltd. v. Unison Industries, L.P., 890 F. Supp. 329, 1995 WL 362387 at *7, was in error.

This is the first time that Lucas has raised this argument; it did not advance this contention either at trial or in its papers on claim construction. When the Court construed claim 17, for example, Lucas never attempted to equate the inductor in claim 17 to the inductor in claim 1. Similarly, Lucas did not try its case under this theory. Nevertheless, the Court has examined the merits of Lucas's argument and finds them lacking. First, Lucas never states why it believes the inductor of claim 17 must be the same inductor as that which creates the "sequence" found in claim 1. Instead, Lucas rehashes its previous rationale for concluding that the inductor of claim 17 must be a saturable core inductor. Compare D.I. 394 at 28-29 (discussing the '073 specification at columns 9 and 10) with D.I. 367 at 6 (same). The Court has already addressed this argument and on this basis finds no error in its construction of claim 17.

Second, Lucas's suggestion that the Court's claim construction permits the patent to cover auxiliary transformers that are, according to Lucas, within the prior art is without merit. While the description of the preferred embodiment does state that auxiliary voltage transformers are "typically...used" to sense current and voltage, the description of the preferred embodiment does not state that they are typically used in igniter technology. See '073 Patent, col. 10 at ln. 2-16. In fact, the only testimony at trial as to this issue suggested that ignition exciters had never previously incorporated sensors to provide diagnostic signals as to igniter plug health. See D.I. 403 at 772-82 (noting that igniter diagnostics internal to the igniter were unknown in the art prior to Unison's invention) (testimony by inventor Frus); see also '073 Patent, col. 10 at ln. 4 (suggesting that auxiliary transformers were not then used in exciter circuits due to insertion losses and physical difficulties in placing the component within an igniter circuit).

Thus, while the description of the preferred embodiment indicates the inventor believed that a sensor incorporated into the saturable core inductor was superior to use of an auxiliary transformer, neither the claim language nor the extrinsic evidence adduced at trial suggests that use of an auxiliary transformer for sensing in an ignition exciter was obvious or common to one skilled in the art of igniter design. Because Lucas did not try the case under this theory, there is no evidence to support it, and, other than using the description of the preferred embodiment to suggest that the inductor referenced in claim 17 is the same inductor that creates the sequence of events in claim 1, i.e., the saturable core inductor, Lucas offers no basis on
which to conclude that the claim 17 inductor is the same inductor that creates the sequence in claim 1. Nothing in the structure of either claim 17 or claim 1 dictates that result. Furthermore, the fact that the preferred embodiment uses the same inductor in both roles does not dictate that result. The carefully selected claim language, passed upon by the Patent and Trademark Office, does not require a saturable core inductor. The Court finds no reason to believe that its construction of claim 17 was in error.

1. "indicator"

EMC asks the Court to construe this term as:

Information which provides a fairly certain sign or symptom of the validity of a predetermined data element. An indicator can include information about data located on a storage device, such as a track, or about data stored in an entire storage device via a device -- level indicator. The requisite first and second indicators may be organized at different levels so long as the second provides information with respect to the validity of the same predetermined data element as the first even if that information is provided indirectly.

HP proposes: "An indicator' is something that indicates,' which means points out or points to, or states or expresses briefly, with certainty."

HP's proposal is an everyday definition of the word, except for the fact that it includes the requirement of "certainty." EMC proposes a construction that would limit the term to the "validity of a predetermined data element," but, instead of requiring "certainty," would require only an "indication" that is "fairly certain." The claim language states that an "indicator" provides an indication of whether a predetermined data element stored on a first or second data storage system is valid, thus supporting EMC's proposed "predetermined data element" limitation. However, that limitation stands on its own and need not be included in the Court's specific construction of the term "indicator."

The claim language does not help to resolve the parties' dispute over the level of certainty required. Indeed, nothing in the claim language explicitly limits the term to "indicates with certainty." The word "indicate," by itself, does not necessarily require certainty; in fact, HP's addition of modifying words suggests that it seeks a particularly narrow construction. The dictionary definition of "indicate" does not include "certainty." ("Indicate" means "to point out or point to," or "to be a sign, symptom, or index of." Webster's Ninth New Collegiate Dictionary.)

Nor is there a requirement of certainty in the specification, which uses the term "indicator" according to its common meaning. For example, the "secondary data storage system controller provides an indication or acknowledgement [sic] to the primary data storage system controller that the primary data to be copied to the secondary data storage system in identical form as secondary data has been received or . . . written." 347:2/63-3/1. The invention is able to "achieve[] nearly 100 percent data integrity." 347:2/34-35. The "indicators" also indicate several measures of "validity." There are indications of "write or copy pending . . . of both the primary data . . . and the secondary data," 347:7/46-47, "pending format change," 347:7/48, and the validity of data storage location, 347:8/10-12. There are also "indicators" of whether a primary or secondary device may be written to and whether a primary and secondary track is not shown. 347:8/23-24 & 8/36. In none of these discussions of the various indicators is there a suggestion or requirement that the indicator indicate with certainty. Such a requirement likely would be a highly significant limitation and improvement, as very few (and possible no) computer systems ever function with absolute certainty.

Accordingly, the Court construes "indicator" as "something that indicates,' which means points out or points to, or to be a sign, symptom, or index of."
EMC contends that an "indicator" is information that gives an indication and an indication is a sign or suggestion of some thing or fact. HP claims that (1) an indicator is a flag bit or binary indicator which provides information about the data and is not the data itself and (2) an indicator provides information with certainty, i.e. the data storage system containing the relevant indicator treats the information provided as definitive thereby determining whether the relevant data is valid or invalid based on the indicator. Although not apparent from the alternative definitions, there are three primary disputes with respect to the claim term "indicator:"

(1) whether an indicator must indicate data validity with certainty;

(2) whether an indicator may indicate data validity not only at the track level but also at the device level; and

(3) whether the required first and second indicators on each data storage system must indicate data validity at the same level, i.e. whether they both must indicate validity at either the track or the device level.

(a) Whether an indicator must indicate data validity with certainty

The plain and ordinary meaning of the term "indicator" is "one that indicates." Webster's Third International Dictionary, 1150 (1981). The term "indicate" means to point out or point to or toward with more or less exactness: show or make known with a fair degree of certainty . . . . to show the probable presence or existence or nature or course of: give fair evidence of: be a fairly certain sign or symptom of: reveal in a fairly clear way . . . .

Id. Nothing in the dictionary definition requires an indicator to indicate data validity with certainty. Indeed, an indication, by nature, provides only a "fair degree" of certainty.

The claim language supports the plain meaning of the term "indicator." In Claim 1 of the '347 Patent, the required index includes "at least" a first and "at least" a second validity indicator with respect to a particular predetermined data element. As EMC persuasively contends, if an "indicator" provided a certain indication of data validity, the inclusion of any further indications would be unnecessary and inefficient, and the inclusion of the claim language "at least" would be surplusage.

Moreover, neither the subject specifications nor the prosecution histories explicitly or implicitly limit the term "indicator" to that which provides information with certainty. In fact, the specifications clearly illustrate numerous kinds of information related to "validity", including invalid track information, device pending information and write disable drive information. See '347 Patent, Col. 7, ln. 32 - Col. 8, ln. 29; '792 Patent, Col. 11, ln. 10 - Col. 12, ln. 7. The fact that the subject specifications contemplate more than one kind of "indicator" with respect to data validity supports EMC's contention that an indicator does not provide an indication of data validity with "certainty."

Although the described indicators provide indications of data validity at different levels, e.g. at the track and device level, the information provided may overlap. That is, the device-disabled indicator may indicate that the second data storage system is disabled and, therefore, that the data thereon is invalid. That "validity indication" may be supplemented by an invalid track indicator which indicates that all tracks on the second data storage device are invalid. See '347 Patent, Col. 8, ll. 25-27. That the subject invention envisions, in some instances, the use of overlapping indicators of data validity, is itself an "indication" that the term "indicator" does not connote certainty.

That evidence notwithstanding and as HP counters, there is some suggestion in the specifications that a validity indicator is treated as "certain" by the respective data storage systems. For example, in addressing the invalid track indicator, the Specification in the '347 Patent notes, in relevant part,

[another background task running on the data storage system such as in the service processor or storage system controller constantly checks invalid track bits on each data storage device and if a bit is found to be set, the copytask is invoked to copy the data from the known good device to the device with the invalid flag track set.]

'347 Patent, Col. 8, ll. 13-18.

- 2511 -
Although that excerpt indicates that the presence of one invalid flag is enough to prompt a copy response (and thus that each individual indicator is treated as certain by the data storage system on which it is maintained), that indication, to use a term with which the parties are intimately familiar, is far from certain. Indeed, the Specification merely states that

[a] background task running on the data storage system . . . checks invalid track bits on each data storage device . . . and if a bit is found to be set, the copy task is invoked to copy the data from the known good device to the device with the invalid flag track set.

347 Patent, Col. 8, ll. 13-18. That provision could be read to imply that the background task checks the indicators on both data storage devices before employing the copy function.

Moreover, even if that part of the Specification indicates that invalid track indicators are treated as certain by the data storage systems in which they reside, there is no suggestion that they or other validity indicators must be so treated. Thus, because limitations from the Specification cannot be imported into the claim language, HP's argument is unavailing.

(b) Whether an indicator indicates data validity at both the track and device levels

EMC asserts that an "indicator" may indicate data validity at either the track level or the device level. In other words, according to the patentee, the subject patents disclose validity indicators which provide information about data stored at a particular storage location on each respective storage device as well as validity indicators which provide information about a particular storage device. The device-level indicators indirectly provide information about all of the data stored on a particular data storage device. HP claims that, to the contrary, the subject patents disclose only indicators of the validity of data stored at a particular location on a storage device, e.g. data stored on a particular track or cylinder.

As a threshold matter, the claim itself does not restrict the application of the term "indicator" to that which provides information about data validity at the track (as opposed to the device) level. Moreover, the Specification of the '347 Patent clearly contemplates validity indicators that provide information about the data located on a particular "track" as well as data located on an entire data storage device. First, the Specification contemplates the inclusion of multiple data storage devices. See '347 Patent, Col 4, ll. 14-17. That fact alone supports the contention that an "indicator" not only provides information about data stored at a particular location on an individual storage device but also information about the data located on an entire storage device (because, where a system contains multiple storage devices each device is merely a larger storage location than a track).

That evidence notwithstanding, the Specification also states, in relevant part,

[a] feature of the present invention is that both the primary or secondary data storage systems maintain a table of the validity of data in the other storage system . . . . Thus, as illustrated in the partial list or table 100, FIG. 2, each data storage system maintains an indication of write or copy pending . . . . Similarly, an index is maintained of a pending format change . . . . In addition to the write pending and format pending bits described above, the present invention also includes several additional general purpose flags to assist in error recovery. As shown in FIG. 3, invalid track flags 120 . . . are utilized . . . to indicate that the data storage location such as a track, does not contain valid data . . . . Additional flags may be provided such as device ready flags . . . which serve to indicate that the device is ready. Similarly, write disable flags 132 may be provided which indicate that a particular . . . drive 136 can presently not be written to. Data can still be copied to the good or enabled drive then later copied to the disabled drive. If one drive or device is bad, the present invention will set all tracks of that drive as not valid to later cause a copy of all the data. Accordingly, each data storage device keeps data validity information about it's [sic] mirrored device.

347 Patent, Col. 7, In. 32 - Col. 8, In. 30.

That part of the Specification makes it abundantly clear that the disclosed invention contemplates validity indicators which provide information about data stored in a particular storage location as well as information about a particular data storage device. Such device-level indicators indirectly provide information about all of the data stored on a particular data storage device. Moreover, nothing in the subject specifications or prosecution histories contradicts that construction or suggests that EMC so limited the term "indicator".
EMC contends, apparently for the first time in its post-Markman claim construction memoranda, that the first and second indicators on each data storage system do not have to be organized at the same level. EMC proposes, rather, that the patent requires only that each indicator provide an indication of whether the same predetermined data element is valid. In other words, the first indicator on a data storage system could provide an indication of data validity at the track level while the second indicator provides an indication of data validity at the device level. Both indicators, so EMC asserts, are providing information about a particular track of data, the second indication is merely giving more information than necessary, i.e. information about the data on an entire storage device.

HP responds that, to the contrary, the first and second indicators on each data storage system must provide information at the same level. Under HP's proposed construction, therefore, if the first indicator on a data storage system provides an indication of data validity at the track level, the second indicator must also provide validity information at the track level.

Here the claim language itself is most instructive. Claim 1 of the '347 Patent discloses an index,

said index including at least a first indicator providing an indication of whether a predetermined data element stored on said first data storage system is valid, and at least a second indicator providing an indication of whether said predetermined data element stored on said second data storage system is valid.

Although that language makes clear that the two indicators must provide an indication of the validity of the same predetermined data element, it does not require that the two indicators be the same, i.e. that the index include two track level or two device level indicators. Moreover, nothing in the claim language requires that the indicators provide a direct, rather than an indirect, indication of data validity.

Thus, as EMC convincingly argues, one embodiment of the disclosed invention could include an index with a first indicator at the track level, indicating the validity of a piece of data on a particular track and a second indicator at the device level, indicating whether a particular storage device which contains the subject data track is disabled and, therefore, whether all of the data on that device is valid. Because the second indicator provides information with respect to all of the data stored on the second data storage device, it would, albeit indirectly, provide information about each track of data stored on that device.

--- Footnotes ---

8 Indeed, the Specification of the '347 Patent states, in relevant part,

If one drive or device is bad, the present invention will set all tracks of that drive as not valid to later cause a copy of all the data.

That provision indicates that the device-level indicators indirectly provide validity information about each individual track of data on the subject device.

--- End Footnotes ---

If the device level indicator indicated that the particular storage device was not functioning, that would be an indication that a particular track of data had not been properly stored on that device. Conversely, if the device-level indicator indicated that the subject storage device was functioning properly, that would be an indication that a particular track of data had been stored correctly in the second storage device. In short, the second device-level indicator would provide "an indication of whether said predetermined data element stored on said second storage system is valid."

Finally, there is nothing in the subject specifications or prosecution histories that requires the two indicators to be organized at the same level. Although Figures 2 and 3 of the Specifications of the '347 and '792 Patents depict such indicators, it is...
well-established that the claim terms are not to be limited by the specification unless the patentee has chosen to become his own lexicographer. See Rambus, 318 F.3d at 1088-89. There is no evidence of that here.

(d) Conclusions: "Indicator"

For the foregoing reasons, the term "indicator," as used in the subject patents, will be construed to mean information which provides a fairly certain sign or symptom of the validity of a predetermined data element. An indicator can include information about data located at a particular storage location on a storage device, such as a track, or about data stored in an entire storage device via a device-level indicator. The requisite first and second indicators may be organized at different levels so long as the second provides information with respect to the validity of the same predetermined data element as the first even if that information is provided indirectly.

5. "PIC indicator" or "indication which has a particular value"

Claim 1 of the '184 patent teaches a method wherein included in a message record is a "PIC indicator" having a value which "is a function of whether or not the interexchange carrier associated with said terminating subscriber is a predetermined one of said interexchange carriers." ('184 patent, col. 7, lns. 11-16) The specification provides that the "PIC indicator" can take various forms, such as a code that identifies the terminating subscriber's PIC or a flag "which indicates, at a minimum, whether or not the terminating subscriber's PIC is" a particular IXC. ('184 patent, col. 4, lns. 13-19) In the preferred embodiment, the value of the "PIC indicator" indicates "whether or not both the terminating and originating subscriber's PICs" are a particular IXC. ('184 patent, col. 4, lns. 21-22) Thus,

    if both of the subscribers are PIC'd to IXC 30, then PIC indicator 3419 is set. Otherwise it is not set. Certainly, then, as noted above, the value of PIC indicator 3419 does indicate whether or not the PIC of the terminating subscriber is or is not IXC 30. Specifically, if PIC indicator 3419 is set, then IXC 30 is the terminating subscriber's PIC. If it is not set, then IXC 30 is not the terminating subscriber's PIC.

    ('184 patent, col. 4, lns. 31-39)

The other asserted independent claims do not disclose inclusion of a "PIC indicator" in a message record. Instead, claim 12 requires provision in a message record of "an indication which has a particular value when the particular interexchange carrier over which said call was carried is the PIC for said terminating subscriber." ('184 patent, col. 8, lns. 24-27) Independent claim 18 also requires provision of "an indication which has a particular value" in a message record but the value of the indication disclosed therein is a function of whether the PIC over which the call was carried is the PIC for both the terminating and originating subscriber. ('184 patent, col. 8, ln. 66-col. 9, ln. 2) Similarly, claim 40 requires "establishing an indicator at a particular value" when the PIC of the terminating subscriber is "said specific interexchange carrier over whose facilities said call was routed." ('184 patent, col. 12, lns. 18-22) Thus, all of the asserted claims require the inclusion in a message of an indicator having a value that reflects, at a minimum, whether or not a particular IXC is the PIC of the particular terminating subscriber. According to the specification, the value of the indicator, "advantageously, . . . can be used in subsequent billing operations" to allow for, "for example, different billing treatments." ('184 patent, col. 4, lns. 44-46)

The court, therefore, shall construe the terms "PIC indicator" and "indication which has a particular value" as requiring a design that indicates, at a minimum, whether a specific IXC is the PIC of the terminating subscriber at the time the call is made. As noted previously, the "PIC indicator" and the "indication which has a particular value" claimed by the '184 patent are not limited to an indicator of the facilities-based IXC over whose network the subscriber's calls are carried or routed.
Claim 1 of the reexamined patent reads as follows:

1. In a computer system including a central processing unit having a keyboard entry station with a plurality of keys for data entry and a pointing device station having a pointer with at least one pointer button for data entry and responsive to positional movement of said pointer, and including system operating functions having successive layers of a main menu of selectable group functions and successive series of a first layer of sub-menus, and at least a second sub-layer of sub-menus having selectable group sub-functions, accessible by successive entries on said keyboard or said pointer to select an ultimate working function, the improvement comprising:

   a. a template for use with said pointing device

   b. indicia arranged on the template and located in a plurality of groups, one group of each corresponding to one predetermined, selectable item of said main menu and all said indica (sic) in a responsive group bearing a common group identifying characteristic;

   c. at least a second plurality of indicia, each of which corresponds to a predetermined selectable item of a sub-menu corresponding to an item of said main menu;

   d. means securing said templates in a fixed orientation to said tablet whereby said pointing device can select a working function with a single movement of the said button.

The parties dispute the meaning of subsections b, c and d.

II. Claim Interpretation

A. Legal Principles of Claim Construction

The determination of a patent infringement claim requires a two-step analysis. First, the court must construe the asserted claims to determine their meaning and scope. See Texas Instruments Inc. v. Cypress Semiconductor Corp., 90 F.3d 1558, 1563 (Fed. Cir. 1996). Only then may the trier of fact determine whether the properly interpreted claims encompass the accused structure. Id.

Claim construction is a question of law for the Court. See Markman v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed.Civ. 1995) (en banc). The objective of claim construction is to ascertain the meaning that a person of ordinary skill in the art would give to the terms in dispute at the time of the application for the patent. Wiener v. NEC Electronics, Inc., 102 F.3d 534, 539 (Fed. Cir. 1996); see Haynes International, Inc. v. Jessop Steel Co., 8 F.3d 1573, 1578 n. 4 (Fed. Cir. 1993). To ascertain the meaning of claim language, the Court looks initially to the three sources of intrinsic evidence of record: 1) the claims themselves, 2) the specification, to the extent that it defines terms in a manner inconsistent with their ordinary meaning, and 3) the prosecution history of the patent, to the extent that it contains the patentee's express representations with respect to the scope of the claims. Vitronics Corp. v. Conceptoric, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Drawings from the specification may be used in interpreting the scope of a claim. See 5 Donald S. Chisum, Patents 18.03[2][c][iii] at 18-108 (1998) (citing cases).

Claim construction begins with the wording of the claims, asserted and non-asserted, which are to be examined in their entirety. Bell Communications Research, Inc. v. Vittal Communications Corp., 55 F.3d 615, 620 (Fed. Cir. 1995). Unless the specification or the prosecution history indicates that the inventor expressly intended otherwise, a claim term will be accorded its ordinary and accustomed meaning. Id.; Markman, 52 F.3d at 979 (stating that "a patentee is free to be his own lexicographer" but that "any special definition given to a word must be clearly defined in the specification").

The Court may look to extrinsic evidence, such as expert testimony, dictionaries and learned treatises, to understand the technology and to construe the claims, only if the claims are ambiguous and only after consideration of all available intrinsic evidence. See Vitronics, 90 F.3d at 1584. Extrinsic evidence, however, may not be used to vary or contradict the terms of the claims. Markman, 52 F.3d at 981. While claims are to be interpreted in light of the specification and with a view to ascertaining the invention, see Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1561-62 (Fed. Cir. 1991), it does not follow that limitations from the specification should be read into the claims. Sjolund v. Musland, 847 F.2d 1573, 1581 (Fed.
Therefore, it is generally improper to limit the scope of the claim to examples used in the specifications. See Electro Medical Systems, S.A. v. Cooper Life Sciences, Inc., 34 F.3d 1048, 1054 (Fed. Cir. 1994).

B. Discussion

The parties in this case contest the meanings of several phrases used in Claim 1, specifically, those phrases in Claim 1, subsections (b), (c) and (d) and the statements made to the PTO during the reexamination proceedings related to those claim sections.

1. Claim 1(b)

a. The Original Claim

For the most part, the parties do not dispute what the language of Claim 1(b) means. Instead, they disagree about the scope of the claim's application. The dispute devolves to whether the limitations contained in Claim 1(b) apply to every group on the template (Baystate's contention) or only to some of the groups (Bowers' contention).

Baystate argues that the phrase in Claim 1(b) "one group of each corresponding to one predetermined, selectable item of said main menu", means that every group on the template must correspond to a Main Menu item in the corresponding software. Baystate notes that DRAFT-PAK contains groups for "View" and "Mask" that are not Cadkey Main Menu items.

Similarly, Baystate contends that Claim 1(b) requires that the indicia located within a particular group on a template must all be contained under the same item of Cadkey's Main Menu. For example anything located within the "Create" group on the Cadjet template must be found under Cadkey's "Create" menu. Baystate points out that DRAFT-PAK contains a function called "Calculate" within its "Files" group even though "Calculate" is not a function under the "Files" menu of Cadkey.

Moreover, Baystate asserts that every command that can be found within a particular menu on Cadkey must be grouped together on the template and share the same "group identifying characteristic." Baystate notes that DRAFT-PAK splits Cadkey's detail menu into two separate groups called "Detail/Set" and "Detail/Change."

Bowers does not contest Baystate's interpretation of the claim but rather argues that the limitations contained in it do not apply to every group on a template. Bowers asserts that the '514 Patent requires only that at least two groups meet the claim's limitations. He relies on the phrase "plurality of groups," which precedes and describes the phrases for which Baystate offers its interpretation discussed above. For example, Bowers argues that "plurality of groups" describes the phrase "one group of each corresponding to one predetermined, selectable item of said main menu", i.e. that each of at least two groups, but not all of the groups, must correspond to one predetermined, selectable item of the Main Menu.

"an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning." York Products v. Central Tractor Farm & Family Center, 99 F.3d 1568, 1572 (Fed. Cir. 1996); Bell Communications Research, Inc. v. Vitalink Communications Corp., 55 F.3d 615, 620 (Fed. Cir. 1995); Markman, 52 F.3d at 980 (a patentee is free to be his own "lexicographer" but any special definitions must be clearly defined in the specification). The '514 Patent contains no alternative definition for the term "plurality" and this Court will, therefore, apply the ordinary meaning of the term.

The dictionary definition of "plurality" is "the state or fact of being plural", American Heritage Dictionary Third Edition 1053 (3d ed. 1997), and "plural" is defined as "of, relating to or being a grammatical form that designates more than one of the things specified." Id. at 1052. Nowhere in either definition is there an indication that "all" of a particular thing is specified. The Court therefore agrees with Bowers' contention that the language of Claim 1(b) requires only that more than one group must correspond to a Main Menu item.

Bower's position is bolstered by the language contained in the specification. The specification states that indicia are arrayed "in a plurality of groups, each of which corresponds to a predetermined selectable item of the main menu." U.S. Patent No. 4,933,514 at "Brief Statement of the Invention", Column 2, lines 12-14. Although Bowers used different language in the actual claim, a claim is to be interpreted in light of the specification contained in the patent. Unique Concepts, Inc. v. Brown, 939 F.2d 1558, 1561-62 (Fed. Cir. 1991). The specification of the '514 Patent clearly calls for a template on which a plurality of groups exists, each of which correspond to a Main Menu item. A template containing two or more groups, where each of those groups correspond to a Main Menu item would satisfy this limitation. Claim 1(b) does not call for a template.
Bowers offers an additional persuasive argument in support of his interpretation of "plurality". Accepting Baystate's interpretation would render the preferred embodiment outside the scope of the patent. If Claim 1(b) were construed to require that every group on the template correspond to a Cadkey Main Menu item, the preferred embodiment elaborated in the '514 Patent would fall outside the scope of the patent because the preferred embodiment (the Cadjet template) contains some groups that are not on Cadkey's Main Menu. It is clear that an interpretation of a patent that renders the preferred embodiment outside the scope of the patent claim is "rarely, if ever, correct and would require highly persuasive evidentiary support." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996). The only evidence that Baystate offers in support of such a "rare" interpretation is Bowers' statement to the PTO during the reexamination proceedings. As explained in the following subsection, Bowers' statement during reexamination proceedings is misinterpreted by Baystate and this Court will not, therefore, construe the '514 Patent claims in such a way as to render them outside the scope of the preferred embodiment.

b. The Claim Post-Reexamination

Baystate contends that its interpretation of the claim is required by virtue of Bowers' statements during the reexamination proceedings before the PTO. The statement on which Baystate relies was as follows:

"Each of the groups of the Keymaster template does not correspond to one selectable item of the main menu of the Cadkey system. To illustrate, the SELECT group which is beneath the Position group on the Keymaster template is in the last sub-menu in the Cadkey system from which one selects the active function . . . ." (Bowers' Appellant Brief on Appeal to the PTO found at Tab 30, p.5 of Exhibits to Bowers' Motion for Partial Summary Judgment on the Issue of Patent Infringement).

In the second sentence, Bowers attempted to distinguish the Keymaster prior art. The Keymaster contained a group called "Select." That group was not, however, a Main Menu item in Cadkey, but rather was accessible lower down in the program's menu hierarchy.

Baystate interprets the statement made at Reexamination as meaning that Claim 1(b) requires that every group of indicia on the template must correspond to a Main Menu item in the application. It contends that Bowers distinguished the Keymaster template because the "Select" group of that template was not part of Cadkey's Main Menu. Bowers responds that he merely told the PTO that "no group on the Keymaster template meets his claim limitations" and then discussed "Select" as an example.

The dispute turns on whether Bowers' phrase "each of the groups . . . does not correspond" means "every group must correspond" (as Baystate contends) or "no groups correspond," (as Bowers contends). Contrary to both contentions, the Court finds that the phrase means only that all of the groups on the Keymaster template do not correspond to one selectable item of the Cadkey Main Menu.

When Bowers stated, "each of the groups of the Keymaster template does not correspond to one selectable item of the Main Menu of the Cadkey system," he apparently meant that 1) not all of the Keymaster's groups correspond to Cadkey's Main Menu functions and 2) some groups do correspond to Cadkey Main Menu functions, while others do not. By referring to an example of the "Select" group which did not correspond to a Main Menu function, Bowers was citing to the PTO an example of at least one group on the Keymaster template that did not correspond to a Cadkey Main Menu function. He could have pointed out other Keymaster groups that do correspond to Cadkey Main Menu functions because there are several present on the Keymaster template.

This Court concludes that Baystate misconstrues Bowers' Reexamination statement and finds that Claim 1(b) requires only that a plurality, or more than one, of the groups meet its limitations.

2. Claim 1(c)

The dispute with respect to Claim 1(c) involves, to a great extent, the divergent interpretations of Claim 1(b). Specifically, the parties dispute whether the limitations contained in Claim 1(c) apply to all of the groups on the template (Baystate) or
only to some of the groups on the template (Bowers).

Because the Court has already determined that the term "plurality" means "more than one," there is no need to elaborate on that point here. Based upon the analysis used in the interpretation of Claim 1(b), the Court applies the same meaning to the terms contained in Claim 1(c). Thus, "plurality" as used in Claim 1(c) again means "more than one."

Claim 1(c) provides for a "second plurality of indicia, each of which corresponds to a predetermined selectable item of a sub-menu. . . " Baystate asserts that that claim limitation applies to all functions on the template, but Bowers responds that it requires only that all of a second plurality of indicia meet the claim limitation.

The plain language of Claim 1(c) requires that a plurality, or more than one, of the indicia contained in a second level of indicia correspond to a predetermined selectable item of a sub-menu. The Court interprets Claim 1(c) in conjunction with Claim 1(b) and finds the former to be consistent with the latter. Thus, within the two or more groups meeting the limitations of Claim 1(b), more than one of the indicia contained in a second level of indicia must correspond to a predetermined selectable item of a sub-menu.

When Claim 1(c) is read in conjunction with Claim 13 (a claim added during the reexamination proceedings), it is apparent that the sub-menu to which the second plurality of indicia described in Claim 1(c) corresponds is the first sub-menu of a Main Menu item. This is so because Claim 13, as expressed in the Reexamination Certificate, states that the second plurality described in Claim 1 "corresponds to the predetermined selectable item of said first sub-layer of sub-menus...."

For example, if a template contains a "Create" group, which corresponds to a Cadkey Main Menu function, more than one of the indicia in the second level contained within that group must correspond to a selectable item of the first sub-menu under "Create." The first sub-menu under "Create" includes "Lines", "Arcs", "Circles", "Points/Conics", "Polygon/Fillet" and "Splines". Therefore, within the "Create" group, in order to meet the limitations of Claim 1(c), the second level of indicia must contain an indicia for at least two of those functions.

Again, consistent with Claim 1(b), the terms of Claim 1(c) must be met in two or more groups that correspond to Main Menu items. Therefore, Claim 1(c) requires that in the groups described by Claim 1(b), there must be a second level of indicia in which more than one of those indicia correspond to an item contained in the first sub-menu of that Main Menu item.

3. Claim 1(d)

The parties' dispute over Claim 1(d) relates to the language "said pointing device can select a working function with a single movement of the button." Baystate argues that Claim 1(d) should be interpreted to mean that all indicia on the template must lead to the selection of an ultimate working function.

Bowers responds, citing Vitronics, that Baystate's interpretation cannot be correct because it would render the preferred embodiment outside the scope of the patent. Bowers argues persuasively that the preferred embodiment contains several items that pull up sub-menus rather than activate a function.

Once again, a patent interpretation that renders the preferred embodiment outside the scope of the patent claim is "rarely, if ever, correct and would require highly persuasive evidentiary support." Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1583 (Fed. Cir. 1996). Baystate's interpretation that would require all indicia on the template to lead to the performance of a function would thrust the preferred embodiment outside the scope of the patent claim. Without clear evidentiary support, a court cannot accept such an interpretation. Id.

Baystate offers only Bowers' reexamination proceeding statement in support of its contention that "the claim precludes indicia which cause a menu to be pulled down." Bowers stated during Reexamination that the capability of "said pointing device can select a working function with a single movement of the button" was "not present in each of the groups of the Keymaster template." Appellant's Brief on Appeal at 7, found at Exhibit 30 to Memorandum in Support of Defendant/Counter-Plaintiff's Motion for Partial Summary Judgment on the Issue of Infringement of Defendant/Counter-Plaintiff's Patent. It does not necessarily follow from this representation that Bowers' claim requires all indicia on his template to activate a function with a single movement of the pointing device.
This Court concludes that Bowers reexamination statement did not limit Claim 1(d) to require all indicia to activate a working function. There is no evidentiary support for Baystate's argument that the Court interpret the patent to exclude the preferred embodiment. The phrase "said pointing device can select a working function with a single movement of the button" will, therefore, be interpreted to mean that the pointing device can, but need not, select a working function with a single movement of the button.

C. Conclusion on Claim Interpretation

Based upon the preceding analysis, this Court concludes that, with respect to contested terms as they are used in claim 1 of the '514 Patent:

1) "indicia arranged on the template and located in a plurality of groups, one group of each corresponding to one predetermined, selectable item of said main menu" means that at least two groups must appear on a template, where one group corresponds to a Main Menu item and the other corresponds to another Main Menu item;

2) "at least a second plurality of indicia, each of which corresponds to a predetermined selectable item of a sub-menu corresponding to an item of said Main Menu" means that at least two indicia contained in the second set of indicia contained within one of the "at least two groups of indicia" described in Claim 1(b) must correspond to an item of the first sub-menu of the Main Menu item to which the group corresponds; and

3) "said pointing device can select a working function with a single movement of the said button" means that the single movement of the pointing device's button can, but need not, select a working function.

The '514 patent describes a template that presents a single visual representation of many of the available CAD program commands. Mr. Bowers asserts claim 1, the only independent claim:

1. In a computer system including a central processing unit having a keyboard entry station with a plurality of keys for data entry and a pointing device station having a pointer with at least one pointer button for data entry and responsive to positionable movement of said pointer, and including system operating functions having successive layers of a main menu of selectable group functions and [a plurality of sub-levels of sub-menus] successive series of a first layer of sub-menus, and at least a second sub-layer of sub-menus having selectable group sub-functions, accessible by successive entries on said keyboard or said pointer to select an ultimate working function, the improvement comprising:

(a) a template for use with said pointing device;

(b) indicia arranged on the template and located in a plurality of groups, one group of each corresponding to one predetermined, selectable item of said main menu and all said indicia in a respective group bearing a common group identifying characteristic;

(c) at least a second plurality of indicia, each of which corresponds to a predetermined selectable item of a sub-menu corresponding to an item of said main menu;

(d) means securing said templates in a fixed orientation to said tablet whereby said pointing device can select a working function with a single movement of the said button.

Figs. 3A-D of the '514 patent illustrate a template according to claim 1 and configured to operate with CADKEY. That template is illustrated below as a composite of Figs. 3A-D. The template includes a variety of indicia that represent selected items from the CADKEY menus. For example, the template includes the main-menu indicia "CREATE" (middle) and
"TRANSFORM" (lower-right corner). In turn, other indicia are associated with those main-menu indicia (e.g., using location and color) to form main-menu indicia groups. To illustrate, the "CREATE" main-menu indicia group includes the sub-menus "Lines," "ArCs," "Arcs," "Points," "Plygns," and "Splines" (sub-menu indicia), but not the remaining "CREATE" sub-menus "Polyin," "Fillet," "Chamfer," or "Conic," see supra at pp. 15-16. In the template, each of the "CREATE" group's sub-menus has working functions in columns below. The working function indicia represent working functions dependent from the relevant sub-menu. For example, the working function indicia associated with the "Lines" sub-menu fall below that heading and include "Tan:ArcPt," "Tan:2Arcs," "Horz," "Vert," and "Horz/Vert."

GET DRAWING SHEET 3 OF 7
GET DRAWING SHEET 4 OF 7
GET DRAWING SHEET 5 OF 7
GET DRAWING SHEET 6 OF 7

The parties dispute the meaning of paragraphs b, c, and d of claim 1. This court agrees generally with the district court's construction of paragraphs b and c. With respect to paragraph d, however, the district court erred in its construction. Under a correct construction of that paragraph, no reasonable jury could find that Baystate infringes claim 1. In view of this court's holding of noninfringement, this court does not reach the alternative ground for challenging the district court's judgment based on patent invalidity.

The district court construed paragraph b: "at least two groups must appear on a template where one group corresponds to a main menu item and the other corresponds to another main menu item." In other words, the template must include at least two main-menu indicia groups, such as the "CREATE" and "TRANSFORM" groups described above. Baystate argues, nevertheless, that the reexamination history requires that "every group of the template must correspond to a main menu item." The history of reexamination indicates otherwise.

During reexamination, Mr. Bowers noted that each group of the Keymaster template did not correspond to a main-menu item. With respect to those groups that did correspond to main-menu items, Mr. Bowers argued that those did not satisfy claim paragraphs c and d. Mr. Bowers thus admitted that a set of Keymaster template groups satisfy claim paragraph b, but he then distinguished them in view of paragraphs c and d. Specifically, Mr. Bowers stated: "Each of the groups of the Keymaster template does not correspond to one selectable item of the main menu of the Cadkey system." Baystate would read this statement to mean that the claim's reference to a "pluralitY" of groups on the template encompasses all groups on the template. In other words, Baystate reads "each" in several of Bowers' statement to mean "all." The claim, however, uses the term "pluralitY," meaning "comprising, or consisting of more than one." The Oxford English Dictionary (2d ed. 1989). Thus, Bowers' references to "each" refers to the "at least two groups" required by the claims. To read Bowers statements too strictly would exclude from claim scope the preferred embodiment of the '514 patent—a disfavored result. That embodiment includes, for example, a group "SET" that is not associated with a CADKEY main-menu item. In sum, this court agrees with the district court's interpretation of paragraph b.

With respect to paragraph c, the district court interpreted claim 1 to require "that at least two indicia contained in the second set of indicia contained within one of the at least two groups of indicia described in claim 1(b) must correspond to an item of the first submenu of the main menu item to which the group corresponds." In other words, at least one of the main-menu indicia groups paragraph b requires must include at least two indicia associated with a sub-menu of the main-menu. '514 patent at col. 4, ll. 9-16. The specification supports the trial court's interpretation. In the preferred embodiment, for example, the sub-menu "Lines" under the "CREATE" group defines two columns of indicia representing working functions. Id. at col. 4, ll. 9-16. The sub-menu indicium "Lines" and the working functions in columns below are associated with the "Lines" sub-menu of the "CREATE" main-menu, thus satisfying the claim requirement. In sum, paragraph c requires that at least one of the main-menu indicia groups include at least two indicia associated with the same sub-menu of the main-menu.

With respect to paragraph d, the district court held "that the single movement of the pointing device's button can, but need not, select a working function." Properly construed, however, this limitation requires that each of the indicia associated with the sub-menu of a main-menu group must represent a working function accessible with a single movement of the pointer button (e.g., as opposed to access through further selection via a drop-down menu). Using the "Lines" sub-menu as an
example, see Figs. 3A-D supra at p. 18, paragraph d requires that all indicia below that sub-menu must represent working functions. The specification and the reexamination history support this construction of paragraph d.

As just described with respect to the "Lines" sub-menu, the '514 patent discloses a sub-menu with one or more columns of working functions. '514 patent at col. 4, ll. 9-16. This arrangement supplies the second plurality of indicia required by paragraph c. Id. at col. 4, ll. 24-26. For example, two columns fall beneath the "Lines" sub-menu within the "CREATE" group. Each indicium in those columns, e.g., "Tan:ArcPt," "Tan:2Arcs," "Horz," "Vert," and "Horz/Vert," represents a working function that depends from the "Lines" sub-menu. Id. at col. 4, ll. 24-65 ("The individual items appearing in the rows of each of these columns [defined by the sub-menu indicia] represent an ultimate working function"). In other words, consistent with this court's construction, all the indicia associated with the sub-menus of the "CREATE" group represent working functions.

* Bowers urges in a conclusory fashion that this construction would render the preferred embodiment outside the scope of the claims, a result that requires "highly persuasive evidentiary support," Vitronics Corp. v Conceptronic, Inc., 90 F.3d 1576, 1583, 39 U.S.P.Q.2D (BNA) 1573, 1578 (Fed. Cir. 1996). Bowers has not established his premise (that the preferred embodiment is outside the claim scope), and even if he had, the reexamination history provides just that highly persuasive evidentiary support, as this court explains below.

The reexamination history also precludes this court from adopting a broader construction. Specifically, with respect to "working functions," the claim language recites only that the "pointing device can select a working function with a single movement of the said button." During the reexamination proceedings, Mr. Bowers argued that the Keymaster template did not satisfy this limitation because that template's "DETAIL" and "TRANSFORM" main-menu groups included indicia that did not represent working functions. With reference to the "DETAIL" group more specifically, that group includes sub-menus "Dim," and "Arr/Wit," and an additional indicium "Misc." The Keymaster "DETAIL" group and relevant portions of the CADKEY 3.02 menu structure are shown in the figure below. In that figure, working functions are highlighted.

[SEE THE ILLUSTRATION IN ORIGINAL]

The indicia "Dim," "Arr/Wit," and "Misc" each have a group of indicia underneath them. However, as shown above, none of those indicia groups includes only working functions. With respect to the group "Misc," Mr. Bowers made clear that the indicia "Note," "X-Hatch," "Change," and "Set," all represented additional menus rather than working functions. For example, selecting the indicium "X-Hatch" simply presents an opportunity to select the actual working cross-hatching functions of "Brick," "Steel," "Copper," "Alloys," "Aluminum," "Rubber," or "Marble" (not shown in the menu structure above). A user simply cannot access these cross-hatching functions through a single movement of the pointing device button using the Keymaster template. In like manner, as shown in the figure, the indicia groups associated with "Dim" and "Arr/Wit," respectively, also include indicia that do not represent working functions.

The '514 patent describes a template that presents a single visual representation of many of the available CAD program commands. Mr. Bowers asserts claim 1, the only independent claim:

1. In a computer system including a central processing unit having a keyboard entry station with a plurality of keys for data entry and a pointing device station having a pointer with at least one pointer button for data entry and responsive to positionable movement of said pointer, and including system operating functions having successive layers of a main menu of selectable group functions and [a plurality of sub-levels of sub-menus] successive series of a first layer of sub- menus, and at least a second sub-layer of sub-menus having selectable group sub-functions, accessible by successive entries on said keyboard or said pointer to select an ultimate working function, the improvement comprising:

- 2521 -
(a) a template for use with said pointing device;

(b) indicia arranged on the template and located in a plurality of groups, one group of each corresponding to one predetermined, selectable item of said main menu and all said indicia in a respective group bearing a common group identifying characteristic;

(c) at least a second plurality of indicia, each of which corresponds to a predetermined selectable item of a sub-menu corresponding to an item of said main menu;

(d) means securing said templates in a fixed orientation to said tablet whereby said pointing device can select a working function with a single movement of the said button.

Figs. 3A-D of the '514 patent illustrate a template according to claim 1 and configured to operate with CADKEY. That template is illustrated below as a composite of Figs. 3A-D. The template includes a variety of indicia that represent selected items from the CADKEY menus. For example, the template includes the main-menu indicia "CREATE" (middle) and "TRANSFORM" (lower-right corner). In turn, other indicia are associated with those main-menu indicia (e.g., using location and color) to form main-menu indicia groups. To illustrate, the "CREATE" main-menu indicia group includes the sub-menus "Lines," "Arcs," "Circ," "Points," "Plygns," and "Splines" (sub-menu indicia), but not the remaining "CREATE" sub-menus "Polyin," "Fillet," "Chamfer," or "Conic," see supra at pp. 15-16. In the template, each of the "CREATE" group's sub-menus has working functions in columns below. The working function indicia represent working functions dependent from the relevant sub-menu. For example, the working function indicia associated with the "Lines" sub-menu fall below that heading and include "Tan:ArcPt," "Tan:2Arcs," "Horz," "Vert," and "Horz/Vert."

GET DRAWING SHEET 4 OF 7.

GET DRAWING SHEET 5 OF 7.

GET DRAWING SHEET 6 OF 7.

The parties dispute the meaning of paragraphs b, c, and d of claim 1. This court agrees generally with the district court's construction of paragraphs b and c. With respect to paragraph d, however, the district court erred in its construction. Under a correct construction of that paragraph, no reasonable jury could find that Baystate infringes claim 1. In view of this court's holding of noninfringement, this court does not reach the alternative ground for challenging the district court's judgment based on patent invalidity.

The district court construed paragraph b: "at least two groups must appear on a template where one group corresponds to a main menu item and the other corresponds to another main menu item." In other words, the template must include at least two main-menu indicia groups, such as the "CREATE" and "TRANSFORM" groups described above. Baystate argues, nevertheless, that the reexamination history requires that "every group of the template must correspond to a main menu item." The history of reexamination indicates otherwise.

During reexamination, Mr. Bowers noted that each group of the Keymaster template did not correspond to a main-menu item. With respect to those groups that did correspond to main-menu items, Mr. Bowers argued that those did not satisfy claim paragraphs c and d. Mr. Bowers thus admitted that a set of Keymaster template groups satisfy claim paragraph b, but he then distinguished them in view of paragraphs c and d. Specifically, Mr. Bowers stated: "Each of the groups of the Keymaster template does not correspond to one selectable item of the main menu of the Cadkey system." Baystate would read this statement to mean that the claim's reference to a "plurality" of groups on the template encompasses all groups on the template. In other words, Baystate reads "each" in several of Bowers' statement to mean "all." The claim, however, uses the term "plurality," meaning "comprising, or consisting of more than one." The Oxford English Dictionary (2d ed. 1989). Thus, Bowers' references to "each" refers to the "at least two groups" required by the claims. To read Bowers statements too
strictly would exclude from claim scope the preferred embodiment of the '514 patent--a disfavored result. That embodiment
includes, for example, a group "SET" that is not associated with a CADKEY main-menu item. In sum, this court agrees with
the district court's interpretation of paragraph b.

With respect to paragraph c, the district court interpreted claim 1 to require "that at least two indicia contained in the second
set of indicia contained within one of the at least two groups of indicia described in claim 1(b) must correspond to an item
of the first submenu of the main menu item to which the group corresponds." In other words, at least one of the main-menu
indicia groups paragraph b requires must include at least two indicia associated with a sub-menu of the main-menu. '514
patent at col. 4, ll. 9-16. The specification supports the trial court's interpretation. In the preferred embodiment, for example,
the sub-menu "Lines" under the "CREATE" group defines two columns of indicia representing working functions. Id. at col.
4, ll. 9-16. The sub-menu indicium "Lines" and the working functions in columns below are associated with the "Lines"
sub-menu of the "CREATE" main-menu, thus satisfying the claim requirement. In sum, paragraph c requires that at least
one of the main-menu indicia groups include at least two indicia associated with the same sub-menu of the main-menu.

With respect to paragraph d, the district court held "that the single movement of the pointing device's button can, but need
not, select a working function." Properly construed, however, this limitation requires that each of the indicia associated
with the sub-menu of a main-menu group must represent a working function accessible with a single movement of the pointer
button (e.g., as opposed to access through further selection via a drop-down menu). Using the "Lines" sub-menu as an
example, see Figs. 3A-D supra at p. 18, paragraph d requires that all indicia below that sub-menu must represent working
functions. The specification and the reexamination history support this construction of paragraph d.

As just described with respect to the "Lines" sub-menu, the '514 patent discloses a sub-menu with one or more columns of
working functions. '514 patent at col. 4, ll. 9-16. This arrangement supplies the second plurality of indicia required by
paragraph c. Id. at col. 4, ll. 9-16. The specification discloses expressly that all indicia associated with sub-menus (i.e.,
"Line," "Arcs," etc.) of the "CREATE" group represent working functions. * Id. at col. 4, ll. 24-26. For example, two
columns fall beneath the "Lines" sub-menu within the "CREATE" group. Each indicium in those columns, e.g.,
"Tan:ArcPt," "Tan:2Arcs," "Horz," "Vert," and "Horz/Vert," represents a working function that depends from the "Lines"
sub-menu. Id. at col. 4, ll. 24-65 ("The individual items appearing in the rows of each of these columns [defined by the sub-
menu indicia] represent an ultimate working function"). In other words, consistent with this court's construction, all the
indicia associated with the sub-menus of the "CREATE" group represent working functions.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - -

* Bowers urges in a conclusory fashion that this construction would render the preferred embodiment outside the scope of
the claims, a result that requires "highly persuasive evidentiary support." Vitrionics Corp. v Conceptron, Inc., 90 F.3d 1576,
1583, 39 USPQ2d 1573, 1578 (Fed. Cir. 1996). Bowers has not established his premise (that the preferred embodiment is
outside the claim scope), and even if he had, the reexamination history provides just that highly persuasive evidentiary
support, as this court explains below.

- - - - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

The reexamination history also precludes this court from adopting a broader construction. Specifically, with respect to
"working functions," the claim language recites only that the "pointing device can select a working function with a single
movement of the said button." During the reexamination proceedings, Mr. Bowers argued that the Keymaster template did
not satisfy this limitation because that template's "DETAIL" and "TRANSFORM" main-menu groups included indicia that
did not represent working functions. With reference to the "DETAIL" group more specifically, that group includes sub-
menus "Dim," and "Arr/Wit," and an additional indicium "Misc." The Keymaster "DETAIL" group and relevant portions of
the CADKEY 3.02 menu structure are shown in the figure below. In that figure, working functions are highlighted.

The indicia "Dim," "Arr/Wit," and "Misc" each have a group of indicia underneath them. However, as shown above, none of
those indicia groups includes only working functions. With respect to the group "Misc," Mr. Bowers made clear that the
indicia "Note," "X-Hatch," "Change," and "Set," all represented additional menus rather than working functions. For
example, selecting the indicium "X-Hatch" simply presents an opportunity to select the actual working cross-hatching
functions of "Brick," "Steel," "Copper," "Alloys," "Aluminum," "Rubber," or "Marble" (not shown in the menu structure
above). A user simply cannot access these cross-hatching functions through a single movement of the pointing device button

- 2523 -
using the Keymaster template. In like manner, as shown in the figure, the indicia groups associated with "Dim" and "Arr/Wit," respectively, also include indicia that do not represent working functions.

11. "[A]n indicia reader input system" 14 is a system for obtaining the information encoded in a symbol. This construction is consistent with the claims as well as the specification: col. 3:45-53, col. 4:56-57, col. 5:49-6:4, col. 6:17-21, col. 7:13-21; col. 7:63-65.

The primary argument offered by American Academy is that the '989 patent's specification limits the construction of "indirectly issuing." In particular, American Academy asks us to limit that claim term to the database simulator program of the preferred embodiment described in the specification:

The data base simulator program 118 is somewhat similar in operation to a data base manager and enables an application program 116 at the user station to call for storage or retrieval of data from the data center as though it were calling for data from a data base resident at the user station 4.

We have cautioned against reading limitations into a claim from the preferred embodiment described in the specification, even if it is the only embodiment described, absent clear disclaimer in the specification. See Liebel-Flarsheim Co. v. Medrad, Inc., 358 F.3d 898, 906 (Fed. Cir. 2004) ("Even when the specification describes only a single embodiment, the claims of the patent will not be read restrictively unless the patentee has demonstrated a clear intention to limit the claim scope using 'words or expressions of manifest exclusion or restriction.'"); Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002).

Rather than restricting the meaning of "indirectly issuing," the specification describes the invention broadly:

In operation, a user station initiates contact (inquires) with a data center using any of a variety of conventional protocol procedures, and the data center, which is always operating in an access mode under control of a data access control program, responds to the inquiry and communication is established.

The specification makes clear that the database simulator is a preferred embodiment, and just one of the "variety of conventional protocol procedures":

In a preferred embodiment of the present invention, the data center computer manages data bases for the independently
operating user computers by means of a data base manager program. The user computers store, retrieve, and update data items in their data bases by communicating data base calls to the data center computer. The user computers run respective user application programs to process their data and to each of which is linked a data base simulator program. When a user application program reaches a point in processing at which a data operation on a data item is needed, the user application program calls the data base simulator program and supplies it with sufficient information to issue a data base call to the data center computer to perform the required data operation.

Id., col. 3, ll. 29-44. Thus, the specification does not limit the term "indirectly issuing" to the use of a database simulator.

As it did in the case of the claim term "user computer," American Academy provided evidence in the form of declarations of Dr. Maryanski in support of its construction of "indirectly issuing." The Board found that those declarations were unpersuasive for the same reasons that they were found unpersuasive with respect to the term "user computer." As we explained above, the Board is entitled to give such weight to declarations as it deems appropriate. The Board was acting within its broad discretion in giving little weight to the declarations. Because the specification does not support American Academy's narrower construction of the claim term "indirectly issuing," the Board properly concluded that the broadest reasonable interpretation of "indirectly issuing" requires "only that a request from the host computer go through some other component before it is sent to the database."

2155

"Individual" and "Individuals"

The membership of "individuals" is perhaps the most contested issue of the asserted claims. Individual(s) appears both in the preamble and the body of the claim. The effect of such usage deserves comment.

Usage in the Preamble

Defendants seek to define "individuals" as it is used in the preamble, and allow that definition to filter to the rest of the claim. This may be crucial to Defendants' position since the operational use of "individual" and "individuals" in the body of the claims is possessive and relates back to the "offer(s)", thus it appears to be less important who enters the offer(s) than who the offeror and the offeree might be.

In a Jepson claim, the preamble generally recites prior art elements and has been determined to be substantive limitation of the claim. Here, the preamble text is: "A method for trading securities between individuals, comprising . . ." The focus of the inquiry is whether or not 'for trading securities between individuals' is merely a statement of intended purpose and thus merely informative and not an actual limitation. Clearly, the claim steps that follow the preamble describe just what the claim says. Security is introduced in the first step as is the concept of the trading and the individual. A fair reading of the entire claim without that phrase gives a firm idea of the nature of the invention. It certainly can not be said that the preamble text is necessary to breathe life into the claim. Thus, the Court concludes that the preamble text is a statement of intended use.

This does not end the inquiry as it does not resolve the issue of whether certain persons might be excluded from the term individual as used in the body of the claim.

In this case, the specification describes the invention as relating "specifically to systems which allow individuals to trade securities directly with other individuals who are not brokers, specialist [sic] or market makers." (c. 1, ll. 11-13) What it does not say is: "systems which allow individuals, who are not brokers; specialists; or market makers, to trade securities directly with other individuals, who also are not brokers; specialists; or market makers." 6 The description of the prior art describes the system whereby brokers profited from executing customer transactions by pocketing the "spread." The import
of the invention is to strip away this veil of secrecy, and allow the Joe Q. Individual to obtain the optimum buy/sell price by being able to view and select the best offer in the available market. Thus, when Minton describes the need for "a data processing system and a network of data processing systems whereby individuals can buy and sell directly from each other, with only minimum involvement from a broker" (c. 2, ll. 47-49) there appears to a paradox in how to define individuals.

6 Henceforth, "brokers, specialists, and market makers" will be identified solely by "brokers."

On the one hand, there appears to be two identifiable groups of individuals: one of which clearly excludes brokers and one which is silent. On the other hand, a single group of individuals which excludes brokers. However, there is a third possibility: "individuals" includes everyone who is a buyer or seller, and that brokers may be excluded based on other limitations.

The First Office Action

In his initial rejection of claims, the examiner first cited Adams, U.S. Patent No. 3,573,747 ( '747 patent) as prior art, noting that he equated the usage of individuals in the '643 application with "subscribers or buyer [sic] and sellers" in the '747 patent. 7 Defendants attack a broad interpretation of individuals by claiming that the examiner excluded brokers by this statement; however that position ignores the context of the examiner's usage, and here the context is crucial. This was not an isolated assertion but a reference for establishing how the '747 patent anticipated several claims in the '643 application. Referencing the specification of the '747 patent, the Court observes no specific reference to brokers. 8 It explicitly does include "institutional investors", which the Court interprets to include retirement plans, insurance funds, and mutual funds; some of these may be broker managed funds. The closest the '747 patent comes to broker is 'intermediary,' which is placed in the context of removing the intermediary between the institutional investor and the trader, however this is overshadowed by the purpose given in the background of the '747 that stated that the "subscribers may be any buyers and sellers desiring to trade any of said fungible properties." ( '747 c. 1, ll. 38-40) (emphasis added.) The strongest support comes from the summary that states:

7 After reading the '747 patent, the Court concludes that the examiner made a clerical errors and intended to say 'buyers' as that term appears in the '747 specification.

8 Remember that matter considered in the prosecution history is intrinsic evidence. The '747 patent was discussed explicitly in the rejection of claims, thus it is more than mere 'prior art' such as other references that may have been disclosed in the IDS.

"It is a further object…wherein the trading [of securities] can be effectuated without the necessity of a human negotiator between buyers and sellers." ( '747 c. 1, ll. 47-50).

Essentially, Adams sought to eliminate the trading floor in which brokerage houses (which include institutional investors) could engage in a preference system through their floor traders; not exclude the presence of brokers altogether.

Thus, the Court finds that the purpose of the examiner's statement was to inform Minton as to how the '747 was compared to his invention for prior art purposes, and not to place a limitation on any claim. Note also that Minton altered his claims in response to an objection, not a rejection. Thus, prosecution history estoppel does not arise against him with respect to this statement. The Court further notes that the '747 patent allowed the creation of offers without a price value and a quantity value, and thus did not teach the necessity of price and quantity in creating an efficient transaction system.

Plain Language Usage in the Claims
Defendants argue that "individual" excludes all persons who are brokers acting in any capacity. Clearly, this is incorrect as can be demonstrated here. Assume that three persons, Merrill; Lynch; and Pierce, all happen to be sitting comfortably at their home computers, and Merrill offers to buy a stock that Lynch and Pierce are both offering for sale through E-trade. The fact that they are also brokers (i.e. members of NASDAQ or NYSE) would not mean that they were not trading as individuals for their own sake. Thus, the definition for "Individuals" offered in one proposed order of construction is far too broad, resulting in far too narrow a claim.

Further, Defendants have a fundamental and clear misconception regarding the function of "an individual" in the context of the claims. In one proposed order, the first clause:

"Entering the offer of a first individual to trade a security on a first data processing system" is to be interpreted as a limitation:

"...this step requires that a first individual perform the step of entering the first individual's offer to trade in a first computer." (Def. order at 2).

Yet, nowhere in that clause is there any limitation as to who or what might enter the offer into a first computer. Nor is any such limitation created by any other clause in the asserted claim. Rather, than repeat the above example for each clause, it should be apparent that the explicit language of the claims places no restriction or limitation on the identity of the traders.

--- Footnotes ---

9 A clause supporting Defendants' position would be: "Entering the offer to trade a security of a first individual by the first individual on a first data processing system" or even, "a first individual entering the offer of the first individual to trade a security on a first data processing system."

--- End Footnotes ---

2156

B. "individualized rule set"

Claim 1 contains the term "individualized rule set": "wherein the authentication accounting server accesses the database and communicates the individualized rule set that correlates with the first user ID" and "wherein data . . . are processed by the redirection server according to the individualized rule set." Although "individualizedrule set" does not appear in the specification, the phrase "rule set" is used frequently:

The rule sets specify elements or conditions about the user's session. Rule sets may contain data about a type of service which may or may not be accessed, a location which may or may not be accessed, how long to keep the rule set active, under what conditions the rule set should be removed, when and how to modify the rule set during a session, and the like.

('118 patent, 4:41-47) (emphasis added).

The plaintiff defines "individualized rule set" as "elements or conditions which apply during a user's session." According to the defendants, this term means "filtering and redirection rules for a particular user ID, which apply during an authorized session." The three primary differences between the parties' proposed constructions are: (1) "elements or conditions" vs. "filtering and redirection rules"; (2) association with a specific user ID; and (3) "user's session" vs. "authorized session."

First, Linksmart argues that "individualized rule set" should be broadly construed to cover "elements or conditions." The specification explicitly states that "rule sets specify elements or conditions." ('118 patent,4:41-42) (emphasis added). In response, the defendants assert that the patent uses the phrase "filtering and redirection information" interchangeably with the term "rule set," e.g., "[t]he database also contains personalized filtering and redirection information" and "[t]he redirection server uses the filter and redirection information . . . to either allow packets to pass through . . . , block . . . , or
modify." ('118 patent, 3:3-4, 3:15-19). But the specification also explains that the rule set may contain data about "how long to keep the rule set active" and "when and how to modify the rule set during a session." ('118 patent, 4:42-47). The narrow "filtering and redirection information" construction would exclude these two alternatives. Therefore the court will adopt the "elements or conditions" construction.

Second, the defendants' proposal requires the "individualized rule set" to be associated with a particular user ID. Linksmart argues that nothing in the specification requires the rule set to be tied to a specific user ID. But the specification refers to a "rule set," while the claims use the term "individualized rule set." Because the modifier "individualized" is included, the court will construe the term to require a link to a specific user ID.

Third, the plaintiff contends that the rule set is applied during a "user's session," but the defendants assert that the rule set is applied during an "authorized session." The specification explains that "[t]he rule sets specify elements or conditions about the user's session." ('118 patent, 4:41-42) (emphasis added). "Authorized session" is not found in the specification. As such, the court is persuaded that the rule set applies during a "user's session." In all, the court construes the term "individualized rule set" as "elements or conditions for a particular user ID that apply during a user's session."

2. Claim Term 9

Claim Term 9 includes the words "the inductor," "an inductor," and "said inductor." See '349 patent, claims 5-11; '400 patent, claims 21-41. UI proposes the following construction for Claim Term 9: "one or more associated windings, with or without a magnetic core, for introducing inductance into an electric circuit." University Comparison Chart at 3-4. Fujitsu's proposed construction is as follows:

An inductor is a piece of wire that is frequently, but not always, wound into the shape of a coil, which is used to introduce inductance -- i.e., a magnetic field effect that causes the coil to oppose changes in current -- into a circuit. Each of the claims at issue is limited to a single inductor that is used for both charging and discharging the panel capacitance.

University Comparison Chart at 4. The primary dispute is whether Claim Term 9 refers to a single inductor through which charging and discharging occurs (as Fujitsu argues) or, alternatively, whether these terms allow for multiple inductors, some of which are used for charging only and others for discharging only. The parties also disagree about the definition of an inductor. UI calls an "inductance element" what Fujitsu calls an inductor, arguing that multiple "inductance elements" may constitute a single inductor.

In determining whether the words "an inductor" and "the inductor" refer to a single inductor or "one or more inductor," the Court looks in the description in the patent to determine whether it reveals a clear intent to limit the invention to a singular embodiment. See KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 (Fed. Cir. 2000). Although the use of the term "a" or "an" may suggest that a single element is claimed, "patent claim parlance also recognizes that an article can carry the meaning of "one or more," for example in a claim using the transitional phrase 'comprising."' Abtox, Inc. v. Exitron Corp., 122 F.3d 1019, 1023 (Fed. Cir. 1997). Where it is unclear whether the claim covers a single element or multiple elements, courts look to the written description in the patent to determine whether there is a "clear intent" to limit the invention to a singular embodiment. KCJ Corp., 223 F.3d at 1356. The fact that there is only a single inductor in the preferred embodiments shown in the patent figures does not justify imposing such a limitation on the claims. See id. (holding that even where the embodiments suggest a single element, such a limitation will not be imposed if the claim language is broader than the embodiments).

Here, the words "an inductor" and "the inductor" follow the open-ended terms "comprising" and "including," supporting the conclusion that "an inductor" means one or more inductors. Fujitsu argues, though, that the use of the words "said inductor" reveals a clear intent on the part of the inventor to limit the term "inductor" to a singular embodiment.

A review of the cases cited by the parties on the significance of the word "said" in patent claims is instructive. In Abtox, a case on which Fujitsu relies, the court addressed whether or not the claim language in dispute provided for a single chamber or rather, whether it meant "one or more chambers." Abtox, 122 F.3d at 1023-1024. The claim provided as follows:
apparatus for sterilization of medical devices and materials in a gas plasma comprising,

(a) a metallic gas-confining chamber having a non-metallic portion;

(b) a microwave energy source including a microwave cavity positioned to couple microwave energy into said chamber through said non-metallic portion, and

(c) means for holding . . . medical devices and materials to be sterilized within said chamber volume and away from said microwave cavity, and including a perforated electrical shielding member positioned within said chamber and in close proximity to said microwave energy source to provide a portion of the internal volume of said chamber shielded from and away from said microwave energy providing a field-free zone containing said devices and materials.

Id. at 1022 (emphasis added). The Court concluded that this claim referred to a single chamber. Id. at 1027. In reaching this conclusion, the Court relied heavily on the language used in the claim, and in particular, on the repeated use of the term, "said chamber." Id at 1024. The court also found that the written description in the patent supported its construction.  Id. at 1024. Specifically, one of the figures in the patent showed a single chamber and "nothing in the written description suggested that the claim language encompassed a device with more than one gas-confining chamber." Id.

In KCJ, the court addressed whether claim language for an air mattress limited the scope of the invention to embodiments using one lower air chamber, or alternatively, whether the scope of the claims covered an embodiment with multiple chambers. 223 F.3d at 1355. The disputed claim provided as follows:

1. An air flotation, ventilated mattress apparatus comprising:

(a) means defining a lower, continuous, inflatable chamber having an air-permeable, flexible upper wall portion,

(b) said upper wall portion being constructed for substantially uniform airflow therethrough over substantially the entire plan surface area of said upper wall portion;

(c) air-permeable secondary wall means above said chamber upper wall portion and operably coupled with said chamber-defining means,

(d) said secondary wall means being constructed for substantially uniform passage of air therethrough over substantially the entire plan surface area of said secondary wall means,

(e) said secondary wall means and upper wall cooperatively defining therebetween an inflatable compartment above said chamber; and

(f) means for continuously introducing positive pressure air into said chamber in order to continuously maintain positive air pressure conditions throughout the entirety of said chamber during the entirety of operation of said mattress apparatus and to inflate both said chamber and compartment by passage of said air into said chamber and thence through said upper wall portion and thereby maintain positive air pressure conditions in said compartment, and to cause said continuous passage of air through said secondary wall means,

(g) said mattress apparatus being free of solid internal support structure for supporting a patient,

(h) said air introduction means, upper wall portion and secondary wall means being cooperatively configured and arranged for continuous passage of sufficient positive pressure airflow through the chamber, upper wall portion, compartment, and secondary wall means for even, substantially uniform flow of air from said mattress apparatus so that a person lying atop the secondary wall means is supported by said pressurized air without the presence of weight-supporting structure within said mattress apparatus.

- 2529 -
Id. at 1353 (emphasis added). The court concluded that the claim language provided "no support for departing from the general rule" that indefinite articles such as "a" and "an" mean one or more. Id. at 1357. It went on to note that neither the written description nor the prosecution history explicitly disclaimed the use of multiple chambers. Id. The court did not address the significance, if any, of the references to "said chamber" in the claim.

In Elkay, the court addressed whether or not a single feed tube was used both for delivering liquid from a container and admitting air into a container. 192 F.3d at 977. The claim provided for "an upstanding feed tube . . . to provide a hygienic flow path for delivering liquid from . . . and for admitting air . . . into said container to displace the liquid delivered therefrom, said feed tube having upper and lower end portions." Id. at 975-976 (emphasis added). Although the preferred embodiment used a single feed tube for both admitting air and delivering liquid, the court concluded that neither the language of the claim nor the written description conclusively established that the scope of the claim was limited to a single feed tube that was used for both functions. Id. at 978. It went on to hold, however, that in the prosecution history, the inventor had disclaimed an embodiment with separate flow paths for air and water. Id.

Finally, in Altiris, the court addressed whether the claim described a single "boot flag" or multiple boot flags. 318 F.3d at 1368. The disputed claim read as follows:

A digital computer system programmed to perform the method of gaining control of the boot procedure of a digital computer, said digital computer comprising:

(A) a central processing unit;

(B) a memory unit;

(C) a long term storage device; and

(D) a means of booting said computer, said means of booting including a first set of commands, said first set of commands resident on said storage device of said digital computer for booting said digital computer, and a second set of commands, said second set of commands resident on a storage device external to said digital computer, for booting said digital computer, the method comprising:

...testing automatically for source of said means of booting; said testing including reading a boot selection flag and comparing said boot selection flag with a known flag setting; transferring control of said computer system to said source of said means of booting; performing said external commands, if said testing automatically step indicates a boot sequence stored externally to said digital computer; setting said boot selection flag; and booting normally, if said testing automatically step indicates a boot sequence stored internal to said digital computer.

Id. at 1368 (emphasis added). The court concluded that the claim was not limited to a system that used a single boot selection flag, but rather, covered a system using more than one boot selection flag as well. Id. at 1373. The court explained its reasoning as follows:

The parties agree that "a" generally means "one or more" in open-ended claims such as those at issue here. KCJ Corp. v. Kinetic Concepts, Inc., 223 F.3d 1351, 1356 . . . (Fed.Cir.2000). Symantec, however, contends that this general rule does not apply here because the sole embodiment described in the patent uses a single flag. Once again, however, there are no statements in the specification or the prosecution history inviting, much less requiring, us to limit the claims to the only disclosed embodiment. This is merely another attempt to limit the invention to the preferred embodiment. We therefore hold that "boot selection flag", encompasses the use of multiple flags to select the boot cycle.

318 F.3d at 1373-1374.

It is apparent that the word "said" as a qualifier does not always signify that the element qualified is limited to a singular embodiment. In KCJ, the court found that the claim language covered an air mattress with multiple chambers even though the claim referred at least once to "said chamber." 223 F.3d at 1357. Similarly, in Altiris, the court found that the claim allowed for more than one boot selection flag, even though the claim language referred to "said boot selection flag." In Elkay, likewise, a reference to "said feed tube" was not found to limit that element to a singular embodiment. Conversely,
the Federal Circuit's decision in Abtox makes clear that the word "said" may be significant where, as in that case, it describes the relationship between different components of the invention covered by the claim. See Abtox, 122 F.3d at 1023. Similarly, the word "said" may reveal the relationship between two functions described in a claim. For example, in Altiris, although the court did not reach the issue, it is likely that the reference to "said boot selection flag" indicated that the boot selection flag that was to be "compared" was the same boot selection flag as was to be "read."

Applying these principles, the Court concludes that the terms "an inductor" and "the inductor" in the disputed claims allow for more than one inductor. However, the claims that describe both charging and discharging through "said" inductor make it clear that the same inductor must be used for both charging and discharging the panel capacitance. For example, claim 38 of the '400 patent refers first to "an inductor coupled to said panel electrodes for charging and discharging." '400 patent, col. 22, ll. 25-28. To the extent that there may be ambiguity as to whether the charging and discharging described by this language must be conducted through the same inductor, that ambiguity is dispelled by the limitations that follow. Those limitations require: 1) a "first switch means coupled to said inductor to enable said panel capacitance to charge through said inductor," '400 patent, col. 22, ll. 29-31; and 2) a "second switch means coupled to said inductor to enable said panel capacitance to discharge through said inductor," '400 patent, col. 22, ll. 37-39. As stated above, the word "said" means "already named or mentioned." The New Shorter Oxford English Dictionary (1993 ed.), p. 2668. Thus, the word "said" in this context reveals that the charging and discharging described in the two limitations quoted above must use the same inductor.

The parties also disagree on the issue of what constitutes a single inductor, as opposed to an "inductance element." Thus, the Court must determine the common and ordinary meaning of the term "inductor" in 1986, or, alternatively, find a clear intent in the patent description to give the word a special or different meaning. See Vitronics, 90 F.3d at 1582. UI argues that an "inductor" may encompass one or more "inductance elements." UI Claim Construction Brief at 21. In support of this position, Dr. Inan relies on the following definition of the term "inductor," from the IEEE Standard Dictionary of Electrical and Electronics Terms ("IEEE Dictionary"), published in 1984:

> A device consisting of one or more associated windings, with or without a magnetic core, for introducing inductance into an electric circuit.

IEEE Dictionary at 440, Exh. K to Nui Decl. UI goes on to cite to Dr. Inan's testimony, in which Dr. Inan states as follows:

> Inductance elements combined to constitute "an inductor" can be electrically connected in various configurations, including series and/or parallel connections. The need for or use of an electrical connection does not imply a need for or the presence of physical proximity of different windings that might be used to introduce a certain inductance value into a circuit.

Inan Report at 20. Thus, UI appears to argue that any windings that are electrically connected in a device are sufficiently "associated," under the definition in the IEEE dictionary, to constitute a single inductor. Finally, UI points to U.S. Patent No. 5,828,353, in which the term "inductance element" is used.

Fujitsu does not disagree that the IEEE definition of an "inductor" provides a starting point for construing the term. However, it argues that the word "associated" requires more than that the windings be electrically connected. Rather, Fujitsu cites to its own expert's testimony to show that the word "associated" requires that the windings share coupled magnetic field lines. Dr. Silzars explains his position as follows:

> An inductor is a device that couples magnetic field lines of associated portions of a conductor. This is called "field coupling." Two elements sitting on a table may have inductance but do not constitute a single inductor unless they intimately and mutually share coupling of their magnetic field lines. . . . I understand that Dr. Inan states that inductors he "associated windings" whether or not they share a field coupling. . . . What those of ordinary skill in the art would call "inductors," Dr. Inan would call "combinations of inductance elements sharing an electrical connection that function together to introduce the desired inductance into a circuit." . . . This is incorrect. Those of ordinary skill in the art in 1986 and indeed today, do not use the term "inductance element" to be distinguishable from an "inductor" . . .

Silzars Decl. at 69 (citations omitted). Fujitsu also cites to three patents in support of its position, U.S. Patent No. 4,070,663, U.S. Patent No. 3,931,528 and U.S. Patent No. 3,833,833, all of which refer to "inductors" rather than "inductance
elements." Finally, Fujitsu points out that UI's former expert, Dr. Bitzer, stated in his expert report in the ITC proceeding that Fujitsu's allegedly infringing device uses "separate inductors." Fujitsu Claim Construction Brief at 19, citing to Expert Report of Donald L. Bitzer, Exh. 6 to Silzars Decl.).

The Court finds no support in the '349 and '400 patents for UI's position. Rather, the description in the Patents supports Fujitsu's position that windings that do not share coupled magnetic field lines constitute separate inductors. First, the term "inductance element" is not used in either patent. Second, the '400 patent uses the word "inductors," in describing the sustain driver circuit claimed in the invention. '400 patent, col. 2, ll. 53-55. In particular, the description states that "the new sustain circuit driver uses inductors in charging and discharging the panel capacitance." Id. This use of the plural "inductors" indicates that there can be multiple "inductors" in the invention as part of the same circuit, and that multiplicity is referred to by the plural "inductors," not by the singular "inductor." This conclusion is confirmed by the figures in the patents. In Figures 5 and 7, the sustain circuit described in the invention includes two sustain drivers, one for each set of sustain electrodes. See Figs. 5, 7 of '349 and '400 patents. Each of these drivers contains a set of windings and these two sets of windings are electrically connected in the same circuit. If UI's proposed definition of an inductor were correct, these two sets of windings should have been referred to as "inductance elements" and not as "inductors" in the plural form. The fact that they were referred to as "inductors" provides strong intrinsic evidence that Fujitsu's proposed definition of an "inductor" is correct.

The Court finds that "associated" means windings that share coupled magnetic field lines. As discussed above, the intrinsic evidence requires that the multiple inductors in the invention each be referred to separately as an "inductor." Moreover, the IEEE dictionary provides not only the definition of "inductor," but also the information necessary to define "associated." In that definition the word "associated" is directly tied to the function of the inductor -- introducing inductance into a circuit. See IEEE Dictionary at 440, Exh. K to Nui Decl. An inductor uses magnetic field lines to introduce inductance into a circuit. See Silzars Decl., PP99-100. Accordingly, to be part of the same device, associated windings in an inductor must share coupled magnetic field lines. 4 Id.

--- Footnotes ---

4 Because the '349 and '400 patent, read in conjunction with the IEEE dictionary, provide a sufficient basis on which to construe the meaning of the word "inductor," the Court declines to consider the Bitzer expert report and the other patents offered by the parties in support of their proposed construction. See Markman, 52 F.3d at 980 (holding that "the court may, in its discretion, receive extrinsic evidence in order to aid the court in coming to a correct conclusion"). Because the Court does not rely on Dr. Bitzer's testimony, it does not reach the question of whether that testimony is admissible as an admission under F. R. Evid. 801(d)(2).

--- End Footnotes ---

The Court defines an inductor as follows:

A device consisting of one or more associated windings for introducing inductance into a circuit. Windings are "associated" for the purposes of this definition only if they share coupled magnetic field lines.

2158

3. Claim 36 - "inductor means"

MagneTek does not contend that the term "inductor means" in claim 36 is in means-plus-function format but nonetheless argues that it must be construed as limited, as indicated in the specification of the '409 patent, to inductors that provide a total inductance large enough to keep the current flowing from the DC source into the inverter substantially constant. We reject this argument. As it did with regard to the term "inverter means," to accept MagneTek's argument would require us to ignore the Federal Circuit's "repeated statements that limitations from the specification are not to be read into the claims." Comark, 156 F.3d at 1186. We construe the term "inductor means" in claim 36 in accordance with its well known meaning to persons skilled in the art, that is, as denoting a coil of wire wound on magnetic material. See D. Fink & H. Beaty, Standard Handbook for Electrical Engineers at 2-10 (13th ed. 1993).
"Inductor Means" in the '409 Patent's Claims 9, 16 and 37

Claims 9, 16 and 37 of the '409 Patent pose the question of how broadly or narrowly the phrase "inductor means" should be construed. 28 N. Mem. 26 says that "inductor" has a commonly understood meaning in the art and points to its dictionary definition (Handbook 2-10):

An inductor is a circuit element whose behavior is described by the fact that it stores electromagnetic energy in its magnetic field.

* * *

In its most elementary form, an inductor is formed by winding a coil of wire--often copper--around a form that may or may not contain ferromagnetic materials.

27 Motorola cites to different numbers--to claims 9 and 36--as those at issue. That difference is due only to the tendency of patent claims to refer back to the language of prior claims. This is thus not problematic because, of course, it is the language that is at issue.

28 It is undisputed that the inductor is connected between the source of DC voltage and the inverter's input terminals.

Though that does fairly describe the universe of inductors as such, it wholly ignores (just as Nilssen's arguments blithely ignore--see both N. Mem. 27-28 and N. Resp. 27-28) Nilssen's conduct before the PTO during the '409 Patent's prosecution. In response to the PTO examiner's objection that the claim at issue represented no patentable advance because it was obvious in light of prior art that employed other types of inductors, Nilssen argued that his "inductor means" was different--that "the direction of the inductor coils in [the prior art] arrangement…is exactly opposite of the way the two coils are arranged in the claimed invention." And that latter reference was to the description in the specification.

Thus Nilssen himself urged on the PTO (indeed, more than once) the use of the specification to ascertain the meaning of "inductor means" in his invention. That calls into play the teaching of Vitronics, 90 F.3d at 1582 (emphasis added):

The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication.

And what Motorola now plumps for as the meaning of the term "inductor means" draws directly on that Nilssen-dictated "dictionary"--the specification--rather than one the more generic Handbook.

Thus Nilssen's generalized attempt to fall back on the general aversion to reading limitations from a specification into a claim is out of place here. Motorola asks that Nilssen be taken at his word, which he gave when it was in his interest to obtain the benefit of the patent he now seeks to sue upon, and this Court honors that request. "Inductor means" will be construed in the manner contended for by Motorola. 29

29 For a second time this opinion has parted company with Judge Kennelly's MagneTek opinion, 1999 WL 982966, at *7. But that opinion makes no reference to Nilssen's PTO representations referred to here in the text--and in the absence of that factor, this Court would also have reached the same conclusion as Judge Kennelly.
Inferring

Claims 1, 20, 22, 23, 33, 34, 35, 36, 37, 38, 39, and 40 contain the term "inferring." SFA defines the term in accordance with a general dictionary definition as "deriving based upon one or more facts or circumstances." SFA makes no effort to analyze the definition with regard to the intrinsic evidence. Claim terms do not occur in a vacuum. Kyocera Wireless Corp. v. Int'l Trade Comm'n, 545 F.3d 1340, 1347 (Fed. Cir. 2008). While technical definitions may often be helpful in understanding a commonly understood meaning, extrinsic evidence is inherently "less significant than the intrinsic record in determining the legally operative meaning of claim language." Phillips, 415 F.3d at 1317 (internal quotation marks omitted). As a result of SFA's failure to examine the intrinsic record, its definition is too broad and unhelpful in understanding the technology. SFA's construction must be rejected.

Conversely, Infor argues that "infer" and all its derivatives (discussed below) are indefinite because they are not specifically defined or discussed in the specification and are open to multiple inconsistent meanings based on the intrinsic and extrinsic evidence. Alternatively, Infor argues that "infer" should be strictly construed in light of the specification to mean "the computerized logical process by which a factual conclusion is derived from known facts by the application of logical rules using the inference engine of an expert system within the event manager." Again, Infor suggests that because the only mention of the word "infer" in the specification is in a description of an inference engine, an inference engine must be attributed to all instances of "inferring" within the claims.

Indefiniteness is a matter of claim construction, and the same principals that generally govern claim construction govern indefiniteness. Praxair, Inc. v. ATMI, Inc., 543 F.3d 1306, 1319 (Fed. Cir. 2008). "A claim satisfies the definiteness requirement of § 112 if one skilled in the art would understand the bounds of the claim when read in light of the specification." Id. (internal quotation marks omitted). A claim is indefinite only where there is clear and convincing evidence that the claim is insolubly ambiguous, and no narrowing construction can be properly adopted. Id. However, the claim is sufficiently clear to avoid indefiniteness "if the meaning of the claim is discernable, even though the task may be formidable and the conclusion may be one over which reasonable persons will disagree . . . ." Id.

In light of these principals, Infor's argument is fatally flawed. A term does not have to be specifically explained in the specification to be understood by one skilled in the art. Med. Instrumentation & Diagnostics Corp. v. Elekta AB, 344 F.3d 1205, 1217 (Fed. Cir. 2003) (finding that though term "computer" never appeared in the specification, those skilled in the art would understand that "computer" was structure to perform the disclosed functions"); Motorola, Inc. v. Analog Devices, Inc., No. 1:03-CV-131, 2004 WL 563737 at *24 (E.D. Tex. June 7, 2004) (Clark, J.) ("In view of the essential agreement between the parties as to the plain meaning of the phrase, the fact that it is not used in the patent specification does not render the term indefinite."). Whenever the term "infer[ring]" appears in the claim, it refers to either an "occurrence of an event," "context," or both. This "inferring" only takes place upon a change in state that is characteristic of some event. Thus, the context surrounding "infer" suggests that "inferring" is a form of event recognition and analysis. This process is disclosed early in the specification as "recogniz[ing] events occurring in the system and determin[ing], on the basis of the event and the context in which the event occurs, what if any other actions or operations should be carried out by the system." S25 Patent at 8:36-39. This is also consistent with the function as it evolved in the prosecution history. Plaintiff's Opening Ex. B, Amendment of Dec. 15, 1997 at 16 (arguing that the prior art fails to teach "event recognition"). Further, the parties agree that the plain and ordinary meaning of the of term is "deriving." The only remaining inquiry is determining the process by which "inferring" is achieved.

Infor uses the ordinary technical definition of "infer" as the backbone of its suggested construction. According to that definition "infer" is a "logical process by which a factual conclusion is derived from known facts by the application of logical rules." "Inference," Free On-Line Dictionary of Computing (2008), http://foldoc.org/index.cgi?query=inference; "Inference, Computer User (2008), http://www.computeruser.com (follow "Dictionary" link, then search "inference"). This definition harmonizes with the specification's description of the "inferring" function as a type of event recognition. Furthermore, the specification provides a detailed description of the functions of the event manager (the structure responsible for "inferring"), both generally and as it relates to particular subsystems. See S25 Patent at 8:34-57. The event
manager is repeatedly described as operating on a set of rules. '525 Patent at 32:13-14, 20-21, 37-40. Thus, one skilled in the art would understand the "inferring" process as a "logical process by which a factual conclusion is derived from known facts by the application of logical rules." Since the meaning of "infer" can be readily deduced by one of ordinary skill in the art, a limiting construction, such as the one proffered by Infor requiring that "inferring" be limited to an embodiment containing an "inference engine," is unnecessary. Infor's indefiniteness objection is overruled.

C. "Information"

The claims of the '585 Patent and the '169 Patent refer to the use in their respective processes of "information" sent by an RFID tag to an RFID reader. Defendants do not contend that the term "information" is ambiguous or has a special meaning as used in the patents; rather, defendants rely on Microsoft to add limitations to the claim, as they argue that "information" should be construed to mean system or process data none of which is actual or real-time temperature measurements. TSI does not believe that any further construction of the term "information" is necessary.

Defendants do not offer any argument or citation to support the requirement that the information be "system or process data." Therefore, the Court rejects that portion of defendants' proposed construction. Defendants instead focus on its proposed limitation that the information cannot include actual temperature measurements.

With respect to the '585 Patent, defendants note that the specification describes the RFID technology as an alternative to photo sensors in determining whether the food container is in place on the heater, see '585 Patent at 6:43-7:32, and describes the information from the RFID tag as relating to the size of the container or the number or duration of trips, see id. at 24:33-53. Thus, defendants argue that the information does not include actual temperature information. Defendants also argue that the '585 specification "teaches away" from the use of actual temperature information to control the heating of the container, and that instead feedback from the RFID tag regarding impedance is used. See id. at 3:4-12, 3:30-45, 14:40-51, 19:12-44. All of these statements, however, relate to embodiments or merely list examples of information that may be sent from the RFID tag. The '585 specification never states that the information from the RFID tag cannot include temperature information; thus, the specification cannot be said to describe the invention as one using information from an RFID tag that cannot include temperature information.

Similarly, with respect to the '169 Patent, defendants cite to a portion of the specification that lists the information from the RFID tag as the identification of the object and the last step performed in the heating algorithm, see '169 Patent at 7:49-53, and they note that temperature information is not included in that list. Defendants also argue that the '169 Patent "teaches away" from using actual temperature to control the heating process, as the specification goes into great detail about how the temperature is estimated by algorithms.

Again, the Court concludes that these citations are not sufficient to support the limitation urged by defendants. The estimation discussion and the list of the types of information in the cited portion of the '169 Patent specification relate to embodiments and not to the invention as a whole. Moreover, in the cited portion, the specification states that the RFID tag should transmit "at least" those types of information--thus, the specification clearly declines to limit the allowable information to those enumerated types. See id. at 7:49-53; see also id. at 3:50 ("typically" the information relates to the object). Indeed, in discussing prior inventions, the Background section of the specification describes how temperature information from the object may be "important," but it is often not sufficient by itself for proper heating control. See id. at 2:47-3:18. Such a description certainly does not mean that temperature information cannot be used along with the additional information that benefits the process. Accordingly, the specifications of the two patents do not provide the requisite description of the invention to support the importation of defendants' no-actual-temperature-information limitation into the claims under Microsoft. 5

--- Footnotes ---

5 TSI also points to a reference in the specification for the '169 Patent to thermal switches in arguing that the patent does contemplate the use of temperature information. In that reference, however, the specification suggests that thermal switches could be used to break a circuit and thus suspend the heating operation when a predetermined temperature is reached. See
'169 Patent at 4:32-43. It did not suggest that the actual temperature could be transmitted by the RFID tag for use in the control process. Thus, the reference to thermal switches does not appear to be relevant to whether defendants' limitation that would preclude the use of actual temperature information is justified.

Defendants also cite to the statements by Mr. Clothier, the inventor, in his '919 Patent and application in which he refers to his prior '585 and '169 Patents as involving systems that do not use actual temperature information. For instance, the '919 Patent itself includes the following statement: "Unfortunately, Clothier [the '585 Patent and the '169 Patent] suffers from a number [of] limitations, including, for example, that it does not employ real-time temperature information from a sensor attached to the vessel." See '919 Patent at 2:62-66. The provisional application for the '919 Patent states: "However, Clothier's system does not employ real-time temperature information from a sensor attached to the vessel, where said sensor information is periodically communicated to the RFID reader/writer." See '919 Patent prov. applic. at 4; see also id. at 6 (noting that one difference from the device in Figure 1 of the '169 Patent is that the subject invention can read real-time temperature information from the RFID tag), 11 (one further capability of the subject invention over the invention in the '169 Patent is that it may read temperature information).

The Court is not persuaded by these citations to impose the urged limitation in claim scope. Defendants have not shown that the '919 Patent is within the same family as the patents at issue here. See Microsoft Corp. v. Multi-Tech Sys., 357 F.3d at 1350 (statements in prosecution of subsequent related patent may not effect estoppel but may be relevant to claim construction). Defendants nevertheless argue (without citation to authority) that statements in a separate patent and its prosecution history might be helpful as extrinsic evidence of the meaning intended by the inventor. "Information" is not an ambiguous or technical term, however; thus, the extrinsic statements here do not provide any evidence from the inventor as lexicographer. Moreover, the inventor's statements about his own invention are not necessarily helpful. See Howmedica Osteonics Corp. v. Wright Med. Tech., Inc., 540 F.3d 1337, 1346-47 (Fed. Cir. 2008) (inventor's understanding of his invention does not equate to an understanding of the patent claims; "inventor testimony as to the inventor's subjective intent is irrelevant to the issue of claim construction"). The statements here do not aid the Court's analysis under Microsoft, as they do not affect whether the subject patents repeatedly and consistently describe their inventions as limited. Finally, defendants have not provided any authority suggesting that an inventor can somehow disclaim or disavow claim scope in subsequent statements, and the statements here do not represent a clear disavowal of claim scope at any rate. See Conoco, Inc. v. Energy & Envtl. Int'l, L.C., 460 F.3d 1349, 1357-58 (Fed. Cir. 2006) (inventor's intention to disclaim or disavow claim scope must be clear from the specification).

For these reasons, the Court rejects defendants' proposed construction of the term "information" as used in the claims of the '585 Patent and the '169 Patent. The Court concludes that no construction of the term is necessary.

C. "Information"

The term "information" appears in all claims for all patents. The term is used in somewhat different contexts. For example, claim 1 of the '511 patent describes using a driver to obtain "first information" about the data structure of a data source by accessing "content of information" stored in a data source, while claim 6 describes using a driver to store "at least some information" from data sources into a database.

Timeline's proposed construction of the term is "facts contained in or describing some or all of a data source." ProClarity's proposed construction is "interpretation of data when seen in context so as to convey meaning."

Timeline's proposed construction of "information" is consistent with the use of the term in the patents and is broad enough to accommodate the different contexts in which the term is used. When the term is used to describe obtaining "first information" about the data structure of a data source, the ordinary meaning of the term would be obtaining facts that describe a data source. When the term is used to describe storing at least some "information" from data sources into a database, the term must be read to include facts contained in a data source.
To be sure, construing "information" to include "facts contained in . . . a data source" would effectively give the term a meaning that is synonymous with the term "data." However, as discussed above, the terms "information" and "data" are often used interchangeably in the patents. In addition, Timeline points to dictionary definitions that define the terms "information" and "data" as synonyms or as interchangeable words. See, e.g., Computer Desktop Encyclopedia (1981-2005) ("Information is the summarization of data. Technically, data are raw facts and figures that are processed into information, such as summaries and totals. But since information can also be the raw data for the next job or person, the two terms cannot be precisely defined and both are used interchangeably"); Webster's New Universal Unabridged Dictionary (1996) (listing "data" and "facts" as synonyms of "information").

By contrast, ProClarity's proposed construction -- "interpretation of data when seen in context so as to convey meaning" -- is strained and unduly narrow. This proposed construction would not accurately reflect the meaning of "information" as it is used throughout the patents, such as when it is used to describe information stored in a data source. ProClarity argues that because Timeline chose to use two different terms ("information" and "data") in its claims, a different meaning must be ascribed to each term. See CAE Screenplates, Inc. v. Heinrich Fiedler GMBH & Co., 224 F.3d 1308, 1317 (Fed. Cir. 2000) ("In the absence of any evidence to the contrary, we must presume that the use of these different terms in the claims connotes different meanings."). However, two different terms may be construed in the same manner when they are used interchangeably by the patentee. See, e.g., Tate Access Floors v. Maxcess Techs., 222 F.3d 958, 968 (Fed. Cir. 2000). As discussed earlier, there is ample evidence that the term "information" was often used interchangeably with "data" in the patents.

Therefore, the court construes the term "information" to mean "facts contained in or describing some or all of a data source."

2163

D. "Information" means "Anything that Can be Represented in Electronic Form, Including Text, Sound Recordings, and Images."

Claims 1, 3, 6, 11, 17, and 19 use the term "information." The ordinary meaning of this term is readily apparent, so much so that the best definition the court can give is a tautology. "Information" means "information." Digeo's proposed definition, "anything that can be represented in electronic form, including text, numbers, sound recordings, and/or visual representations," follows the ordinary meaning and adds the limitation that the information be of the sort that one can represent in an electronic format. Audible does not argue that the ordinary meaning of the term is different, but insists that the patentees limited the claimed "information" to "content that is obtained from a publisher and that is visually perceived by a user." Audible's proposed construction presents two questions for the court: whether the invention covers only information that a user can see, and not information that a user can hear; and whether the claimed "information" is solely information that comes from a content publisher?

1. Did the Patentees Limit Their Claims to Visual Information?

The specification contradicts Audible's claim that the 823 Patent covers only visually perceptible information. In describing the "Book Bank" unit in the system, the inventors explained that "[a]lthough the term Book Bank may imply book-type' material, such term is not so limited. The material may be of many types, such as movies, music, video, audio, and computer software material." 823 Patent at 2:37-42. Nothing in the remainder of the specification suggests that the inventors reversed course and limited their invention to visually perceptible information. n6

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

n6 Although it is not dispositive of the issue, the court notes that the end user device that the 891 Patent covers contains a set of headphones. 891 Patent, Figs. 1-2. Headphones would be an unusual accessory if the patented system from which the device is to obtain information did not transmit information that a user could experience audibly.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - - -
Again, Audible relies on the prosecution history to provide what the specification does not. In a December 1995 pro se communication, Mr. Saigh stated that his invention "relates to the transmission, storage, and encryption of the software instructions and codes that will generate a visual image upon the monitor of the user reading device . . . " PH at 500-585.

Had Mr. Saigh been distinguishing his invention from a prior art reference relating to audible information, the court might accept his statement as evidence of a surrender of claim scope. Instead, he was distinguishing a reference that described a "Visual Interface for Retrieval of Electronic Formed Books." PH at 500-584. Audible also notes that Mr. Saigh described his invention as a "network designed for the electronic transmission of intellectual properties . . . to one or more end users with the data to be viewed by the user. . . ." PH at 500-586. Once again, Mr. Saigh was distinguishing his invention over a reference describing electronic books, PH at 500-585, leaving the court with no basis to conclude that he was disclaiming coverage for non-visual information.

2. Did the Patentees Limit Their Claims to Information Acquired from Publishers?

The 823 Patent contains countless references to information of many types. One type is the media content (i.e., the "movies, music, video, audio, [or] computer software material" disclosed in Column 2) that publishers provide for distribution over the patented system. Another type is transactional information, including information related to the number of times a user copies an item on the network (e.g., Claim 7), information related to the length of time in which a user accesses an item from the network (e.g., Claim 14), and "information related to transactions performed by" the first unit of the local unit (Claim 11). Still another type is information stored on the user's storage media that assists in encrypting information. Claim 3 (disclosing a "local unit further configured to utilize information stored on the electronic storage media to encrypt information").

Each of the foregoing examples illustrates that when the patentees wished to limit "information" to information of a particular type, they did so by including explicit language in the claim. Where claims cover solely transactional or encryption-related information, the limitation is unambiguous. But in discussing the "information" to be sent from the network to the user's storage media, the patentees included no restriction limiting that information to information obtained from the publisher. For that reason, the court finds no basis for limiting the generic term "information" to information that comes from a publisher. See Johnson Worldwide, 175 F.3d at 989 ("[M]odifiers will not be added to broad terms standing alone.").

For the foregoing reasons, the court construes "information" to mean "anything that can be represented in electronic form, including text, sound recordings, and images."
dimensional directions.

The Court finds that the specification uses the terms "information" and "data" interchangeably. As the Federal Circuit has recently reaffirmed, the specification is the single best guide to the meaning of a disputed term. Phillips v. AWH Corp., 415 F.3d 1303, 2005 WL 1620331 at *7 (Fed. Cir. 2005) (citing Vitronics Corp. v Conceptor Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996).) Moreover, this result is confirmed by common usage. Merriam-Webster's online dictionary defines "information" as "facts" and "data," Merriam-Webster Online Dictionary, available at www.merriam-webster.com. At least with respect to these terms, this would appear to be a case where "the ordinary meaning of claim language as understood by a person of skill in the art may be readily apparent even to lay judges," a setting in which "general purpose dictionaries may be helpful." Phillips, 415 F.3d 1303, 2005 WL 1620331 at *6. While "information" and "data" are interchangeable, both are equally subject, of course, to the noted storage and correlation limitations. n2

With regard to Meade's second request, that the term "data" be construed to include positional information developed by a calculation, the Court finds that such a construction is precluded, at least in part, by the identified limitations: capability of being stored in a database and correlated with three-dimensional directions. Under these limitations, the terms information and data in the '203 Patent may include the precise area of the sky, or three-dimensional direction, that a user is viewing, the exact coordinates of stars that the user may desire to view, again three-dimensional directions, and whether the three-dimensional direction a user is viewing matches the three-dimensional direction of a star that the user desires to view. The Court, however, cannot agree that the terms data and information as used in the '203 Patent covers real-time calculations about the precise relationship between the direction a user is looking and the direction a user would need move so as to place the desired stars in the field of view. Such calculations, while perhaps drawing upon data, or three-dimensional coordinates, located in the database, produce unique results each time they are run based upon many factors, including where a user is standing on the earth, the angle at which he or she is holding the device, etc. Accordingly, such results, and any directional guidance that may stem therefrom, do not constitute data or information that is capable of being stored in a database or organized by three-dimensional directions. n3 The Court, therefore, must reject Meade's proposed construction insofar as it seeks to construe these terms to include such calculations, their results or any directional guidance stemming therefrom.

With regard to Meade's second request, that the term "data" be construed to include positional information developed by a calculation, the Court finds that such a construction is precluded, at least in part, by the identified limitations: capability of being stored in a database and correlated with three-dimensional directions. Under these limitations, the terms information and data in the '203 Patent may include the precise area of the sky, or three-dimensional direction, that a user is viewing, the exact coordinates of stars that the user may desire to view, again three-dimensional directions, and whether the three-dimensional direction a user is viewing matches the three-dimensional direction of a star that the user desires to view. The Court, however, cannot agree that the terms data and information as used in the '203 Patent covers real-time calculations about the precise relationship between the direction a user is looking and the direction a user would need move so as to place the desired stars in the field of view. Such calculations, while perhaps drawing upon data, or three-dimensional coordinates, located in the database, produce unique results each time they are run based upon many factors, including where a user is standing on the earth, the angle at which he or she is holding the device, etc. Accordingly, such results, and any directional guidance that may stem therefrom, do not constitute data or information that is capable of being stored in a database or organized by three-dimensional directions. n3 The Court, therefore, must reject Meade's proposed construction insofar as it seeks to construe these terms to include such calculations, their results or any directional guidance stemming therefrom.

Meade also challenges the district court's construction of the term "data." The crux of the dispute over that term is whether directional arrows that guide a user to a selected object, when the device is operated in the find mode, constitute "data," as that term is used in the '203 patent. The directional arrows are overlaid on the field of view in Yamcon's device so that they are "simultaneously presented to the user as the user observes the field of view." Thus, if directional arrows constitute "data," Yamcon's device would meet the disputed limitation.

Meade argues that directional arrows constitute "data," as broadly defined, and that the district court erred by concluding that the claims use the term in a narrower sense. The problem with Meade's argument is that the claims and the specification make it clear that the claim is referring to a predetermined set of data that has been entered into the device's database, not...
merely to any abstract bit of data in the broadest sense of the term.

The disputed limitation in claim 1 refers to "the provided data." The antecedent basis in the claims for that "provided data" requires that it be taken from a database "containing data about the predetermined subject [i.e., celestial feature], the data being arranged in said database to be correlated with three-dimensional direction." Claim 15 contains a similar antecedent basis for "data." Thus, the word "data" in claims 1 and 15 refers to a preselected set of information that is entered into the database about predetermined celestial features and is then provided to the user during operation of the device.

The specification provides several examples of such data, including "such information as the equatorial coordinates of the [celestial] object, its apparent magnitude, and a label for the object." '203 patent, col. 5, ll. 65-67; see also col. 2, ll. 21-27 (discussing an embodiment that displays graphic representation and labels for prominent astronomical features); col. 11, ll. 39-47 (noting that a potential data display might read "The bright star is Betelgeuse in the constellation Orion"). Thus, as used in claims 1 and 15, the word "data" refers to preselected facts about celestial features that can be stored in the device's database and then presented to the user when the user views that particular celestial feature.

In Yamcon's device, neither the directional arrows nor the information that they represent (i.e., the direction from the user's current field of view to the relevant celestial feature) is part of any preselected set of data that is stored in the database. Rather, the directional arrows are purely the result of dynamic real-time calculations. Moreover, the claims require that the data be "about features of the subject visible in the field of view," those "subjects" being "predetermined." When Yamcon's device displays directional arrows, the only information those arrows convey is that the targeted celestial object is in the current field of view or that the device must be moved in a particular direction to put the object in the field of view. It strains the ordinary meaning of the phrase to say that such information is information "about features of the subject visible in the field of view," and it is contrary to the meaning of the phrase as used in the '203 patent.

Meade points out that all of the information displayed on the screen of the patented device is in a sense the product of calculations, just as Yamcon's directional arrows are the product of calculations. Thus, in order for the device to display the relevant educational fact (e.g., "This is Saturn, the sixth planet from the Sun"), the device must perform calculations to match the three-dimensional location of the field of view with the location of the relevant celestial object (e.g., Saturn). For that reason, Meade argues, it is inappropriate to exclude the arrows from the definition of "data" merely because the arrows are the result of calculations. That argument, however, obscures a critical distinction. In the case of matching Saturn with the field of view, the calculations involve determining which data to pull from the database by ascertaining the direction the device is pointing. The data that is ultimately displayed is information that is stored in the database about the target celestial object. Yamcon's directional arrows, on the other hand, are purely the result of a real-time calculation. They are not data that is preselected and stored in the database, and they are not "about" the target celestial object in the sense referred to in the specification. Based on that distinction, the district court correctly ruled that the directional arrows in Yamcon's device are not "data" within the meaning of claims 1 or 15.

As an alternative ground for affirmance, Yamcon argues that its SkyScout device does not meet the claim requirement that the reference data that is presented to the user must be automatically updated to correspond to where the device is being pointed. The district court found it unnecessary to address that issue, and for the same reason we decline to do so. In addition, although the district court addressed and rejected Meade's argument of infringement under the doctrine of equivalents, Meade did not raise that argument in its opening brief, and we therefore treat that argument as waived. See SmithKline Beecham Corp. v. Apotex Corp., 439 F.3d 1312, 1319 (Fed. Cir. 2006); Amoco Oil Co. v. United States, 234 F.3d 1374, 1377 (Fed. Cir. 2000).
transmitted data"

The Court finds that claim 53 of the '702 patent requires that "first information:" (i) is related to communications between the SPNAN and a user at a first network accessible node; (ii) is stored on the first network accessible node so that it can be used on subsequent network connections; and (iii) is utilized in subsequent network communications between the SPNAN and the first network accessible node. Claim 53 also requires that "first responsive information" (i) indicates the presence of the "first information" on the first network accessible node and (ii) identifies the first user. Claim 53 also requires that the "first information" is sent to the first network accessible node from the SPNAN and that the "first responsive information" is sent to the SPNAN. Unasserted claim 8 of the '702 patent, dependent upon a different independent claim, recites that the "first information" includes executable instructions for receiving advertisement information via the network." The Court finds that the patentee did not use the term "program" or "instructions," and instead used the broader term "information." The Court finds that Defendants' proposed construction to limit "first information" to a "computer program, such as a daemon" would improperly limit "first information" to an example in the specification. Further, the Court finds that the term "information" is clearly broader than Defendants' proposed construction and there is no support in the specification of the claims for limiting the term to Defendants' proposal. Beneficial has provided dictionary definitions of the term "information" of "processed, stored, or transmitted data" and "computer data at any stage of processing." Further, the parties agree that "advertising related information" means "advertising data that is processed into the advertising presentation," implying that information, by itself, is a type of data that is processed or can be processed. Thus, the Court construes the phrase "first information" to mean "first data that can be processed."

GO BACK

4. "creating a database entry containing information accepted from a user" (claim 7)

This term also incorporates the court's first two claim constructions. Plaintiff argues that the term means "an entry in a database is created containing information submitted by a user over a computer network." Defendant argues that the term should be construed to mean "creating a database entry containing information accepted from a user in which the content is entirely user-controlled." For the reasons previously addressed, the court construes this term to mean "creating a database entry containing information accepted from a user over a public computer network wherein the information content and classification is entirely controlled by the user."

GO BACK

"Information bearing optical signal" means "an optical signal which has been coded with any type of information; any optical signal that has been modulated constitutes an information bearing optical signal."

XI. "information block" -- '051 patent

The disputed claim term "information block" appears only in the '051 patent. The parties propose constructions of "information block" as follows:

<table>
<thead>
<tr>
<th>Lexar's proposed construction:</th>
<th>Toshiba's proposed construction:</th>
<th>Pretec's proposed construction:</th>
</tr>
</thead>
<tbody>
<tr>
<td>initial construction:</td>
<td>an amount of data logically</td>
<td>an individually erasable unit</td>
</tr>
<tr>
<td>data organized into units of</td>
<td>associated with a host</td>
<td>of data that may be larger than</td>
</tr>
<tr>
<td>blocks</td>
<td>provided LBA</td>
<td>one sector in size</td>
</tr>
</tbody>
</table>

compromise construction offered

- 2541 -
The invention contemplated in the '051 patent links, using an LBA, already-programmed sectors that have been designated for erasure into a single "information block" so that the ready-for-erasure sectors can be erased together. The parties propose three separate constructions for this claim phrase and here, the Court finds that a combination of the three proposed constructions best defines the term at issue here.

As Lexar points out, Toshiba's proposed language "an amount of data" adds nothing to the construction of the claim phrase because the amount of data is simply not at issue. Furthermore, the construction of "information block" need not explain that the LBA is provided by a host. To do so is unnecessary as it is made clear by surrounding claim language as well as in the construction of LBA itself. Pretec's proposed construction is a better fit because an "information block" is made up of sectors that contain data to be erased. But as Lexar points out, Pretec's construction can equally encompass a mere "block." The portion of Pretec's construction that accounts for the information block's erasability should be included but the rest of the proffered construction does not accurately define the term.

The Court now turns to Lexar's proposed construction. Lexar initially proposed that the claim phrase "information block" should be construed as "data organized into units of blocks," but at oral argument, Lexar offered a compromise construction: "a plurality of sectors that are logically associated with a group of LBAs." The Court agrees with Toshiba that Lexar's original proposed construction provides no meaning. (Claim Construction Hearing Transcript at 105.) However, Lexar's compromise construction deserves further scrutiny even though neither Toshiba nor Pretec directly addressed it at oral argument. The proposed compromise construction accounts for the portions of data included in the information block and explains how they are linked to one another. Lexar's proposed construction is better in that regard. However, Lexar's construction does not account for the erasability of the "information block." Because the purpose behind the organization of such a block is erasure, it would appear significant to include this limitation in the construction itself as well, as Pretec does. The Court finds that Lexar's proposed compromise construction, with the erasure function added in as discussed supra, works best. The Court therefore construes "information block" as a plurality of sectors that are logically associated with a group of LBAs for erasure.

1. "Information-carrying symbol(s)" (Claims 1, 7)

Neither of the parties claims that the phrase "information-carrying symbols" had a customary meaning in the field of OFDM technology at the time this patent was filed and neither purport to have found the phrase "information-carrying symbol" in a dictionary. 12 Accordingly, the Court looks to the intrinsic evidence, beginning with the claim language itself. See Vitronics, 90 F.3d at 1382.

- - - - - - - - - - - - - - Footnotes - - - - - - - - - - - - - - -

12 At the Markman hearing and in post-Markman briefing, Broadcom proffered the deposition testimony of Dr. Richard van Nee, the sole inventor of the '786 patent. (Broadcom's Submission of Requested Information at 4-6.) In his deposition, Dr. van Nee claims that the term "information-carrying symbol" did have a customary meaning to a person of skill in the art at the relevant time and that, in a "pure technical sense," that meaning excludes preamble symbols. (van Nee Dep. at 156, 159-60.) As two persons of skill in the art have testified that this term did not have a customary meaning and in the absence of a dictionary or other evidence supporting Dr. van Nee's testimony, the Court finds that this phrase did not have a customary meaning to a person of skill in the art at the relevant time. E-Pass Tech. v. 3Com Corp., 343 F.3d 1364, 1370 n.5 (Fed. Cir. 2003) ("This Court has often repeated that inventor testimony is of little probative value for purposes of claim construction."); see also Markman, 52 F.3d at 985 (noting that inventor's opinion regarding meaning of claim term is not accorded any added weight in claim construction).
The descriptive phrase "information-carrying" modifies the word "symbol" in the claim language. The parties' disagreement concerns how this modifying phrase limits the meaning of "symbol." Agere contends that the phrase "information-carrying" distinguishes between symbols and guard intervals. 13 (R. at 98 (May 7, 2004).) According to Agere's expert, Dr. Goodman, the term "symbol" alone may refer to both the guard time and the informational portion of the symbol together or to the informational portion of the symbol alone. (Goodman Rep. P 58.) Therefore, the prefix "information-carrying" was added to the term "symbol" in this patent to narrow the patent's reference to the informational portion only. (Id. P 58.) Dr. Goodman's argument, however, is belied by the claim language itself. Claim 1 describes a transmission scheme "wherein a guard time is interposed between successive ones of said information-carrying symbols." ('786 patent, col. 4, ll. 59-60.) As the claim language explicitly distinguishes between symbols and guard times, Agere's construction would render the "information-carrying" modifier superfluous. Thus, the phrase "information-carrying" could not have been intended to alleviate the ambiguity Agere suggests.

13 Guard intervals do not carry information that is used and therefore are purposefully ignored by the receiver. (Agere Opening at 41-42.)

According to Broadcom's expert, Dr. Cox, the phrase "information-carrying" is used to distinguish between the data portion of the transmission and preamble symbols. Preamble symbols are symbols sent by the transmitter before the data, or "payload," portion of the transmission. They consist of known symbols, based on a mathematical equation set out in the 802.11a standard, that are used by the receiver to discern characteristics of the communication channel. (Goodman Rep. P 54-55; R. at 95 (May 7, 2004).) The transmitter sends the preamble symbols to the receiver, which runs an algorithm that generates the same preamble symbols internally and then compares those generated symbols with the received symbols in order to discern whether the preamble was distorted as it traveled through the communication channel. (Goodman Rep. P 54-55; Cox Dep. at 76; R. at 92-95 (May 7, 2004).) Once the receiver has determined whether there are distortions in the channel, it takes that distortion into account when evaluating subsequent receptions. (Broadcom Resp. at 43.) With this background in mind, Dr. Cox bases his construction on a technical dictionary's definition of the term "information," which is "knowledge or intelligence unknown to the receiver before its receipt." 14 (Cox Rep. at 41-42 (citing Cambridge Dictionary of Science and Technology).) Because the preamble portion of the packet only contains known values used to discern the characteristics of the channel, and because "information" is "unknown to the receiver before its receipt," Dr. Cox concludes that it is axiomatic that the phrase "information-carrying symbols" does not include the preamble. (Id. at 42.)

14 In support of its opposing construction, Agere cites the Academic Press Dictionary of Science and Technology definition: "data that are transmitted by signals via telecommunication channels." ACADEMIC PRESS DICTIONARY OF SCIENCE AND TECHNOLOGY 1107 (Christopher Morris ed., 1992). This definition, which defines information as data, appears to support either party's proposed construction.

The Court finds that Broadcom's proposed construction for the modifier "information-carrying" is consistent with the technical dictionary definition noted above and, unlike Agere's proposal, is also consistent with the use of the term in the claim language. Therefore, Broadcom's construction is adopted, with the exception of the reference to "packet," which is omitted for reasons described in the next section. See infra Part II.C.2. Accordingly, the following construction is adopted:

"Symbol(s) containing data, but not preamble symbols."
Claim Construction

Chesapeake, as cross-appellant, contends that the district court erred in its construction of the claims of the '951 patent. Claim construction is a matter of law which this court reviews without deference. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456, 46 U.S.P.Q.2d (BNA) 1169, 1174 (Fed. Cir. 1998) (en banc). In its Markman ruling, the district court correctly interpreted "strata in the earth" and "said strata" to mean identifiable and distinguishable layers of material (e.g., rock) beneath the surface of the earth. Union Pac. Res. Co. v. Chesapeake, 4:96-CV-726-Y, slip op. at 7 (N.D. Tex. Nov. 30, 1998, Order Granting In Part Defendants' Motion for Claim Interpretation Based on Intrinsic Evidence) (Markman Motion). The court also correctly interpreted "information characterizes said strata," "characterizing information of said strata," and "characterizing information" to mean data produced by logging methods conventional in the industry. These conventional methods permit identification of distinguishing characteristics between layers of rock beneath the surface of the earth. Markman Motion at 7-8. In particular, these phrases can refer to information such as: (1) an X offset (east/west coordinate); (2) a Y offset (north/south coordinate); (3) a true vertical depth (TVD) or Z offset; and (4) a value from a gamma ray log. '951 patent, col. 2, ll. 5-8; col. 5, ll. 47-56.

"Information database." Used in claims 1, 2, 7, 10, 16, 17, 22, 25, 37, 39, and 44.

For this term, Finisar initially proposed "a collection of information" and gave some examples. n2 DirecTV suggested "[a] collection of non-transient data files that can be searched and retrieved." Their dispute centered on two points:

1. whether the data can be in several locations or must be "non-transient;" and
2. whether the definition must specify that the data can be "searched and retrieved."

Since the claim language alone does not resolve this dispute, the court looks to the specification.

n2 By itself "collection of information" is not very useful. Data which has been deleted from a hard drive is a collection of information, which a forensic expert could retrieve if it has not been overwritten. But it would not be considered part of a database.

The specification demonstrates that the database is not isolated. "The goal of the present invention is to provide widespread, high speed access to a virtual omniscient database . . . ." 505 patent, col. 1, 11. 54-56. (emphasis added); see also, col. 5, 11. 12-13. The specification analogizes the system to "having access" to a large collection of books in a library, even if all books are not instantly available. 505 patent, col. 2, 11. 17-23. All of the information in the database is tagged with indices to form a hierarchical structure to provide subscribers with access to various parts of the database according to different transmission schedules. 505 patent, col. 2, 11. 52-59. Accordingly, the information database is computerized information which can be accessed in some fashion.

There is no need to impose the limitation of "searched and retrieved" which implies a more specific search and retrieval system than the claims and specification describe. Nothing in the claim or specification indicates that the database must be searchable to any particular level of specificity. For example, common legal research systems allow very narrow searches, such as by case name, by judge name, and even by a particular word. In contrast, some of the data in the 505 system can only be referenced in broader terms, such as a search for a movie by title, but not necessarily by words used in a movie or group of movies.

As to the argument that the data in the database be "non-transient," it is important to note that one skilled in the art would know that computerized information is made up of electronic impulses -- the classic "ones and zeros" of the binary system. It would also be known that a database could exist on a network of computers and memory storage devices. This is
described as a possible embodiment. 505 patent, col. 6, 11. 61-64. Moreover, the use of the phrase "non-transient" will likely not be helpful to a lay jury. It is not helpful to focus on the time period during which data is being sent from the supplier station to the satellite and then to the subscriber station, as shown in Figure 1 of the patent.

This claim term will be construed as follows:

"information database" means "a collection of computerized information which can be accessed."

A. "Information Database."

The phrase "information database" was recited in each of the independent claims. By way of example, claim 16 recited in part (col. 21:34-50):

16. An information transmission system comprising the steps of: storing an information database on one or more memory devices; generating and storing on said memory devices a hierarchically arranged set of indices for referencing data in said information database, including distinct indices for referencing distinct portions thereof, and embedding said indices in said information database;

scheduling transmission of selected portions of said information database, including assigning each selected portion of said information database one or more scheduled transmission times;

transmitting a stream of data packets containing said selected portions of said information database in accordance with said scheduled transmission times;

* * *

Comcast contends that this term should mean "a non-transient and integrated collection of data, organized so that the collection can be searched." By "non-transient," Comcast means that the information must persist for some amount of time in the database. Finisar argues that it should be construed as "a collection of computerized information which can be accessed." Finisar's proposed construction was adopted by the Texas claim construction decisions. 1

--- Footnotes ---
1 The Texas Court construed the term "information database" to mean "a collection of computerized information which can be accessed" (Melgar Decl. Exh. B at 6).
--- End Footnotes ---

Both parties agree that this term indicates some grouping of data. Lay jury members would understand the term "information," and also that a "database" is stored in some fashion. This much is clear. The parties, however, part company on three issues: (1) whether the information database stores only digital or "computerized" information; (2) whether information on the database may be transient or if it must persist for some time; and (3) whether the information database must be integrated and searchable.

(1) Digital Information.

A "database" is defined as "a structured collection of data held in computer storage." Oxford English Dictionary (2d. ed. 2001). All the claims indicated that the information is stored electronically, for instance, in a computer memory device. All sides agree that the format must be digital rather than analog.

The substance of the dispute seems to be over whether the information must be "digital," as Comcast proposes, or "computerized," as Finisar proposes. The plain meaning of the whole disputed term "information database" clearly indicates that the information is stored by a computer. Thus, using the word "computerized" adds little to the term's definition. The
term "digital" or "digitized" is sufficient to make clear that the information is not stored on the database in analog form. This order will define "information database" to mean "a structured collection of digitized data capable of being held in computer storage."

(2) Dynamic Database.

Comcast would require that the information within the database be "non-transient" while Finisar would include "transient" information. Comcast's argument seems to be that while the information within the database can be updated frequently, the information must exist in a fixed location. Finisar concurs in the idea that the database can be updated frequently, but would not require that the information exist in a fixed location. This order holds that the database can be dynamic, that is, the information within the database can be updated frequently even though the changed information is placed in the same storage location within the database as the replaced information.

In the specification, the patentee analogized his invention to the stacks of books of Widener Library at Harvard (col. 2:9-23). Both the books in a library and a database can be updated. Even a traditional set of encyclopedias in book form is updated from time to time. A librarian replaces the older set with a newer version. In the same way, a subscriber to the inventive system may want to have the latest score of the Final Four basketball games. This information would be updated very frequently. At one time, the score may be tied. Less than a second later one team may have pulled ahead by a three-point shot. The information in the database can be dynamically updated as events happen, and the new information can be sent to the subscriber. The data can be found, at any given instance, at the same location in the database, stored temporarily, for example, under a subheading called "Final Four."

This concept of a dynamic database finds support from the specification. It taught that the "basic service provides unlimited access to a base set of information, which in the preferred embodiment is about fifty gigabytes of public service information such as newspapers, weather reports and the like that are updated frequently" (col. 4:5-10). Thus, the information in the database can be dynamic.

Again, even if frequently updated, the information can still exist in the same location. Returning to the patentee's analogy, even though a book at Widener may be updated, it is still placed in the same aisle within the same stack. It is also accessible through the same catalog. In the patented system at issue here, the updated information is accessible in the same indices used to find information. This is so because even though the information may have changed, the place that the system finds it has not.

Finisar also argues that data within the database need not have a fixed location. This is correct, at least as follows. The index itself can be (but need not be) dynamic. For example, as each issue of a magazine is released, a new sublocation in the overall index can be added to isolate and refer to a single magazine issue. In this way, the current issue as well as past issues of the magazine can be found. The new, updated index can be transmitted as root information to subscribers. Depending on the subscriber's needs, the local filter system may or may not have to be adjusted in the subsection to pluck the new subindex from the transmission. Thus, the database may be dynamic not only as to the contents but also as to the indices.

(3) Integration and Searchability.

The parties also disagree as to whether the information database must be integrated and searchable. Both parties do agree, however, that the information database need not exist on a single device or in a single place. The claims provide support. Claim 1 recited "[a]n information transmission system comprising a set of one or more computer memory devices on which is stored an information database" (col. 17:68-18:2). The same limitation appeared in the first paragraph of all independent claims.

Comcast and Finisar part company on the degree to which data on the one or more computer memory devices must be integrated. Comcast contends that it must all reside within the same hierarchical structure. The specification taught that "[t]he system has a program supplier which stores an information database and tags all the information in the database with indices so as to form a single hierarchical structure which encompasses the entire database" (col. 2:52-56). Furthermore, the patentee analogized his invention to a large university library (col. 2:14-23). A single, expansive library collection may be so large that it is stored in several buildings, but it is still organized and accessible using a centralized system. Thus, the database must be integrated, that is, it must be accessible using a single structure.
Comcast contends that the information database must be "searchable," while Finisar contends that the information database must only be "accessible." Finisar's contention follows logically from the invention's purpose of sending information to subscribers. The idea that the information database is "searchable," however, is a larger leap. The claims specifically recited a system of indices embedded within the information database. The indices tag parts of the database so that those parts can be referenced. In claim 28, the indices are used to cross-reference the information, while in claim 16, asserted in this action, the indices are used to reference the information. Neither claim indicates that the information should be "searchable" beyond the navigability implied by the index itself.

Comcast further argues that the invention contemplates a system in which subscribers may request information. This is true. The requests, however, are not "word searches" a la Westlaw or LexisNexis. Rather, the requests are based on the system of indices. Thus, there is no basis to impose the additional limitation of "searchability" to this disputed term.

Accordingly, the term "information database" is construed as "a dynamic, structured collection of digitized data capable of being held in computer storage."

8. "information describing the associated/selected attraction"

The Plaintiff proposes that this phrase be construed generally to mean "data representing at least one characteristic of any aspect of the associated attraction." The Defendants contend that "information describing the associated/selected attraction" means:

Preset static information, such as attraction's capacity, throughput, description of the attraction, height and weight requirements for patrons, geographic location, hours of operation, cycle capacity, estimated throughput, estimated downtime, nominal staff; or dynamic information such as current status, current throughput, current staff, today's throughput, and today's downtime for a particular attraction selected on the user interface of the PCD and specified in the Attraction ID of the reservation request generated by the PCD.

The Plaintiff argues that this construction improperly imports specific types of information about the attraction that are not required by the claim language or specification.

The Defendants' construction mirrors a portion of the specification that discusses the system architecture, and the attraction computer in particular. Although that section describes various implementation embodiments of the attraction computer, the specification makes clear that "[e]ach attraction computer maintains information describing the associated attraction." (col. 5, ll.33-34.) The specification explains that the information maintained in the attraction computer includes "general static information such as the attraction's capacity, throughput, description of the attraction, height and weight requirements for patrons, geographic location, hours of operation, and the like." (col. 5, ll. 34-38.) The specification further states that the attraction computer "maintains information describing the current state and reservation status of the attraction." (col. 5, ll. 38-40.) In a later section, the specification describes examples of static and dynamic information associated with the attraction that are used in scheduling reservations. (col. 11, l. 18 to col. 12, l.3.) The specific types of information listed in this section, such as operating hours, cycle capacity, and current status, are "merely illustrative" of attraction information that may be stored. (col. 12, l. 8.) However, it is apparent that attraction information should include some type of static and dynamic information. Therefore, modifying the Defendants' proposed construction, the Court construes "information describing the associated/selected attraction" to mean "preset static information, such as cycle capacity, estimated throughput, and operating hours, and dynamic information, such as current status and current staff, for a particular attraction."
Claim 19 discloses a method for storing in the transmission system, "information from items" in a compressed data form. The parties dispute the proper construction of the phrase "information from items."

Given the Court's previous construction of "items containing information," the Court defines "information from items" as follows:

In a distribution method as disclosed in Claim 19 of the '992 Patent, in which a transmission system sends information to receiving systems at remote locations in response to a user's request, "information from items" refers to audio information, video information or both audio and video information, which is derived by the transmission system from a physical item such as a tape, a film, or a computer storage disk.
As Plaintiff points out in his reply, the inventor does not need to "delineate all aspects of a functional, working system." Pl. Reply at 12 (citing Rodime PLC v. Seagate Tech., Inc., 174 F.3d 1294, 1303 (Fed. Cir. 1999)). The text of this claim does not require specific account identification. Moreover, the information required need only be "for identifying," not "that identifies." The Court construes the term to mean, "information that is used to identify an account of the first/second party."

b. "Information Identifying" (Claim 18)

The disputed limitation at issue in claim 18 of the reissued '121 patent recites: "storing information identifying the selected programs, said stored information identifying broadcast schedule times, channels, and program titles." Re'121 patent, col. 5, ll. 25-27. The parties principally dispute whether "information identifying" should require storage of actual data, and if not, whether program titles must be separately stored.

(1) Actual Data or References to Data

Based on the plain claim language, the ITC construed "information identifying" to be broadcast schedule times, channels, and program titles, and further required "that this information is stored after the data processor selects the programs on the basis of combined user selection criteria." FID Opinion 2002 ITC LEXIS 812 at *107. Thus, the ITC rejected Gemstar's arguments that "information identifying" could include an address or software pointer to the broadcast schedule times, channels, or program titles data. Id.

Citing to definitions of "information" and "identifying" in Webster's Ninth New Collegiate Dictionary (1988), Gemstar argues that the ordinary meaning of "information identifying" is data that can establish the identity of the relevant times, channels, and titles of selected television programs, encompassing software pointers in addition to the actual data. Gemstar argues that the ITC's construction, which required the storage of actual data, was nonsensical and inconsistent with similar language in claim 57 of the '121 patent, which used the word "comprising" in place of "information identifying," to indicate the storage of actual data.

Scientific-Atlanta argues that Gemstar's proposed ordinary meaning is incorrect, because the ordinary meaning of "identify" is "to establish the identity of," which is not reflected in Gemstar's construction, "data that can establish the identity of the relevant times, channels, and titles." Further, Scientific-Atlanta contends that Gemstar's proposed construction that "information identifying" encompasses software pointers is misleading and conflicts with the prosecution history. According to Scientific-Atlanta, Gemstar's "pointers" are not limited to software pointers, but could include time and channel information that could be used to retrieve program titles from a schedule.

The claim language calls for the storage of "information identifying the selected programs, said stored information identifying broadcast schedule times, channels, and program titles." Re'121 patent, claim 18. The construction of this limitation turns on the meaning of the term "information identifying." "Information" is defined as "facts or figures ready for communication or use as distinguished from those incorporated into a formally organized branch of knowledge: DATA." Webster's Third New International Dictionary 1160 (1993). "Identifying" is defined as "to link in an inseparable fashion: make correlative with something." Id. at 1123. Thus, the ordinary meaning of storing "information identifying" broadcast schedule times, channels, and program titles is the storage of data that can be linked or correlated with broadcast schedule times, channels, and program titles. "Information identifying" is not limited to the storage of the actual broadcast schedule times, channels, and program titles data, but includes storage of either the actual data or references to the actual data, such as addresses or software pointers.

The written description does not restrict "information identifying" to the storage of actual data supplied by the user. The '121 patent describes the broadcast of "schedule information" to the television receiver, conversion to digital format, and supplying the digitized information to the CPU. See '121 patent, col. 7, ll. 33-46. Then:

The CPU 110 supplies control outputs, based on user selections, to a programmable TV tuner 132 on line 134.
Information identifying programs selected from the schedule information on the basis of the user selection criteria is stored in memory 111 by the CPU 110. The CPU retrieves the information at the appropriate time for generating the control outputs.

Id. at col. 7, ll. 60-66 (emphasis added). Thus, even in the embodiment presented in the '121 patent where "information identifying" is stored in memory, there is no additional requirement that only actual data is stored. Instead, references to the actual data could be stored and used by the CPU to look up the actual data in order to generate control outputs.

(2) Separate Storage of Program Title

After reviewing the prosecution history, the ITC held that "information identifying" must include program titles because Gemstar had repeatedly distinguished prior art on that basis. FID Opinion 2002 ITC LEXIS 812, [slip op.] at 52-55.

Scientific-Atlanta argues that the ITC's claim construction correctly requires the storage of television program titles. It argues that Gemstar is estopped from arguing otherwise, because it repeatedly argued during prosecution that claim 18 required storing program titles in addition to times and channels to overcome prior art that only required the storage of times and channels.

As the ITC correctly recognized, the prosecution history requires that "information identifying" must include the separate storage of program titles. During reexamination, Gemstar amended claim 18 to include the language, "said stored information identifying broadcast schedule times, channels, and program titles." Supplemental Amendment After Final, Feb. 25, 1993, at 7. When submitting this amendment, Gemstar referenced its prior arguments that the current claims were distinguishable over prior art systems that did not require storage of program title data:

In response to earlier arguments that claims require schedule information including program title to be stored for selected programs, the Examiner only argued that the term "schedule information" was not defined so as to require program title.

Several claims have been amended to specify the storage of program title for the selected programs and are thus believed to be allowable. As previously noted, prior art systems simply program the VCR with channels and times for selected programs; information identifying the title was not stored.

Id. at 23 (emphasis added). This statement makes clear that "information identifying" must separately reference program title, since prior art systems included storage of only broadcast schedule times and channels. Because the storage of "information identifying . . . broadcast schedule times, channels, and program titles" in claim 18 requires storage of the actual data or references to such data, each category of data must be actually stored or have its own separate reference (e.g., software pointer or address). In other words, this limitation is not met if the "information identifying" program title is derived from the storage of "information identifying" broadcast schedule times and channels. Storage of the "information identifying" program title must be storage of the actual title itself or a reference directly indicating where the stored actual program title data may be found.

In short, "information identifying" includes the storage of either the actual "broadcast schedule times, channels, and program titles" data or separate references, such as addresses or software pointers, to the location of the actual data. If references are used, there must be separate references for the broadcast schedule time, channel, and program title parameters.

5. A voice synthesis system for providing audible information "wherein said audible information comprises information indicating undesired movement of the distal end of the surgical instrument." Requires synthesized speech indicating that the distal end of the surgical instrument has moved in an undesired way.
A. "information management and synchronous communications system"

"Information management and synchronous communications system" is the claimed apparatus and appears in the preamble of every asserted independent claim: "An information management and synchronous communications system for generating and transmitting menus comprising . . . ." Ameranth contends that the clients may be devices or Web pages, and the clients are not required to have local databases. In contrast, the defendants argue that the point of sale clients must be hardware devices and each client must contain a local database.

Claim 1 of the ’850 patent indicates that the client is "a wireless handheld computer device or Web page." According to the defendants, "Web page" is not a software client but has been given a specialized definition in the specification: "an automated download procedure is provided to transfer the desktop database onto a handheld device and/or Web page." (’850 patent, 9:66-10:1); see 3M Innovative Props. Co. v. Avery Dennison Corp., 350 F.3d 1365, 1374 (Fed. Cir. 2003) (holding that when the patentee acts as his own lexicographer, the definition in the specification controls, not the dictionary definition). The defendants assert that this language, "transfer the desktop database onto," explicitly requires the clients to have a local database. In addition, the defendants allege that, because a database is transferred onto the Web page, the Web page cannot be a software client. Claim 12 of the ’850 patent also supports the defendants' assertion that "Web page" is not a conventional website: "at least one Web page on which hospitality applications and data are stored." (emphasis added).

Elsewhere in the specification, a traditional Web client is disclosed: "The software running on the user's client computer that enables the user to view HTML documents on the computer's video monitor and enter selections using the computer's keyboard and mouse is known as a browser." (’850 patent, 12:29-33). Furthermore, the specification consistently distinguishes "Web page" as distinct from handheld devices, e.g., "the menu can be downloaded to either a handheld device or Web page." (’850 patent, 3:37-38) (emphasis added).

As discussed above, the specification does mention transferring databases onto the clients. (See also ’850 patent, 10:34-36 ("Advanced database functions are provided in the preferred embodiment of the invention, including an automated download process onto handheld devices and/or Web sites.").) The specification discusses a central database, but does not talk about local databases on the clients, e.g., "fast synchronization between a central database and multiple handheld devices." As used by the patentee, downloading or transferring databases to clients means downloading or transferring the data from the database, but not the database itself. Thus, it is not necessary that the clients have local databases.

The defendants' proposed construction suggests synchronization between the clients: "a change made to any database is immediately reflected in all databases." However, throughout the specification and claims, the patents contemplate changes
being communicated between the clients and the central server. (E.g., '850 patent, 6:22-25 ("configuring a menu on the desktop PC and then downloading the menu configuration onto the POS interface on the handheld device"); 11:36-42 ("For example, a reservation made online is automatically communicated to the backoffice server which then synchronizes with all the wireless handheld devices wirelessly. Similarly, changes made on any of the wireless handheld devices will be reflected instantaneously on the backoffice server and the other handheld devices. ")) Therefore, the term simply requires synchronization between the clients and the central server, not between the clients themselves.

For its part, Ameranth's proposal limits the scope to a "computerized hospitality system." The defendants' proposal does not limit the system to hospitality functions. The specification makes plain that the invention is not limited to use in restaurants and the hospitality industry: "While the preferred embodiment is for the generation of restaurant menus and the like, the broad scope of the invention is far greater." ('850 patent, 13:37-39). This limitation is accordingly rejected. The court construes the term to mean "a computerized system having multiple devices in which a change to data made on a central server is updated on client devices and vice versa."

III. Information Manufacturing Machine

As with the term point of sale location, the district court made several findings with regard to the construction of the term IMM. For this term, however, we disagree with most of the district court's findings. We address each below.

1.

The district court required that the IMM functionality be divided into at least the following four "separate and distinct components: (a) a Manufacturing Control Unit, (b) a Master File Unit, (c) an Information Manufacturing Unit, and (d) a Reproduction Unit." Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1810 (emphasis added). IGE maintains that the district court improperly read the limitations of an embodiment into the claims. The appellees respond that these four components are required because Figure 1 of the Freeny patent, which contains these components, depicts the invention and not merely an embodiment of the invention. We agree with IGE.

Again, we turn first to the claim language itself. The independent claims do not recite any of these four components and do not convey any clear meaning of an IMM to one skilled in the art. The only limitations in the exemplary independent claims pertaining to the IMM relate to its placement at a point of sale location and to certain functions that it must perform, namely, storing information to be reproduced, receiving a request reproduction code, receiving an authorization code, and reproducing the requested information in a material object. See Freeny patent, col. 28, ll. 26-47 (claim 1), col. 36, ll. 47-64 (claim 37).

The specification describes an embodiment of the IMM containing the four components noted by the district court and performing the functions recited in the claims. See id. at col. 6, ll. 27-30, col. 9, l. 39 - col. 10, l. 49. The disclosed embodiment of the IMM also performs the functions, not explicitly recited in either claim 1 or claim 37, of transmitting a request reproduction code and receiving and decoding encoded information. Of these, only five functions, namely, storing information to be reproduced, receiving and transmitting a request reproduction code, receiving an authorization code, and reproducing the requested information in a material object, are critical to the operation of the IMM as defined in the specification. See id. at col. 5, l. 21 - col. 6, l. 23. As explained below, the receiving and decoding of encoded information is not essential to the present invention. There is no general description or definition of what constitutes an IMM other than this narrow functional definition presented in the specification. That is the only definition on which the public can rely, and it is therefore reasonable to conclude that an IMM must contain these five functions. To the extent that the district court's decision, by requiring all four components of the disclosed IMM to be present, requires more than these five critical functions to be performed by the IMM, it is in error.

In its analysis, the district court looked to the specification, and specifically the embodiment depicted in Figure 1, and correctly concluded that the disclosed IMM contained each of the four functional components listed above. See Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1807 (After stating that "the IMM is comprised of four separate and distinct components," the district court cited to column 6, lines 27-30, which identifies the four components in the IMM depicted in
Figure 1.). However, while the five functions identified above are required in an IMM, there is nothing in the specification that requires that these functions be performed by the particular components of Figure 1 or that such components be separate and distinct. See Freeny patent, col. 9, l. 39 - col. 10, l. 68. These five functions of the IMM are all of a type that can be performed within a computer, and it is well within the reasonable expectation of a person skilled in the art to move the boundaries between the four identified components to suit a desired application. Such movement would allow, for example, any one piece of the IMM to perform any number of the five required functions. See Intellicall, 952 F.2d at 1387, 21 U.S.P.Q.2D (BNA) at 1386.

2.

The district court also held that the IMM must "receive a 'request reproduction code,'" must "transmit the 'request reproduction code' to an 'information control machine' ('ICM')," and must "receive an 'authorization code' from the ICM." Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1810. As just explained, we agree that an IMM must receive and transmit these codes. We further agree that the IMM must transmit the request reproduction code to, and receive the authorization code from, a central device, such as an ICM, but the device need not be restricted to an ICM.

We note first that neither claim 1 nor claim 37 recites the details of the ICM of the preferred embodiment. However, it is critical to the operation of the IMM, as defined in the specification, that the IMM send the request reproduction code to the same device that then sends the authorization code to the IMM. See Freeny patent, col. 5, l. 51 - col. 6, l. 23. While this device takes the form of an ICM in the preferred embodiment, there is nothing in the specification that would suggest to a person skilled in the art that an IMM would only work with the particular ICM defined in the specification. See id. at col. 5, ll. 32-50 (emphasizing that the ICM is located at a location remote from the IMMs); Intellicall, 952 F.2d at 1387, 21 U.S.P.Q.2D (BNA) at 1386.

Thus, we construe the term IMM to require communication with a remote device, such as but not restricted to an ICM, and hold that the district court's definition of IMM as requiring communication with an ICM is erroneous.

3.

The district court also held that the Master File Unit and the Reproduction Unit components of the IMM must, at a minimum, contain a number of detailed attributes. See Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1810. IGE argues that the language of the claims does not recite any of these limitations. Again, we agree with IGE.

There is no recitation of the specific attributes of the Master File Unit or the Reproduction Unit in the language of the independent claims. There is also no support for these limitations in the text of the specification referenced in IGE's asserted definition of the IMM before the district court. See Freeny patent, col. 5, ll. 32-47. Further, the invention is primarily concerned with distributed reproduction, and there is nothing to suggest that a person skilled in the art would not readily understand that the invention could be practiced without the received information being encoded, without decoding the received information, or without receiving information "on a unidirectional signal path . . . in analog form." Interactive Gift Express, 47 U.S.P.Q.2D (BNA) at 1810; see Freeny patent, col. 1, ll. 7-9, col. 4, ll. 13-18 (revealing that the invention is primarily concerned with distributed reproduction); Intellicall, 952 F.2d at 1387, 21 U.S.P.Q.2D (BNA) at 1386 (indicating that terms are construed according to the understanding of one skilled in the art). We conclude that the district court erred and impermissibly read these limitations into the claims.

4.

Accordingly, we hold that an IMM must contain one or more components for performing at least the functions of: (1) storing information to be reproduced; (2) receiving a request reproduction code; (3) transmitting a request reproduction code to a device remotely located from the IMM; (4) receiving an authorization code from the device remotely located from the IMM; and (5) reproducing the requested information in a material object in response to receiving the authorization code. An IMM need not contain the four separate and distinct components of the preferred embodiment.
Claim Construction

The first step in any invalidity or infringement analysis is claim construction. Rockwell Int'l Corp. v. United States, 147 F.3d 1358, 1362, 47 U.S.P.Q.2D (BNA) 1027, 1029 (Fed. Cir. 1998). PMC argues that in granting summary determination, the ALJ "failed to construe inferences of the meaning of 'information of a selected television programming unit' supplied by the specification in the light most favorable to PMC." We reject this argument.

As we stated in Cybor, claim construction is a purely legal question. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1455, 46 U.S.P.Q.2D (BNA) 1169, 1174 (Fed. Cir. 1998) (in banc) (stating that questions of construction are questions of law for the judge, not questions of fact for the jury). Claim construction is reviewed de novo on appeal, including any allegedly fact-based questions relating to claim construction. Id. at 1456, 46 U.S.P.Q.2D (BNA) at 1174. Thus, there are no facts underlying claim interpretation which must be viewed in the light most favorable to the non-moving party.

In construing a claim, we look first to the intrinsic evidence, consisting of the claims themselves, the written description, and, if in evidence, the prosecution history. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582, 39 U.S.P.Q.2D (BNA) 1573, 1576 (Fed. Cir. 1996). Unless the patent clearly states a special definition, words in the claim are to be given their clear and ordinary meaning. Id.

Claim 35 requires a controller for storing "information of a selected television program unit" which can cause the tuner "to select a television transmission containing programming of the television unit at a specific time." A "selected television program unit" is a particular television program, such as Wall Street Week. The ordinary meaning of the claim phrase is that the controller must store information about a particular television program sufficient to enable the controller to instruct the tuner to display the selected television program. No additional limitation on the type of information is expressly stated or suggested in the claim.

PMC's argument that the doctrine of claim differentiation creates a presumption that "information" of a selected television program unit cannot mean just "channel" and "time" information is not persuasive. It is true that the use of different terms within a claim indicates that different meanings are associated with the terms. However, here "information" does have a different meaning from channel and time. Information is a generic term encompassing different types of information whereas "channel and time" are merely one type of information.

We also reject PMC's argument that functionally claim 35 requires the controller to store information that uniquely identifies the desired television program so that if the desired program is aired on a different channel or at different time, the controller can scan all channels for embedded data signals in order to determine what channel the desired program is on. The claims do not recite any scanning function. Rather, a scanning function requirement is inconsistent with the clear language of the claim which requires that the tuner select a television transmission at a specific time. The use of a scanning function to delay the tuning of a program (such as when a proceeding program, like a sporting event, runs later than expected) would take the system outside of claim 35's scope since the last clause of the claim requires that the tuning occur at "a specific time".

Neither the written description of the '277 patent nor of U.S. Patent No. 4,694,490 ("the '490 patent"), from which the '277 patent derives priority, provide a definition that alters the plain meaning of claim 35. While examples disclosed in the preferred embodiments may aid in the proper interpretation of a claim term, the particular embodiments appearing in the written description will not be read into the claims when the claim language is broader than such embodiments. Electro Med. Sys. S.A. v. Cooper Life Sciences, Inc., 34 F.3d 1048, 1054, 32 U.S.P.Q.2D (BNA) 1017, 1021 (Fed. Cir. 1994). Here, the written description does not, either explicitly or implicitly, define "information" to mean a unique programming code. The written description does not uniformly use the term "information" with respect to "a selected television program unit" in a way that requires the nonstandard definition that PMC now advocates. Rather, it simply details how the system utilizes the unique program in a single embodiment of the invention.

The written description uses the term "information" as a broad term which embraces many different types of information. For example, the written description uses "meter-monitor information" as a broad term to include different types of information such as "dates and times," "unique identifier codes for each program unit (including commercials)," "unique codes from programming (other than programming identified by program unit codes) whose use obligates users to make payments," "origins of transmissions (e.g., network source stations, broadcast stations, cable head end stations)," and
"unique codes that identify the sources and suppliers of computer data." '277 patent, col. 29:20-41 & 60-61. Similarly, the '490 patent teaches that "input information" can include the cable television system's complete programming schedule, with each discrete unit of programming identified with a unique program code, information about when and where the cable head end facility should expect to receive the programming, and information about when and on which channel or channels the head end facility should transmit each program unit. '490 patent, col. 11:18-30.

While it may be true that the patentees developed and described a system which enables a television subscriber station to automatically tune into a particular television program through the use of a unique program identifier, the claims do not recite a unique program identifier and thus are not so limited. It is the claims of a patent, not the written description, that define the scope of the patentee's right to exclude. See E.I. du Pont de Nemours & Co. v. Phillips Petroleum Co., 849 F.2d 1430, 1433, 7 U.S.P.Q.2d (BNA) 1129, 1131 (Fed. Cir. 1988).

PMC also asserts that claim 35 cannot be interpreted to read on the Heathkit TV device because two prior art patents, United States Patent Nos. 4,081,753 (the '753 patent) and 4,170,782 (the '782 patent) disclosing devices similar to the Heathkit TV were cited during prosecution. PMC asserts that it was "incumbent upon the ALJ to recognize the importance of and to review thoroughly the prosecution history of the '277 patent as an aid to interpreting claim 35" and that the ALJ's failure to consider the prosecution history should be considered "clear error."

We reject the argument that it is clear error for the ALJ to have failed to thoroughly review each and every document cited in the patent when neither of the parties raises the specific relevance of the cited documents. PMC did not cite the '277 patent's prosecution history to support its claim interpretation either before the ALJ or the Commission in its petition for review. PMC did not specifically mention the '782 or '753 patents below or argue that the patents are relevant for claim construction purposes. To require that the ALJ thoroughly review and consider each of the over 250 references, or risk reversal due to clear error, when the parties themselves do not raise the relevance of the references, is an inefficient use of the ALJ's resources and is not required by our precedent.

Further, review of the prior art patents does not change our claim interpretation. There are over 250 references cited in the '277 patent. Other than the fact that the Examiner initialed the Initial Disclosure Statement, there is no evidence that the Examiner specifically considered the two patents when he allowed claim 35. Indeed, the fact that PMC did not discuss the two patents before the ITC and instead discussed the two patents for the first time on appeal, belies the notion that the two cited patents were considered to be pertinent to an interpretation of the disputed phrase, either by the applicant or the Examiner. Further, PMC has not demonstrated that there are no other limitations in the claim that would distinguish claim 35 over the prior art patents. Thus, we conclude that the prosecution history does not prevent the term "information of a selected television unit" from reading on channel and time information, as provided in the prior art Heathkit TV.

PMC also argues that the Final Determination should be reversed because the ALJ erroneously relied on a claim chart that PMC prepared for settlement negotiations in construing claim 35. We disagree. Even if the ALJ unnecessarily relied on extrinsic evidence when construing the claim, such reliance would constitute harmless error as we have reached the same claim construction as the ALJ, relying solely on intrinsic evidence.

We therefore hold that the ITC was correct in interpreting the term "information of a selected television unit" as including the channel and time information of a particular television program.

4. "information pertaining to the item being auctioned"

Claim 1 describes a bid system operable to, inter alia, transmit "information pertaining to the item being auctioned." Similarly, Claims 2 and 3 describe a method comprising, in part, transmitting "information about the item being auctioned" and "information regarding the item being auctioned" respectively. LGB proposes that these terms should mean "information describing the item being auctioned other than information regarding the acceptance or rejection of bids and the live video of the auction." AMS does not offer argument on this issue in its briefs, but asserted during argument that the terms of Claims 1, 2, and 3 should mean "facts or data pertaining to the item being auctioned;" "facts or data about the item being auctioned;" and "facts or data regarding the item being auctioned" respectively.
The Court agrees with LGB that these terms must be construed in light of the other claim limitations. Accordingly, the terms "information pertaining to the item being auctioned" in Claim 1, "information about the item being auctioned" in Claim 2, and "information regarding the item being auctioned" in Claim 3 shall mean "facts or data pertaining to the item being auctioned other than information regarding the acceptance or rejection of bids and the live audio and video of the auction."

D. "Information Processor"

Plaintiffs seek the following construction of the term "information processor":

An "information processor" is a computing system that processes information to determine a proper location of each identified compartment.

(Docket Entry No. 40, p. 24). Universal contends that the term "information processor" in claim 13 is in means-plus-function format because it lacks sufficiently definite structure to perform the claimed function. Universal argues that claim 13 calls for an information processor that performs the function of "determin[ing] the proper location of the identified components using preprogrammed information" and controlling the location indicator. (Docket Entry No. 46, p. 43; '943 Patent, col. 5, 1.55-1.61).

Claim 13 does not use the word "means" in claiming the information processor; this court must presume that section 112, P 6 does not apply. Technical dictionaries provide definitions of the term "information processor" that connote sufficient structure to avoid application of section 112, P 6. The NEW IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS (5th ed. 1993) defines "processor" as "a system or mechanism that accepts a program as input, prepares it for execution, and executes the process so defined with data to produce results." (Docket Entry No. 49, Ex. A, Ex. 2). The IBM DICTIONARY OF COMPUTING (10th ed. 1993) defines "information processor" as "in a conceptual schema language, the mechanism that, in response to a command, executes an action on the conceptual schema, or on the information base." (Id. at Ex. A, Ex. 1). The term "processor" has a well-known meaning to those of skill in the electrical and computer arts. Although the term does not connote a precise physical structure, it does connote sufficient structure to avoid the application of section 112, P 6. See Personalized Media, 161 F.3d at 704-705 (term "detector" connoted sufficient structure even though it did not connote a precise structure and was defined in terms of its function); Apex, 325 F.3d 1364, 2003 WL at *7. The identifying adjective "information" provides additional structural meaning to one of ordinary skill in the art.

Universal contends that the information processor described in claim 13 does not recite sufficient structure to carry out its function in the invention. Universal cites WMS Gaming, Inc. v. Int'l Game Tech., 184 F.3d 1339 (Fed. Cir. 1999) for the proposition that reference to a general purpose computer recites insufficient structure to perform the functions of the computer in the particular invention and that without a recitation of the programming structure or algorithm used by the computer, the claim is in means-plus-function format.

WMS Gaming is distinguishable from the facts of this case. The disputed claims in WMS Gaming were undisputedly written in means-plus-function format and properly analyzed under section 112, P 6. The issue in WMS Gaming was whether the district court's construction of the disputed terms was consistent with the structure recited in the written specification. The appellate court held that "in a means-plus-function claim in which the disclosed structure is a computer, or microprocessor, programmed to carry out an algorithm, the disclosed structure is not the general purpose computer, but rather the special purpose computer programmed to perform the disclosed algorithm." 184 F.3d at 1349 (citing In re Alappat, 33 F.3d 1526, 1545 (Fed. Cir. 1994)). The court stated that "the instructions of the software program that carry out the algorithm electrically change the general purpose computer by creating electrical paths within the device. These electrical paths create a special purpose machine for carrying out the particular algorithm." Id.

In WMS Gaming, the court had to confine its construction of the means-plus-function claims to the structure described in the specification and its equivalents. Kahn v. GMC, 135 F.3d 1472, 1476 (Fed. Cir. 1998). In the present case, by contrast, the claims are not written in means-plus-function format. In contrast to the structure disclosed in WMS Gaming, which was
a computer programmed solely to carry out the algorithm, the structure disclosed in the '943 Patent is not limited to the disclosed algorithm. Claims that are not in means-plus-function format are not required to be limited to the preferred embodiments described in the specification. The algorithm described in the specification of the '943 Patent creates one particular set of electrical connections -- one particular structure -- for using the invention. ('943 Patent, col. 12, 1.25-col. 18, 1.31). That algorithm represents only a preferred embodiment of the invention, not the only possible embodiment. This court does not limit the term "information processor" to the single algorithm described.

Other factors also weigh against limiting the term "information processor" to the operational algorithm presented in the written description. The written description does not contain words or expressions of manifest exclusion or restriction that would clearly disavow other possible algorithms that could be used with the invention. The prosecution history reveals that the apparatus can be operated with algorithms other than the one described. This court adopts plaintiffs' proposed construction of the term "information processor," which states that an "information processor" is a computing system that process information to determine a proper location of each identified component.

2184

1. "creating a database entry containing information received from a user" (claim 1)

The plaintiff argues that this term means "that an entry in a database is created containing information submitted by a user over a computer network." Defendant argues that the term means "creating a database entry containing information received from a user in which the content is entirely user controlled." The disagreement between the parties is whether the claim requires that the user control the content of the information contained in a database entry.

The defendant cites to portions of the specification that expressly require the user to control the content and the classification of the information content of a database entry. See, e.g., 1:13-3:40; 10:34-42. Plaintiff's arguments ignore the plain language in the specification concerning the user's control over the content and classification of the information contained in a database entry. For example, the specification states that the "information content is entirely user-controlled" and that "the user controls both the content of an entry and the manner in which it is classified." 2:60-64; 3:22-28.

The court agrees with the defendant that the user controls the content of the information contained in the database. Consequently, the court construes the phrase to mean "creating a database entry containing information received from a user in which the user entirely controls the information content of a database entry and the manner in which the information is classified."

2185

A

First and foremost, the analytical focus of claim construction must begin, and remain centered, on the language of the claims themselves. Tex. Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1201-02 (Fed. Cir. 2002) (quoting Interactive Gift Express, Inc. v. Compuserve, Inc., 256 F.3d 1323, 1331 (Fed. Cir. 2001)). Because the claim language is chosen by the patentee to "particularly point[ ] out and distinctly claim[ ] the subject matter" of the invention, 35 U.S.C. § 112, P 2, the claim terms chosen by the patentee carry a presumption that "they mean what they say and have the ordinary meaning that would be attributed to those words by persons skilled in the relevant art." Tex. Digital, 308 F.3d at 1202. In the absence of an express intent to impart a novel meaning to the claim terms, the words are presumed to take on the ordinary and customary meanings attributed to them by those of ordinary skill in the art. See, e.g., Teleflex, Inc. v. Ficosa N. Am. Corp., 299 F.3d 1313, 1325 (Fed. Cir. 2002). The ordinary and customary meaning of a claim term may be determined by reviewing a variety of sources, including the claims themselves, see Process Control Corp. v. HydReclaim Corp., 190 F.3d 1350, 1357 (Fed. Cir. 1999); dictionaries and treatises, Tex. Digital, 308 F.3d at 1202; and the written description, the drawings, and the prosecution history, see, e.g., DeMarini Sports, Inc. v. Worth, Inc., 239 F.3d 1314, 1324 (Fed. Cir. 2001).

ACTV, in arguing that the ordinary and customary meaning of the term URL encompasses both relative and absolute URLs, provides a document entitled Request for Comments 1808 ("RFC 1808"), from the World Wide Web Consortium ("W3C"), an industry working group, as authoritative support for this position. RFC 1808 discusses both absolute and relative URLs, noting that a relative URL "is a shortened form of that for [an absolute URL]" and that a relative URL is "a compact representation of the location of a resource." In response, Disney offers an earlier document entitled Request for Comments 1738 ("RFC 1738"), from the same organization, in support of its argument that URL encompasses only absolute URLs. Specifically, RFC 1738 indicates that a URL has a typical syntax requiring both a protocol type and a resource locator. RFC 1738 also distinguishes between "relative links," in which the expression of a related resource is described "in the same place as this one except with the following relative path," and general URL syntax, which provides "an abstract identification of the resource location."

As this court has previously noted,

dictionaries, encyclopedias and treatises, publicly available at the time the patent is issued, are objective resources that serve as reliable sources of information on the established meanings that would have been attributed to the terms of the claims by those of skill in the art. Such references are unbiased reflections of common understanding not influenced by expert testimony or events subsequent to the fixing of the intrinsic record by the grant of the patent, not colored by the motives of the parties, and not inspired by litigation. Indeed, these materials may be the most meaningful sources of information to aid judges in better understanding both the technology and the terminology used by those skilled in the art to describe the technology.

Tex. Digital, 308 F.3d at 1202-03.

As a preliminary matter, we consider whether the RFCs presented by the parties rise to the level of unbiased, contemporaneous reflection of the common understanding of the technical terms in question as to be considered a reliable source of information on the meaning attributed to those terms by those skilled in the art. The purpose of the W3C organization is "to lead the World Wide Web to its full potential by developing common protocols that promote its evolution and ensure its interoperability." About the World Wide Web Consortium (W3C), at http://www.w3.org/ Consortium/ (last visited Aug. 7, 2003) ("W3C Website"). To this end, members of W3C (including various industry groups, manufacturers, and others, each with their own conceivable interests in the agenda) are involved in developing standards to describe the various building blocks of the Internet. Id. Both RFC 1738 and RFC 1808 are working papers generated during standardization discussions by one subset, or working group, within W3C. See, e.g., Uniform Resource Locators (RFC 1738), at http://www.w3.org/Addressing/rfc1738.txt (T. Berners-Lee et al. eds. Dec. 1994) ("This document specifies an Internet standards track protocol . . . ."). The purpose of the RFCs is thus to collect commentary and to select language to facilitate a common understanding, or to select a standard, from a variety of competing technologies and vocabularies and from a variety of potentially competing interests. Indeed, the acronym "RFC" suggests that end: "Request for Comments." This purpose is in sharp contrast to the role of dictionaries and treatises, which aim not to select or give meaning to a word or phrase, but to report the meaning already established and commonly understood by those skilled in the art. See, e.g., Samuel A. Thumma & Jeffrey L. Kirchmeier, The Lexicon Has Become a Fortress: The United States Supreme Court's Use of Dictionaries, 47 Buff. L. Rev. 227, 291 (1999) (stating that first resort to a dictionary may be appropriate in determining meaning because "dictionaries are designed to reflect usage." (emphasis added)).

Both parties offer these RFC documents as authoritative, unbiased sources relating to the meaning of the expression URL. Because the RFCs were not designed to reflect common usage, but rather to assign language to facilitate further conversation, and because of the seeming contradictions between RFC 1738 and RFC 1808, we conclude that both documents are extrinsic evidence, and in light of the discussion below, we decline to rely on them in our claim construction analysis. See Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996) ("[I]f an analysis of the intrinsic evidence alone will resolve any ambiguity in a disputed claim term . . . it is improper to rely on extrinsic evidence."). It should be understood, however, that there is no general prohibition on the use of publications from standards-setting organizations to aid in determining the ordinary and customary meaning of technical terms. Where such a document reflects common usage by those skilled in the relevant art, the document may indeed be an appropriate reference. Where, as in this case, the documents of the standards-setting organizations do not reflect common usage, but purport to select language to be
used in the future, elevation of these Requests for Comments to the same authoritative, unbiased level as dictionaries is improper.

In the present case, the construction of URL is principally informed by the plain language and surrounding context of the claims themselves. See Broookhill-Wilk, 334 F.3d at 1299. The claims recite that a URL "specifies one or more Internet addresses of the information segments which relate specifically to the content of the video and audio signals of the programming." '181 patent, col. 59, ll. 8-12 (emphasis added). In construing the claim term URL, these additional terms contained in the claimed means-plus-function expressions provide context for the term URL and must themselves be construed. See, e.g., Hockerson-Halberstadt, 183 F.3d at 1374 ("Proper claim construction, however, demands interpretation of the entire claim in context, not a single element in isolation."). Thus, even though the district court's constructions of "Internet address" and "information segments" were not explicitly appealed, we must also construe those terms to properly construe the appealed term URL.

The district court's construction of "information segments" as "simply referring to parts into which information on the Internet is commonly divided" is supported by the claim language and the specification. See Markman Memorandum, 204 F. Supp. 2d at 653; '181 patent, col. 3, l. 6, col. 6, l. 12; 664 patent, col. 3, l. 31, col. 8, l. 32; 768 patent, col. 3, l. 33, col. 8, l. 55. These parts are exemplified by, but not limited to, items such as web pages, audio clips, and images. See id. However, the district court's construction of the term "Internet address," as "a particular host on the Internet, specified by a uniform resource locator that is unique to that host," Markman Memorandum, 204 F. Supp. 2d at 654, is not supported by the claim language or specification, and relies on circular reasoning related back to URL. Rather, the context of the term "Internet address" informs that it is simply a reference to a location of the information segment on the Internet. There is no support for the district court's added requirements that the "Internet address" be a particular host or that it be unique. A URL, then, as defined by the language and context of the claims, is something that identifies the location of relevant information segments. This can include web pages, audio clips, images, and the like. It can be an absolute URL or a relative URL, as long as it specifies one or more addresses of information segments relating to Internet content.

2. Information Source: A place or thing which originates electronic information concerning particular subjects without executing electronic mail programming.

3. "creating a database entry containing the information submitted via the entry form" (claim 4)

This term necessarily incorporates the court's first two claim constructions. Plaintiff argues that this term means "that an entry in a database is created containing information submitted by a user via an entry form displayed to the user over a computer network." Defendant argues that the term should be construed to mean "creating a database entry containing information in an entry form submitted by the user over the World Wide Web in which the content is entirely user-controlled." Again, the parties' disputes relate to the breadth of the network and the user's control over the information content. For the reasons outlined above, the court construes this term to mean "creating a database entry containing information submitted by a user via an entry form displayed to the user over a public computer network wherein the information content and classification is entirely controlled by the user."

On April 4, 2008, the district court construed nine disputed sets of claim limitations. Only the first set--"information transmitter" and "recognition device"--is challenged on appeal. The district court construed "information transmitter" to mean "a device that communicates with a recognition device via electromagnetic waves, after being actuated by that recognition device, without requiring any sort of personal action by the passenger." Claim Construction Order, 561 F. Supp. 2d at 362. It construed "recognition device" to mean "a device that actuates and reads data transmitted by an information
transmitter without requiring any sort of personal action by the passenger." Id. In the claim construction order, the district court declined to specify the particular kind of "personal action" prohibited under its construction, but stated that it "rules out, not just standing in front of the recognition device, or inputting data into the information transmitter by hand, but any and all types of personal action by the passenger." Id. (emphasis added).

The parties then cross-moved for summary judgment on the issue of infringement. Schindler argued that the RFID cards of the accused system are "information transmitters" and that the card readers embedded in the security turnstiles are "recognition devices." Otis countered that neither of these limitations is met because the use of a passenger's hands to bring a RFID card within the 3.5-inch effective range of a card reader constitutes prohibited "personal action."

The district court issued its summary judgment ruling on November 17, 2008. Although it had previously said that "any and all types of personal action" were prohibited under its construction, the district court refined its understanding of "personal action" on summary judgment to expressly permit "walking into the monitored area." Summary Judgment Order, 586 F. Supp. 2d at 237. The district court went on to note that a user of the accused device must "do something in order to bring the card (not just themselves) to a point at which the device embedded in the turnstiles can read it," such as taking the card out of a pocket or holding the card over the glass surface of the turnstile. Id. at 238. Accordingly, the district court held that Otis's accused system could not meet the "information transmitter" and "recognition device" limitations and thus did not infringe the '094 patent as a matter of law.

DISCUSSION
I. Standard of Review

"An infringement analysis entails two steps. The first step is determining the meaning and scope of the patent claims asserted to be infringed. The second step is comparing the properly construed claims to the device accused of infringing." Markman v. Westview Instruments, Inc., 52 F.3d 967, 976 (Fed. Cir. 1995) (en banc) (citations omitted), aff'd, 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996). Claim construction is a question of law, which we review de novo. Cybor Corp. v. FAS Techs., Inc., 138 F.3d 1448, 1456 (Fed. Cir. 1998) (en banc). "While infringement is a question of fact, we review a district court's grant of summary judgment without deference." Bd. of Regents of the Univ. of Tex. Sys. v. BENQ Am. Corp., 533 F.3d 1362, 1367 (Fed. Cir. 2008) (internal citations omitted). Summary judgment is proper only "if the pleadings, the discovery and disclosure materials on file, and any affidavits show that there is no genuine issue as to any material fact and that the movant is entitled to judgment as a matter of law." Fed. R. Civ. P. 56(c).

II. Analysis

Schindler challenges the district court's construction of the terms "information transmitter" and "recognition device." Schindler also challenges the district court's grant of summary judgment of noninfringement, under the district court's construction and under Schindler's proposed construction.

A. Claim Construction

Schindler argues that the district court improperly limited the terms "information transmitter" and "recognition device" by requiring those devices to operate "without any sort of personal action by the passenger" and by further defining "personal action" to mean any action "other than walking into the monitored area." According to Schindler, nowhere does the intrinsic evidence prohibit a passenger from using his hands to simply bring an information transmitter within range of a recognition device. The phrase "personal action" appears only once in the specification. In Schindler's view, "personal action" encompasses the action of manually pressing buttons to actuate the transmitter or to select a destination floor, not to the initial act of bringing the transmitter within range of the recognition device. Schindler therefore requests that we remove any reference to "personal action" from each construction. 1

--- Footnotes ---

1 Schindler also requests that we strike the phrase "via electromagnetic waves" from the district court's construction of "information transmitter." But the construction of "information transmitter" that Schindler proposed to the district court
included that very phrase. We therefore decline to alter the district court's construction as it pertains to electromagnetic waves.

Otis responds that the district court correctly relied on statements in the specification and prosecution history that describe "hands-free," "automatic," and "contactless" elevator operations, as clearly disavowing all "personal action."

As we shall explain, we agree with Schindler that the district court's construction is too narrow. The statements in the specification and prosecution history on which the district court relied were directed to elevator operations that occur only after the information transmitter is already within range of the recognition device, not to the initial act of bringing the information transmitter within range of the recognition device.

A claim term is generally given its "ordinary and customary meaning," which is "the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention." Phillips v. AWH Corp., 415 F.3d 1303, 1313 (Fed. Cir. 2005) (en banc). "[T]he court looks to 'those sources available to the public that show what a person of skill in the art would have understood disputed claim language to mean,' . . . includ[ing] 'the words of the claims themselves, the remainder of the specification, the prosecution history, and extrinsic evidence concerning relevant scientific principles, the meaning of technical terms, and the state of the art.'" Id. at 1314 (quoting Innova/Pure Water, Inc. v. Safari Water Filtration Sys., Inc., 381 F.3d 1111, 1116 (Fed. Cir. 2004)). Because the parties do not rely on any extrinsic evidence, we focus our analysis on the claim language, the specification, and the prosecution history.

1. Claim Language

"Quite apart from the written description and the prosecution history, the claims themselves provide substantial guidance as to the meaning of particular claim terms." Id. Here, the district court overlooked several important aspects of the claim language which themselves shed light on whether and to what extent an elevator user undertakes "personal action" in the invention.

First, "the context in which a term is used in the asserted claim can be highly instructive." Id. In claim 1, the term "information transmitter" itself suggests that the transmitter is a thing, separate and apart from an "elevator user" (a separate limitation), which transmits information. The claim also provides that "elevator calls [are] entered at an entry location by an information transmitter." Thus, at least with regard to the transmission of information and the entry of calls, it is the information transmitter--not the elevator user--that performs these tasks. Similarly, the claim provides that a "recognition device . . . actu[ates] the information transmitter" and that "a unit . . . independently reads data transmitted from the information transmitter." Accordingly, the tasks of actuating the transmitter and reading data are performed by the recognition device and the unit, respectively, not by the elevator user. The claim also explicitly provides that the transmitter is "carried by an elevator user." Carrying a transmitter is thus a type of "personal action" that is expressly required in the claims. Nowhere does claim 1 limit the act of carrying to any specific manner of carrying.

Second, "[o]ther claims of the patent in question, both asserted and unasserted, can also be valuable sources of enlightenment as to the meaning of a claim term." Id. Claim 7 depends from claim 1 and adds the phrase "wherein the recognition device reads a key having a code." A "key" is disclosed in the specification as a "building key," which is embedded with an information transmitter that is actuated by a recognition device mounted near a "door lock" of a building. '094 patent col.5 ll.30-32. The door lock recognizes the building key when the passenger uses his key to open the door. Id. col.5 ll.32-33. The specification, in describing a variation of this information transmitter "key" embodiment, notes that the recognition device may be mounted near a "time clock," and an elevator is dispatched when a user clocks in or out of work. Id. col.5 ll.33-35. Because a user would need to use his hands to bring the transmitter key within range of the recognition device to unlock the door, or to clock in or out of work, these types of personal action are implicitly permitted in claim 7 and, by extension, in claim 1. Thus, the claims appear to permit at least those types of personal action that are necessary to bring the information transmitter within range of the recognition device.

2. Specification

"[C]laims 'must be read in view of the specification, of which they are a part.'" Phillips, 415 F.3d at 1315 (quoting Markman
v. Westview Instruments, Inc., 52 F.3d 967, 979 (Fed. Cir. 1995) (en banc), aff'd, 517 U.S. 370, 116 S. Ct. 1384, 134 L. Ed. 2d 577 (1996)). "[T]he specification 'is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.'" Id. (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)).

The phrase "personal action" is used only once in the specification, in the following sentence:

> The advantages achieved by the invention reside in the fact that the desired journey destination is communicated automatically to the elevator control by [(1)] the information transmitters carried by the elevator users or by [(2)] the recognition of features of the elevator users without any personal action being required by the passenger.  

'094 patent col.2 ll.49-54 (emphases and bracketed numbers added). Notably, this sentence refers to the patent's two disclosed embodiments: (1) the claimed "information transmitter" embodiment and (2) the unclaimed "individual features" embodiment. 2 In the latter, instead of actuating an information transmitter, the recognition device "recognizes a passenger with the aid of an individual feature, for example in an optical manner (facial contours, finger prints [sic], iris, etc.) or by reason of the speech thereof." Id. col.4 ll.48-51 (emphasis added). Because a passenger would need to place his hand on the optical recognition device for it to read his fingerprints, this cannot be the "personal action" to which the sentence refers. Instead, the structure of the sentence-- "communicated . . . by [(1)] . . . or by [(2)]"--makes clear that the two enumerated embodiments are the means by which "the desired journey destination is communicated," and that the ultimate phrase "without any personal action being required by the passenger" describes how the information is communicated. The sentence says nothing about how the passenger initially brings his transmitter (or fingerprints) within recognition range, but merely that, once in range, he need not use personal action to communicate his journey destination to the elevator control.

--- Footnotes --- End Footnotes ---

2 The concurring opinion asserts that, because the "individual features" embodiment was "abandoned," it would not be relevant to the scope of the disclaimer of "personal action." Post at 4 n.3. With all due respect, neither assertion is correct. The embodiment was not "abandoned," it simply was never claimed in the application that led to this particular patent. Moreover, because the phrase "without any personal action" applies equally to both embodiments, the latter embodiment is indeed relevant to discerning what kinds of "personal action" this sentence prohibits.

The same is true of all statements in the specification describing "hands-free," "automatic," and "contactless" elevator operations. Each time those terms are used, they modify the elevator's "call entry" operation, an operation that necessarily occurs after the information transmitter has been brought within range of the recognition device and after the transmitter has been actuated by the recognition device. Id. Abstract ("[T]he call entry taking place automatically, contactless and independent of the orientation of the information transmitter . . .").

The district court's prohibition against all actions other than walking, the specification itself provides examples where a user would need to do more than just walk to bring his transmitter into recognition range. As mentioned, the "key" embodiment of claim 7 requires a user to unlock a door using a key, and only upon "opening of the door" by the user will an elevator be dispatched. Id. col.5 ll.27-35. The transmitter "can also be mounted on any desired object," id. col.4 ll.64-65, like a "luggage or shopping cart," and an elevator is dispatched when the user pushes his cart into the vicinity of the recognition device, id. col.5 ll.1-13. Thus, unlocking a door and pushing a cart are two "personal actions," other than simply walking, which are disclosed in the specification as actions needed to bring a transmitter within range of the recognition device. Once in range, the transmitter is actuated by the recognition device and transmits its encoded data without personal action by the user.

3. Prosecution History
During prosecution, Schindler amended the claims in response to an obviousness rejection over U.S. Patent No. 5,304,752 ("Hayashi") in view of U.S. Patent No. 4,685,538 ("Kamaike"). It was at this time that Schindler first added the "information transmitter" limitation to the claims, and further required that the transmitter be "actuat[ed]" by the recognition device. J.A. 314-17 ("the recognition device . . . actuating the information transmitter" (amendment emphasized)). Schindler argued that Hayashi "fails to show calls for the elevator made by a transmitter identifying the destination of the passenger," J.A. 319, and that Kamaike, which requires a user to manually actuate a transmitter by pressing buttons, "fails to disclose or suggest . . . a recognition device actuating a transmitting device carried by the elevator user for transmitting data," J.A. 322. Schindler went on to explain:

Because the information transmitter of the present invention is not equipped with user operable keys, it is not necessary that the information transmitter be in the elevator user's hands to select the desired floor. Thus, the call commands are pre-programmed to occur automatically, contactlessly, and independently of the orientation of the information transmitter.

J.A. 320. The examiner allowed the claims to issue in amended form.

The district court reviewed the prosecution history and concluded that Schindler had surrendered coverage of its originally claimed invention and, through its arguments, had disavowed any coverage of elevator systems that do not operate "automatically" and "hands-free." Claim Construction Order, 561 F. Supp. 2d at 361. We agree with the district court that Schindler is not entitled to any interpretation that it disclaimed during prosecution. See Chimie v. PPG Indus., Inc., 402 F.3d 1371, 1384 (Fed. Cir. 2005) ("The purpose of consulting the prosecution history in construing a claim is to 'exclude any interpretation that was disclaimed during prosecution.'" (quoting ZMI Corp. v. Cardiac Resuscitator Corp., 844 F.2d 1576, 1580 (Fed. Cir. 1988))). But we disagree as to the extent of that disclaimer.

The doctrine of prosecution disclaimer attaches where an applicant, whether by amendment or by argument, "unequivocally disavowed a certain meaning to obtain his patent." Omega Eng'g, Inc. v. Raytek Corp., 334 F.3d 1314, 1324 (Fed. Cir. 2003). For example, an amendment that clearly narrows the scope of a claim, such as by the addition of a new claim limitation, constitutes a disclaimer of any claim interpretation that would effectively eliminate the limitation or that would otherwise recapture the claim's original scope. Here, the district court construed the term "recognition device" as a device that "actuates and reads data transmitted by an information transmitter." Because this construction already provides that the recognition device--not the elevator user--actuates the transmitter, there is no risk that Schindler would recapture a broader claim scope than that existing before it added the "information transmitter" and "actuating" language to the claims.

An argument made to an examiner constitutes a disclaimer only if it is "clear and unmistakable." Purdue Pharma L.P. v. Endo Pharms., Inc., 438 F.3d 1123, 1136 (Fed. Cir. 2006). An "ambiguous disavowal" will not suffice. Computer Docking Station Corp. v. Dell, Inc., 519 F.3d 1366, 1375 (Fed. Cir. 2008). Here, the district court found statements in the prosecution history, similar to those in the specification, which describe the invention as operating "automatically, contactlessly, and independently of the orientation of the information transmitter." The district court read these statements as unambiguously disavowing the use of a passenger's hands for any and all purposes. We disagree. As in the specification, those terms modify actions that take place only after the passenger has brought the transmitter within range of the recognition device--specifically, the actuation of the transmitter, the entry of call commands, and the selection of a destination floor. J.A. 320 ("[I]t is not necessary that the information transmitter be in the elevator user's hands to select the desired floor." (emphasis added)); 320 ("Thus, the call commands are pre-programmed to occur automatically, contactlessly, and independently of the orientation of the information transmitter." (emphasis added)); 322 ("[N]either applied document of record discloses or suggests, inter alia, the unique hands-free, automatic, and contactless elevator call system recited in the pending claims via a recognition device that actuates a transmitting device . . . ." (emphases added)); 325 ("Because none of the applied documents of record disclose or suggest actuation of the transmitting device by the recognized device, recited in the combination of features in at least independent claim 1, to enable truly hands-free operation of elevator calls, Applicants respectfully submit that no combination of the applied documents of record can even arguably render obvious the present invention as recited in claim 7." (emphases added)). Significantly, the last of these prosecution statements is specifically directed to dependent claim 7, which recites the "key" feature. It is clear that "truly hands-free" modifies "operation of the elevator calls" and does not--indeed, can not--refer to the initial act of bringing the key within range of the recognition
device. None of these statements speaks to the role a user plays in bringing a transmitter within range of a recognition device; nor was the prior art distinguished on that basis. These prosecution statements, which, contrary to the concurrence, the applicant actually made and not merely could have made, do not constitute a "clear and unmistakable" disavowal of personal action for the limited purpose of bringing the transmitter within range of the recognition device.

Instead, we read the prosecution history in this case "as support for the construction already discerned from the claim language and confirmed by the written description." 800 Adept, Inc. v. Murex Sec., Ltd., 539 F.3d 1354, 1365 (Fed. Cir. 2008). That construction excludes coverage of systems in which an elevator user manually presses buttons to actuate the information transmitter or to select a default journey destination. Those types of personal action are properly excluded under the portions of the district court's existing construction specifying that the information transmitter is what "communicates with a recognition device via electromagnetic waves, after being actuated by that recognition device," and that the recognition device is what "actuates and reads data transmitted by an information transmitter." However, a user ought to be able to use his hands, or take other personal action, to simply bring the transmitter within the effective range of the recognition device. We therefore modify the district court's construction of "information transmitter" and "recognition device" by striking the phrase "without requiring any sort of personal action by the passenger" from each construction.

3 The concurring opinion would only allow a user to take personal action to the extent that the action is "required to gain entry to the building," but would prohibit a user from otherwise taking personal action simply to bring the transmitter within range of the recognition device. Post at 2. Respectfully, there is nothing in the language of the claims, the specification, or the prosecution history that draws such a distinction. As explained above, the intrinsic evidence speaks only to user actions taken after the transmitter is within recognition range; it is entirely unconcerned with the way in which the transmitter initially gets there.

B. Infringement

Under our modified construction of "information transmitter" and "recognition device," Schindler's evidence was sufficient to create a genuine issue of material fact that the RFID cards of the accused system communicate with a card reader via electromagnetic waves after being actuated by the card reader, and that the card reader actuates and reads data transmitted by the RFID cards. On that basis, the district court should not have granted summary judgment of noninfringement.

Below, Otis also moved for summary judgment of noninfringement under the district court's construction of two other limitations ("in the vicinity of the elevators" and "coupled between"), which the district court did not reach. The parties have not challenged the construction of those limitations on appeal. Otis's arguments that it does not infringe under the district court's construction of those two limitations thus remain open for consideration on remand.

CONCLUSION

We modify the district court's construction of "information transmitter" and "recognition device" by striking the phrase "without requiring any sort of personal action by the passenger" from each construction. We vacate the grant of summary judgment of noninfringement and remand for further proceedings consistent with this opinion.
satisfied, because using the building key to call the elevator requires no additional personal action by the user.

1 The specification provides: "A further variation consists in that information transmitter 1 is not carried along as a separate card, but executed as coded key means. For example, in a residential or in an office building, the building key can be provided with information transmitter 1. Recognition device 5 is then mounted at the door lock so that elevator control 10 also receives the destination call upon the opening of the door." '094 patent col. 5 ll.27-33.

Unfortunately, the majority is not content to rest its decision on this simple point. Rather, it interprets the claim broadly as including a swipe card device that is not tied to building access and declines to give effect to the significant disclaimer appearing in both the specification and prosecution history--disclaiming devices that are not "hands-free" and "automatic." Contrary to the majority, it seems to me that the action of swiping a card to call the elevator separate from the action required to gain entry to the building is clearly within the disclaimer of both the specification and prosecution history.

How does the majority avoid this disclaimer? The majority's theory is that there is no requirement of hands-free or automatic action until the transmitter is within range of the recognition device. In other words, the device would be "hands-free" and "automatic" even though the user has to take elaborate action to bring the device within range. See Majority Op. at 16 ("[A] user ought to be able to use his hands, or take other personal action, to simply bring the transmitter within the effective range of the recognition device"). I find this reading of the disclaimer to be inherently improbable and quite inconsistent with the language of the specification and prosecution history. The specification and prosecution history make no such distinction, and consistently emphasize the hands-free and automatic nature of the device without regard to whether it is in range or not. The specification requires that "the desired journey destination [be] communicated automatically to the elevator control by the information transmitters carried by the elevator users . . . without any personal action being required by the passenger," '094 patent col.2 ll.49-54 (emphasis added), and that the entire call entry take place "hands-free, contactless and independent of the orientation of the information transmitter," id. at col.4 ll.27-29. The prosecution history similarly distinguishes the prior art on the ground that the call commands occur "automatically, contactlessly, and independently of the orientation of the information transmitter." J.A. 320. Neither the specification nor the prosecution history distinguished between actions taken within range or out of range of the recognition device.

The patentees, unlike the majority, argue that the disclaimer has no application to devices where the signal came from the recognition device. 2 On this theory, the disclaimer is rendered entirely meaningless because the patent only covers devices in which the signal is initiated by the recognition device, and the disclaimer is read only to apply to devices in which the signal is initiated by the transmitter.

2 At oral argument, appellant stated that "]if the signal is initiated from the card, that is disclaimed by the amendment . . . . It doesn't matter whether the actuation is by buttons . . . . The point is, the initiation of the communication is initiated by the recognition device so that the card can now be passive . . . . That was the distinction [made in the prosecution history], not whether it was buttons or not, but the actuation no longer came from the information transmitter." Oral Arg. at 40:43-41:27 (emphasis added).

The prior art device involved a system whereby the user activated a transmitter by entering a code that signaled the recognition device. The applicant could have distinguished this prior art solely on the ground that the signal here goes from the recognition device to the transmitter. The applicant did not choose to rest on this ground alone (likely because this was an obvious variant of the prior art), but instead emphasized that the patented device was distinguishable both because of the signal direction and because it was hands-free and automatic. The patentee agreed at oral argument that a card swipe was no less covered by the disclaimer than the pressing of buttons.

We have repeatedly held that a disclaimer cannot be avoided simply by pointing out that the prior art could have been
distinguished on another ground. See, e.g., Norian Corp. v. Stryker Corp., 432 F.3d 1356, 1361-62 (Fed. Cir. 2005) (holding that patentees must be held to the scope of what they ultimately claim, and are not allowed to assert that claims should be construed to surrender only what was necessary to avoid the prior art); Fantasy Sports Properties, Inc. v. Sportsline.com, Inc., 287 F.3d 1108, 1115 (Fed. Cir. 2002) ("Fantasy acquiesced in [the examiner's] rejections by canceling all claims that did not contain the 'bonus points' limitation at issue on appeal, and thus cannot now be heard to argue post hoc that it was the combination of the aforementioned limitations that rendered its invention patentable over the prior art."). Schindler's disclaimer must be based on what he said, not on what he could have said. Thus, I find Schindler's reading of the disclaimer to be just as untenable as the majority's reading.

A competitor reading the specification and the prosecution history is entitled to rely on the patent and prosecution history. In my view, the majority's claim construction artificially eliminates that disclaimer in limiting it to actions taken after the transmitter is in range of the recognition device. 3

--- Footnotes ---

3 The majority opinion also appears to rely on the unclaimed "individual features" embodiment relating to finger print recognition. See Majority Op. at 10-11. Given that this embodiment was abandoned, I do not think that it suggests anything regarding the scope of the claims that were retained. In particular, the prosecution history disclaimer cannot have been addressed to the abandoned claims.

</tbody>
</table>

n.7 Pursuant to the June 9, 2006 joint submission, the parties have agreed that these claim terms should be construed synonymously.

The Court's previous analysis of the term "unique" is equally applicable here, and therefore, Microsoft's "one-of-a-kind" language will not be adopted. Thus, the main point of difference focuses on Microsoft's reading of the words "intending" and "intended" to mean that the user does not become a licensee until the user completes the registration process. Without relying on intrinsic or extrinsic evidence, Uniloc objects to this theory, arguing that the term licensee is distinct from registered user because "the user must be licensed by the software vendor to load the software into his or her computer in the first place." Having agreed to treat these terms synonymously, however, Uniloc now seems to implicitly agree that a licensee is the same as a registered user - i.e., a user who has completed the registration process.

Nevertheless, even if Uniloc intends to press its objection, the Court notes that upon scrutinizing the claim terms in the
context of claims 2 and 12, the ordinary meaning of the terms at issue becomes readily apparent by applying the widely accepted definitions of the adjectives "intended" and "intending" - both of which describe a person that expects in the future to be a licensee. See Merriam-Webster's Collegiate Dictionary 607 (10th ed. 2002) (defining "intended" as "expected to be such in the future" and defining "intending" as "prospective, aspiring"). Applying these ordinary meanings, an intended/intending licensee in claims 2 and 12 clearly refers to a person who has software on his or her computer and plans on becoming a licensee by registering the software so as to access the full functionality of the software. It is logical, therefore, that the user who intends to become a licensee cannot already be a licensee as that term is used in claims 2 and 12. The remainder of the specification supports this reading by explaining that prior to registration, a person uses the software in an unlicensed mode. For instance, in the explanation of use mode, the '216 Patent unambiguously states:

In this specification, "use mode" refers to use of the digital data or software by its execution on a platform so as to fulfill the seller's/licensor's obligations in relation to the sale or license of the right to execute the digital data or software in the use mode. The use mode is to be distinguished from what might generally be termed unlicensed modes of operation (which is not to say unauthorized modes of operation) as typified by the demonstration modes later described in this specification.

See '216 Patent, col. 2, ll. 40-49 (emphasis added); see also id. at fig. 2a (illustrating that a user, after being able to try the software in a demonstration mode, then agrees to a licensing agreement upon registering).

Accordingly, the Court construes these terms as follows: Information that is uniquely associated with a person who intends to become a licensee so as to access full functionality of the digital data.

7. "inhibiting"

Substep (ii) discloses performing the "applying" step: "in a manner inhibiting leaked partial statistical information about said internal secret state from usefully describing said updated secret state." The parties dispute the construction which should be given to the word "inhibiting." The dispute centers on whether the word "inhibiting" should be construed as "prohibiting" leaked information or whether "leak resistance" is meant.

This dispute is a manifestation of the continuing dispute over the degree of security claimed by the patents-in-suit. 5 The Abstract provides:

Methods and apparatuses for increasing the leak-resistance of cryptographic systems using an indexed key update techniques are disclosed.

The "Detailed Description of the Invention" provides:

The invention enables parties to perform cryptographic operations with increased security against external monitoring attacks.

('092 Patent, Col.3:34-36.)
Next, the "inhibiting" term within Claim 1(e) requires construction. Agrizap argues that "inhibiting" means "any manner of preventing the triggering step once the high voltage and current generator has been triggered, the prohibiting provided through hardware, software/ firmware or any combination thereof." (Agrizap's Reply Br., at 15). Woodstream argues that "inhibiting" means "the triggering step is inhibited upon each and every activation of the triggering of the generator until the power on reset signal is detected; each time the high voltage generator is activated, further triggering cannot take place, at least until the power on reset signal is detected." (Woodstream's Reply Br., at 13).

This Court will adopt Woodstream's construction of the "inhibiting" term. As shown above in the construction of the "reset signal" term, the specification provides support for the construction that the triggering step is inhibited until the power on reset signal is detected. See Phillips, 415 F.3d at 1315 (stating that specification is single best guide for determining meaning of disputed term). Specifically, the specification states that "[o]nce triggered, the electronic portion 1 cannot be retriggered until power is turned off and then on again via switch 2." (636 patent, col. 6, lines 46-48). Furthermore, it states that the "Timer Module 112 remains latched even after the predetermined time has elapsed and PTIME 95 has returned to a logic low level. The logic low value of ARM 93 therefore prevents any retrigger of Timer Chip 18 until the power is cycled off and then on by the user." (636 patent, col. 9, lines 5-10). It also states that "Timer Module 112 cannot be retriggered until it is reset via an active low logic signal on POR 97. (636 patent, col. 7, lines 63-65). Therefore, the triggering step is inhibited until the power on reset signal is detected.

Having considered the parties' competing proposals on this term, the Court adopts the following compromise construction: "programming information received by a POL regulator after power-up but prior to the first generation of an output voltage." See '798 patent, col. 2:10-23; col. 4:51 - col. 5:49; col. 6:43-54; Figure 6.

The phrase "initial intended delay" appears nowhere in the specification. As Synopsys points out, however, the use of the...
Accordingly, "initial intended delay" also may change once selected. Cells, both of which are subject to change, (see, e.g., '446 Patent at 3:30-37), which further suggests that the "initial intended area" of the cells and the "initial intended lengths" of the wires connecting the cells, both of which are subject to change, (see, e.g., '446 Patent at 3:30-37), which further suggests that the "initial intended delay" that requires the delay to be fixed once chosen runs afoul of the plain language of the claims.

Magma's proposal that the "initial intended delay" must remain fixed once selected is based on language describing one embodiment of the invention. (See id. at 6:33-37.) In particular, the specification, in describing such embodiment, states that "[d]uring the library analysis 207, the delay D is determined for each gate to be used in the digital circuit," (see id. at 6:33-34), and "the gate size is adjusted after cell placement based on changes in the capacitive load in order to maintain D as 'constant.'" (See id. at 6:48-51.) The specification, however, expressly provides that descriptions of particular embodiments are "illustrative only and not in any way limiting" and that "other embodiments of the invention will readily suggest themselves to those skilled in the art." (See id. at 4:55-58.) Given that portions of the specification, as well as the claims themselves, discuss "stretching" or "compressing" the "initial intended delay," the Court agrees with Synopsys that any construction of "initial intended delay" that precludes changes to the delay once selected would be erroneous. See Phillips v. AWH Corp., 415 F.3d 1303, 2005 WL 1620331 at *15 ("although the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments").

For the same reason, the Court disagrees with Magma's proposal that the "initial intended delay" must be determined during "library analysis." Although a discussion of "library analysis" appears in the specification in a description of a particular embodiment of the invention, (see '446 Patent at 6:26-9:9), the term "library analysis" appears in none of the claims. Moreover, the claims themselves suggest that the determination of the "initial intended delay" may occur at different stages of the process. For example, claim 1 requires that cells be selected from a cell library, and that "at least some of the selected plurality of cells" have "an initial intended delay associated therewith." (See id. at 17:14-25.) Claim 21, on the other hand, requires that cells be "selected from a cell library," and that "the electronic circuit description include[ ] an initial intended delay associated with each cell." (See id. at 18:45-56.) Synopsys's expert, David Harris, Ph.D. ("Dr. Harris"), attests that it is well known to those of ordinary skill in the art that the "initial intended delay" may be included in or derived from either the electronic circuit description or library analysis. (See Harris Decl. P 32.) According to Dr. Harris, Magma's proposed construction renders claims 21 "self-contradictory," because "an 'initial intended delay' cannot be 'determined during library analysis' and also be included within the 'electronic circuit description.'" (See id. P 49.) Indeed, the specification supports Dr. Harris's view by expressly stating that library analysis "is not dependent on the actual circuit which is being synthesized and thus can be performed separately from the circuit design process[.]" (See '446 Patent at 6:30-33.) Dr. Harris further attests that it would make "no sense, in light of the purpose of the invention, to require that the 'initial intended delay' be obtained during library analysis," because "[t]he invention would work just fine for its intended purpose regardless of whether the initial intended delay is specified in the netlist, the delay is calculated during library analysis, or the delay is obtained in some other manner." (See id. P 50.) For all of these reasons, the Court finds there is no limitation that the "initial intended delay" be determined during library analysis.

By contrast, Synopsys's construction of "initial intended delay" as a "delay set as a target" comports with the ordinary meaning of the claim language and the specification. As noted, both the specification and the claims discuss stretching and compressing the "initial intended delay," as necessary, (see, e.g., '446 Patent at 14:19-15:62; 18:14-35), which demonstrates that the "initial intended delay" is an estimate or target, rather than a fixed requirement. The Court also notes that the specification discusses the "initial intended area" of the cells and the "initial intended lengths" of the wires connecting the cells, both of which are subject to change, (see, e.g., '446 Patent at 3:30-37), which further suggests that the "initial intended delay" also may change once selected.

Accordingly, the Court will construe "initial intended delay" as "a delay set as a target."
The '479 Patent tracks a website visitor's traffic patterns through the use of a website cookie that is transferred between a server and the website visitor's browser. However, the first time a web user visits a website, the user's web browser will not have a website cookie for the requested website. In the '479 Patent, a server will produce a website cookie which contains "an initial set of traffic path analysis data for the current website" when a browser does not send a cookie along with a request for a page. Patent at col. 12, ll. 58-61.

The parties dispute the meaning of the phrase "an initial set of traffic path analysis data for the current website." Joint Claims Construction Chart at 4. Netratings contends that the phrase means "the website traffic path analysis data for the current website, including the current website page requested and cumulative values set to zero." Websidestory argues that Netratings' proposed construction improperly imports limitations from the specification, and defines the phrase as an "initial data set of traffic path analysis data." In support of its construction, Websidestory cites to a dictionary definition of "data set," as well as to the prosecution history.

In construing the phrase "an initial set of traffic path analysis data for the current website," the Court starts by examining the claims in the '479 Patent. Bell Communications Research, Inc., 55 F.3d at 620. The '479 Patent first uses the phrase at claim 1, element 3, but the language surrounding the disputed phrase does not identify or define the contents of "an initial set of traffic path analysis data for the current website." Patent at col. 12, ll. 50-61. During an updating step described in claim 1, element 5, the '479 Patent provides:

setting the traffic path analysis data of the website cookie to initial values if the website cookie has expired, and otherwise updating traffic path analysis data for a current website visit by the network browser by adding the current requested website page to the traffic path analysis data and thereby showing the complete path of website pages requested during the current website visit.

Patent at col. 12, l. 65 - col. 13, l. 5. The Court concludes that this fifth element instructs on what is included in the term "an initial set of website traffic path analysis data for the current website."

Claim 1, element 5 requires that "a complete path" of traffic analysis data be shown after the "adding the current requested page" step. Accordingly, the Court finds that the current requested page must be part of "an initial set of traffic path analysis data for the current website" as described in claim 1, element 3 at col. 12, ll. 57-62; see also col. 12, ll. 54-57. If this were not the case, it would be impossible to have the "complete path" of traffic path analysis data after execution of claim 1, element 5, because adding only the current requested page to a non-expired cookie would not indicate previous webpages visited. This conclusion is also supported by the summary of the invention portion of the specification, which states that "[f]or every website page requested by a website visitor, the state of the visitor's browser is recorded." Patent at col. 4, ll. 37-40.

Netratings contends that "an initial set of traffic path analysis data for the current website" must also include "cumulative values set to zero." Joint Claims Construction Chart at 4. In previously construing "website traffic path analysis data," the Court rejected Netratings' arguments that "website traffic path analysis data" must include cumulative values and statistics. Consistent with that construction, the Court concludes that the '479 Patent does not require cumulative values set to zero as part of "an initial set of traffic path analysis data for the current website," since neither the claims nor the specification
requires an initial set of traffic path analysis data for the current website to include cumulative values set to zero.

After reviewing the '479 Patent claims and specification, as well as the parties' arguments, the Court concludes that the acquired meaning of "an initial set of traffic path analysis data for the current website" is: "an initial set of traffic path analysis data for the current website, which includes at least the current website page requested."

Initialization NSP; initialization log-in data; initializing set of identification information

Defendants seek definitions similar to the one agreed upon for "initial use set of log-in information," where "initial" is roughly equivalent to "first time." MyMail asserts the "first time" limitation is unique to Claim 1 [the claim where "initial use set of log-in information" appears] since it does not appear in Claims 12 and 13 [the claims where the above disputed phrases appear]. In the context of Claims 12 and 13, MyMail asserts that the words "initial" and "initializing" refer to the beginning of a particular session. The Court finds MyMail's arguments to be circular and unpersuasive. The limitation in Claim 1 to which MyMail refers -- "initial use set of log-in information for initially communicating with an access SP" -- merely restates that the "initial use set" is "initially" used. It does not shed light on the meaning of "initial" in the patent.

The word "initial" and variations of that word are used consistently throughout the specification to refer to the first time the user contacts the ASP. Sec. e.g., Col. 6:50-51, 57; 13:24-25; 15:55; 16:42-45, 60. The Court therefore defines "initialization NSP" as "an NSP used the first time the user contacts the ASP," "initialization log-in data" as "log-in data used the first time the user contacts the ASP," and "initializing set of identification information" as "a set of information used the first time the user contacts the ASP."

To the extent the definition of "initial" in different claims should constitute a question of claim differentiation -- as MyMail seems to hint -- the Court notes that the "first-time" limitation is not absolute. Rather it refers to the first-time a user configures and establishes communications with an ASP or network, and distinguishes subsequent sessions where the user is simply reestablishing, without any reconfiguration, communications. Cf. Col. 6:50-51; 13:24-25. Put simply, there could be more than one first-time and the different claim language accounts for that, allowing a global definition of "initial" to suffice.

host computer is initially accessed by said client computer through a web page

Claim 1 contains the term "host computer is initially accessed by said client computer through a web page." Accolade contends that the term should be given its plain and commonly understood meaning and does not need construction. Alternatively, Accolade argues that "host computer is initially accessed by said client computer through a web page" means "client computer first interacts with the host computer by means of a web page." Citrix contends that the term means "the client computer first accesses the host computer via a web page by obtaining the internet address of the host computer from the web page." The parties dispute the meaning of "accessed" and whether the client computer must obtain the host computer's IP address.

"Host computer is initially accessed by said client computer through a web page" does not require construction. The terms, "host computer," "access," "client computer," and "web page" have been addressed above. Also, "initially" is a commonly understood word, and the intrinsic record does not contradict the commonly understood meaning of "initially." Thus, no terms in "host computer is initially accessed by said client computer through a web page" require further construction.

8 The Court addressed and resolved the parties' dispute about "access" in its discussion on "controlling a computer" and "host computer . . . being capable of being accessed by said client computer."
The remaining issue is whether the client computer must obtain the host computer's IP address. Citrix argues that the client computer must obtain the host computer's IP address because the IP address is required for the client and host computers to bypass the webpage and communicate directly. However, claim 1 states that the client and host computers can communicate "directly or indirectly." Col. 14:10-11. Because the client and host computers can communicate indirectly, they may communicate, for example, through a server that does not require transmission of the IP address. Furthermore, dependent claim 4 states that the "address" of the host computer is transmitted, creating a presumption that the independent claim does not include the limitation. Col. 14:22-24; Phillips, 415 F.3d at 1314-15. This presumption cannot be successfully rebutted in light of the claim language that expressly indicates that the client and host computers can communicate directly or indirectly. Thus, claim 1 does not require that the client computer obtain the host computer's IP address.

A. Claim Construction

USVO alleges that Movielink infringes the '792 patent by direct literal infringement, by inducing infringement, by contributing to infringement, and by infringement under the doctrine of equivalents. (D.I. 1 at P 20.) Specifically, USVO alleges that Movielink's Multi-CDN system infringes claim 1 of the '792 patent, and the parties' claim construction briefs and arguments regarding infringement are directed solely to interpreting claim 1. (D.I. 126 at 12; D.I. 131 at 1.)

Claim 1 of the '792 patent is as follows:

1. A system for transmitting video programs to remote locations over a switched telephone network, comprising:

   a central data facility having means for storing digital compressed versions of video programs;

   a request interface connected to said central data facility and to the telephone network, wherein said request interface receives requests for video programs made over the telephone network and communicates them to said central data facility;

   a distribution interface connected to said central data facility and to the telephone network, wherein said distribution interface initiates connections over the telephone network with remote locations in response to requests received by said request interface, and transmits thereto compressed versions of video programs previously requested through said request interface, such compressed versions being transmitted in less time than is required to view the programs in real time;

   a receiver at each remote location for connecting to the telephone network and receiving compressed video programs transmitted from said distribution interface, for storing the received programs, and for subsequently playing the video programs at a real time rate on a video display.

('792 patent, col. 7, II. 41-66 (emphasis added).)

While the parties have identified several terms in claim 1 as requiring construction, I have limited my discussion to interpreting one claim term which, as discussed in detail below, see infra Part IV.B.1-3, is dispositive of the outcome of this case. That term is "initiates," as noted in emphasis in the above quotation.

1. The Parties' Proposed Constructions

The parties have identified this claim term as "initiates connections" and therefore their proposed constructions encompass not only the term "initiates," but also the term "connections." (D.I. 148 at 12.) USVO proposes that I construe "initiates connections" to mean "creates an association between two or more endpoints (a distribution interface and the remote locations) for the transfer of data. (D.I. 126 at 32; D.I. 148 at 12.) Movielink proposes that I construe "initiates connections" to mean "places calls over a switched telephone network by dialing preauthorized numbers." (D.I. 131 at 22; D.I. 148 at 12.)

The arguments made by both parties in the claim construction briefing are focused on the term "connections," and not on the
term "initiates." USVO, however, recognizes that the term "initiates" is synonymous with "starts," when it states: "Even though both parties to the connection participate in forming the connection, one party starts or initiates the process." (D.I. 126 at 34 (emphasis added.))

2. The Court's Construction

The claim term "initiates" in the phrase "wherein said distribution interface initiates connections over the telephone network with remote locations in response to requests received by said request interface" (792 patent, col. 7, II. 52-56 (emphasis added)), has a plain and ordinary meaning. I will not read limitations into the claim from the specification when the term is easily construed according to its ordinary meaning as understood by a person of ordinary skill in the art. See Texas Digital Sys., Inc., 308 F.3d at 1205. According to Webster's Third New International Dictionary, "initiate" means "to begin or set going." Webster's Third New International Dictionary 1164 (3d ed. 1986). The disclosures in the patent specification and prosecution history do not suggest that any other meaning of "initiates" was intended by inventors Tindell and Crawford. See Teleflex, Inc., 299 F.3d at 1325 (internal citation omitted).

Claim 1, as represented above, was not originally included in the patent application. (D.I. 139, Tiu Dec., Ex. F at 18, Tiu Dec.,'792 patent application.) It was added by amendment (id., Ex. H at 2, Amendment) after original claim 1 was withdrawn following its rejection for, among other things, being anticipated by Cohen, a prior art patent. (Id., Ex. G at 1-6, Office Action mailed Dec. 17, 1990.) In arguments made to the Patent and Trademark Office distinguishing Cohen, the applicants stated: "The Cohen reference describes a system in which a local unit … initiates a download of a video program such as a movie. … The telephonic connection and request is made by the local unit itself. …" (Id., Ex. H at 7, Amendment (emphasis added).) The applicants argued that the invention claimed in the '792 patent, however, was distinguishable because of the function of the distribution interface: "A distribution interface … initiates a call to a remote unit, and transmits a compressed video program to it. … The distribution interface initiates all calls to remote units before transmitting the video programs to them." (Id., Ex. H at 8, Amendment (emphasis added).)

In addition, the applicants argued that their claimed system was different than the prior art because in their system, the central unit is "in control," rather than the local unit. The "control" aspect of the claimed system is directly related to the claim term "initiates" as seen in the following argument:

The difference in the claimed system as described above and the references leads to a system which is construed on entirely different philosophical lines than in the prior art. In the prior art, the local unit is in charge of the transaction, ordering and receiving a program at its convenience. In the claimed system, the user merely requests a program; the central facility ten [sic] initiates a new connection at its convenience and sends a program to the remote unit identified in the request. Since the central unit is in control rather than the remote unit, it is easier to design the central unit to make it run very efficiently.

(Id., Ex. H at 9, Amendment (emphasis added).)

Based on the applicants' arguments, it is clear that the inventors did not manifest "an express intent to depart from [the plain and ordinary] meaning." Teleflex, Inc., 299 F.3d at 1325 (internal citation omitted). Therefore, consistent with its plain and ordinary meaning, I construe "initiates" to mean "begins."

2. "initiates a diagnostic operation in the office machine system"

The next disputed claim term appears in Claims 57 and 58 of the '554 Patent. Ricoh asserts that "initiates a diagnostic operation in the office machine system" means "a command sent from the diagnostic processor to the office machine system causes the office machine system to begin a diagnostic operation." (Chart at 9). Pitney asserts that the term should be construed as "to start a routine in the office machine system to analyze the cause or nature of errors in software or hardware." (Id.).

The Court notes that the term "initiate" appears in several of the claims of the '554 Patent. '554 Patent, Claims 50-51, 57-58.
For example, Claim 57 recites:

A system, comprising:

an office machine system . . . and

a diagnostic processor . . . wherein:

said diagnostic processor includes means for sending a command from the diagnostic processor to the office machine system over the communication line which initiates a diagnostic operation in the office machine system; and

data is transmitted from the office machine system to the diagnostic processor over the communication line after the diagnostic operation is initiated.

'554 Patent, Claim 57 (emphasis added). In these claims, the claim describes a command being sent from the diagnostic processor to the office machine system which causes a diagnostic operation to "initiate." The claims also indicate that processed data is transmitted after the initiation of the diagnostic operation. Id.

Once again, the Court finds itself in a position where minimal guidance is provided in the written description -- particularly in light of the fact the term "initiate" does not appear in the written description. As such, the Court must rely on the plain language of the claims which provide some guidance on this issue. Having concluded that "diagnostic operation" does not require the presence of error, the Court concludes that Ricoh's construction more accurately reflects the proper interpretation. Thus, the Court adopts that construction. Accordingly, "initiates a diagnostic operation in the office machine system" means "a command sent from the diagnostic processor to the office machine system causes the office machine system to begin a diagnostic operation."

4. initiating a next-line inquiry

OPTi contends that the phrase "initiating a next-line inquiry" means "sending a command to snoop the next line." nVidia asserts that "initiating a next-line inquiry" means "sending a command to snoop the next-line (e.g., asserting EADS #), without an associated request to transfer the corresponding line from secondary memory."

The parties again offer very similar constructions. The only issue for the Court to decide for this construction is whether "initiating a next-line inquiry" requires the additional limitation nVidia offers of "without an associated request to transfer the corresponding line from secondary memory."

There is no basis in the language of the claims to support nVidia's construction. Nor has nVidia pointed to a clear disavowal in the specification or prosecution history that would require adoption of this negative limitation. Accordingly, it is rejected.

The Court adopts OPTi's proposed construction.

5. initiating a next-line inquiry . . . to determine whether an N+1'th byte line of said secondary memory is cached in a modified state in said first cache memory

OPTi proposes that this phrase means "initiating a next-line inquiry to determine whether the next-line has been modified by the CPU." nVidia responds by asserting that the proposed construction of the phrase should be "initiating a next-line inquiry to determine whether the next-line has been modified by the CPU or may be read by the bus master without any further concern that the cache contains a more current copy of the data."
Once again, the parties have narrowed the dispute to a single question. In this case, the Court need only decide whether the additional limitation "or may be read by the bus master without any further concern that the cache contains a more current copy of the data" is required.

nVidia contends that OPTi's construction could allow for stale data as it is not limited in time. Thus, nVidia seeks to add the additional limitation recited above. nVidia's concern has merit as the goal of the invention is to prevent the transfer of stale data. However, nVidia's proposed construction would likely confuse the jury and is therefore rejected. The Court instead construes "initiating a next-line inquiry . . . to determine whether an N+1'th byte line of said secondary memory is cached in a modified state in said first cache memory" to mean "initiating a next-line inquiry to determine whether the next-line of data in the secondary memory is different from the corresponding data in the cache."

Pitney asserts that the claims expressly require the business office device to initiate the communication. For example, Claim 1 provides:

A method, comprising the steps of:

storing semi-static state data in a business office device, the semi-static state data including data which may change infrequently over a life of the business office device;

initiating communication between the business office device and a computer, by the business office [device];

transmitting the semi-static state data from the business office device to the computer; and

receiving the semi-static state data by the computer.

'289 Patent, Claim 1 (emphasis added). Claim 22 also claims a system that has a business office device which includes a "means for initiating communication between the business office device and the computer, before the transmitting device transmits the static state data." Id., Claim 22. Additionally, Claim 68 provides that the "business office device" includes a "means for initiating communication between the business office device and the operation terminal." Id., Claim 68. The Court agrees with Pitney that the claim language supports the conclusion that, with regard to this term, the communication is being initiated by the business office device.

Pitney further argues that its construction is consistent with the specification. Pitney references the specification which provides:

At power-on time, System Control Process 102 not only brings up the target device 10, but also establishes the communication with attached devices by first checking the physical connection and then establishing the communication by means which will be described below.

Copier engine 10 is idle until a user specifies some function through Operation Panel 20. During the idle time, however,
System Control Process 102 continuously monitors its state through Monitoring Process 104. If abnormal states are detected, System Control Process 102 sends data to Communication Process 101, which codes data and sends the coded data to the Operation panel 20 through communication media line 12. Communication Process 201 sends acknowledgment . . . .

'289 Patent, col. 2, l. 65 - col. 3, l. 10 (emphasis added). Based on this reference to the specification, Pitney argues that the claim term requires the business office device, rather than a user, to initiate communication with the operation panel. Pitney asserts that the specification distinguishes between a communication initiated by the business office device and a communication initiated by a user. The patent describes the latter as being initiated by a user only when the user specifies the function through the operation panel. According to Pitney, this was a feature that Motoyoma used to distinguish his invention from the prior art. ('289 Patent Prosecution History, Dec. 22, 1995 Amendment at 26-27).

In response, Ricoh argues that a person of ordinary skill in the art reading the patent would understand that a device initiates communication "even if a human has started a function, for example by turning power on, the properly construed claims cover the interactions between the various modules of the device." (Ricoh's Reply at 16-17). Ricoh relies on the specification and expert opinion of Adams for this proposition.

The Court concludes that Pitney's construction more accurately reflects the meaning of this specific claim term. As aforementioned, the Court agrees with Pitney that the express language of the claim requires the communication to be initiated by the business office device. See Phillips, 415 F.3d at 1312 (noting the "bedrock principle of patent law that the claims of a patent define the invention to which the patentee is entitled the right to exclude") (quotations omitted). The claim here identifies the business office device as what initiates the communication and does not reference a user.

The Court rejects Ricoh's construction because it fails to account for the key term "initiate." For example, the limitation that the business office device has the "intelligence and capability of establishing communications" ignores the plain and ordinary meaning of the term "initiate" which is to start something. Because the claim language itself indicates what performs the "initiation," i.e., the business office device or a means contained in the business office device, this should be incorporated in the term's construction.

The Court will therefore adopt Pitney's construction. Accordingly, "initiating communication between the business office device and a computer, by the business office device" and "initiating communication between the printer and the computer by the printer" mean that "the business office device/printer itself starts or establishes communication with the computer." n7

n7 To clarify, the Court concludes that these claim terms require the business office device or printer to initiate the communication with the computer. Based on the claim language, any actions that may occur before the business office device or printer actually initiates communication, e.g. a user pressing a button, need not be included in the claim construction. As such, an act involving human intervention may read on this limitation so long as the requirement that the business office device or printer initiates the communication with the computer is met.

--- End Footnotes ---

--- Disputed Claim Term: "Initiator group (igroup)"

*2*(claims 2, 8, 18, 21, 25, 26, 29, 33)

Sun's construction: A logical named entity with a human-friendly name that is assigned to one or more addresses associated with one or more initiators. Membership

NetApp's construction: This term does not need to be construed because its plain meaning suffices and this term is already clearly defined in the body of the
in the entity can be modified at any time by adding or removing initiators.

The parties dispute whether or not the claim term needs construction in the first instance. Insofar as the Court agrees that the term needs construction, the parties' constructions present two main disputes: whether an igroup must have a human-friendly name, and whether an igroup must be capable of being modified by adding or removing initiators. Sun contends that igroups must have these characteristics.

As to the first issue, NetApp notes that the claims already define "igroup." Claim 25, cited above, describes "selecting a selectable name for the igroup, where the igroup is a logical named entity that is assigned to one or more addresses associated with the one or more clients." NetApp argues that this definition of igroup -- "a logical named entity that is assigned to one or more addresses associated with the one or more clients" -- is sufficient and complete because it explains that an igroup is assigned to one or more clients and the igroup is itself named, which permits the benefit described in the patent of referring to the igroup by its name, eliminating the need to refer to individual clients. However, as Sun points out, this definition is not included in all of the claims in which the term appears, see, e.g., Claim 8, which could mean that the term as it is used throughout the claims has a different meaning than the definition set forth in certain specific claims.

NetApp relies on TIP Systems, LLC v. Phillips & Brooks/ Gladwin, Inc., 529 F.3d 1364, 1369 (Fed. Cir. 2008), noting that the Federal Circuit upheld the District Court's construction where it relied "heavily on the claim language to construe the claim term." In that case, the court's construction was "supported by an identical definition in the specification." Id. Here, too, the specification states: "An igroup is a logical named entity that is assigned to one or more addresses associated with one or more initiators." '152 patent at 2:42-45. The use of the word "is" in the specification may "signify that a patentee is serving as its own lexicographer." Sinorgchem Co. v. ITC, 511 F.3d 1132, 1136 (Fed. Cir. 2007) (citation omitted). 11 TIP Systems is somewhat distinguishable, however, as appellant there was arguing for a construction that was contrary to the express language in the claim and specification, while Sun's proposed definition would supplement (with additional limitations), rather than contradict, the definition contained in the specification and the claim. See 529 F.3d at 1369. Despite this distinction, the Federal Circuit's analysis supports NetApp's proposed construction, but the Court turns to other portions of the specification for further guidance.

--- Footnotes ---

11 Here, unlike in Sinorgchem, the patentee did not set off the term "igroup" in quotation marks, which are an indicator of an explicit definition.

--- End Footnotes ---

Sun argues that the summary of the invention requires the human-friendly limitation. See C.R. Bard, Inc. v. U.S. Surgical Corp., 388 F.3d 858, 864 (Fed. Cir. 2004) ("Statements that describe the invention as a whole, rather than statements that describe only preferred embodiments, are more likely to support a limiting definition of a claim term . . . . Statements that describe the invention as a whole are more likely to be found in certain sections of the specification, such as the Summary of the Invention."). The summary of the invention begins:

The present invention overcomes the disadvantages of the prior art by providing a technique that enables efficient access to logical unit numbers (luns) or virtual disks (vdisks) stored on a storage system, such as a multi-protocol storage appliance. The technique allows a grouping of initiators by a "human-friendly" logical name that is mapped to a lun or vdisk on the storage appliance. By "human-friendly" it is meant, generally, a hierarchical naming convention that may use a spoken language name including an arbitrary label selected by a user or administrator. . . .

The inventive technique enables access to the vdisk by all initiators that are members of the initiator group (igroup). An igroup is a logical named entity that is assigned to one or more addresses associated with one or more initiators. These
addresses may comprise fibre channel (FC) world wide name (WWN) or iSCSI name identifiers (IDs). Therefore, rather than having to specify these IDs when desiring access to a vdisk, an initiator need only specify the human-friendly name of the igroup.

'152 patent at 2:26-48 (emphasis added).

The summary then states: "According to the invention, the technique includes a method of creating logical igroups of initiators, each identified by a human-friendly name or label, and binding of each created igroup to one or more WWN or iSCSI IDs." Id. at 2:49-52 (emphasis added). The abstract, excerpted in the above description of the '152 patent, also discusses the human friendly name, noting that the technique of the invention allows a grouping of initiators by a human friendly logical name, so that an initiator need only specify the human friendly name of the igroup when desiring access to a vdisk.

The detailed description portion of the specification further states:

The present invention relates to a technique that allows a grouping of initiators by a "human friendly" logical name that is mapped to a lun or vdisk stored on the multi-protocol storage appliance to thereby enable access to the vdisk by all initiators that are members of the initiator group (igroup). As used herein, a "human friendly" logical name is an arbitrary label selected by the user of administrator that may be a spoken name, a path designation or include a hierarchical naming convention. An exemplary human friendly name would be "administrators" for a name of an igroup that comprises the administrators of a given network.

Id. at 10:36-47. See also id. at 10:54-58 (rather than having to specify certain name identifiers when desiring access to a vdisk, "an initiator need only specify the human friendly name of the igroup"); id. at 12:17-21 ("According to the invention, the novel technique includes a method of creating logical igroups of initiators, each identified by a human friendly name or label").

Sun argues that each of these statements in the specification establishes that the invention itself, not merely a preferred embodiment, consists of an igroup with a human friendly name. However, the specification also makes clear that the term "human friendly" does not mean user-friendly as perhaps a juror would understand the term. Rather, it has a specific meaning, which is a "hierarchical naming convention that may use a spoken language name including an arbitrary label selected by a user or administrator" or "an arbitrary label selected by the user of [sic] administrator that may be a spoken name, a path designation or include a hierarchical naming convention." '152 patent at 2:32-35, 10:36-47. A path designation, for example, is often not a simple English, user-friendly name. Therefore, at a minimum, if the construction contains the "human friendly" limitation, it must also define that term so as not to confuse a jury.

In addition, as NetApp's expert points out, the specification discusses "allowing" grouping initiators by a human friendly name, suggesting that their use is not required. Ganger Decl. P 34. However, as Sun notes, the phrase "allow" is not used in every instance cited above. In addition, despite using the word "allow" in some instances, the specification still seems to be describing the nature of the invention as a whole. "Human friendly," therefore, seems to be part of the definition of "igroup." The claim language and specification, when taken together, show that the claimed invention, at a minimum, permits a human friendly name for igroups.

NetApp also argues that the claim language and its history reveal that the "human friendly" limitation is not a requirement of the invention. The claims themselves never mention "human friendly," and instead only require that an igroup name be "selectable." See, e.g., '152 patent at 18:7 (Claim 25). Dr. Ganger notes that the claims used to contain the term "human friendly," but were amended to "user selected," which was then changed to "selectable." Ganger Decl. P 34. In other words, "human friendly" was explicitly removed from the claims, which is strong evidence that the limitation should not be imported into the construction. When the applicant filed the application for the '152 patent, some of the original claims (e.g., independent claims 1 and 6, which became 8) included the term "human-friendly." See Weber Decl., Ex. 9 (U.S. Patent Application) at NAC0000940-44. Others (e.g., independent claims 16 and 19, which became claims 18 and 21, respectively) instead simply used the phrase "initiator group (igroup) name." Id. To one of ordinary skill in the art, this history would have indicated that, for some claims, a human-friendly name was required for the initiator group and, for others, it was not. Further, in the April 4, 2006 amendment, the applicant changed several occurrences of "human-friendly" in the claims to "user selected," explicitly removing the human-friendly name requirement from the subset of claims that originally included
it. Weber Decl., Ex. 10 (April 4, 2006 Amendment) at NAC0001656-63. The applicant later changed two instances of "user selected" to "selectable." Weber Decl., Ex. 11 (August 25, 2006 Amendment) at NAC0001683-91. Ganger Decl. P 34. The patent prosecution history, therefore, indicates that the human friendly limitation may be a permissive limitation, but is not a requirement of the invention.

The Federal Circuit's analysis in Liebel-Flarsheim Co. v. Medrad, 358 F.3d 898 (Fed. Cir. 2004), sheds some light on the meaning of the specification and the prosecution history here. In Liebel-Flarsheim, the Federal Circuit considered the scope of claims in patents related to fluid injectors used during medical procedures. Id. at 900. The Court found that the language in the patent abstract did not suggest that a pressure jacket was an essential component of the invention, nor was there language in the specification that disclaimed the use of the invention in the absence of a pressure jacket. Id. at 908 (where abstract stated that an injector and method of replacing the injector was provided "in which the syringe is loadable and unloadable into and from the injector through the open front end of a pressure jacket of the injector," and the summary of invention stated that "according to the principles of the present invention, there is provided an . . . injector having a front end loadable syringe that can be loaded into and removed from the injector pressure jacket . . ."). The present case is in a somewhat different posture, insofar as the patent here distinguishes prior art on the basis that it required specifying various name identifiers when desiring access to a vdisk, unlike the igroup. See '152 patent at 2:26-48. Therefore, the specification in the present case provides somewhat stronger evidence for limiting the claim term than did the specification in Liebel-Flarsheim.

However, in Liebel-Flarsheim, the patent applicants specifically replaced claims with references to a pressure jacket with a new set of claims, many of which omitted that limitation. Id. at 909. This prosecution history is quite similar to that of the '152 patent. The Federal Circuit noted that the replacement was a "strong indication that the applicants intended those claims to reach injectors that did not use pressure jackets." Id. (emphasis added). While the prosecution history in that case contained an explicit statement of intention (lacking in this case), as applicants stated that there was not necessarily a pressure jacket in the amended claims, id., in the present case, the omission of the "human friendly" term from the claims (and replacement of that term with "user selected" and then "selectable") provides similarly strong evidence that the applicant intended to broaden its claims.

After examining the patent prosecution history, the Liebel-Flarsheim Court noted that "[t]he only remaining question is whether the applicants failed in their effort and the pressure jacket limitation remained a part of all of the claims, even those from which the reference to the pressure jacket had been removed." Id. The Court, however, was unpersuaded by that argument, especially in light of the express statement in the prosecution history. Finally, the Federal Circuit also held that "[t]he fact that a patent asserts that an invention achieves several objectives does not require that each of the claims be construed as limited to structures that are capable of achieving all the objectives." Id. at 908. Similarly, here, there are multiple objectives of the invention, and each claim need not achieve all of them. Applying Liebel-Flarsheim's analysis to the present case, the Court finds that the prosecution history, when read with the specification and claim language, indicates that igroups may, but need not, have a "human friendly" name.

As to the second issue -- whether an igroup must be capable of being modified by adding or removing members from the group -- Sun argues that an igroup cannot be static and must be capable of modification. According to Sun, NetApp's construction would permit an igroup that is incapable of being modified once it is created.

The claim language does not require or mention this "modification" characteristic. The parties' arguments primarily hinge upon the specification. NetApp notes that the summary of the invention contains a definition of igroup, which omits any reference to being modifiable. The summary states: "An igroup is a logical named entity that is assigned to on or more end loadable syringe that can be loaded into and removed from the injector pressure jacket . . ."). The present case is in a somewhat different posture, insofar as the patent here distinguishes prior art on the basis that it required specifying various name identifiers when desiring access to a vdisk, unlike the igroup. See '152 patent at 2:26-48. Therefore, the specification in the present case provides somewhat stronger evidence for limiting the claim term than did the specification in Liebel-Flarsheim.

An igroup has certain attributes, such as transport protocol type and operating system type of the member initiators. Illustratively, the igroup need not be homogeneous in terms of these attributes, i.e., an igroup can contain initiators having different combinations of FCP and/or iSCSI as a transport. For example, iSCSI and FCP initiators can be combined into a single igroup. In addition, igroup can support various operating system initiator members. This allows operations, such as graceful rolling upgrade of a FCP SAN cluster to an iSCSI cluster, with no application downtime. Moreover, membership of the igroups can be modified at any time, i.e., initiators can be added to or removed from an igroup and, as a consequence, inherit or lose the mappings of the igroup, respectively.
'152 patent at 2:64-3:10. See also id. at 3:16-20 ("e.g., when replacing an initiator in a client"), 15:18-22 (same); 14:29-33 (discussing illustrative embodiment, noting "[i]n addition, membership of the igroups can be modified at any time, i.e., initiators can be added to or removed from an igroup.").

NetApp argues that the above paragraph makes clear that the listed features, including the modifiable feature, are examples, as the paragraph uses the terms "illustratively" and "for example." However, the word preceding the modifiable discussion is "moreover," which means in addition to what has been said. Thus, the paragraph is ambiguous as to whether or not the "modifiable" feature is a necessary aspect of the igroup, or is merely an example of a characteristic of an igroup. But it is clear that the modifiable feature is just one of the many listed attributes.

Sun notes that NetApp does not challenge the facts that: (1) there is no teaching in the patent of a static igroup, and (2) the teaching of the patent is to the contrary. At the hearing, however, the parties discussed whether or not the patent contained an example of an igroup that was not capable of being modified. NetApp noted that the address change example in the patent involves an igroup that is associated with multiple vdisks and is not modified. When the initiator that is bound to the igroup is replaced, only the initiator address is changed. Therefore, the initiator address, as opposed to the igroup itself, is modified, which requires no additions, changes, or deletions to the igroup itself. See '152 patent at 14:34-60. The address change example, therefore, weighs slightly in favor of NetApp's construction, because it is an example in which the igroup does not change and the membership itself is not modified.

Sun also relies on extrinsic evidence, noting that the term "group" has a well-understood meaning in computer science consistent with its construction, as it is well-understood by those of ordinary skill in the art that groups can be modified by adding or removing members of the group. Declaration of Dr. Scott Brandt P 49. Conversely, a single-member set that is incapable of adding or removing members would not be considered to be a group. Id. P 50. Dr. Ganger, however, contests this point, noting that to one of ordinary skill in the art, a "group" is simply a named set of one or more things (its members). While groups usually allow modification of membership, this feature is not a definitional aspect. Also, neither the Microsoft computer dictionary definition nor the BSD book excerpt provided by Sun's expert Dr. Brandt mentions that groups are modifiable. See Ganger Decl. P 36; Brandt Decl. PP 48-49 & Ex. 3. Accordingly, the Court does not find Dr. Brandt's opinion to be persuasive and does not find that an igroup must be capable of being modified.

In sum, the Court construes the term "initiator group (igroup)" as "a logical named entity that may have a human friendly name assigned to one or more addresses associated with one or more initiators. As used in the patent, 'human friendly name' means an arbitrary label selected by the user or administrator that may be a spoken name, a path designation or include a hierarchical naming convention."

EMC asks the Court to construe this term as: "A command that signals to the peripheral device the beginning of the process of replacing resident microcode." EMC also is willing to add the following to its proposal: "This command is sent by the operating system to a peripheral device in response to an initiator peripheral device request sent by an application program to the operating system, and causes the peripheral device to enter a waiting state ready to receive new microcode." HP proposes (in its opposition brief):

A command sent by the operating system to a peripheral device in response to an initiator peripheral device request sent by an application program to the operating system. The command causes the peripheral device to enter a waiting state ready to receive new microcode. The command is separate and functionally different from a subsequently received transfer peripheral device command.

The initiator peripheral device command is one that an operating system sends to the peripheral device in response to a routine legitimately called by an application program (e.g., a write or read request), as opposed to a special command for the peripheral device to which an application program would not normally have access.
Although the claim language does not clearly define the term, it indicates that the peripheral device enters the waiting period in response to the initiator peripheral device command. Additionally, the initiator peripheral device command corresponds to an initiator peripheral device request sent from the application program -- executed by the computer system processor -- to the operating system routine. The written description further explains:

The operating system provides operating system routines, legitimately accessible to an application program, for providing such access. In response to a call by an application program to such an operating system routine, the operating system will send a specific peripheral device control command . . . to the peripheral device to perform the requested access.

801:2/4-10.

It is not clear from the claim language whether the transfer and initiator commands must be "separate and functionally different." The claim language indicates that the peripheral device enters a waiting state in response to the initiator peripheral device command and that transfer of microcode to the peripheral device cannot occur in the absence of a transfer peripheral device command, strongly suggesting that there are two distinct commands. The claim does not state that microcode may be transferred in response to the initiator peripheral device command or that the transfer peripheral device command can induce a waiting state. Thus, it appears from the claim language alone that the two commands are distinct. The specification strongly suggests that the transfer and initiator commands must be different commands. For example, the resident processor of the peripheral device

detect[s] a first disk control command, called the initiator command . . ., in response to which the disk drive is placed in a state waiting to receive new control microcode. When in this waiting state, a second disk control command, called the transfer command . . ., is detected which contains the new control microcode for the disk drive.

801:6/37-44. Similarly, "[w]hen the initiator command is detected, no transfer of data is performed to the disk drive platters 114. Instead, the disk drive enters a state ready to receive new microcode." 801:8/63-65. Finally, the prosecution history indicates that the patentee distinguished the invention from prior art that disclosed a "system which enters the waiting state when a single . . . command containing the complete replacement microcode is being received and processed," and the patentee referred to the present invention as using a "two command sequence . . . to download replacement microcode." Declaration of Steven E. Derringer in Support of Plaintiffs and Counterclaim Defendants' Opposition Claim Construction Brief on Key Terms ("Derringer Decl."), Separate Appendix, vol. 1, pp. 0170, 0174-75. The patentee's description is consistent with the claim language and the specification. Accordingly, in the claimed invention, the peripheral device must receive two distinct commands in order to receive microcode.

HP also proposes language excluding a "special command." The basis for the limitation is found in the prosecution history, in which the patentee distinguished the claimed invention from the prior art by stating that it allowed for updating of resident microcode via operating system routine, in contrast to special commands that would require shutting down the computer system. This statement is consistent with a construction that includes reference to operating system routines that respond to application programs, in that a special command, by definition, does not utilize this process. See Derringer Decl., Separate Appendix, Vol.1, p. App. 0170 (The "operating system forbids access to "special commands" by the application program."). Thus, the inclusion of reference to "special commands" is unnecessary.

Accordingly, the Court construes this term as "a command sent by the operating system to a peripheral device in response to an initiator peripheral device request sent by an application program to the operating system, and which causes the peripheral device to enter a waiting state ready to receive new microcode."
penetration of the ink to the back surface such that the ink resides on the back surface of the sheet - not through the back sheet. We agree with the trial court's construction that ink must reside on or at the back surface of the sheet - but does not have to permeate through the back surface of the sheet.

--- Footnotes ---
n3 In so construing this claim limitation during a hearing on summary judgment (of invalidity under the on-sale bar and of co-ownership), the trial court noted that, prior to claim construction, it had "met with the parties and received a list of those phrases and aspects of claims that were in dispute, and this was not one of them." During the summary judgment hearing, then, the court construed the limitation. "There is no question[] in my mind . . . that that claim . . . requires the ink to be on or at the back surface." While an argument could have been made that the government waived any disagreement with the court's construction, it was not made. Moreover, liability turns on the correctness of the construction. Hence, we will review it.

-- End Footnotes --

The claim language itself of the limitation "ink permeates through the sheet from said printed front surface to said back surface to provide the indicia in mirror image form on said back surface" supports the trial court's interpretation. While it is true that the claim limitation contains the term "through," this word cannot carry the government's argument. For example, claim 10 states that the ink permeates "through the sheet" - not "through the back of the sheet." Claim 10 further explains how far the permeation goes - "from said . . . front surface to said back surface." Thus, the ink travels to the back surface of the sheet - not through the back surface of the sheet. Thus, the claim language provides no support for the government's argument. Indeed, it refutes the argument.

The specification further bolsters the correctness of the trial court's construction. In the Description of a Preferred Embodiment, the written description discloses that the ink "permeat[es] from the upper to lower surface of the top sheet." '283 patent, col. 5, ll. 19-20. Later, the written description explains what "through the sheet" means and how far the ink must travel - "the ink permeates through the top sheet from its front surface to its back surface." Id. at col. 7, ll. 49-51 (emphasis added). In yet another instance, it teaches that the ink "permeat[es] through the paper sheet . . . from the front to the back." Id. at col. 7, ll. 56-57 (emphasis added). Thus, in each instance, the specification explains how far the ink permeate[s] - through the sheet, but only to the back of the sheet - not through the back of the sheet. Nor does the prosecution history require a different construction.

The extrinsic evidence of dictionary definitions supplied by Paymaster strengthens this distinction between "to" and "through" as well. "To" means: "in a direction toward," "reaching as far as," "to the degree or extent of," "towards a specific state," "in contact with," and "in front of." Webster's II New College Dictionary (2d ed. 1999) (emphasis added). These definitions indicate that "to" means something that has not penetrated through another thing, but rather something that travels "toward something" and "contacts" it to be "in front of" it. The government does not supply contrary definitions of "to" and does not offer any definitions of "through."

Moreover, the government's argument is impractical, for if the ink came out the back side of the sheet, it would smear the surface below. Therefore, it is difficult to understand how the government can expect us to accept its argument which lacks support in the claims, the written description, dictionaries, and practicality.

GO BACK

2206

1. Input

The first element of claim 1 provides: "A method for generating an input to a physical system to minimize unwanted dynamics in the physical system response ..." (635 patent Col. 10 lines 41-42) (emphasis added).

Plaintiffs allege that the term "input" encompasses any "information that is delivered to the system from outside the system", relying on the plain dictionary definition of the term. (Pls.' Claim Construction Br. At 39). The dictionary definition of "input" is "data or similar information fed into a computer or accounting machine." Merriam-Webster's Third
New International Dictionary Unabridged, Merriam-Webster, Inc., 1993. 6 Defendants respond, relying principally on the specification, that an "input" is "the second signal that is applied to a control system to cause a desired action in the control system such that the altering of the first signal to create the second signal is unaffected by the actual action of the control system." (Joint Claim Construction and Prehearing Statement at Exhibit B, '635 Patent 1). The principal distinction in defendants' definition is that the signal sent to the physical system is "an altered signal generated outside the control loop." (Defs.' Proposed Claim Construction Order for U.S. Patent Nos. '635; '267 and '473 at 10). Defendants seek to exclude situations where the input shaping is performed within the control loop. The control loop is a configuration where a system receives an input, acts in response to it, then measures whether the system reached the desired state. If the system did not respond as anticipated, then the system is adjusted repeatedly until the correct state is reached.

6 While this definition has not been offered into evidence by either party, dictionaries are usable "As resources and references to inform and aid courts and judges in the understanding of technology and terminology . . . at any stage of a litigation, regardless of whether they have been offered by a party in evidence or not." Texas Digital Sys. V. Telegenix, Inc., 308 F.3d 1193, 1203 (Fed. Cir. 2002).

The plain meaning of "input" is consistent with its use throughout the patent. Particularly relevant are two uses in claim 11. The preamble provides: "Method for shaping an arbitrary command input to a dynamic physical system . . ." ('635 patent Col. 11 lines 17-19). The third element provides: "controlling the physical system based on the shaped command input . . ." ('635 patent Col. 11 lines 24-25). Any interpretation of the term "input" must be consistent across these uses. There is a "presumption that the same terms appearing in different portions of the claims should be given the same meaning unless it is clear . . . that the terms have different meanings at different portions of the claims." Fin Control Systems Pty, Ltd., v. OAM, Inc., 265 F.3d 1311, 1318 (Fed. Cir. 2001). The use in the preamble of claim 11 clearly indicates that the "input" therein is the input to the physical system that is going to be shaped, as the second element provides that the input is shaped by "convolving the impulse sequence with the arbitrary command input." ('635 patent Col. 11 lines 22-23). The use in the third element is modified by "shaped command," indicating that the input has been shaped as disclosed in the first two elements. The plain meaning of "input" offered by plaintiffs is consistent with all these uses. "Input" covers, generally, a piece of information which is delivered to a system. In the preamble of claim 11, this input is the unshaped input to a physical system which the invention addresses. In element three, it is the shaped element produced by the invention.

Defendants offer two main arguments for their proposed construction. The first is that the patent only discloses a system where the shaped command input is generated outside the control loop. (Defs.' Responsive Claim Construction at 11). An inquiry into whether or not a patent adequately discloses an invention is a question of validity. See, e.g., Moba v. Diamond Automation, 325 F.3d 1306 (Fed. Cir. 2003). It is improper to determine validity before properly constructing the claims. See Markman, 52 F.3d 967. It is apparent that plaintiffs have not disclaimed the situation where input shaping is performed within the control loop. Whether or not they have adequately disclosed a method which can be used within the control loop is question of validity. Plaintiffs have asserted a construction that is supported by the plain language of the specification, and accordingly bear the risk that the patent will subsequently be found invalid.

Defendants' second argument is that Plaintiffs' construction "would necessarily cover an unaltered input that would result in the very unwanted vibrations the alleged inventions are intended to eliminate." (Defs.' Responsible Claim Construction at 10). This assertion lacks merit. Adopting plaintiffs' construction merely indicates that an "input" follows the plain and ordinary meaning of the term. Concerns that the patent will be broadened beyond what is claimed, "a method for generating an input . . . to minimize dynamics," are unfounded as infringement requires that each limitation of the claim be met, either literally or under the 'doctrine of equivalents.' See Frank's Casing Crew & Rental Tools, Inc., v. Weatherford Int'l, Inc., 389 F.3d 1370, 1377 (noting "literal infringement requires that each and every limitation set forth in a claim appear in an accused product"); Riles v. Shell Exploration and Production Co., 298 F.3d 1302, 1309 (stating "infringement under the doctrine of equivalents requires that the accused product contain each limitation of the claim or its equivalent.") An accused infringer must meet the other limitations of the claim in order to infringe, including that the method "minimize unwanted dynamics." If an input does not "minimize unwanted dynamics," then it is not covered by claim 1 because it has failed to meet all the elements of that claim.
Accordingly, plaintiffs' proposed construction for the term "input" is adopted. The term "input," as used in independent claims 1, 11, 21, and 24, and dependent claim 2, is interpreted to mean: "information that is delivered to the system from outside the system."

D. "an input port and an output port"

1. The Parties' Proposed Constructions

The parties' dispute whether the claim language "an input port and an output port" requires separate input and output ports, or just a single port capable of performing both input and output functions. In contrast with its argument regarding "video image," Ampex argues that "input port" and "output port" should be construed separately, rather than in the context of the phrase used in the claims. (D.I. 300 at 34.) Ampex proposes that "port" should be construed to mean "an interface between a communications channel and a unit of computer hardware." (D.I. 305 at 42.) In accordance with this construction, Ampex asserts that "input port" means "a port for inputting data into the claimed random access memory," and "output port" means "a port for outputting data from the claimed random access memory." (Id.) Ampex bases its construction on a technical dictionary definition of "port" and the ordinary meaning of "input" and "output." (D.I. 300 at 34.) Ampex also argues that a RAM with separate input and output ports had a specialized name at the time the '121 patent was filed, and that there is no intrinsic evidence to support reading that narrower term into the claims. (Id.)

Defendants assert that "an input port and an output port" should be construed as one phrase meaning a random access memory with "an input port and a separate output port." (D.I. 305 at 42.) Defendants' proposal relies on the language of the claim and the one drawing included in the specification of the '121 patent. (D.I. 299 at 16.) Defendants also set forth a claim differentiation argument in support of their claim construction. (Id. at 16-17.)

2. The Court's Construction

Although the specification does not state that the random access memory has any particular input or output structure, the language in claims 8 and 14 imposes a limitation. Claims 8 and 14 disclose an apparatus that includes a "random access memory means having an input port and an output port." (121 Patent at 6:53-54, 9:1-2.) These claim recite an input port and an output port, which suggests that the input port is "structurally distinct" from the output port. Cf. Gen. Am. Transp. Corp. v. Cryo-Trans, Inc., 93 F.3d 766, 769-70 (Fed. Cir. 1996) (holding that claim language requiring "openings ... adjacent each of said side walls and ends walls' ... suggests that the openings adjacent to the side walls are structurally distinct from the openings adjacent to the end walls" (original emphasis)). Thus, the plain language of the claims favors Defendants' proposed construction.

Defendants' position that the language in claims 8 and 14 requires separate input and output ports is also supported by the lack of any similar language in claim 7. The doctrine of claim differentiation is often cited for "the presumption that an independent claim should not be construed as requiring a limitation added by a dependent claim." Curtiss-Wright Flow Control Corp. v. Velan, Inc., 438 F.3d 1374, 1380 (Fed. Cir. 2006). But, there is also "a presumption that two independent claims have different scope when different words or phrases are used in those claims." Seachange Int'l, Inc. v. C-Cor Inc., 413 F.3d 1361, 1369 (Fed. Cir. 2005). It must be noted that the doctrine is "'not a rigid rule,'" and it has been applied cautiously so that parties cannot "'broaden claims beyond their correct scope.'" Curtiss-Wright, 438 F.3d at 1381 (quoting Laitram Corp. v. Rexnord, Inc., 939 F.2d 1533, 1538 (Fed. Cir. 1991); Fantasy Sports Props., Inc. v. Sportsline.com, Inc., 287 F.3d 1108, 1115 (Fed. Cir. 2002)). This concern arises primarily when a party argues that one independent claim must be broader than another because of differences in the claim language. See, e.g., Seachange, 413 F.3d at 1369 (holding that the difference in claim language creates a presumption that one independent claim does not require the limitation present in another independent claim). However, in this case, Defendants argue that an independent claim must be narrower than another because it contains language that is not present in the other independent claim. Therefore, the usual concern with applying claim differentiation is not present in this case, and, as a result, the differences between the claims may serve as a "useful guide in understanding the meaning of particular claim terms." Phillips v. AWH Corp., 415 F.3d 1303, 1314 (Fed. Cir. 2005).
As previously discussed, claims 8 and 14 of the '121 patent recite an apparatus comprising, among other elements, a "random access memory means having an input port and an output port." ('121 patent at 6:53-54, 9:1-2.) Claim 7 also describes an apparatus with a "random access memory means," but makes no reference to any input or output ports. (Id. at 6:27-31.) The parties appear to agree that a random access memory must have input and output capability. (D.I. 299 at 16; D.I. 300 at 34-35.) Furthermore, both parties submit that, at the time the patent was filed, a random access memory could have a single port with both input and output capability, or a separate input and output port. (D.I. 346 at 20; D.I. 348 at 29.) Therefore, according to the parties, no language was necessary to specify that the random access memory in claim 7 had input and output capability. This supports Defendants' proposition that the additional language in claims 8 and 14 serves to specify one of the available input/output structures, namely separate input and output ports.

Ampex argues that this is not the proper construction because a random access memory with separate input and output ports was called a "dual-ported RAM," and that this specialized term does not appear in any of the intrinsic evidence. (D.I. 300 at 34-35; D.I. 346 at 20.) While that is true, the language that does appear in claims 7, 8, and 14 favors Defendants' proposed claim construction. Therefore, I will construe the phrase "an input and an output port" to mean "an input port and a separate output port."

Broadcom argues that "input data" should be construed as "information received from an external source," which would include data sent directly to the two encoders but not data passing through the first encoder and entering the second. Agere argues for the construction "data-bearing bits," which would include all data other than output data. 69

69 The limitation that Agere's construction would not include output data is asserted by Agere alone and belied by the plain text of Agere's construction. Because the Court rejects this construction on other grounds, however, it need not determine whether its overbreadth is also fatal. In addition, the Court need not reach the issue of whether Agere's construction impermissibly reads the word "input" out of the claim term, but the Court notes that even Agere's own expert, Dr. Fuja, does not entirely concur with the omission of this word. (See Fuja Rep. P 33 (defining term as "'data-bearing bits' input into a particular system to attain an output" (emphasis added)).

The claim language clearly supports Broadcom's construction. Claims 1 and 11 describe a process in which some of the "input data" is redundancy encoded "to provide a first encoded signal," and other portions of the "input data" are combined with the first portion of that "first encoded signal" using another redundancy code. This language clearly differentiates between the "input data," which is that data sent directly to the two encoders, and the "first encoded signal," which is the data sent from the first encoder to the second encoder. Agere's construction attempts to obliterate this distinction by including the "first encoded signal" within the definition of "input data." Accordingly, the Court rejects Agere's construction as inconsistent with the claim text at issue.

By contrast, Broadcom's construction maintains the distinction between "input data," i.e., data from an external source, and the "first encoded signal," which would not be input data because it is produced internally. Broadcom's construction is also supported by the testimony of Dr. Heegard and at least three dictionary definitions in effect at the time of the patent. (Heegard Rep. at 19 (citing IEEE dictionary definition as "data received from an external source," McGraw-Hill dictionary definition as "information . . . from the external world," and Webster's dictionary definition as "information fed into a computer").) Agere's expert, Dr. Fuja, provides no evidence to counter Dr. Heegard's conclusions except for a dictionary citation taken from a 2001 dictionary, nine years after the '551 patent was filed. (Fuja Rep. P 33.) Accordingly, the Court credits Dr. Heegard's conclusion that a person of ordinary skill in the art would agree with Broadcom's construction, and that construction is therefore adopted. 70
70 In its supplemental brief, Agere appears to argue for a new construction of this term as "data received directly or indirectly from an external source." (Agere Supplemental Br. at 16.) This "directly or indirectly" language, however, is ambiguous and dodges the substantive issue at hand. In addition, the Court notes that Agere's oft-repeated argument that the data emerging from the first encoder is "mostly" or "almost entirely" input data (id. at 15; see also Wei Dep. at 174 (stating that first encoded signal "includes" input data)), fails because it would defy logic to construe the term to include this data when even Agere tacitly admits that is not entirely input data.

This phrase means: "any input device used to prepare or submit bids."

---

# 2210

# 1 -- "input device" -- (appears in claims 14, 15, 17, 19, 29, 30, 32, 34, 44 and 45) Luma's Construction (Luma May 4, 2005, p.1).

MASTER'S CONSTRUCTION

# 1 -- "input device" -- means a device for generating, obtaining or acquiring an image during a medical procedure.

REASONS

INTRINSIC EVIDENCE

The Patent claim 14 recites "input device for obtaining said images". (Col. 48, L.13). The preamble of the claims state the images are those images acquired during a medical procedure. (Col. 48, Ls. 11-12). The Specification of the Patent has a number of references to "input device". A few examples:

(i) a system for acquiring images during a medical procedure" (Col. 1, Ls. 28-30);

(ii) images obtained by an input device (Col. 1, L. 32); and

(iii) "images generated by * * * image input devices" (Col. 5, Ls. 46-47).

The ordinary meaning of the term "input device" as used in context of the Patent in the Specification and claims has been applied. This is what a person of ordinary skill in this art would understand the term to mean.

The construction is consistent with the file history. Applicant for the Patent stated operation of input devices that acquire images during a medical procedure such as an endoscopy (Applicant's Response Bates LUM 0000204) to Examiner's Action dated January 30, 1995, p. 7 under "REMARKS" P 2, Ls. 4-5, p. 8, Ls. 2-3; 3RD P, L.5; p. 9, L.5. The Examiner refers to input devices such as endoscopes for obtaining medical imaging data (Office Action (Bates LUM 0000403) dated

- 2586 -

EXTRINSIC EVIDENCE

Testimony given by Branson is consistent with the above intrinsic evidence in the Patent (Markman Hearing, Branson, Tr. 35:24 - 36:3).

LUMA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

Luma's Construction (Luma May 4, 2005, p. 1) and the Master's Construction are consistent. The Master added "generating" in the disjunctive to the construction.

STRYKER'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

Stryker's position is set forth in (Stryker May 23, 2005, p. 1). Stryker states that Luma does not address the position Luma took in a summary judgment that ultrasound devices cannot be an "input device" because ultrasound devices do not obtain images. (Stryker May 23, 2005, p. 1).

Stryker points out that the Patent refers to an ultrasound device as an "input device". (Citing Patent, Col. 6, Ls. 9-19).

Interesting Issue

If an ultrasound scanner would not generate, obtain or acquire an image then an ultrasound scanner would not be within the Master's Construction of "input device". However, the intrinsic evidence (the Patent) states that "input device" includes an ultrasound scanner. The Master construes that the "input device" must be capable of either obtaining, acquiring or generating an image. The Master does not decide whether an ultrasound scanner can or cannot generate, obtain or acquire an image.

KSEA'S POSITION AND MASTER'S COMMENTS ON THAT POSITION

KSEA's position is set forth in (KSEA May 23, 2005, Sheet 2).

KSEA wants the word "generating" inserted into the construction. The Master agrees. "Generating" as indicated above is found in the Patent when describing the "input device". Generating is part of a function of the "input device".

KSEA proposes that in order for a dispute over the this claim element to be resolved KSEA proposes that image refers to two-dimensional representation of an object (KSEA's May 23, 2005 Sheet 2, Paragraph 2). The Master disagrees. There is nothing found in the intrinsic record (the Patent) that would require a limitation of limiting the "input device" to one generating a specific image such as a two-dimensional representation.

B. "Input Entries"

The term "input entries" as found in claim 20 presents a more contentious dispute. Defendants propose that "input entries" be construed as "[f]eatures that allow a user to enter information into a page, such as text entry fields, icons, menu items, and check-fields." MShift, by contrast, proposes that "input entries" be more broadly construed as "[f]eatures that allow a user to provide input." As its briefing makes clear, plaintiff intends its proposed construction to encompass descriptive labels that accompany text entry fields as well as hidden data not even displayed to depositors on a web page.

As a preliminary matter, both sides agree that the features encompassed by defendants' proposed construction — namely, features that "allow a user to enter information into a page, such as text entry fields, icons, menu items, and check-fields" — are "input entries" within the meaning of the '881 patent. Indeed, the specification expressly lists "text-entry fields, icons, check-fields assigning Boolean values, and selectable items provided in a menu" as specific examples of "input features"
Where the parties diverge, however, is on whether "input entries" can extend beyond "features that allow a user to enter information into a page" to labels and hidden form elements that are never displayed on a web page. As explained below, the intrinsic evidence does not support such a broad construction. First, the ordinary and customary meaning of the term "input entries" to a person having ordinary skill in the relevant art supports defendants' narrower construction. Indeed, MShift's own expert, Dr. Sandeep Chatterjee, who is proffered by plaintiff as being someone with ordinary skill in the relevant art, conceded in his declaration that "defendants' proposed construction of "input entries" provides more detail and clarity [than plaintiff's proposed construction], which is consistent with and supported by the patent" (Chatterjee Claim Const. Decl. ¶ 27). Dr. Chatterjee no doubt recognized that plaintiff's proposed construction lacked sufficient detail and clarity and could be used to improperly cover web page features that did not allow a user to enter information into a page.

Second, plaintiff's proposed construction would improperly cover features that the specification clearly indicated were not "input entries." As stated, the specification made frequent reference to mobile devices that used HDML to request and receive content from network sites. In this connection, the specification expressly recognized that HDML was "limited to displaying a single input feature per rendered network page" (col. 7:48-53) (emphasis added). Displaying multiple selectable links on the same page, however, was clearly not a problem for HDML-based mobile devices. This can be concluded because the restructuring of a plurality of input entries into multiple selectable links was exactly the workaround proposed by the '881 patent to bypass the "single input feature" problem. As such, "selectable links" are clearly not "input features" or "input entries" within the meaning of the '881 patent. The specification also made clear that the physical buttons on a mobile device and "wording or graphics" on a web page were not "input entries" (see cols. 4:5-10, 8:30-34). Plaintiff's proposed construction, however, could easily be used to cover "selectable links," "wording or graphics," and the physical buttons on a mobile device due to its overly broad wording. This would be improper. By contrast, defendants' proposed construction more closely tracks what the term "input entries" was intended to cover in light of the intrinsic evidence: features displayed on a web page, like text entry fields, menu items, and check fields, that allow a user to enter information into the page (see col. 7:50-58).

Third, the prosecution history — and in particular, MShift's representations to the USPTO to distinguish the claims of the '881 patent from the prior art — provides the final nail in the coffin for plaintiff's proposed construction. To allow MShift to expand the meaning of "input entries" beyond its HDML (or equivalent) context would enable plaintiff to recapture territory that it surrendered during the course of prosecuting the asserted patent. As stated, the Schwartz and Jamtgaard references disclosed the use of a conversion engine between mobile devices and network sites to reformat web pages, translate between different programming languages, and "break up" content into multiple pages using selectable links (see Yamashita Claim Const. Decl. Exhs. 1, 3). 10 After the USPTO repeatedly rejected its patent application due to these prior art references, MShift finally obtained the '881 patent by arguing to the patent examiner that the Schwartz and Jamtgaard references did not teach the particular "restructuring" of "input entries" — necessitated by the inherent limitations of HDML — as set forth in the claims. To allow MShift to now expand the meaning of "input entries" to encompass mere labels and other web-page features that do not allow a user to input information into the page would be improper in light of this history. See Phillips, 415 F.3d at 1318 (citations omitted).

--- Footnotes ---

10 Specifically, the USPTO recognized that Schwartz disclosed a conversion engine capable of translating between different programming languages (see Yamashita Claim Const. Decl. Exh. 6, col. 8:55-67), while Jamtgaard disclosed a system that could reformat Internet content for mobile devices by breaking the content into pieces and using selectable links to navigate between them (id. at Exh. 5, col. 18:23-39).

--- End Footnotes ---

For these reasons, this order construes "input entries" as "features displayed on a web page that allow a user to enter information into the page, like text entry fields, menu items, and check fields."
For the same reasons given above, the Court rejects both parties' proposed constructions. The Court construes "input key" to mean "a user-actuated input device, which allows the user to choose one of two options, e.g., select or deselect, such as a keyboard key, for changing the value of one of the hue, lightness, and saturation values."

a. "an input keyboard"
AMI contends that “an input keyboard” means “an interface for selecting a song to be played.” Opening Brief at 32. It contends that there is no limitation upon the form the input keyboard can take, and that the specification “expressly contemplates that the input keyboard may be an electronic keyboard with depressible keys or a touchscreen” because it teaches that “the input keyboard may also be replaced by a touchscreen.” Resp. Brief, Ex. 18 at 4:26-28. Ecast argues that the specification language cited by AMI actually differentiates an input keyboard from a touchscreen. In other words, because the specification discloses that a touchscreen is an alternative to an input keyboard, an input keyboard cannot be a touchscreen.

The specification repeatedly teaches that the keyboard is distinct from the screen. For example, “[i]nput/output unit 20 is connected by way of a line 22 with a viewing screen 24 which constitutes the display ... moreover, input/output unit 20 is connected by way of a line 26 with an input keyboard 28.” Id. at 4:13-20. “The selection instructions fed in by way of the input keyboard are displayed on viewing screen 24 ....” Id. at 4:20-21. “This jukebox includes a housing 40 which is provided with a viewing screen 24 and an input keyboard 28.” Id. at 4:50-53. In addition, figures 1 and 2 both depict the keyboard as separate from the viewing screen. For these reasons, construing the input keyboard to be the screen would be inconsistent with the specification.

The specification's teaching that the input keyboard can be replaced by a touchscreen appears to mean exactly what it says: instead of an input keyboard, the device can utilize a touchscreen. That is not the same thing as saying that the input keyboard can be a touchscreen. Nor does it mean that the patentee claimed such an invention. If AMI wanted the claim to include a visual touchscreen and a keyboard, it easily could have said so.

For these reasons, the Court construes “an input
keyboard" as used in claim 1 of the 350 patent to mean “a hardware device consisting of a number of mechanical buttons (keys) which the user presses to input characters to a computer.”

Claims 1, 3, and 12 of the '183 patent contain the term "user input device for receiving signals from a user" and claims 21, 24, 56, and 59 of the '412 patent contain the term "input means for receiving signals from a user." IPI suggests that the term "input device" means "a keyboard, mouse, or other pointer control device," and Defendants argue the term is restricted to a "mouse or keyboard." IPI further contends that "input means" should be construed the same as "input device," while Defendants urge that the term is a means-plus-function limitation with a function of "receiving signals from a user" and a structure consisting of a "mouse or keyboard, and their equivalents."

IPI first contends that "input" connotes sufficient structure to remove the term "input means" from 35 U.S.C. § 112 P 6. Essentially, IPI argues that since the phrase "input signals for receiving signals from a user" is understood by one skilled in the art, that the related phrase "input means for receiving signals from a user" should be construed similarly.

There is a presumption that terms containing the word "means" are governed by § 112 P 6. TriMed, Inc. v. Stryker Corp., 514 F.3d 1256, 1259 (Fed. Cir. 2008). IPI provides no intrinsic evidence overcoming this presumption. The simple fact that the patentee included a similar phrase in a different patent does not constitute evidence of inherent structure. Additionally, as Defendants note, IPI's reliance on Verizon California Inc. v. Ronald A. Katz Technology Licensing, L.P. is misplaced. See 326 F. Supp. 2d 1060, 1086-87 (C.D. Cal. 2003). There, the parties agreed that the term "digital input means" was not governed by § 112 P 6 and the court was not clearly presented with the issue disputed here. There is nothing in the claims or the specification to suggest that "input means for receiving signals from a user" inherently discloses sufficient structure to remove it from § 112 P 6. Thus, the Court construes the term under § 112 P 6.

The parties further disagree over whether the definition of an "input means" and "input device," should include "other pointer control devices." In addition to a keyboard and a mouse, the specification clearly discloses "other pointer control devices" as a way that a user interacts with the computer. See '412 Patent at 1:23-28; 34:38-41. Defendants' only argument for excising this phrase from the definition of the disputed terms is that the scope of the phrase is already captured by § 112 P 6 equivalence. 2 However, the applicability of § 112 P 6 requires that a means-plus-function term be given the full scope of the structure described in the specification. 35 U.S.C. § 112 P 6 ("such claim shall be construed to cover the corresponding structure, material, or acts described in the specification"). In addition, principals of claim construction generally require courts to give effect to the full scope of the invention described in the specification. Home Diagnostics, Inc. v. LifeScan, Inc., 381 F.3d 1352, 1357 (Fed. Cir. 2004). Accordingly, "input means" is governed by § 112 P 6 with a function of "receiving signals from a user" and a structure of "a keyboard, mouse, or other pointer control device, and their equivalents." The term "input device" is defined as "a keyboard, a mouse, or other pointer control device."

2 Defendants' briefing discusses that the scope of "other pointer control devices" is captured by the doctrine of equivalents. However, as the doctrine of equivalents pertains to the issue of direct infringement, the Court assumes that Defendants are referring to § 112 P 6 equivalence.

1. "input means"

The term "input means" appears in six claims, in each of the '995, '932 and '705 Patents. Claim 1 from the '995 Patent is representative:

1. An audio/video transceiver apparatus comprising: input means for receiving audio/visual source information;

   compression means, coupled to said input means, for compressing the said audio/video source information into a time compressed representation thereof having an associated time period that is shorter than a time period associated with a real time representation of said audio/video source information;

   random access storage means, coupled to said compression means, for storing the time compressed representation of said audio/video source information; and

   output means, coupled to said random access storage means, for receiving the time compressed audio/video source information stored in said random access storage means for transmission away from said audio/video transceiver apparatus.

In support of its view that "input means" is not a means-plus-function term, Burst asserts that the word "input" connotes a certain set of structures to one ordinarily skilled in the art, specifically an "input port or terminal capable of receiving information." It offers several dictionary definitions to support this reading. See Cole v. Kimberly-Clark Corp., 102 F.3d 524, 531 (Fed. Cir. 1996) (relying on dictionary definitions for similar purpose). These include "the device or collection of devices used for bringing data into another device." IEEE Standard Dictionary of Electrical and Electronic Terms 474 (4th ed. 1988). A second, more specific dictionary definition states that "input" is "the terminals, jack, or receptacle provided for the introduction of an electrical signal or electric power into a device or system." Modern Dictionary of Electronics at 495. Significantly, Figure 2 in the patent specifications uses "input" and "input/output ports" interchangeably; this supports Burst's contention that "input" connotes a specific type of port or device. See, e.g., '995 Patent at Fig. 2. Burst's expert, Dr. Hemami, further explains that the term "connotes a physical port or terminal on a device through which information is received" to a person of ordinary skill in the art. Hemami Report at 29-30. At the Markman hearing, the experts agreed that a certain subset of the input devices listed in the Modern Dictionary of Electronics could all perform the functions described in the claim. Apple's expert observed that one ordinarily skilled in the art would need to know the speed of the information to be received in order to select an electrical jack capable of performing the function of the input means. Burst's expert responded that information in the specification regarding the compression and the type of audio/video information would permit one ordinarily skilled in the art to select the correct jack.

Apple argues that the word "input" is not a structural term and would have the court apply section 112(6) to identify four different sets of structures for the various uses of "input means." Apple contends that "input" is insufficiently definite because it includes "every conceivable way or means" of receiving audio/video source information. Mas-Hamilton Group v. LaGard, Inc., 156 F.3d 1206, 1214 (Fed. Cir. 1998); see also Laitram, 939 F.2d at 1536. n5 The word "input" is not as indefinite as the phrase "lever moving element" which would apply to "any device that can cause the lever to move." Mas-Hamilton, 156 F.3d at 1214 (holding that section 112(6) applies to the term "lever moving element" because "moving element" does not connote sufficient structure). The dictionary definitions provided for "input" are more limited here. Moreover, even when a structure is described in terms of its function, it is still a sufficient structure if the "term, as a name for structure, has a reasonably well understood meaning in the art." Greenberg, 91 F.3d at 1583 ("detent" defined by its function but not subject to means-plus-function analysis because it has a generally understood structural meaning in the mechanical arts) (emphasis added). Here, Burst has satisfied the court that the term "input" connotes a structure in the relevant field.

--- Footnotes ---

n5 In Laitram, the Federal Circuit held that the district court erred by construing what was essentially functional language as structure. 939 F.2d at 1536. The district court concluded that the following language was the structure:

   of said holes of said plurality are arranged coaxially, the axes of the holes of said second plurality are arranged coaxially and the axes or respective holes of both pluralities of link ends are substantially.
for the term "means for joining said pluralities to one another." Laitram Corp. v. Rexnord, Inc., No. 87-C-110, 1990 WL 71418, *13 (E.D. Wis. Apr. 26, 1990). It was this alleged structure that the Federal Circuit concluded was insufficient because it encompassed "any and every means" for performing the function. Laitram, 939 F.2d at 1536.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - - - -

Several other considerations weigh in favor of concluding that "input," as used in the patents, is a structural term. First, the structure of the "input" supports the described function. Here, the "input" supports the described function of "receiving of audio/video source information." Also, description of a purported structure's location supports the conclusion that section 112(6) does not apply. Cole, 102 F.3d at 53 (relying on location of the structure to conclude that lamn element with such a detailed recitation of its structure, as opposed to its function" cannot be a means-plus-function term). The specification describes the location of the "input means." Compare Cole, 102 F.3d at 531 (describing the location of the "perforation"as "extending from the leg band to the waist band") with '995 Patent at 10:62 ("compression means, coupled to said input means"). Thus, the court finds that Burst has overcome the presumption that section 112(6) applies; "input means" is not a means-plus-function term.

Apple offers no construction for "input means" other than its proposed construction of the term pursuant to section 112(6). Burst construes the phrase to mean "an input port or terminal capable of receiving audio/video source information." Burst's proposed construction is consistent with the dictionary definitions and expert testimony. Accordingly, the court adopts this construction: "input means" is "an input port or terminal capable of receiving audio/video source information."

2216

1. "Input Portion"

Claims 1 and 17 of the '148 Patent recite a signal conditioning apparatus containing two broad elements, an input portion and an output portion. Fiori asserts that the input portion of claims 1 and 17 are identical and clearly defined in the specification as an operational amplifier such as operational amplifier 63, which functions as a preamplifier. n9 (Pl.'s Markman Br. at 20.) The operational amplifier is configured to receive an electrical signal from a signal conductor. n10 The operational amplifier generates an intermediate signal which is proportional to the potential difference between the received electrical signal and the reference signal. Id. Fiori claims that this is illustrated and described in the specification as the output of the operational amplifier (e.g., 63) and the ground reference potential signal 18. Id.

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

n9 The preamble to claim 17 recites a signal communication system including a source device, destination device and a signal conditioning device identical to claim 1 of the '148 Patent. The '148 Patent, column 9.

n10 This process is exemplified as the wire leading from element 16 and a correspondence reference signal from a signal conductor. This is shown as the ground reference potential signal conductor at point 18.

- - - - - - - - - - - - End Footnotes- - - - - - - - - - - -

Defendant Rockford disagrees. Rockford argues: (a) that the phrase "input portion" of claims 1 and 17 of the '148 Patent is a "means-plus-function" limitation under 35 U.S.C. § 112 (6), whose structure includes a power supply transformer because isolation is required to perform the recited function, and the transformer provides isolation; n11 (b) the term "proportional" of claims 1 and 17 permits different gain factors; and (c) the term "input portion" of claims 1 and 17 requires the signal source to be physically located in a separate mechanical housing as the source of electrical signals because the claims do not limit the location of the sources. (Def.'s Markman Br. at 11.)

- - - - - - - - - - - - Footnotes - - - - - - - - - - - -

n11 Rockford further asserts that in the presence of a function and the absence of a structure, the phrase "generating an
"intermediate electrical signal" of the input portion is subject to the 35 U.S.C. § 112 (6) analysis as well. (Def.'s Markman Br. at 13.) Rockford claims that this phrase is in "means-plus-function" format even though it does not use the word "means" because the claim language fails to identify a structure for performing that function. Id. Rockford points to extrinsic evidence, such as Fiori's Proposed Markman Constructions at 7, Fiori Deposition at 2548, and Fiori's Technical Brief at 6 to assert that in order to perform the function of "generating the intermediate electrical signal," the input portion (op-amp 63) must be isolated from the output portion (op-amp 65), as well as to argue that the necessary components and corresponding structure to perform the "generating" function include op-amp 64, resistors 10, 11, transformer 32, diodes 14, 15, and capacitors 12, 13. Id. at 15.

--- End Footnotes ---

a. Means-Plus-Function Limitation

In certain circumstances, pursuant to 35 U.S.C. § 112(6), n12 a claim element can be expressed as a means for performing a specified function without reciting structure or material. 35 U.S.C. § 112 (6) (1984). Whether an element of a claim is in means-plus-function form is a claim construction question. Wenger Mfg. v. Coating Mach. Sys.,239 F.3d 1225, 1231 (Fed. Cir. 2001). Use of the term "means" creates a presumption that the element is to be construed in accordance with 35 U.S.C. § 112 (6). Altiris, Inc. v. Symantec Corp.,318 F.3d 1363, 1375 (Fed. Cir. 2002). This presumption may be rebutted, however, when the claim element recites sufficiently definite structure or material to perform the claimed function. Id. Conversely, absence of the term "means" creates a presumption that the element is not to be construed in accordance with 35 U.S.C. § 112 (6). Id. However, this presumption may be rebutted when the claim element does not recite sufficiently definite structure or material to perform the claimed function. Id. In determining whether these presumptions have been rebutted by a preponderance of the evidence, the court may examine the intrinsic evidence and any relevant extrinsic evidence. Personalized Media Commun., L.L.C. v. ITC, 161 F.3d 696, 704-05, (Fed. Cir. 1998).

--- Footnotes ---

n12 35 U.S.C. § 112 (6) provides as follows:

An element in a claim for a combination may be expressed as a means or step for performing a specified function without the recital of structure, material, or acts in support thereof, and such claim shall be construed to cover the corresponding structure, material, or acts described in the specification and equivalents thereof.

--- End Footnotes ---

Rockford correctly asserts that 35 U.S.C. § 112 (6) can be triggered even if the claim does not use the word "means." See Raytheon Co. v. Roper Corp., 724 F.2d 951, 957 (Fed. Cir. 1983). "Nonetheless, the use of the term 'means' has come to be so closely associated with 'means-plus-function' claiming that it is fair to state that the use of the term 'means' (particularly as used in the phrase 'means for') generally invokes section 112(6) and that the use of a different formulation does not." I. Melbourne Greenberg, M.D. v. Ethicon Endo-Surgery, Inc., 91 F.3d 1580 (Fed. Cir. 1996). In the present case, "means-for-function" language is expressly used in only three instances in the five (5) claims of either of the patents-in-suit. n13

--- Footnotes ---

n13 Plaintiff implements the language in a section of the output stage of claims 1 and 17 of the '148 Patent and as part of the voltage regulation of claim 38 of the Reissue Patent.

--- End Footnotes ---

As a matter of law, claim construction is the duty of the court. Markman, 52 F.3d at 973. This Court does not find that "input portion" is a means-plus-function limitation under 35 U.S.C. § 112 (6) whose structure includes a power supply transformer because isolation is required to perform the recited function, and the transformer provides isolation. This Court finds that the input stage of claims 1 and 17 are specifically defined physical structures. Moreover, it is defined in the specification and file history as an operational amplifier such as op-amp 63. The structure is specifically connected to two conductors.
(physical structures) and is recited as generating the intermediate signal. Nowhere is the element referred to in terms of its functionality in the specification. Accordingly, Rockford's "means-plus-function construction" of the phrase "generating an intermediate electrical signal" is erroneous. There is no evidence that Fiori "intended to claim in means-plus-function fashion" except in those places identified by Plaintiff. Id. at 1584.

TiVo argues no construction of these terms is needed, or, if construed, should be limited to the definition of "Input Section" as "hardware and/or code that changes or adapts the form or function of the TV program data to an MPEG format suitable for internal transfer and manipulation." See TiVo's Op. Br. at 8-11; '389 patent at cols. 2:13-14, 3:30-4:2, 6:26-27, 6:30-33, 12:40-42, 12:44-47; TiVo's Markman Slides at 69-84.

EchoStar argues "Input Section" is specially defined by the '389 patent as "a separate module that obtains input from outside an assembly, tunes to a signal carrying a particular television program, and includes an MPEG encoder that encodes the program into MPEG." 2 '389 patent at cols. 3:32-33, 3:43-52, 4:15, & Fig. 1; EchoStar's Opening Br. at 16-17; EchoStar's Response Br. at 15; EchoStar's Slide Presentation at 99-104.

In support of its proffered construction, EchoStar argues that the capitalization of terms in a patent indicates that the terms were specially defined by the patentee and therefore must be given a special meaning instead of their plain meaning. EchoStar argues that because three terms in the '389 patent were capitalized - Input Section, Media Switch, and Output Section - the patentee necessarily acted as his own lexicographer and that these terms cannot be construed to have a plain meaning. EchoStar Opening Br. at 15 ("By using terms that are proper nouns and not generic terms of art, the applicants acted as their own lexicographers… In order to understand what was intended by the capitalized terms, therefore, one must refer to the specification."). Notably, EchoStar does not cite any patent cases for this proposition and instead, draws an analogy to contract law wherein, EchoStar argues, capitalization of a term indicates the creation of a term of art. Id. This Court has not found this rule in patent case law and does not here create such a rule. Instead, this Court will follow Federal Circuit precedent in determining whether or not a patentee chose act as his own lexicographer. Bell Atl. Network Servs., Inc. v. Covad Communs. Group, Inc., 262 F.3d 1258, 1268 (Fed. Cir. 2001).

EchoStar further argues "said Input Section converts said specific program to an Moving Pictures Experts Group (MPEG) formatted stream" means "the Input Section changes the format of the TV program data signal from non-MPEG to MPEG." See '389 patent at col. 2:10-14; EchoStar's Opening Br. at 9-11, 16-17; EchoStar's Response Br. at 15; EchoStar's Slide Presentation at 59-75.

The Court need look no further than the claims themselves to define these terms, as the specification does not explicitly define them. See '389 patent at cols. 12:43-46, 15:25-28. The plain and ordinary meaning of an "Input Section" is "the portion of a device that receives inputs." The claim term "converts" needs no further construction. Though EchoStar argued in favor of construing "convert" as "change," no such construction is necessary. 3

EchoStar cites Superguide Corp. v. DirectTV Enters., Inc., 358 F.3d 870, 891 (Fed. Cir. 2004) in support of its proposed construction of "convert." EchoStar argues that in that case, the Federal Circuit "[held] that in the television broadcasting field, the ordinary meaning of 'convert' is 'changing from one form or format to another.'" In Superguide, the Federal Circuit considered the construction of a claim phrase containing the term "converting." In support of their respective proposed constructions, the two parties each proposed constructions of "converting" that used the term "change" and the district court's final construction of the term construed "conversion" as "change." The construction of this term, however, was not squarely before the court. Further, though the Federal Circuit, affirmed the district court's claim construction, the court did
not hold generally that the ordinary meaning of "conversion" in the television broadcasting field is "change."

Therefore, the Court construes "providing at least one Input Section, wherein said Input Section converts said specific program to an Moving Pictures Experts Group (MPEG) formatted stream for internal transfer and manipulation" as "providing at least one portion of a device that receives inputs, wherein said portion of the device that receives inputs converts said specified frequency range to an Moving Picture Experts Group (MPEG) formatted stream for internal transfer and manipulation."

7. Claim Six

Claim 6 of the '581 patent recites: "(a) receiving a plurality of input signals comprising beam requests from the treatment rooms and a beam path configuration signal from the switchyard identifying a beam path through the switchyard to one of the treatment rooms; (b) comparing the input signals to verify the authenticity of a request from a selected one of the treatment rooms; and (c) in response to such verification, allowing beam transport to the selected treatment room."

(Rosenberg Decl. Ex. 2, the '581 Patent at 9:37-10:2.) Plaintiff offers the following definition of the terms "input signals": "detectable messages that convey information." The other claim terms have already been construed or are undisputed. (See Ion Beam Opp'n at 10:8-14.) Defendant Ion Beam, on the other hand, suggests the term "input signals" be construed as "detectable messages that are entered into a computer for processing."

As already discussed, the term "signal" means "detectable message," and that point is not disputed. (Compare id.; and Optivus P.&A. at 19:28-20:2.) Plaintiff offers the following definitions in support of its argument: (1) Microsoft defines input as "information entered into a computer for processing (Airhart Decl. Ex. P. at p. 246.); (2) Random House defines the word to mean data to be entered into a computer for processing. (Id., Ex. H at p. 132.1.) Random House also includes the following definitions: "something that is put in 2. the act or process of putting in." (Id.) Turning to the specification, the term "input signal" is discussed in the following context: "A method of including the generation and reception of a plurality of different input signals and the processing of such signals in a treatment room selection verification system . . . . a more specific method of the present invention includes a step of generating in the treatment rooms, treatment room beam request signals and beam configuration request signals." (Rosenberg Decl. Ex. 2, the '581 Patent at 5:65-6-4.) Because the claim term is used in the specification in a manner consistent with the Microsoft definition, the court hereby defines the term "input signals" to mean "detectable messages that are entered into a computer for processing."

4. "input terminal pin" and "output terminal pin"

These terms are used in the claims to define the termini of the filter circuit. Pulse offers that these terms do not require specific construction by the court because they are readily understood by one of ordinary skill in the art in the context of the patents at issue. Mascon argues these terms are indefinite because the "claim fails to identify the intended external connections" to the pins and signals would flow through the circuit in a direction opposite to that implied by the claims' nomenclature (e.g., signals actually flow in at the pins called "output" and out the pins called "input").

Analyzing the term in light of the intrinsic evidence, the court concludes these terms would be clear to one skilled in the art. First, signals across the circuit flow in both directions, and the labels merely describe the pins' positions in the circuit. For example, the "input terminal pins" are the eight on the left in Figure 2 of the '347 patent which connect to the "incoming telephone line wires." (See also, '347 patent, Col. 4, ll. 51-57; '992 patent, Col. 5, ll. 35-41 and Col. 7, ll. 49-51.) The "output terminal pins" are on the right side of the drawings and connect to the alarm panel. Even if these terms had been used in an unusual way, a specification "may reveal a special definition given to a claim term by the patentee that differs from the meaning it would otherwise possess. In such cases, the inventor's lexicography governs." Phillips, 415 F.3d at
The court therefore finds these terms are not "insolubly ambiguous," and thus, they are not indefinite and they do not require specific construction by the court.

5. "input/output device"

The next disputed claim term appears in Claim 43 of the '289 Patent. (Chart at 23). Ricoh proposes that the term means "a device that can input commands and display information." (Id.). Pitney contends that the proper construction is "[a] device that can input commands and display information that is separate and external from the business office device." (Id.). Based on the parties' proposed constructions, the disputed issue with respect to this term again is whether the "input/output device" is physically separate and external to the business office device. Ricoh seeks to exclude the limitation that the input/output device is physically separate from the business office device for substantially the same reasons provided for "office machine system." (Tr. of Markman Hr'g at 18:3-20:25, 29:14-30:12).

As the Court discussed in detail above, the Court disagrees with Ricoh. The intrinsic evidence indicates that the "input/output device" corresponds to the "operation panel." For example, the specification provides:

Input Process 203 receives input from a user and sends the data to System Control Process 202, which then echoes back the input through Display Process 204, so that the user can yet (sic) feedback of his/her input. The data from the user is then coded in Communication Process 201. The coded data is then sent to Copier Engine through line 12.

'289 Patent, col. 3, ll. 19-24. Moreover, the patentee clearly stated his intent during the prosecution of the '289 patent. The patentee explained to the PTO:

An input/output device is a device which both inputs commands and displays information of the business office device.

("289 Patent Prosecution History, Dec. 22, 1995 Amendment at 18). The patentee further explained that "Claim 59 requires an input/output device (which corresponds to the operation panel in the specification) connected to a business office device." (Id. at 25) (emphasis added).

For the reasons discussed above, the Court already concluded that the operation panel is physically separate and external to the business office device. See infra II.A.1. Based on the intrinsic evidence, this conclusion clearly applies to the input/output device as well, since the patentee stated that the input/output device corresponds to the operation panel. Ricoh fails to provide an additional basis for concluding otherwise. Thus, the Court adopts Pitney's proposed construction. Accordingly, "input/output device" means "[a] device that can input commands and display information that is separate and external from the business office device."

2. "An optical coupling means having an input, an input/output and an output" and "a first optical coupler having an input, an input/output and an output"

(b) Construction of Disputed Claim Language

The dispute between the parties on this matter centers on the structure of the aforementioned optical coupler referred to in both claims 1 and 7 of the '459 Patent. Specifically, at issue is whether the "input/output" connection or port of the optical coupler has to be bidirectional, i.e., has an input going in one direction and has an output going in the opposite direction. 
within the same connection. Pirelli contends that the "input/output" language should not be limited to this specific structure. Instead, Pirelli asserts that the "input/output" connection can serve as either an input or an output, or both. Whereas Ciena maintains that the "input/output" of the optical coupler can only be bidirectional.

(i) The Claim

Again, the Court starts with the language of the claim itself. Claim 1 of the '459 Patent, in relevant part, reads: "an optical coupling means having an input, an input/output and an output and having its output coupled to the input of said optical amplifier . . . ." Col.8, lines 1-3. Claim 7 reads in relevant part: "a first optical coupler having an input, an input/output and an output and having its output coupled to the input of each active fiber . . . ." Col.9, lines 14-16. As already determined, the "optical coupling means" and the "first optical coupler" will be treated identically for purposes of claim construction.

Pirelli contends the claim language mandates that one of the "ports" must be bidirectional. To lend support to this conclusion, Pirelli argues that the diagonal (/) is defined as a "mark . . . used typically to denote 'or' (as in and/or) . . . ." See Webster's New Collegiate Dictionary (1979). Ciena, on the other hand, argues that this claim element requires that one of the ports performs the function of both an input and an output and that the other ports must be input only and output only.

(ii) The Specification

Pirelli asserts that the specification also does not preclude the optical coupler from having a non-bidirectional set up. Pirelli points to the following specification language to support its argument:

Optical coupler [is] inserted in the line and [is] suitable for coupling within the line fiber and/or for extracting from it the optical service signals. With the optical amplifier, or with each optical amplifier, there is at least one means associated therewith for injecting or for extracting optical service signals.

Col.2, lines 34-37 (emphasis added). Moreover, Pirelli comments that the three-wavelength optical coupler described at Col. 6, lines 30-66 and illustrated in Figure 4 has four "ports" or connections. Lastly, Pirelli argues that this four port embodiment of the optical coupler is a preferred embodiment that should not be read out of the scope of the claim. See Vitronics, 90 F.3d at 1583.

Ciena points to patent drawing Fig. 2 for support that the coupler is only connected by three ports and therefore, one of the ports by necessity must be a dual purpose port so that both the function of putting signals into the coupler and taking signals out of the coupler can be accomplished. If this were not the case, the "connecting unit", which is shown with both an input and output on the side opposite from the optical coupler, could not operate properly. Moreover, Ciena contends the coupler's function is defined by the function of each of its three ports. Thus, the specification refers to one port connected to a fiber line from the transmitter, another port is connected to an optical amplifier and the third port is connected to a service channel device for injecting and/or extracting service signals from the optical fiber line. See Col.2, lines 16-42. Further, Ciena asserts that the necessarily bidirectionality of the input/output of the coupler is supported by a description of the preferred embodiments. See Col.6, lines 47-53.

(iii) Claim Construction

A subtle distinction exists between the use of the specification to clarify otherwise ambiguous language in the claim and the extraction of limitations from the specification to impose those limitations on the claims. See CCPI Inc. v. American Premier, Inc., 966 F. Supp. 276, 282 (D.Del. 1997) (citing CVI/Beta Ventures, 112 F.3d at 1158; Electro Medical, 34 F.3d at 1054; In re Van Geuns, 988 F.2d 1181, 1184 (Fed. Cir. 1993); Intervet Am., 887 F.2d at 1053; Fonar Corp. v. Johnson & Johnson, 821 F.2d 627, 632 (Fed. Cir. 1987)). While the former is proper practice, the latter is impermissible. See id. Although the patent drawings in the specifications referred to by both parties are highly relevant in construing the "input/output" language of the claim, see CVI/Beta Ventures, 112 F.3d at 1153, "claims are not to be interpreted by adding limitations appearing only in the specification." Electro Medical, 34 F.3d at 1054.

In the case at bar, the term "input/output" is ambiguous. In addition, the language and drawings found in the specification are inconclusive and could support either a bidirectional connection or other types of connections. The Court is counseled by the well-known patent law principle that "claims are not to be interpreted by adding limitations appearing only in the
specification." See id. Further, "the claims are not limited to devices operated precisely as the specification describe[s] [the] devices operating, unless the specification requires a certain limitation." See Specialty Composites, 845 F.2d at 987 (citing Lemelson v. United States, 752 F.2d 1538, 1552 (Fed. Cir. 1985)). In the case sub judice, there is no such required limitation in the specification.

The Court is led inexorably back to the plain language of the claim. The "input/output" port or connection of the optical coupler should be read as broadly as possible within the parameters that the claim language permits. See Electro Medical Systems, 34 F.3d at 1054 ("Particular embodiments appearing in a specification will not be read into the claims when the claim language is broader than such embodiments.") (emphasis added). The Court is convinced that the claim language "input/output" is broader than any of the specification language or patent drawings referred to by either party. This reading of the language is supported by the fact that a diagonal (/) is defined as typically meaning "or". See Webster's Third New International Dictionary 622 (1971). 8 It follows the "input/output" port of the optical coupler can be either a bidirectional connection or a connection that supports only an input or output connection.

--- Footnotes ---

8 Dictionaries are a favored form of extrinsic evidence and may be consulted as long as they do not contradict anything in the patent documents. See supra note 2. Here, the interpretation of the diagonal (/) causes no such contradiction.

--- End Footnotes ---

The Court holds that the optical coupler of claim 1 and claim 7 of the '459 Patent means is a device having at least three "ports" or "connections", one of which may, but need not, be bidirectional.

8. "inputting an item having information into the transmission system"

The additional limitations of Claim 14 provide:

wherein the transmitting step comprises:

inputting an item having information into the transmission system;

assigning a unique identification code to the item having information;

formatting the item having information as a sequence of addressable data blocks;

compressing the formatted and sequenced data blocks;

storing, as a file, the compressed, formatted, and sequenced data blocks with the assigned unique identification code; and

sending at least a portion of the file at the non-real time rate to the local distribution system.

The first additional limitation of the transmitting step which the Court addresses include as an element, "inputting an item having information into the transmission system." Up to this point, none of the other distribution methods of the Yurt family of patents have disclosed the act of "inputting" in an element. The Court finds that one of ordinary skill in the art reading the patent documents would understand the phrase "inputting an item" in its plain ordinary sense, i.e., "putting the item in the transmission system."

Moreover, this particular additional limitation requires that the item which is being input be "an item having information." In the December 14 Order, the Court construed the phrase "items containing information" as used in Claim 19 of the '992 Patent to mean physical items such as videotapes or computer disks, which contain audio/video information. The Court construed the phrase "items having information" as used in Claim 41 of the '992 Patent to have the same meaning as "items
containing information." (See December 14 Order at Sections IA7 and ID4.)

The Federal Circuit has held if an identical term appears in claims issuing from both a parent and a continuation application, a consistent meaning is preferred. Advanced Cardiovascular Sys., Inc. v. Medtronic, Inc., 265 F.3d 1294, 1305 (Fed. Cir. 2001). Accordingly, with respect to these additional limitations, the Court gives the phrase "inputting an item having information into the transmission system" a meaning consistent with its previous construction as follows:

In a distribution method in which compressed, digitized data is transmitted to a local distribution system, the phrase "inputting an item having information into the transmission system" means "putting physical items containing audio information or video information or both into the transmission system.

TERM # 10: "inputting data associated with at least one bid for at least one fixed income financial instrument into said bidder's computer via said input device" - Defendants contend that this phrase should be construed to require that data be defined as only "information necessary to calculate an interest cost value" and that such data be stored on the bidder's computer. We find no support for imposing such limitations on the plain words of this claim phrase. Contrary to defendants' argument, the fact that data is inputted into the bidder's computer, and the bid is submitted, in part, from bidder's computer, does not necessarily imply that the data is stored in the memory of the bidder's computer. As plaintiff correctly notes, the invention contemplates that servers can be used to make calculations and store information. This phrase means: "putting information, in a form suitable for processing by a computer, associated with a bid to buy a fixed income financial instrument into a computer used by a bidder to access an electronic auction via any input device used to prepare or submit bids."

L. "inquiry" and "inquiring"

Independent Claims One, Eleven, and Fourteen of the '399 Patent and independent Claims One, Seventeen, and Eighteen of the '449 Patent recite that the host device sends an "inquiry" to the interface device to determine the type of device attached to the host device. '399 Patent, col. 12:66 (Claim One), col. 14:6 (Claim Eleven) & col. 14:47 (Claim 14, using the word "inquiring" instead of "inquiry"); '449 Patent, col. 11:61 (Claim One), col. 13:28 (Claim Seventeen) & col. 14:19 (Claim Eighteen, using the word "inquiring" instead of "inquiry"). Papst asserts that "inquiry" should be defined generally to mean "an instruction seeking information concerning the type of the device attached to a computer." Papst's App. at 3. Relying on
the specification, the Camera Manufacturers contend that "inquiry" should be defined specifically as "the SCSI inquiry command" and that "inquiring" should be defined as "sending the SCSI inquiry command." CMs' Markman Br. at 33.

The specification uses the word "inquiry" as follows:

Preferably, the interface device according to the present invention simulates a hard disk with a root directory whose entries are "virtual" files which can be created for the most varied functions. When the host device system with which the interface device according to the present invention is connected is booted and a data transmit/receive device is also attached to the interface device 10, usual BIOS routines or multi-purpose interface programs issue an instruction, known by those skilled in the art as the INQUIRY instruction, to the input/output interfaces in the host device. The digital signal processor 13 receives this inquiry instruction via the first connecting device and generates a signal which is sent to the host device (not shown) again via the first connecting device 12 and the host line 11. This signal indicates to the host device that, for example, a hard disk drive is attached at the interface to which the INQUIRY instruction was sent.

The parties disagree regarding the meaning of "inquiry" when lowercase letters are used. The Camera Manufacturers assert that the word "inquiry" in the Claims must mean the SCSI inquiry because when the specification uses the lower case word "inquiry" it says "this inquiry instruction" referring back to the phrase "the INQUIRY instruction." CMs' Slides at 120. Papst would interpret "inquiry" to be broader than a SCSI INQUIRY because the Claims do not state "inquiry" in all capital letters. "[W]hen you're using lower case letters that means you are talking in normal English. In the claims here they're using the lower case version meaning it's generic." Tr. 2:78 (Papst). Papst further explains its position: "I think it's wise to follow the convention of how to use those examples that's [sic] given in the SCSI specification which does draw the distinction between using all caps and the lower case." Tr. 2:101 (Papst).

The distinction between independent and dependent claims supports Papst's construction. As explained above, a dependent claim incorporates all of the limitations of the claim from which it "depends" and adds something new. See 35 U.S.C. § 112. Thus, a dependent claim necessarily has a narrower scope than the claim from which it depends. Dependent Claim Four, not in contention here, recites that the multi-purpose interface of the computer is a SCSI interface and that the first connecting device also comprises a SCSI interface. "So that's why the . . . first command interpreter is not limited to the SCSI command set because that limitation is added by a dependent claim and you get a presumption that there must be some difference" between Claim One and Claim Four. Tr. 2:79 (Papst).

The Camera Manufacturers argue that the specification actually defines the word "inquiry," so that Mr. Tasler acted as his own lexicographer. See Vitronics, 90 F.3d at 1582. They go on to argue that this express definition trumps Papst's claim differentiation argument. See O.I. Corp., 115 F.3d at 1583; see also Hormone Research Found., Inc. v. Genentech, Inc., 904 F.2d 1558, 1567 n.15 (Fed. Cir. 1990) (the doctrine of claim differentiation "cannot overshadow the express and contrary intentions of the patent draftsman"). The Camera Manufacturers note that Mr. Tasler knew to state "for example" when merely providing an example. See '399 Patent, col. 6:14-16 ("[t]his signal indicates to the host device that, for example, a hard disk drive is attached at the interface . . . .") (emphasis added).

Despite the fact that the specification does not use the words "for example," the context of the paragraph makes it clear that the SCSI INQUIRY is discussed as an example of a preferred embodiment of the invention. The Camera Manufacturers' interpretation takes the phrase "this inquiry instruction" out of context and makes too much of it. The paragraph begins with the word "preferably," indicating that the specification is discussing a preferred embodiment. In the phrase "this inquiry device," the word "this" refers back to the example being discussed, the SCSI INQUIRY. The paragraph does not assert more -- it does not say the inquiry instruction is the SCSI INQUIRY. The language of the Claims ultimately controls, and the Claims use the lower case term "inquiry." The Court thus construes the term "inquiry" as "an instruction seeking information concerning the type of the device attached to a computer" and the term "inquiring" as "sending an instruction seeking information concerning the type of the device attached to a computer."
As provided in Claim 1 of the '825 Patent, the "insert locator data" identifies the "predetermined storage locations" at which the digitally formatted local video signals have been stored. '825 Patent, col.11, 11.12-20. Claim 1 of the '825 Patent also provides that the insert locator data is sent to the switching system, with the switch commands, over the second telecommunications network. See id. col.11, 11.7-10. Because the insert locator data is sent with the switch commands via the second telecommunications network, the insert locator data must originate from the same remote source--the remote control center--as the switch commands and the commercial insert signal.

b. "insertable storage medium having information stored therein"

"Insertable storage medium" is not a means-plus-function element. It would therefore be improper to define this term solely with reference to "corresponding structures" found in the specification.

Plaintiff believes that the correct interpretation of this phrase is simply "any insertable storage medium." Pl.'s Opp. Memo. on Claim Construction, at 6. The Court rejects plaintiff's interpretation because it does not contribute to the task of claim construction. The parties have filed numerous briefs arguing about the definition of "insertable storage medium." Its meaning is not self-evident. Plaintiff's tautological suggestion is not helpful in resolving the difficult issues presented in this case.

Plaintiff also suggests in his motion papers that the medium in which the information is stored is irrelevant to the patent: that the "software" "can come from any type of medium." Id. at 16 (emphasis in original). Similar statements were made elsewhere, for instance that "it makes absolutely no difference to the result which medium is used. The medium is as insignificant to the invention as the choice between UPS and the Postal Service is to the delivery of a package." Plaintiff's Memo. in Opposition to Defendants Motion of Non-Infringement ("Pl.'s Opp. Memo. on Infringement") at 5; see also id. at 10 ("The medium could be anything"); id. at 5 ("The medium can be a floppy disk, a hard disk, a tape, a broadcast from a cable company, or next year's favorite medium"). Plaintiff appears to be suggesting that the term "insertable storage medium" should actually be defined as "any storage medium" (or perhaps "any medium"). This is confirmed by a brief submitted by plaintiff during the prosecution of his patent, see Pl.'s Opp. Memo. on Claim Construction, Ex. 1, at 3. (arguing that some of the claims, including the one in issue here, "are broad enough to cover any storage medium"), and statements plaintiff made during oral argument. See Aug. 14, 1997 Tr. at 45 ("For whatever reason, the word 'insertable' is in there. I'm not worried about it."). To the extent plaintiff believes that "insertable storage medium" should be construed to mean "any storage medium," the Court rejects that view because it seeks to read the term "insertable" out of the claim. See Becton Dickinson & Co. v. C.R. Bard, Inc., 922 F.2d 792, 798 (Fed. Cir. 1990) (all limitations in a claim are material). Defining "insertable storage medium" as "any storage medium" would erase the distinction drawn in the claim between internal and insertable storage media. See, e.g., Patent '857, Figures 1 and 2 (showing insertable ROM cartridge 12 and internal RAM 24, auxiliary RAM 24a and ROM 24b). Words in a patent are to be given their ordinary meaning, unless it is clear that the patentee intended a special definition. See Vitronics Corp. v. Conceptronic Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1997). There is no indication in the patent that plaintiff used "insertable" in a special or unusual manner. To the contrary, the term is used in an ordinary manner elsewhere in the patent. For instance, the patent uses the following terminology to mean the same thing: compare "when a cartridge is first placed in the machine . . . . ", Patent '857, col. 2, line 10-11; with "when a new cartridge is inserted into the machine . . . . " col. 4, line 9; and "the cartridge is insertable into an appropriate slot in the machine . . . . " col. 3, lines 38-39. Because "insertable" is used in the ordinary sense of the word, the Court will not construe the claim language to entirely disregard a meaningful term. In addition, construing the phrase to mean "any storage medium" does not advance the cause of claim construction, because that phrase is broad to the point of ambiguity. To the extent that a broad reading of a claim renders it ambiguous, the claim should be construed against the patentee and given a narrower construction. See Chisum on Patents § 18.03[2][f][iii], at 18-149 (citing cases).
As discussed above, defendant asks to the Court to construe this claim limitation to mean "a physical device which stores information and is inserted into a machine by the user." Def.'s Reply Memo. on Claim Construction, at 1. The first place the Court will look to understand the meaning of the claim phrase is the words of the claim itself. It is clear that the phrase "insertable storage medium having information stored therein" envisions that the storage medium or storage device itself must store information. This seems indisputable -- after all, the medium is a "storage" medium, and it has "information stored therein."

It is also evident from the plain language of the claim that this information-storing medium or device is itself insertable into the machine. 3 It is not an external cable or connector that is "insertable," but rather the storage medium itself is "insertable." In the Court's view, the ordinary meaning of the words "insertable storage medium having information stored therein" dictates this construction: the device having the information stored on it is itself insertable. This conclusion is bolstered by the examples of insertable storage media that the specification and claims disclose: a video game cartridge and a disc. 4 See Patent '857, col. 1., lines 52-58. The way that the patent uses the term "inserted" and "insertable" also supports this reading of the claim language. Both parties agree that a video game cartridge is an example of an insertable storage medium. Such a cartridge is clearly conceived of as a physical, memory-storing device that is itself placed into the machine by the user. See id., col. 1, lines 13-15 ("a cartridge, containing a ROM, is inserted in a slot provided for this purpose"); col. 2, line 10-11 ("When a cartridge is first placed in the machine . . ."); col. 4, line 9 ("When a new cartridge is inserted into the machine . . ."). The specification then states that not only cartridges, but "other types of insertable storage media" may be used to implement the invention. Col. 1, line 55. The other type of "insertable storage medium" disclosed is a "program[] furnished on discs designed for use with a microcomputer." Col. 1., lines 57-58. The clear implication of this is that insertable storage media are information-holding physical devices that are themselves "inserted into" or "placed in" the machine. Defendant's expert, Dr. Thomas A. Berson, also agrees with this interpretation. See Berson Declaration P 9.

3 The word "machine" is used extensively throughout the patent. The patent uses "machine" to mean the entire system shown by Figures 1 and 2, excluding the cartridge (12) and its contacts (15).

4 For reasons discussed below, the Court believes that the patent's reference to a "disc[]" can only be construed to mean a floppy diskette.

The conclusion that the storage medium itself is insertable, rather than merely connected to the machine by means of a cable, is further supported by the language of the specification the specification draws a distinction between a television display monitor which is "connectable" to the machine, and a memory-containing cartridge that is "insertable" into the machine. Compare Patent '857, col. 3, line 26 with col. 3, line 38; see also col. 1, lines 13-14 (a video game unit is "connected to a television receiver, and a cartridge, containing a ROM, is inserted in a slot"). Plaintiff has not pointed to any aspect of the claim, specification or prosecution history which contradicts this common-sense reading of the claim language.

The Court also finds that the claim envisions that the storage medium is a physical device that is inserted into the machine in order to operate the machine. See col. 8, lines 35-36 (machines operate "responsive to insertion of the same storage medium"); col. 8, lines 19-21 (data processing means accesses information from "inserted storage medium"). This construction of the plain language of Claim 5 is confirmed by the examples of insertable storage media given by the patentee: a video game cartridge and a "disc[]," a term which, as indicated earlier, can only be interpreted to mean floppy diskette.

Plaintiff has argued that the reference in the specification to an alternate embodiment employing a different storage medium, see col. 1., lines 56-58 ("the principles of the invention may be applied to programs furnished on discs designed for use with a microcomputer"), would call to mind, to one skilled in the art at the time of the patent application, disk drives.

The Court finds that the reference in the patent to "programs furnished on discs" must be construed to mean floppy diskettes, not disk drives. The claim language requires that the "insertable storage medium" have "information stored therein" and that the system operated "responsive to insertion" of the storage medium. However, a disk drive does not have information stored on it (only the disk itself does), see Declaration of Berson P 19, and computers do not operate in
response to disk drives, but rather in response to information on disks. See id.; see also id. P 21. In construing the language of the patent claims, the court "interprets words in a claim as one of skill in the art at the time of the invention would understand them." Eastman Kodak, 114 F.3d at 1555 (citing Intellicall, 952 F.2d at 1387); accord Markman, 52 F.3d at 986. Defendant's expert argues persuasively that in the context of a claim referring to "a plurality of mass-produced identical systems" each working "responsive to insertion of the same storage medium," the phrase "insertable storage medium" would call to mind, to one skilled in the art in 1981, a storage device such as a floppy diskette, a cartridge or a cassette, not a disk drive. See Declaration of Berson PP 10-11, 19, 22-23. Based on the foregoing and his understanding of the usage of computer terminology in the early 1980's, defendant's expert testified that one skilled in the art would not believe that the term "discs" referred to a disk drive. See id. PP 19, 24, 25.

The testimony of plaintiff's expert does not undermine this conclusion. Mr. Dubner admits in his declaration that the word disk only refers to a hard disk drive if the word is used "loosely." Dubner Declaration P 8. In the Court's view, this admission and Mr. Dubner's deposition testimony reveal that even he believes it is a bit of a stretch to contend, as plaintiff does, that "disk" equals hard disk drive. See Def.'s Reply Memo. on Infringement, Ex. S at 49-50, 52-53, 58-59. Faced with a choice between an ordinary definition of a word and a strained or "loose" definition offered only during litigation (rather than in the patent itself), the Court must -- according to well-established principles of claim construction -- adopt the ordinary definition of the word. See Digital Biometrics, 149 F.3d at 1344 ("Without an express intent to impart a novel meaning to claim terms, an inventor's claim terms take on their ordinary meaning."); see also Quantum Corp. v. Rodime PLC, 851 F. Supp. 1382, 1385 (D. Minn. 1994) ("the meaning which the investor gives to his words can not be made to depend upon subsequent events, but should appear when the application is filed") (citations omitted), aff'd, 65 F.3d 1577 (Fed. Cir. 1995). 5

5 Although plaintiff has provided the Court with computer product catalogues and articles that use the word "disk" to refer (apparently) to a disk drive, these do not alter the proper construction of the term. The occasional use of synecdoche in popular speech does not transform the fundamental meaning of a word, especially a technical term. In addition, as defendant points out, several of the publications that plaintiff has provided the Court actually draw a distinction between a disk and a disk drive. See Def.'s Memo. in Support of Non-Infringement at 10.

Therefore, the Court finds that the phrase "insertable storage medium having information stored therein" must be construed to require that the storage medium is a physical device which itself stores information; and that the storage medium is itself inserted into the machine (rather than being connected in some other manner) in order to operate it.

The Court recognizes that during the forthcoming infringement analysis under the doctrine of equivalents, distinctions that may be found or implied in this claim construction may not be dispositive in conducting that analysis.
The parties agree that "inserter" is a term of art in the data broadcasting industry. Broadcast's Opening Claim Construction Brief, at p. 22 ("The claimed 'inserter' is a common device in the industry"); and Defendants Joint Opening Claim Construction Brief for the '094 Patent, at pp.33-34 ("The term[] 'inserter' . . . [is a term] of art in the data broadcasting industry"). They disagree, however, on whether it is limited to "a device for embedding data into the VBI lines of a video signal," as the defendants contend, id., or whether it is broader and encompasses a device that can "be used to deliver a data stream over any one of a number of known transmissions methods, " including VHF/UHF, microwave, satellite, and fibre optics, as the plaintiff contends. Broadcast's Opening Claim Construction Brief, at p. 22.

Claims are to be construed in light of the specification. Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996). Accordingly:

The specification acts as a dictionary when it expressly defines terms used in the claims or when it defines terms by implication. . . . The specification contains a written description of the invention which must be clear and complete enough to enable those of ordinary skill in the art to make and use it. Thus, the specification is always highly relevant to the claim construction analysis. Usually, it is dispositive; it is the single best guide to the meaning of a disputed term.

Id.

The specification here describes the inserter as follows:

The datacast network utilizes television signals to convey digital information for text display at the receiver stations. In this respect, the central station 11 generates a stream of data which is encoded into datacast packets as defined by the World Standard Teletext specification and know [sic] as Packet 31 data. This data stream is inserted into the vertical blanking interval (VBI) of the television broadcast signal transmitted from the central station 11 and is subsequently broadcast over the ether to be received by the receiver stations 13 at which are located display screens 15, such as television receiver sets or video monitors. . . .

* * *

The file server 17 is connected to a processing means in the form of a data broadcast inserter. The inserter 19 is adapted to extract digital records in the form of database data from the file server 17 and generate a sequential data stream from this database data for distribution. Importantly, the inserter is adapted to insert this data stream into the VBI of the broadcast television signal. This combined signal is passed on to a transmission means 21 which includes appropriate modulation and transmission circuitry for encoding and transmitting the sequential data stream via an antenna in accordance with conventional broadcast practice.

'094 Patent, col. 4, lines 13-22 and 30-42 (emphasis added).

The specification uses the term "inserter" to describe a device that inserts data into the vertical blanking interval of a television video signal. No other function is assigned to the inserter, and no other definition is provided by the patentee.

The plaintiff argues incorrectly that "the '094 patent also discloses embodiments where the data is inserted into a digital data stream for transmission over conventional methods, such as VHF/UHF transmission, microwave transmission or satellite transmission," citing the specification at col.15, lines 49-54. To the contrary, the specification indicates that the inserter acts on the video signal before the combined video signal with embedded data is modulated for transmission. The inserter embeds data into the VBI after the television signal is created but before it reaches any transmission means to deliver the signal, such as VHF/UHF, microwave, or satellite transmission.

Similarly, the specification uses the term "decoder" to describe a device that extracts the data from the vertical blanking interval:

The decoder means is particularly designed, to decode the transmitted data so as to reconstitute the database from the transmitted data.
'094 Patent, col. 4, lines 50-52. This is further, but consistently, described in the specification at col. 5, lines 33-54.

I construe the term "inserter" to mean a device for embedding data into the vertical blanking interval of a television video signal.

I construe the term "decoder" to mean a device for extracting data embedded into the vertical blanking interval of a television video signal or commercial radio sideband.

2230

1. "inserting . . . into"

The parties disagree about the meaning of the words "inserting . . . into" in the phrase "inserting a category identification signal into the scrambled program signal at the remote location for transmission thereof with the program signal" of claim 4. IPPV contends that "inserting . . . into" requires that the identification signal be within some time or space limitations of the program signal. Echostar on the other hand, argues that "inserting . . . into" requires the identification signal to be placed inside the program signal.

Having reviewed the language of the claim and the specification, the court concludes that there is no reason to modify the plain meaning of "insert," which means "to set (something) in." Webster's Their New International Dictionary 1168 (3d. ed. 1986). Thus, the court will construe "inserting . . . into" as requiring the identification signal to be placed inside the program signal.

2231

b. "inspecting"

For this term, IP offers the following definition: analyzing a certain element or location and one or more at least partially surrounding or neighboring elements of an image to determine the desirability of creating elements (in time or space) or modifying the location, value, brightness, shape, position, intensity or size of at least one element so as to improve the spatial and/or temporal resolution relationship between the elements, which may neighbor in time or space. Lexmark and Dell offer the following: examining or measuring to verify whether an item or activity conforms to specified requirements.

IP's definition of "inspecting" is overly broad and impermissibly reads limitations from the specification into the claim. The intrinsic evidence may disclose the subject matter of IP's definition, but the intrinsic evidence does not support the conclusion that the patentee gave a special meaning to the term "inspecting" as IP suggests. In such circumstances the ordinary and customary definition is to be used. Therefore, the court adopts Lexmark and Dell's definition: examining or measuring to verify whether an item or activity conforms to specified requirements.

GO BACK

2232

i. Inspecting

IP's proffered construction of the term "inspecting" is: analyzing a certain element or location and one or more at least partially surrounding or neighboring elements of an image to determine the desirability of creating elements (in time or space) or modifying the location, value, brightness, shape, position, intensity, or size of at least one element so as to improve the spatial and/or temporal resolution relationship between elements, which may neighbor in time or space. Sony proposes that the Court adopt its construction of the function of the "inspection means" limitation found in claim 1.

The Court agrees with Sony that the term "inspecting" should be construed consistent with the "inspection means" function of claim 1. See Phillips, 415 F.3d 1303, 2005 WL 1620331 at *7 (noting that claim terms are normally used consistently
throughout the patent). These claims share nearly identical language and context. Thus, the Court adopts the following construction of the claim term: to conduct an appraisal of at least two of the partially surrounding image elements provided by the neighboring element means in order to determine the presence of a void at a particular position in the image.

2233
c. "Inspecting a Plurality of Said at Least Partially Surrounding Image Elements of the Image to Determine the Presence of the Void"

IP offers the following definition for this term: inspecting two or more of the at least partially surrounding image elements of the group from the original image for the purpose of determining the presence of a void at the particular position. Lexmark and Dell propose: taking the at least partially surrounding pixels of the electronically coded input image, and examining or measuring two or more of those pixels without matching them to a pattern of elements.

Lexmark and Dell's definition seeks to add impermissible language such as "a pattern of elements" and "electronically coded." The defendant is adding the language based on the prosecution history of the 637 patent. On the hand, IP's definition reflects the ordinary and customary meaning of the term. Similar to the situation with the term "comparing a first of said selected pixels to at least a second of selected pixels" in claim 15 of the 780 patent, Lexmark and Dell's proposed definition includes limitations not found in the plain language of the claim. Therefore, we construe this term to mean inspecting two or more of the at least partially surrounding image elements of the group from the original image for the purpose of determining the presence of a void at the particular position.

2234
3. "instance" ('366 and '702 patents)

Beneficial's Proposed Construction
"an occurrence"

Defendants' Proposed Construction
"an occurrence of multiple user interactions stored at a server, where each interaction limits subsequent interactions"

Both parties agree that the term means occurrence, but the Defendants include additional limitations to the proposed construction. Beneficial has provided dictionary definitions that show that the definition of "instance" means "a case or occurrence of something." The Court finds that the Defendants' proposal is too limiting and is inconsistent with the ordinary meaning of the term. The specification of the '702 patent refers to "instances" as multiple occurrences of something and uses the "plural" of the term "instance." See '702 patent, 30:63-31:14. The Court finds that "instance" can be just a single occurrence of something and is not necessarily limited to plural instances. Further, requiring an "instance" to have multiple interactions would render the additional limitation of "includes a plurality of user interactions" in claim 1 meaningless. Thus, the Court construes the term "instance" as "occurrence."

2235
1. "instigating the analysis circuit simultaneously to the actuation of the charging circuit"

Claim 16 of the '085 Patent describes the method for delivering a defibrillating shock, including a step of "instigating the analysis circuit simultaneously to the actuation of the charging circuit." Philips contends that this term should be defined as "performing analysis for the first time when the high voltage capacitor begins to charge." Cardiac Science asserts that the term "instigate" should be construed as "trigger or provoke" and "actuation" means "activation." Cardiac Science offers no further construction of the phrase.
The '085 Patent specification reads:

The provision of additional safety controls to prevent the inadvertent release of a defibrillation shock reduces the need for the prior art method of sequential charging of the capacitors of the charging circuit, only after the completion of monitoring and analysis by the processor. Instead, the charging system may begin simultaneously with the monitoring and analysis function of the processor.

('085 Patent at c. 6, 11: 3-9.) However, contrary to Philips' proposed construction, neither the specification nor the claim language requires that the analysis be performed "for the first time" when the high voltage capacitor begins to charge. Rather, the word "simultaneously" in the claim language, coupled with the specification, describes the analysis occurring at the same time as the high voltage capacitor begins to charge. Thus, the Court construes the term "instigating the analysis circuit simultaneously to the actuation of the charging circuit" as "performing analysis at the same time as the high voltage capacitor begins to charge."

Construction of the term "instruction" was the primary focus of ARM's summary judgment motion. n2 Modern computers typically have a central processing unit ("CPU") that includes circuitry to fetch, decode and execute each operation specified by the instructions provided to it. The '215 patent describes this circuitry as part of a multi-stage pipeline: the "fetch" stage retrieves each successive instruction; the instruction then is passed to the "decode" stage, which recognizes each instruction and generates a control signal indicating that a particular operation or function is to be performed; and the "execute logic" stage, consisting of adders, shifters and multipliers, performs the operation or function. See '215 patent, col. 5, 11. 12-17 and fig.3. ARM argued that as used in the '215 patent, an instruction is a command provided to the CPU as input to the decode stage. ARM distinguished these instructions provided prior to the decode stage from the "control signals" generated by the decoder. In opposition to the motion, Nazomi argued that an instruction is any command that specifies or causes performance of an operation or function, including the control signals generated by the processor's decoder.

n2 The Court permitted the parties to present their arguments as to the appropriate construction of the term "instruction" in the context of ARM's motion for partial summary judgment; the Court did not hold a claim construction hearing prior to ruling on ARM's motion.

The Court did not wholly adopt ARM's proposed construction, but concluded that the '215 patent discloses "a hardware unit or subunit that converts stack-based instructions into the register-based instructions prior to the processing of those instructions by the processor in the so-called 'decode stage.' Based upon this construction, the Court granted ARM's motion for partial summary judgment. The parties then stipulated to Nazomi's dismissal of its claims of infringement by ARM's Revision 2 Jazelle products and to ARM's dismissal of its counterclaim for declaratory judgment.

On April 11, 2005, the Federal Circuit vacated this Court's grant of partial summary judgment for ARM and remanded for further proceedings after concluding that this Court had failed to construe the term instruction in sufficient detail for appellate review. This Court set a claim construction hearing and solicited briefing from the parties. The parties have confined their arguments to the term "instruction," but have reserved their rights to brief and argue other terms in the event construction of the term "instruction" does not result in disposition of the litigation.

II. LEGAL STANDARD

Claim construction analysis begins with the words of the claim. Nystrom v. Trex Co., Inc., 424 F.3d 1136, 1142 (Fed. Cir. 2005). A particular claim term generally is given its ordinary and customary meaning, that is, "the meaning that the term would have to a person of ordinary skill in the art in question at the time of the invention." Phillips v. AWH Corp., 415 F.3d 1303, 1312-13 (Fed. Cir. 2005). In determining how one of ordinary skill in the art would define a claim term, the Court looks to 'the words of the claims themselves, the remainder of the specification, the prosecution history, and extrinsic
evidence concerning relevant scientific principles, the meaning of technical terms, and the state of the art." Id. at 1314 (quoting Innova /Pure Water, Inc. v. Safari Water Filtration Systems, Inc., 381 F.3d 1111, 1116 (Fed. Cir. 2004)). The Court therefore does not determine the meaning that one skilled in the art would attribute to a particular term if he or she were operating in a vacuum, but rather the meaning that one skilled in the art would find if he or she were to view the claim term in light of the entire intrinsic record. Nystrom, 424 F.3d at 1142.

The specification may reveal that the inventor has given a claim term a special meaning that differs from the meaning it otherwise would possess. Phillips, 415 F.3d at 1316. "In such cases, the inventor's lexicography governs." Id. Alternatively, "the specification may reveal an intentional disclaimer, or disavowal, of claim scope by the inventor." Id. The inventor's intentions as revealed in the specification are dispositive. Id. The specification is considered "the single best guide to the meaning of a disputed term." Phillips, 415 F.3d at 1315 (quoting Vitronics Corp. v. Conceptronic, Inc., 90 F.3d 1576, 1582 (Fed. Cir. 1996)).

The prosecution history likewise provides guidance as to how the Patent and Trademark Office and the inventor understood the invention, and whether the inventor limited the invention during the course of prosecution. Phillips, 415 F.3d at 1317.

As noted above, extrinsic evidence such as technical dictionaries and expert testimony may be useful to educate the Court as to the field if the invention generally and the likely meaning that would be attributed to a particular claim term by one of ordinary skill in the art. See Phillips, 415 F.3d at 1318. However, "conclusory, unsupported assertions by experts as to the definition of a claim term are not useful." Id. Moreover, technical dictionaries and treatises may provide multiple definitions so expansive as to extend patent protection beyond what properly should be afforded. Id. at 1321. For these and other reasons, extrinsic evidence is considered to be a less reliable guide to claim construction than are the patent and its prosecution history. Id. at 1318.

III. DISCUSSION

The '215 patent contains seventy claims, including independent claims 1, 33, 36, 39, 69 and 70. Claim 1 is representative, and is set forth in full as follows with the disputed term "instructions" highlighted in bold:

1. A system comprising:

   a central processing unit having a register file, the central processing unit adapted to execute register-based instructions; and

   a hardware unit associated with the central processing unit, the hardware unit adapted to convert stack-based instructions into register-based instructions, wherein a portion of the operand stack is stored in the register file of the central processing unit and wherein the hardware unit is adapted to produce at least one of overflow or underflow indications for the portion of the operand stack stored in the register file, wherein the hardware unit is adapted to swap parts of the operand stack in and out of the register file from a memory, the system including an indication of the depth of the portion of operand stack, wherein a overflow or underflow produces an operand transfer between the register file in the central processing unit and memory.

The essence of the patented invention is a hardware accelerator that quickly and efficiently translates Java bytecodes (stack-based instructions) into native instructions (register-based instructions) for a CPU. See '215 patent, col. 2, ll. 3-6. Claim 1 describes this invention in a fairly straightforward manner, specifying a system comprising (1) a CPU that executes register-based instructions and (2) an associated hardware unit that converts stack-based instructions into register-based instructions. The parties dispute the scope of the term "instruction."

ARM proposes the following construction: "an element of an instruction set architecture, which specifies the interface between computer programs and a processor, that element having an operation code and zero or more operand specifiers, such that the processor can recognize the instruction and perform the specified operation." As the Court understands it, the instruction set architecture ("ISA") of a particular system is the universe of native instructions recognizable at the input of the CPU's decode stage. An immediate problem with ARM's proposed construction presents itself, because Claim 1 refers not only to register-based instructions, which would be elements of the system's ISA, but also to stack-based instructions, which would not be recognizable to the CPU given the explicit statement that the CPU executes register-based instructions.
This definitional glitch notwithstanding, the thrust of ARM's contention clearly is that the "instructions" described by the claims are inputs to the CPU prior to the decode stage.

Nazomi proposes a much broader construction: "a command that specifies or causes an operation or function to be performed." Under Nazomi's proposed construction, the "instructions" described by the claims could be either inputs to the CPU prior to the decode stage or outputs of the CPU, i.e., the control signals that cause the specified operation or function to be performed. Nazomi refers to these post-decode control signals as "low-level instructions" or "microinstructions."

A. Claim Language

Applying the relevant legal standards, the Court first must determine the meaning that one of ordinary skill in the art would give the term "instruction" as used in the patent claims. The parties agree that a person of ordinary skill in the art would have a Bachelor of Science or equivalent degree in electrical engineering, computer engineering or computer science, and two or three years of experience working with computer architecture. Nazomi initially expressed concern that ARM was attempting to limit the person's work experience to programming or other experience with the external architecture of CPUs; however, ARM has clarified that it agrees with Nazomi that one of ordinary skill in the art would be knowledgeable regarding the internal architecture of CPUs as well. ARM initially argued that one of ordinary skill in the art would have at least one year of experience with Java. However, in light of Nazomi's objection to this requirement, ARM has agreed that for purposes of construing the term "instruction" Java experience is not required. Accordingly, the parties are in agreement as to the qualifications of one of ordinary skill in the art.

Predictably, both parties present extrinsic evidence to support their arguments as to how the above-described person of ordinary skill in the art would understand the term "instruction." For example, Nazomi's expert, Dr. Yalamanchili, states that "instruction" is a general term that is used to identify commands at multiple levels of the computer architecture. Yalamanchili Decl. PP 25, 27; Yalamanchili Suppl. Decl. PP 5, 8. Dr. Yalamanchili states that qualifiers such as "micro" are used before the term "instruction" (as in "microinstruction") to distinguish instructions at different levels of abstraction. Id. at P 8. ARM attacks Dr. Yalamanchili's opinion, citing deposition testimony that when teaching a class on computer basics at the Georgia Institute of Technology, Dr. Yalamanchili distinguished between "instructions" as input to the CPU's decoder and "microinstructions" as output of the decoder. Yalamanchili Depo. 111:7 - 112:7, 169:18-21. ARM also cites to various texts in support of its position that the term "instruction" generally refers to an element of the ISA.

As the Federal Circuit recently noted, "there is a virtually unbounded universe of potential extrinsic evidence of some marginal relevance that could be brought to bear on any claim construction question. In the course of litigation, each party will naturally choose the pieces of extrinsic evidence most favorable to its cause, leaving the court with the considerable task of filtering the useful extrinsic evidence from the fluff" Phillips, 415 F.3d at 1318. The conflicting evidence submitted by the parties is not particularly useful in aiding the Court to determine how one of ordinary skill in the art would understand the term "instruction." Based upon all of the evidence in the record, this Court concludes that, at least in the abstract, one of ordinary skill in the art might understand the term "instruction" to apply to multiple levels of computer architecture. The relevant question, however, is how a person of ordinary skill in the art would understand the term "instruction" in the context of this patent. See Nystrom, 424 F.3d at 1142 (holding that "[t]he person of ordinary skill in the art views the claim term in light of the entire intrinsic record").

The problem addressed by the patent is the slow and inefficient manner in which the prior art translated Java bytecodes into native instructions that can be executed by a CPU. See '215 patent, col. 1, 11. 38-67. The essence of the patented invention is a hardware accelerator that speeds up this translation. See id., col. 2, 11. 1-7. All of the claims describe a hardware unit that translates stack-based instructions, e.g., Java bytecodes, into register-based instructions. Given this context, the Court concludes that a person of ordinary skill in the art would understand the term "instructions" to refer to Java bytecodes or the native instructions to which those bytecodes are translated. See Nystrom, 424 F.3d at 1145 (holding that the background section of the specification frames the invention in context and can implicitly limit claim terms); Irdeto Access, Inc. v. Echostar Satellite Corp., 383 F.3d 1295, 1300 (Fed. Cir. 2004) ("Even when guidance is not provided in explicit definitional format, the specification may define claim terms by implication such that the meaning may be found in or ascertained by a reading of the patent documents") (citations omitted). This translation, as described by the specification, necessarily occurs upstream of the CPU's decode stage--otherwise, the CPU would not be able to process the Java bytecodes. See '215 patent, col. 1, 11. 24-38.
Nazomi points to claim 30, "wherein the central processing unit includes an execution unit to execute the register-based instructions." Nazomi also points to claim 32, "wherein register-based instructions cause the manipulation of the register file," pointing out that the register file provides input to the execute logic stage. Read literally then, these claims would appear to indicate that "instructions" exist after the decode stage. Such a reading, however, would not make sense. It appears clear from a reading of the entire specification that the register-based instructions referred to by the claims are native instructions input at the beginning of the pipeline, i.e., at the instruction fetch stage. Such instructions do not exist in the same form after the decode stage. While it acknowledges that the language of claims 30 and 32 could be confusing, the Court concludes that the most likely explanation is that the inventor was using the term "instruction" imprecisely in these two instances. Certainly, when native instructions are processed in the pipeline they "cause" a downstream effect, e.g., manipulation of the register file. The Court concludes that the inventor must have been referring to this downstream effect rather than indicating that native instructions exist after the decode stage.

B. Specification

The foregoing construction is consistent with the specification, which consistently uses the term "instruction" to refer either to Java bytecodes or to native processor instructions. The specification never indicates that the term "instruction" means the control signals that are the output of the decode stage and never uses the phrase "microinstruction" or "low level instruction." Nazomi points to the following language:

The CPU is divided into pipeline stages including the instruction fetch 26a, instruction decode 26b, execute logic 26c, memory access logic 26d, and writeback logic 26e. The execute logic 26c executes the native instructions and thus can determine whether a branch instruction is taken and issue the "branch taken" signal.

'215 patent, col. 5,11.12-17. Again, Nazomi is trying to demonstrate that "instructions" exist after the decode stage and in fact are executed by the execute logic stage. Such a literal reading would make no sense here, however; according to the background section of the specification, native instructions are the result of a compiler or Java translator and are inputs to the CPU's decode stage. See '215 patent, col. 1, 11. 13-45. Taken in context, the stray references cited by Nazomi must be shorthand for the fact that the execute logic stage carries out the operations specified by the native instructions.

Nazomi also makes reference to the following language in the specification indicating that the hardware accelerator "can be incorporated into" the CPU:

Although the Java hardware accelerator is shown in FIG. 1 as separate from the central processing unit, the Java hardware accelerator can be incorporated into a central processing unit. In that case, the central processing unit has a Java hardware accelerator subunit to translate Java bytecode into the native instructions operated on by the main portion of the CPU.

Nazomi argues that the reference to "incorporation" into the CPU refers to logical incorporation, that is, insertion of the hardware accelerator into the pipeline such that the register-based instructions that are the output of the accelerator would not be input to the decode stage. There does not appear to be any support for this argument in the specification itself, which gives no indication that the translated Java bytecodes enter the pipeline at anyplace other than the instruction fetch stage. Nazomi submits a second declaration of the inventor, Mr. Patel, providing several figures showing how the hardware accelerator could be integrated into the CPU pipeline. None of these figures appears in the patent specification, however.

The Court notes that the specification references an "embedded solution in which the hardware accelerator is positioned on the same chip as the existing CPU design." '215 patent, col. 6,11.56-59. Arguably the reference to "incorporation" refers to this "embedded" solution, in which the hardware accelerator is merely on the same chip as the CPU. Even if the reference to "incorporation" means physical incorporation into the CPU, however, the Court concludes that the specification gives no indication that the logical relationship between the hardware unit's output and the pipeline would be changed. In other words, there is no indication that the hardware unit ever is located anywhere other than upstream of the decode stage. n
n3 Nazomi devotes extensive argument to its position that the presence of the hardware unit on the same chip as the CPU, or within the CPU but upstream of the pipeline, would not satisfy the requirement of an "integrated embodiment." The patent does not use the phrase "integrated embodiment" or even the term "integrated." The term used by the patent is "incorporated." Nazomi appears to have transmuted the term "incorporated" into "integrated." The patent does not use the term "integrated."

C. Prosecution History

The Federal Circuit's remand order suggests that the Court consider the prior art references by Krall, et al. and Dickol, et al. Nazomi, 403 F.3d at 1369. Both the Krall article and the Dickol patent use the term "instruction" to refer to Java bytecodes or native instructions; neither uses the term "instruction" to refer to the control signals that are the output of the decode stage.

Nazomi cites other prior art references, Coon and Trembley. Neither were discussed by the examiner. Nazomi nonetheless argues that these references use the term "instructions" broadly to encompass multiple levels of computer architecture. As it noted above, the Court is prepared to accept the proposition that, in the abstract, the term "instruction" could have the very broad meaning attributed to it by Nazomi. The question, however, is the meaning of the term as used in this patent. Because the prosecution history does not disclose any discussion of Coon or Trembley, these references are not useful to this inquiry.

D. Appropriate Construction

As the Federal Circuit noted, and as is described above, "[i]n this patent, it appears that the inventor defined 'instructions' in an indirect manner. Specifically, the specification refers primarily to what the instructions do and where they may do it." Nazomi, 403 F.3d at 1369. Consistent with the manner in which the inventor defined the term, the Court construes the term "instruction" to mean either a stack-based instruction that is to be translated into a register-based instruction, or a register-based instructions that is input to the CPU pipeline. In either case the "instruction" must be upstream of the decode stage of the CPU pipeline. As used in the claims of the patent, "instruction" cannot mean the control signals that are the output of the decode stage.
of fields that is universally used by computer programmers.

Defendant does not challenge plaintiff's representation of the ordinary and customary meaning of the term instruction, but urges that within the four corners of the patent, the term has a specialized meaning, that is, that it is limited to the particular format of OP, S1, S2, D. Although this particular instruction format is found in the preferred embodiment, it is not found in all of the claims. It is well established that it is improper to read a particular preferred embodiment into the claims. See Texas Digital, 308 F.3d at 1203. Moreover, inasmuch as the OP, S1, S2, D instruction format is found only in some claims (e.g., dependent claim 2) but not in others (e.g., independent claim 1, from which claim 2 depends), defendant's proposed construction violates the doctrine of claim differentiation. Thus, defendant has not overcome the heavy presumption that the claim term carries its ordinary and customary meaning. See Altiris, Inc. v. Symantec Corp., 318 F.3d 1363.

The contemporaneous ordinary and customary meaning of the term "instruction" is fully consistent with the patent. There is no basis in the patent or the prosecution history to limit the instruction in claims 1, 14 and 15 to a particular format. As will be seen below, the Court construes the patent as teaching a technique for detecting dependency free computer instructions and finds no basis to construe the technique as limited to environments in which the instructions have particular formats. Thus, the Court construes the term "instruction" in independent claims 1, 14 and 15 to mean "an expression that specifies one or more operations and identifies the applicable operands."

Instruction (claim 6)

Independent claim 6 recites a specific instruction format: OP, S1, S2, D. Accordingly, the term "instruction" in claim 6 means "an expression that has a specific format (i.e., OP, S1, S2, D)."

Instruction cycle/variable number of instruction cycles

This term appears in claims 1-12 of the '037 patent. The court construes this term as proposed by Biax. The term means "the period of time between the issuing of two successive instructions." No additional construction of "variable number of instruction cycles" is required.

"a site instruction file"

Southwest argues that the term means "an electronic file containing instructions which tell the data processing system at each remote location which general coupon templates to download and which site specific information files to download," which is the agreed upon construction for the term "a location instruction file" as used in claim 1 of the '673 patent. 3T argues that the term "site instruction file" is indefinite because the term does not appear in the specification, it only appears in claim 6 of the '673 patent, and that it has no readily ascertainable meaning. Claim 6 of the '673 patent requires both a "site specific information file" and a "site instruction file." Claim 1 requires a "site specific information file" and a "site instruction file." Claim 1 has a "site specific information file" and a "location instruction file." The parties have agreed to a construction of the terms "site specific information file" and "location instruction file," but disagree as to the term "site instruction file."

The Court does not find this term to be indefinite. A claim is indefinite only if the "claim is insolubly ambiguous, and no narrowing construction can properly be adopted." Exxon, 265 F.3d at 1375; Honeywell, 341 F.3d at 1338-39. This term is not "insolubly ambiguous" so as to prevent construction. See Young, 492 F.3d at 1346 (claims are considered indefinite when they are "not amenable to construction or are insolubly ambiguous"). While it is true that "site instruction file" is not defined or used in the specification, the terms "site" and "location" have the same meaning as found throughout the specification and as agreed upon by the parties. Thus, one of ordinary skill in the art would understand that "site instruction file" and "location instruction file" mean the same thing, and would thereby understand the metes and bounds of the claim. See Exxon, 265 F.3d at 1375 ("If the meaning of the claim is discernible, even though the task may be formidable and the
conclusion may be one over which reasonable persons will disagree, we have held the claim sufficiently clear to avoid invalidity on indefiniteness grounds.

The Court finds that the term "a site instruction file" should have the same meaning as the agreed upon construction for "a location instruction file." Thus, the Court construes the term "a site instruction file" to mean "an electronic file containing instructions which tell the data processing system at each remote location which general coupon templates to download and which site specific information files to download."

6. Instruction firing time

The next dispute relates to the term "instruction firing time." The term appears in various claims of the '755 and the '945 patents. In the patents, the TOLL software adds intelligence to the instruction stream. Some of that intelligence provides an "instruction firing time" or IFT. The parties dispute whether the IFT may be a relative time or whether it must mean a specific time. The court is persuaded that the plaintiff's view of this term is more appropriate. One passage from the specification supports the view that the instruction firing time may be a relative one: "[i]n the preferred embodiment of the invention, [the added intelligence] is the assignment of an instruction's execution time relative to the execution times of the other instructions in the stream." '755 patent, col. 10,11.28-31. After considering the parties' arguments on this point, the court concludes that the definition adopted by the ITC judge in Biax's collateral proceeding against Texas Instruments is correct. The court construes the term in this case to mean "intelligence used to indicate when a given instruction may be executed."

c. "Instruction groups"

The next term is "Instruction groups." The plaintiffs' proposed construction is "sets of from 1 to a maximum number of sequential instructions, each set being provided to the instruction register as a unit and having a boundary." The defendants propose "sets of from 1 to a maximum number of sequential instructions, in which the execution of the instruction depends on each set being provided to the instruction register as a unit and in which any operand that is present must be right justified and which cannot encompass a single 32-bit traditional conventional instruction." The dispute is whether an operand that is present in the instruction group must be right justified and whether the instruction group may encompass a single 32-bit traditional conventional instruction.

The plaintiffs contend that right justified operands are a feature of the preferred embodiment. The plaintiffs also argue that the claim language was broadened during prosecution history when the language "selecting, in accordance with position in said instruction register of one of said instructions of one of said instruction groups, an operand from said one of said instruction groups" was removed from the claim. Amendment, June 12, 1997, at 6. In addition, the plaintiffs point out that the specification includes 32-bit instructions. See '584 patent, 20:41-42.

The defendants argue that the specification states that "operands must be right justified in the instruction register." '584 patent, 16:15-16. In addition, the defendants argue that the applicants limited operands in this manner to overcome prior art rejections. See Amendment, June 17, 1997, at 13; Amendment, February 5, 1998, at 7. The defendants also contend that although the specification includes 32-bit instructions, the specification never identifies a single 32-bit instruction as instruction groups. According to the defendants, the specification defines "instruction group" as "being 8-bit and 16 or 24-bit instructions." '584 patent, 23:4-7.

The specification and prosecution history refer to the fact that operands in the instruction register must be right justified. The applicants, however, did not exclude a single 32-bit instruction as an instruction group. In a preferred embodiment, a microprocessor fetches instructions "in 32-bit chunks called 4-byte instruction groups" where an "instruction group may contain from one to four instructions." '584 patent, 23:4-5, 19:18-19. If a 4-byte (or 32-bit) instruction group contains one instruction, then the instruction group may contain a single 32-bit instruction. The Court construes "instruction groups" to mean "sets of from 1 to a maximum number of sequential instructions, each set being provided to the instruction register as
2. "Instructions"

Data General contends that "instructions" means S-Instructions which are a level below high-level language instructions and
a level above conventional machine language instructions. IBM argues that "instructions" means conventional machine
instructions into which programs written in high-level user languages are compiled for execution by the processor.

Claim 1 provides in relevant part:

...instructions, each one of said instructions containing an operation code of a plurality of operations codes, said
operation codes belonging to a plurality of functionally different operation code sets, said operation codes in a given one of
said operation code sets being definable solely with reference to said given operation code set....

'797 Patent, col. 4, ll. 29-36. Claim 1 also provides that the processor means receives and responds to said instructions by
performing the operation in the instruction. See '797 Patent, col. 4, ll. 38-44.

IBM offers extrinsic evidence that "instructions," to persons skilled in the art, means executable machine language
instructions into which high-level language programs are compiled. Before relying on extrinsic evidence, however, this
Court must look to the Common Specification to understand what the drafter of the patent meant by "instructions."

The Common Specification provides that:

CS 101 is both an S-Language machine and a Name-space machine. That is, operations to be executed by CS are
expressed as S-Language Operations (SOPs) while operands are identified by Names. SOPs are of a lower, more detailed,
level than user language instructions, for example FORTRAN and COBOL, but of a higher level than conventional machine
language instructions. SOPs are specific to particular user languages rather than a particular embodiment of CS 101, while
conventional machine language instructions are specific to particular machines. SOPs are in turn interpreted and executed
by microcode. There will be a S-Language Dialect, a set of SOPs, for each user languages (sic). CS 101, for example, may
have SOP Dialects for COBOL, FORTRAN, and SPL.

'602 Specification, col. 21, l. 57 - col. 22, l. 3. (emphasis added). Thus, the Common Specification makes it clear that the
claim language referring to functionally different operation code sets refers to the S-Instructions (or SOPs) of S-Languages.

IBM's contention that Data General would have used the word "S-Instructions" rather than "instructions" if it had meant the
former is baseless. Because the concept of "S-Instructions" and a mechanism to compile high-level languages into such
instructions which are then converted into machine instructions by S-Language interpreters was a novel concept when the
patent was issued, it stands to reason that the patent drafters would explain S-Instructions in a detailed manner.

Furthermore, it is not necessarily true, as IBM implies, that the processor cannot execute S-Instructions, and that the
instructions which the processor receives from memory and responds to must therefore be conventional machine
instructions. Its implication is inaccurate because the processor receives S-Instructions and uses an S-Language interpreter
to convert them to machine instructions. Thus "instructions" received by the processor may be S-Instructions.

IBM argues that "instructions" could not mean S-Instructions because it would render superfluous all of the limitations set
forth in the claim. That argument is nonsensical. The Court does not construe "instructions" as S-Instructions, thereby
rendering the surrounding language superfluous, but rather, interprets the entire description of "instructions," including the
descriptive characteristics which follow it, as S-Instructions.

Nor does construing "instructions" to mean S-Instructions "disregard" the plain meaning of the word "said," as IBM argues.
Claim 1 first establishes that "said" instructions refer to instructions which are part of the data provided by the memory
means and then describes the characteristics of such instructions.

This Court construes "instructions" to mean "S-Instructions" which are a level below high-level language instructions and a
level above conventional machine language instructions.

8. "Instructions" (Claim 10)
Despite Broadcom's assertion that no construction is necessary, the Court finds that the technical meaning of this term in the context of the '705 patent requires some clarification for the trier-of-fact. At the Markman hearing, both parties agreed that the IEEE definition of "any executable statement in a computer program" is an accurate construction of the claim term. IEEE STANDARD DICTIONARY OF ELECTRICAL AND ELECTRONICS TERMS 232 (5th ed. 1996); (see R. at 331, 335 (May 6, 2004).) Accordingly, the Court adopts this definition as the construction of the term "instructions."

C. "Instructions"

Intel's next contention is that the district court erroneously construed the term "instruction," found in both the '028 and the '003 patents, to have different meanings in different parts of the claims. Intel urges us to interpret the term "instruction" to mean "a complete instruction corresponding to a traditional programmer visible command that uniquely describes one basic computer operation." Under either the district court's construction or its own proposed construction, Intel contends that the accused devices do not infringe because they do not store "instructions" with embedded pipeline identifiers or route "instructions" through the crossbar as the claims require.

Intergraph counters that the district court's construction of the term "instruction" is both consistent and correct because, at every stage, an "instruction" is the smallest unit of work capable of being processed. Intergraph further argues that the accused devices' syllables and templates are the "instructions" in the storage stage and that the accused devices' syllables are the "instructions" in the routing stage.

We agree with Intergraph that the district court did not err in construing the claim term "instruction." Claim 20 of the '028 patent and claims 1, 6, and 22 of the '003 patent refer to storing "instructions" in VLIW or super-scaler storage and then routing "instructions" to appropriate processing pipelines. Taking into account both the storage stage and the routing stage, the district court interpreted the term "instructions" to mean simply "the smallest unit of work capable of being processed at any particular stage in the computer." That construction does not run afoul of the general rule that a claim term should be interpreted consistently throughout a claim, see Phonometrics, Inc. v. N. Telecom Inc., 133 F.3d 1459, 1465 (Fed. Cir. 1998); Southwall Techs., Inc. v. Cardinal IG Co., 54 F.3d 1570, 1579 (Fed. Cir. 1995), for it treats an "instruction" as always being the "smallest unit of work capable of being processed." Moreover, the patent does not require that an "instruction" contain a specific, or even unvarying, number of bits. On the contrary, the specification of the '028 patent shows that an "instruction" may contain 64 bits in the storage stage and only 57 bits in the routing stage, after the group and pipeline identifiers have been discarded. See '028 patent, col. 7, l. 56 ("As shown [in Figure 7], the instructions are expanded to 64 bit length . . . "); id., col. 9, ll. 30-62 & fig. 10 (depicting 64-bit "instructions" as each consisting of a 57-bit word, a 3-bit group identifier, and a 4-bit pipeline identifier); id., col. 10, ll. 31-32 & fig. 11 (referring to the 57-bit words as "instructions" that are executed by the processing pipelines). It is therefore irrelevant whether the number of bits composing an "instruction" is constant throughout all of the recited stages of processing. We accordingly affirm the district court's construction of the term "instructions."

We also agree with Intergraph that the district court did not clearly err in finding that the accused devices have "instructions" in both the storage and the routing stages. First, the record supports the finding that the accused devices' syllables and templates constitute "instructions" in the storage stage. To be sure, the parties offered conflicting evidence regarding whether the accused devices' templates ever reach the rotate buffer and hence ever reside in VLIW or super-scaler storage. Nonetheless, the district court reasonably chose to rely on the testimony of Intergraph's expert, who stated that, based on his review of an Intel design document, both the syllables and the templates in the accused devices are sent to the rotate buffer. See Findings and Conclusions, 2002 U.S. Dist. LEXIS 27116. Moreover, that Intel document also appears to show bundles, which include both syllables and templates, as leaving the rotator in the accused devices. It was therefore not clearly erroneous for the court to resolve this factual dispute by finding that the accused devices have "instructions," which include embedded pipeline identifiers in the form of the templates, in the storage stage. 2002 U.S. Dist. LEXIS 27116.

Second, the record also supports the finding that the accused devices' syllables constitute "instructions" in the routing stage. On this point, Intel's own expert agreed that the accused devices' syllables are the smallest units that an execution pipeline needs for processing, thereby fitting the court's definition of "instructions" in the routing stage. We therefore conclude that the district court's finding that the accused devices have the recited "instructions" was not clearly erroneous.
executable instructions for building a displayable inventory of works

This term appears in claim 1 of the '345 patent. After briefing its proposed construction of this term in its opening brief, Premier, in its reply brief, asked the court to withdraw this term from consideration. At oral argument, Apple urged the court to construe this term. The court will construe this term.

Premier's originally proposed construction of this term is "executable computer instructions for creating a displayable inventory of works, without the user having to manually transfer each song or enter information about each song." Apple's counter-construction is "instructions which cause the circuitry to create an inventory of works that can be displayed." The court construes this term to mean "computer instructions for automatically creating an inventory of works that can be displayed."

c. The "Automatic" and "Electronic" Limitations

The parties also dispute the level of user interaction required by the claims to complete the registration step and to enable the software beyond the grace period previously enabled by the initial authorization code. This dispute implicates two related limitations recited in the asserted claims. Claims 44 and 131 of the '471 patent recite "requiring the user to selectively choose either manual or electronic registration" (emphasis added), while claim 32 of the '825 patent recites "instructions for automatically contacting an authorized representative . . . to communicate registration information and obtaining authorization for continued operation" (emphasis added). Despite the difference in the language of the claims, the parties agree that for purposes of this appeal, the terms "automatic" and "electronic" may be analyzed together.

At the district court, Microsoft suggested a construction of the term "automatically" to be "without user discretion or intervention." The district court disagreed and instead construed the term to mean "instructions (i.e. a computer code) that enable a user's computer to contact an authorized representative of the software." Claim Construction Opinion at 6-8. The court did not construe the term "electronic," but noted that "[i]n open court, the parties agreed to use the claim language for this term." Id. at 8. Microsoft further agreed that it would not argue at trial 'that 'electronic' means 'without user intervention' without leave of Court." Id.

On appeal, Microsoft contends that once users choose the electronic or automatic registration mode (as contrasted with the manual mode), the initiation of the registration communication must commence without any user interaction.

We find Microsoft's claim construction arguments to be without merit. As the district court carefully observed, the claims are silent as to the initiation of the registration process, although the claims and specification "clearly contemplate[ ] a user choice as to whether registration will be automatic or manual." Id. at 6 (citing '471 patent col.7 ll.7-18 ("The user is allowed to choose between automatic or manual registration.")); see also '825 patent claims 44 & 131 ("requiring the user to selectively choose either manual or electronic registration"). Although the specification discloses that automatic registration is performed "without user intervention," '471 patent col.4 ll.50-54 (emphasis added), the claims require at least a minimal level of user interaction to select this registration mode. Indeed, nothing in the claims or specification precludes user interaction in the selection or initialization of the automatic registration. Thus, the district court correctly rejected Microsoft's attempt to exclude any user interaction from the claims, and we affirm its construction of this term. Microsoft makes no effort to argue non-infringement under this construction, and its own product documentation, which was presented to the jury, characterizes the Internet option as "automatically activating the [accused product]."

Moreover, even under Microsoft's proposed construction, its sole non-infringement argument is artificial at best. Specifically, Microsoft argues that although the accused products allow users to choose between Internet (i.e., automatic or electronic) or phone (i.e., manual) activation, if the user chooses the Internet option, "nothing happens after that manual
choice until the user additionally manually presses the 'next' button . . . " Microsoft Br. at 23. Thus, even under Microsoft's construction, a reasonable juror could find that "manually press[ing] the 'next' button" is merely part of the selection process. Therefore, we affirm the judgment of infringement with respect to these limitations as well.

7. **executable instructions for creating at least one play list by selecting works in accordance with a predetermined criterion**

This term appears in claim 31 of the '345 patent. The plaintiff's proposed construction is "executable computer instructions for automatically creating a play list by selecting works corresponding to a user-selected characteristic (as defined above), without the user having to individually select each work to be included in the play list." The defendant contends that no construction of this term is necessary. Alternatively, the defendant proposes a construction of "instructions for creating at least one play list by selecting works corresponding to a user-selected criterion, such as, for example, Artist, Genre, Beats Per Minute, and Most Played." At the Markman hearing, Apple argued that Premier's inclusion of "automatically creating a play list" in its construction was improper because such construction excludes a preferred embodiment from the claims, e.g. the creation of a play list by a user. Other claims, however, embrace the concept of a play list created with the user's intervention. See, e.g., '725 patent, cl. 1. This fact, coupled with the disclosure of Figure 4H, supports Premier's construction.

The court construes this term to mean "computer instructions for automatically creating at least one play list based on a user-selected criterion."

13. **instructions for effecting royalty payments to appropriate recipients**

This term appears in claim 84 of the '725 patent. The plaintiff proposes a construction of "computer instructions that cause royalty payments to be made to third parties entitled to royalties for the works." The defendant counters with "instructions that make royalty payments for the works." The dispute is the extent to which the instructions must automate the entire payment process. Consistent with its construction of the preceding terms relating to computer instructions, the court construes this term to mean "computer instructions that automatically cause royalty payments to be made to appropriate recipients."

6. **the circuitry includes instructions for selecting works to be included in the displayable list in accordance with a selected characteristic**

This term appears in claim 11 of the '345 patent. The plaintiff proposes a construction of "executable computer instructions for automatically selecting works to be included in the displayable play list corresponding to a user-selected characteristic (as defined above), without the user having to individually select each work to be included in the list." The defendant urges that no construction of this term is necessary. In the alternative, however, the defendant suggests the following construction: "instructions for selecting works to be included in the displayable list based on a chosen characteristic (as defined above)."

The parties dispute 1) whether a "displayable list" as used in the above term is really a "play list," and 2) whether the phrase "instructions for selecting works" means that instructions, as opposed to a user, selects the works for inclusion in the displayable list. Claim 11 of the '345 patent, in conjunction with Figure 4H, clarifies these issues. In contrast to many of the claims of the patents-in-suit, which are drawn to play lists, claim 11 of the '345 patent is drawn instead to a "displayable list." As shown in Figure 4H, the upper list, labeled "Media Inventory," is a listing of works in the media inventory. As shown by the "Source Song Selection Parameters" window in Figure 4H, a user can select characteristics and automatically generate a "displayable list" via computer instructions. The "displayable list" is a sub-set of the media inventory. It is then displayed as the source of songs from which a user may build a play list. Claim 11 is directed toward the automatic creation, via computer instructions, of a "displayable list," as opposed to a play list. For these reasons, the court construes the above
term to mean "computer instructions for automatically selecting works to be included in the displayable list based on a user-selected characteristic."

2252

2. Construction of "Microcontroller Set of Instructions Signals Received from the Call Progress Detector Circuitry"

For reasons stated on the record during the Markman hearing, this Court construes "microcontroller set of instructions signals received from the call progress detector circuitry" to mean "the call progress detector circuitry outputs a signal corresponding to the call waiting signal to recognition circuitry." This phrase is found in claim 1 of the '771 Patent.

GO BACK

2253

G. "instrument" and "payment instrument"

Term
"an originator party creating an instrument for transferring funds to a recipient party, the instrument information comprising (i) a variable authentication number (VAN), and (ii) one or more pieces of payment information including an amount, information for identifying the recipient party or the originator party, a date, and a check control or serial number" '148, Claim 35.

Plaintiff's Definition
Instrument: document (including paper or electronic) that is used to transfer funds to a recipient party

Defendants' Definition
A document, that is an instrument of commerce, used to transfer funds to a recipient party

Payment instrument: a document (including paper or electronic) that is used to transfer funds to a recipient party in connection with a payment.

This term appears in claims 34 and 35 of the '148 patent. The parties' essential dispute is whether the instrument can be mere instructions to pay the recipient party or whether the instrument must be commercial paper. Plaintiff argues that the specification is not limited to checks, but can include a set of instructions. Defendants argue that Plaintiff's proposal is overbroad. Defendants believe that the scope of the invention is limited to negotiable instruments.

The specification's inclusion of a cashless system indicates electronic instructions are within the scope of the invention. The Court adopts Plaintiff's construction.

GO BACK

2254

C. "Instrument" or "Payment Instrument"

The claims in the '148 patent state that an instrument is "for transferring funds." ('148 patent, col. 24, ll. 43-44; col. 28, ll. 37-38) Similarly, a payment instrument is "to make a payment." ('148 patent, col. 26, ll. 12-13) Accordingly, the term "instrument" or "payment instrument" shall be construed to mean "a document used to transfer funds to a recipient party."
8. "insulated lead wire having first and second ends"

Claims 1, 12, and 17 of the '919 Patent disclose an "insulated lead wire having first and second ends." Philips asserts that this term should be defined as "a round wire covered by an electrically insulating material, such as polyvinyl chloride, and having two ends used to connect two points in a circuit." Cardiac Science maintains that a "lead wire" is a "conductive wire, trace, or strip."

The Court finds no support for Philips' assertions that the term should be construed to include a "round" wire covered by a specific insulating material. These descriptors merely impart limitations from the preferred embodiment into the claim construction. In the specification, the "wire lead" deals with the electrical contact that is made between the gel layer and the AED. However, this need not be a lead wire with "two ends used to connect two points in a circuit." The Court finds that the term is properly described as an "insulated conductive wire."

2256

1. "an insulating film covering the surface of said substrate on which the MOSFET is formed"

Toshiba contends that this term does not need construction, but if construed, it means "a non-conducting film that is over a portion of the surface of a substrate on which the MOSFET is formed." Jt Cl Const, Ex A at 1. Hynix instead proposes a construction of "an insulating film that spreads over and is in contact with the entire surface of the semiconductor substrate in which source and drain regions are formed." Id.

There appear to be three points of disagreement between the parties on this term: (1) Can the film cover just a portion of the "surface of said substrate" or must the film cover the entire surface? (2) Can the film merely be over the surface or must the film be in contact with the surface? (3) Should the term "surface of said substrate on which the MOSFET if formed" be left as is or should it be redefined as the "surface of the semiconductor substrate in which source and drain regions are formed?"

Regarding the first point, the court observes that the clause in which this term appears states in full: "a bit line connected to one of the source and drain regions of said MOSFET through a bit line contact hole made in an insulating film covering the surface of said substrate on which the MOSFET is formed." Based on this language, Toshiba contends, "[T]he insulating film cannot possibly cover the entire semiconductor substrate, as the insulating film must have contact holes in it that reach to the substrate." Doc # 26 of 05-4100 VRW (Toshiba Br) at 5. Hynix counters that "[c]laim 1 only requires that the insulating film be 'covering' the substrate before the contact holes are made in it." Doc # 33 of 05-4100 VRW (Hynix Rep) at 3 (emphasis in original).

In its submission to the court in support of its Markman presentation, Toshiba admitted that Hynix is factually correct on this point, Toshiba Markman Presentation at 5, but explained that claim 1 describes a finished product; hence, to say that the insulating film spread over "the entire surface of the semiconductor substrate" is misleading. Toshiba Br at 4-5. But Toshiba's construction is also misleading because it suggests that even before the contact holes were made, the insulating film only covered a portion of the substrate surface.

Instead, the original claim language is superior to both parties' constructions. Without describing the scope of the insulating film's initial coverage of the substrate surface, the claim states that the insulating film's coverage decreases after the contact holes are made. To infer that, prior to making the contact holes, the insulating film covered either the entire surface or only a part of the surface would be impermissibly to read in a limitation from the specification. Teleflex, 299 F3d at 1326.

Accordingly, the court declines to construe the term on this point.

Turning to the second issue, Hynix cites to various portions of the specification to argue, "[T]he term 'covering' is used repeatedly to refer to a film that is spread over and in contact with the entire surface of the structure." Doc # 29 of 05-4100 VRW (Hynix Br) at 5. But in every embodiment that Hynix cites, only the MOSFET's gate electrode is in contact with the
insulating film, not the portions of the MOSFET within the semiconductor substrate (i.e., the source and drain regions). See '579 patent at 6:29-31, FIG 1(b); 10:36-38, FIG 16(b); 14:10-13, FIG 25(a). Indeed, as Toshiba notes, "if the entire surface of the substrate (including the source and drain regions) were covered and in contact with the insulating film, then the source and drain could not connect to the bit line and storage node electrode as required by the claim." Doc # 30 of 05-4100 VRW (Toshiba Rep) at 2. Because Hynix's proposed construction on this point cannot be correct and because there is no indication that the phrase "insulating film covering the surface" is necessarily limited to the situation in which the film is in contact with the surface, the court declines to construe the term on this point.

Finally, Hynix proposes equating "surface of said substrate on which the MOSFET is formed" with "surface of the semiconductor substrate in which source and drain regions are formed." Even if this proposed construction correct, it appears unnecessary. The claim states that the memory device comprises "a MOSFET including a gate electrode and source and drain regions of a second electrical conductivity type impurity material formed in a surface of a semiconductor substrate." This description clearly indicates the MOSFET's location in relation to the semiconductor surface; hence, it is unnecessary to further define what constitutes the "surface of [the] substrate on which the MOSFET is formed."

In sum, because the language for this term is both sufficiently clear and is in fact superior to the proposed constructions, the court declines to construe this term.

3. "Insulating housing"

The term "insulating housing" appears in claim 1 of the '641 patent as follows:

1. A modular jack to be mounted on a circuit board, said modular jack comprising:

   a printed board containing an electronic element for suppressing noise;

   a contactor for contacting with a plug, said contactor being electrically connected with the electronic element by a wire on the printed board;

   a terminal for contacting with the circuit board, said terminal being electrically connected with the electronic element by a wire on the printed board; and an insulating housing for encasing the printed board.

Murata argues that "insulating housing" means "a covering which has a high electrical resistance and which can serve to prevent a short circuit between components." Murata's Opening Brief, at 22. Bel Fuse argues that "insulating housing" means "an enclosure for separating a part or mechanism from an electrical conductor by means of an electrical non-conductor to prevent transfer of electricity between the part or mechanism and the conductor." Bel Fuse's Responsive Brief, at 29. The primary difference between the proposed constructions is that Murata's would require the housing to be made of non-conductive material while Bel Fuse's would not require non-conductive material as long as the housing still performed the function of insulating.

Again, the court begins with a review of the specification of the '641 Patent. When describing the first preferred embodiment, the specification states: "[A] modular jack has an insulating housing 12 which comprises a base 14 and a lid 16 which are engaged by interlocked coupling. Both the base 14 and the lid 16 are made of an insulating material such as plastic." '641 Patent, col. 3, 11 3-7. The specification is otherwise silent on the insulating properties of the housing.

Murata argues that the housing must be made of insulating material because if it were made of conductive material, the preferred embodiment would be inoperable. See, e.g., Pfizer, Inc. v. Teva Pharmaceuticals, USA, Inc., 429 F.3d 1364, 1374 (Fed. Cir. 2005) ("A claim construction that excludes a preferred embodiment is rarely, if ever, correct.") (internal quotations and punctuation omitted). As shown in Figure 1 of the '641 patent, the contactor 35 and terminals 36 are both in direct contact with the housing. Thus, if the housing were made of conductive material, the contactor and terminals would short circuit with the housing, rendering this embodiment inoperable. However, the court disagrees that Bel Fuse's proposed construction would exclude the preferred embodiment because Bel Fuse's construction permits, but does not require, the
housing to be made of conductive material. Because under Bel Fuse's proposed construction the housing could be made of non-conductive material, the preferred embodiment would still fall within the scope of the claim 1.

That being said, the court nevertheless finds that a person of ordinary skill in the art would find that an "insulating housing" as that term is used in claim 1 of the '641 Patent must be made of insulating material. Bel Fuse spends much of its brief on this term arguing the merits of its inequitable conduct defense and gives short shrift to explaining how a person of ordinary skill in the art would have interpreted this term.

Even if the court accepts Bel Fuse's grammatical argument, however, the court must still reject Bel Fuse's proposed construction. The court fails to see how a housing made of conductive material could be used for the purpose of insulating. Bel Fuse posits that the housing can still be insulating if separated from the components by a non-conductive insert or by air. However, in those cases, it seems that the insert or the air has the purpose of insulating, not the housing. For the housing to have the purpose of insulating, it must perform that function itself, and the only way it can do so is to be made from insulating material. Thus, the court finds that the "insulating housing" as used in claim 1 of the '641 Patent must be made of insulating material. This limitation is supported both by the language of the claim which requires an insulating housing and by the specification, which states that the housing of the preferred embodiment is made of an insulating material such as plastic. Accordingly, "insulating housing" means "a covering which has a high electrical resistance and which can serve to prevent a short circuit between components."

Bel Fuse has not provided any suggestion that a person of ordinary skill in the art would interpret "insulating housing" in the modular jack of the '641 Patent as being made of conductive material, and has not shown that a modular jack with a conductive housing would even be operable. Under claim 1 of the '641 Patent, the modular jack includes a contactor for contacting with a plug, and the contactor is electrically connected with electronic element for suppressing noise by a wire on the printed board. The printed board is encased in the insulated housing. It is difficult to imagine how the housing for the jack could be made of conductive material and still be insulated from the contactor; the same holds true for the terminals. Thus, the court finds that a person of ordinary skill in the art would find that "insulating housing" refers to a housing made of non-conductive material.
The Court agrees with Samsung and construes the term "insulating layer" in claim 11 of the '339 patent and claim 3 of the '442 patent as "a layer made of one or more materials that are poor conductors of electricity." MEI argues that the construction should be "a layer of one material that is a poor conductor of electricity." MEI's construction is overly narrow--the patent clearly encompasses an insulating layer composed of more than one material or sublayer. See '339 Patent Figs. 7d-7f (disclosing an insulating layer composed of two sublayers); col. 3:39-41 (disclosing an insulating layer made of two materials).

A. "Insulating Material"

The district court construed "insulating material" as follows:

- a material with poor electrical conduction that acts to suppress switching noise generated by a pulse width modulation control of the direct driving motor, thereby suppressing the video screen and audio noise caused by electrical noise produced by the capstan motor.

Daewoo argues that the court's definition of insulating material as a material having "poor electrical conduction" renders the claim construction fatally flawed because it improperly uses comparative language. Daewoo states that the district court in its claim construction merely replaced one vague term ("insulating") with an even vaguer term ("poor electrical conduction"). Daewoo argues that the word "poor" is a comparative term, raising but not answering the question of "poor relative to what?" Daewoo states that an adequate definition of "insulating material" requires a numerical resistivity limit, such as 107 ohm-cm or greater, which corresponds to the resistivity of materials illustrated in the '210 specification, in order to provide certainty and clarity to the claims. Funai responds that "poor electrical conduction" adequately describes the insulating material used in this context, and that a person of ordinary skill in the field of insulating motors and reading the specification would have no trouble understanding what is covered by the claim.

Daewoo also argues that the district court's further description of "insulating material" as a material that "acts to suppress switching noise generated by a pulse width modulation control of the direct driving motor" is "functional" and therefore "circular," and thus improper. In response Funai points to the specification's statement that the insulating material suppresses such noise, as supporting the court's construction.

The use of comparative and functional language to construe and explain a claim term is not improper. A description of what a component does may add clarity and understanding to the meaning and scope of the claim. The criterion is whether the explanation aids the court and the jury in understanding the term as it is used in the claimed invention. There was evidence in the district court that persons experienced in this field would understand this description of the insulating material, in the context in which it is used, as a poor electrical conductor serving the function set forth in the claim. No error can be attributed to this use of comparative and functional explanation in construing these claims.

10. "Insulating Member."

The court shall apply the ordinary definition of the phrase "insulating member." Thus, the phrase "insulating member" shall be construed to mean "a member which provides a high degree of resistance to the passage of charge."
Insulator Member

PPC objects to Magistrate Judge Peebles' recommended construction of the term "insulator member" as: "A single piece of material surrounding all or a portion of the conductor in the female connector passageway that inhibits or prevents the flow of electricity between the conductor and the female connector." Instead, PPC proposes the following construction: "A single piece of material surrounding all or all but an insubstantial portion of the conductor in the female connector passageway that inhibits or prevents the flow of electricity between the conductor and the female connector."

2 Although Arcom argued before Magistrate Judge Peebles that the term "insulator member" should not be limited to a single piece of material, Arcom does not object to his recommendation that it be so limited.

On reading the disputed term in the context of claims 23 and 25 themselves and in the context of the entire patent, the Court finds no support for the addition of the limitation propounded by PPC. Further, upon review of the prosecution history of the patent, the Court rejects PPC's argument that Arcom disowned or relinquished an insulator member that surrounds less than "all or all but an insubstantial portion of the conductor in the female connector passageway." Nor are PPC's other arguments persuasive. On de novo review, the Court adopts Magistrate Judge Peebles' recommended construction of the term "insulator member."

"Integrated aggregation module" appears in independent claim 15. Hyperion contends the term means a "module, performing aggregation, that is contained within an RDBMS program." Joint Cl Const at 33. HyperRoll instead contends that the term should be construed as a "software module that aggregates fact data and that works with an RDBMS." Id. Accordingly, the primary dispute here appears to be whether the module is contained within the RDBMS or instead whether it merely works with the RDBMS.

Hyperion contends that the prosecution history supports its construction because a patent examiner stated in a summary of an October 16, 2001, interview that "[t]he difference between the invention and the prior art is the approach that integrates the MDDB into an RDBMS in order to gain the benefits from each while overcoming the limitations of each." Doc # 197, Ex B at 1. Hyperion's argument does not even get off the ground because it is the applicant, not the examiner, who must give up or disclaim subject matter that would otherwise fall within the scope of the claims." Sorensen v ITC, 427 F3d 1375, 1379 (Fed Cir 2005) (internal citations and quotations omitted). But even if the applicant had made the statement that Hyperion relies upon, the language is ambiguous enough to support either HyperRoll's or Hyperion's constructions. See id at 1378-79 ("Disclaimers based on disavowing actions or statements during prosecution * * * must be both clear and unmistakable.").

Moreover, Hyperion's claim construction is problematic because it introduces the term "contained within," whose meaning is unclear. Indeed, Hyperion itself provided varying definitions of "contained within" in its opening brief and its reply brief. In its opening brief, Hyperion explained: "[C]omputer code that makes up the 'aggregation module' is contained within the computer code that makes up the RDBMS program. If they are separate pieces of software, they are not be [sic] integrated." Hyperion Br at 13-14. In its reply brief, however, Hyperion proposed a somewhat different definition: "If the module cannot operate independently of the RDBMS program, [the module] is 'contained within' the RDBMS program and thus integrated within it. If [the module] can operate independently of the RDBMS program, then [the module] is not integrated within it."
Hyperion Reply Br at 7. Hence, Hyperion has provided two different definitions of "contained within:" the first focuses on the location of the software module's code whereas the second focuses on the functionality of the module. Accordingly, Hyperion's proposed construction would not clarify the meaning of the term "integrated aggregation module."

Moreover, at no point does the specification require that software code for the "integrated aggregation module" be physically located in the same software code for the RDBMS. Rather, the specification appears to describe the relationship between the "integrated aggregation module" and the components in the RDBMS in functional terms. See '604 patent at FIG 6A and accompanying discussion. Common sense also suggests that the patentees did not intend to require the code for the "integrated aggregation module" to be located physically within the RDBMS, given that it would be trivial to design around such a claimed invention; for example, a software designer could link the "integrated aggregation module" to the RDBMS to avoid including the module's code within the RDBMS but to achieve the same result.

Nonetheless, HyperRoll's definition also is problematic because it unnecessarily imports functional limitations into the definition of "integrated aggregation module." The claim language already describes the functional relationship between the "integrated aggregation module" and the other components in the RDBMS. See '604 patent at claim 15 ("providing an integrated aggregation module, operatively coupled to the relational data store, for aggregating the fact data and storing the resultant aggregated data in a non-relational multi-dimensional data store"). Hence, it would be superfluous to interpret "integrated aggregation module" as containing these functional limitations.

Although the court presently declines to construe "integrated aggregation module," it flags two issues that might become relevant later. First, although not raised by either party, the court notes that the term "integrated aggregation module" appears to be used in claim 15 in almost the identical manner in which "aggregation module" is used in claim 1. Compare '604 patent at claim 1 ("an aggregation module, operatively coupled to the relational data store, for aggregating the fact data and storing the resultant aggregated data in a non-relational multi-dimensional data store") with id at claim 15 ("providing an integrated aggregation module, operatively coupled to the relational data store, for aggregating the fact data and storing the resultant aggregated data in a non-relational multi-dimensional data store"). This suggests either that the term "integrated" adds a separate limitation in claim 15 that does not exist in claim 1 or that the patentees are essentially using "aggregation module" and "integrated aggregation module" interchangeably. If necessary, this issue could be revisited at a later stage in these proceedings.

Additionally, it is conceivable, as Hyperion suggests, that the claim language sweeps too broadly and encompasses "clearly disparate programs [that should not] be considered 'integrated' in an RDBMS." Hyperion Reply Br at 7. The proper time for Hyperion to raise this argument is at the summary judgment stage, at which time it may argue that the patent is invalid in light of the prior art.

At the present time, however, because the meaning of "integrated aggregation module" is sufficiently clear based on the claim language, the court declines to construe this term.

C. "Integrated Circuit Means" and "Integrated Circuit"

The next terms to construe are "integrated circuit means" found in claims 2, 6, 20, and 27, and "integrated circuit" found in claim 8. Digital Angel argues that the term "integrated circuit" has a well known meaning to those of skill in the art, and therefore the presumption that 35 U.S.C. § 112, P 6 applies as a result of the use of the word "means" is rebutted. n3 Digital Angel supports its contention by referencing dictionary definitions of "integrated circuit" and highlighting the absence of the word "means" with respect to "integrated circuit" in claim 8. Digital Angel averrs that the claim language and specification evince an intent by the inventors to use the term "integrated circuit" in a broad manner rather than limiting the term to a particular type of integrated circuit. The invention should not be limited by the description of the preferred embodiment, and additional limitations in some of the dependent claims demonstrate that "integrated circuit" in the independent claims is to be interpreted broadly.
Digital Angel argues that none of the terms at issue are means-plus-function elements, and therefore, 35 U.S.C. § 112, P 6 does not apply to any of the terms. Because Defendants aver that 35 U.S.C. § 112, P 6 applies to the disputed claim terms that use the word "means," Digital Angel has provided the Court with alternate claim constructions: one that applies if the terms are construed to be means-plus-function elements, and one that applies if they are not. Defendants have only provided the Court with constructions of the disputed terms that assume that the terms are means-plus-function elements.

Consequently, Digital Angel defines "integrated circuit" and "integrated circuit means" as "any complex set of electronic components and their interconnections that are etched or imprinted on a chip." Joint Claim Constr. Statement, App. A at 2, 5-6, 11, 13. Digital Angel adds to the definition by reciting the functions that the "integrated circuit" must perform: store an identification code, output the identification code upon reception of an interrogation signal by said coil means, and generate a transmission frequency signal by dividing the frequency of the interrogation signal. Id.

Digital Angel proposes an alternative construction if "integrated circuit" is treated as a means-plus-function element. Digital Angel avers the functions recited in the claims are "storing an identification code and outputting the same upon reception of an interrogation signal by said coil means, and for generating a transmission frequency by dividing the frequency of the interrogation signal; detecting said interrogation signal; and transmitting an identification signal substantially instantaneously upon detection of the interrogation signal." Id. at 2, 5, 7, 11, 14. Digital Angel avers that the structure disclosed in the specification for performing the stated functions is "integrated circuit chip 54 and equivalents thereto," and the integrated circuit chip is "a completely self-contained unit that contains all the circuitry necessary to perform the transponder functions." Id.

By contrast, Defendants argue that the inclusion of the word "means" in "integrated circuit means" activates the presumption that 35 U.S.C. § 112, P 6 applies. Additionally, the presumption that 35 U.S.C. § 112, P 6 does not apply to the term "integrated circuit" in claim 8 because the word "means" is not specifically used, is rebutted because the term "integrated circuit" fails to recite sufficient structure for performing the functions stated in the claim. Defendants aver that the "integrated circuit means" claims recite the following functions, with some of the functions being performed by more than one of the claims: "detecting an interrogation signal, storing an identification code (and outputting the same upon reception of an interrogation signal), generating a transmission frequency by dividing the frequency of the interrogation signal, and generating and transmitting an identification signal." Id. at 2, 5-7, 11, 13-14. Defendants aver that the specification discloses separate and distinct structure for performing each of the stated functions:

. The corresponding structure for detecting an interrogation signal is a full wave rectifier and voltage regulator having the structure illustrated in Fig. 12 of the '129 patent.

. The corresponding structure for storing (and outputting) an identification code is a 40-bit programmable array consisting of 40 individual cells arranged in an 8x5 matrix, each cell consisting of two transistors connected by a fusible link to one of five common bus lines, each of the fusible links structured to be "blown" or "vaporized" for storing a respective bit of the identification code.

. The corresponding structure for generating a transmission frequency by dividing the frequency of the interrogation signal (by integer division or otherwise) is a Schmitt trigger and a counter circuit coupled to the Schmitt trigger and including multiple J-K flip/flops configured to divide the interrogation signal by 100 to produce a 4kHz transmission frequency.

. The corresponding structure for transmitting and generating an identification signal is a rectifier/regulator configured to receive the "Signal +" and "Signal -" signals communicated by the integrated circuit chip to modulate the interrogation frequency in accordance with the identification signal to be transmitted to the reader.

Id.

As an initial matter, the Court must determine whether "integrated circuit means" is a means-plus-function element. While a close question, the Court determines that the term "integrated circuit" has a reasonably well understood meaning in the art and connotes sufficient structure to rebut the presumption that the term is a mean-plus-function element. See Apex, Inc. v.
Raritan Computer, Inc., 325 F.3d 1364, 1373 (Fed. Cir. 2003)("While we do not find it necessary to hold that the term 'circuit' by itself always connotes sufficient structure, the term 'circuit' with an appropriate identifier such as 'interface,' 'programming,' and 'logic,' certainly identifies some structural meaning to one of ordinary skill in the art.").

"Integrated circuit" and "integrated circuit means" are construed as "any complex set of electronic components and their interconnections that are etched or imprinted on a chip and are capable of performing the functions stated in the claims, including storing an identification code, detecting an interrogation signal, outputting the identification code upon reception of an interrogation signal by said coil means, and generating a transmission frequency signal by dividing the frequency of the interrogation signal." n4 This conclusion is supported by the specification, which describes the integrated circuit and its circuitry in great detail. '129 patent, cols. 9-12. The specification also contains a specific disclaimer:

What a preferred embodiment of the invention has been described, numerous modifications and improvements can be made thereto without departure from the essential spirit and scope. The above disclosure of the invention should be considered exemplary only and not as a limitation on the invention, which is limited only by the following claims.

Id. at col. 13:1-7. While the specification describes a preferred embodiment of the invention, the claims are not limited to only the preferred embodiment, and the specification as well as the claim language indicate that any integrated circuit that can perform the stated required functions is within the scope of the invention. See Phillips v. AWH Corp., 415 F.3d 1303, 1323 (Fed. Cir. 2005)("Although the specification often describes very specific embodiments of the invention, we have repeatedly warned against confining the claims to those embodiments.").

n4 The functions of the integrated circuit are summarized here, but for purposes of this invention, the integrated circuit must be capable of performing all of the functions specifically stated in the claims.

--- Footnotes ---

[is] formed as part of an integrated circuit formed on said semiconductor substrate

Claim 12 contains the term "[is] formed as part of an integrated circuit formed on said semiconductor substrate." Lonestar contends that "[is] formed as part of an integrated circuit formed on said semiconductor substrate" means "the capacitor structure is one of a combination of interconnected circuit elements etched, deposited or created on the semiconductor substrate, and formed as part of an integrated circuit fabrication process." Nintendo contends that no construction is necessary. The dispute is whether construction is necessary for the jury to understand the term, and if so, whether that construction should include Lonestar's additional limitations.

The Court construes "integrated circuit" as "a combination of multiple circuit elements." Lonestar cites to a dictionary to define "integrated circuit" as "A combination of interconnected circuit elements inseparably associated on or within a continuous substrate." THE AUTHORITATIVE DICTIONARY OF IEEE STANDARDS TERMS 570 (7th ed. 2000). Nintendo on the other hand does not offer any intrinsic or extrinsic evidence on the meaning of "integrated circuit" or why the term does not require construction. Instead, the only support Nintendo's briefs offer on "integrated circuit" is a general assertion that no construction is necessary for "[is] formed as part of an integrated circuit formed on said semiconductor substrate" while not providing any support for why "integrated circuit" does not require construction. In fact, Nintendo did not make a single statement specific to "integrated circuit" in its briefs. Even when the Court prompted a discussion about the meaning of "integrated circuit" at the Markman Hearing, Nintendo still did not provide any intrinsic or extrinsic evidence to support its position on "integrated circuit." As a result, the Court has only the extrinsic evidence provided by Lonestar for guidance on construing "integrated circuit" and observes that the Court's construction is consistent with Lonestar's dictionary definition. A jury would not require further detail to understand the meaning of "integrated circuit," and the Court accordingly does not further complicate its construction.

As for the remaining portion of the claim term in question, additional construction is not needed. The Court has construed
"semiconductor substrate" as "a semiconducting base material having resistivity between a metal and an insulator." Additionally, a jury would understand "on a semiconductor substrate" to mean that elements are located on the semiconductor substrate. No further construction is necessary.

Lonestar's construction works more to complicate rather than clarify the claim term. Lonestar proposes "the capacitor structure is one of a combination of interconnected circuit elements etched, deposited or created on the semiconductor substrate, and formed as part of an integrated circuit fabrication process." Lonestar's use of "interconnected" rather than "integrated" does not substantially clarify the language. Also, Lonestar includes details of the circuit fabrication process that unnecessarily complicates the claim term, using words particular to the circuit fabrication industry like "etched." Thus, Lonestar's proposed construction would not advance the purpose of clarifying claim terms to a jury.

Furthermore, there is no support in the claim language for adding limitations regarding the circuit fabrication process. Claim 12 simply states "[is] formed as part of an integrated circuit." No further limitation is indicated. Lonestar's proposed circuit fabrication process limitations arise from the specification. See Col. 5:29-57 (applying "deposited" and "etching" language). However, "[a]lthough the specification may aid the court in interpreting the meaning of disputed claim language, particular embodiments and examples appearing in the specification will not generally be read into the claims." Comark Commc'ns, Inc., 156 F.3d at 1187. Lonestar derives its proposed limitations from the Detailed Description of Specific Embodiments. See Col. 5:29-57. Thus, the Court declines to read in Lonestar's proposed limitations regarding the circuit fabrication process. Accordingly, the Court construes "integrated circuit" as "a combination of multiple circuit elements."

a. Preamble: "An integrated circuit for processing compressed video signal, segments of which having been encoded using different encoding processes, to provide decompressed video signal representing moving images, said integrated circuit comprising:"

Both parties agree that the preamble term "integrated circuit" means that the elements of claim 10 must be contained on a single chip. The court agrees. The ordinary meaning of "integrated circuit" is a device having a number of connected circuit elements fabricated on a single chip of semiconductor material. See Microsoft Computer Dictionary 238 (4th ed. 1999). This meaning is confirmed by the patent specification. See Col. 4:62-63 (video processing circuitry 210 is implemented as a single integrated circuit); Fig. 2 (dotted line around circuitry 210). Thus, claim 10 recites a single chip for processing a compressed video signal.

I. "Control integrated circuit"

This term appears in several claims in the '734 and '440 patents. Defendants assert that it should be defined as "a microelectronics device with at least 1 transistor." Sightsound does not contest that this is an accurate description of a control integrated circuit, but notes that this is an incomplete definition, as it potentially includes devices, such as an Operational Amplifier (Docket # 74, Exhibit B, Tab 3 at 340), which would fit this definition but would make the claimed invention inoperable. Defendants respond that the "control integrated circuits" of the claimed inventions "perform too many functions to be defined with any more specificity." The court, however, sees no need to define them any more specifically than the plain language of the patents suggest: a microelectronics device which is capable of performing the functions identified in the patents.

A. Integrated Circuit Device

The district court construed "integrated circuit device" in claim 26 of the '804 patent to include a device identification
register, interface circuitry, and comparison circuitry.

Claim 26 recites:

26. An integrated circuit device having at least one memory section which includes a plurality of memory cells, wherein the integrated circuit device outputs data on an external bus synchronously with respect to first and second external clock signals, the integrated circuit device comprises:

a first internal register to store a value which is representative of a number of clock cycles to transpire before the integrated circuit device responds to a read request;

delay locked loop circuitry to generate an internal clock signal using the first and second external clock signals; and

interface circuitry, coupled to the external bus to receive a read request, the interface circuitry includes a plurality of output drivers, coupled to the external bus, to output data on the external bus in response to the internal clock signal, synchronously with respect to the first and second external clock signals and in accordance with the value stored in the first internal register.

'804 patent, col. 28, ll. 1-21. Nothing in the claim language indicates that "integrated circuit device" necessarily includes a device identification register, interface circuitry, and comparison circuitry. The terms "comparison circuitry" and "device identification register" do not appear anywhere in the text of claim 26. n4 "Comparison circuitry" is different from the "delay locked loop circuitry" limitation recited in claim 26. Likewise, a "device identification register" is different from the limitation "first internal register to store a value which is representative of a number of clock cycles." Thus, the claim does not require comparison circuitry or a device identification register. The district court's construction did not merely clarify or construe the actual words of the claim. Without any claim language addressing comparison circuitry or a device identification register, the court's construction reads into the claim two new limitations not required by the claim language. See N. Telecom, 215 F.3d at 1290.

n4 Claim 26 does recite an "interface circuitry" limitation. While it is proper to construe claim 26 as requiring interface circuitry, it technically is not proper to read the "interface circuitry" limitation into the meaning of the term "integrated circuit device" itself. The generic term "integrated circuit device" has a broad and accepted meaning within the art that does not depend on the limitations of claim 26. Therefore, in construing the meaning of this broad generic term, this court does not include limitations from specific patent claims.

The district court erred by placing too much emphasis on a single introductory comment in the prosecution history of the '804 patent. This comment appeared in the prosecution history after the examiner rejected the pending claims in light of U.S. Patent No. 4,458,357. Responding to the rejection, the patentee submitted twenty-six new claims, four of which were independent claims. In accompanying remarks, the patentee stated:

These newly submitted claims are directed to a memory device (or an integrated circuit having memory) having (1) an internal register for storing an identification value, (2) interface circuitry to receive a request on an external bus, and (3) comparison circuitry to determine whether the identification information in the request corresponds to the identification value in the internal register - wherein when the identification information corresponds to the identification value, the memory device responds to the request.

While the first three independent claims (issued claims 1, 15, and 23) recited, with some modifications, the three limitations listed above, the fourth independent claim (issued claim 26) recited only one of the above listed limitations. Specifically, claim 26, the claim at issue here, includes only the "interface circuitry" limitation. Claim 26, however, contains two other limitations not listed above: an internal register to store a value representative of a number of clock cycles and delay locked loop circuitry.
The prosecution history statement introduces in general terms the new claims. In this sense, the statement properly introduces three features that appear in some of the claims. This general introductory statement, however, is not correct in suggesting that these features appear in each of the new claims. This incorrect statement in the prosecution history does not govern the meaning of the claims. Therefore, consistent with Intervet America, Inc. v. Kee-Vet Laboratories, Inc., 887 F.2d 1050, 12 USPQ2d 1474 (Fed. Cir. 1989), the imprecise statement in the prosecution history does not limit claim 26. The claim language itself controls the bounds of the claim, not a facially inaccurate remark during prosecution.

The patent at issue in Intervet involved a vaccine for a poultry disease. Id. at 1051. In that case the examiner rejected the pending claims because they were not limited to a single vaccination. The examiner said that a single vaccination limitation would distinguish the invention over the prior art. Id. at 1053-54. The prosecuting attorney amended three of the claims to recite "single administration," but did not so amend the remaining claims. Id. at 1054. In accompanying remarks, the attorney inaccurately described all the claims as "restricted to a single vaccination scheme." Id. After this erroneous remark, the examiner had two interviews with the attorney and made two examiner's amendments before allowing the claims. Id. Reviewing this prosecution history, this court in Intervet held that the claims control over a loose remark in the course of prosecution:

When it comes to the question of which should control, an erroneous remark by an attorney in the course of prosecution of an application or the claims of the patent as finally worded and issued by the [PTO] as an official grant, we think the law allows for no choice. The claims themselves control. . . . It is not for the courts to say that they contain limitations which are not in them.

Id. The Intervet court thus did not restrict all of the claims to a single vaccination. Id.; see also Hockerson-Halberstadt v. Avia Group Int'l, 222 F.3d 951, 957, 55 USPQ2d 1487, 1491 (Fed. Cir. 2000).

The present case parallels Intervet. Here, claim 26 does not contain all the limitations found in claims 1, 15, and 23 of the '804 patent. The prosecuting attorney's incorrect description of the four new claims does not govern over the language of those claims. Moreover, in this case, the examiner made an examiner's amendment and amended each of the claims -- including claim 26 -- after this untrue remark by the prosecuting attorney. In this context, a reasonable competitor would not rely on an untrue statement in the prosecution history over the express terms of the claims. In the present case, like Intervet, this court perceives no justification for reading unstated limitations into claim 26.

The term "integrated circuit device," as used in claim 26, instead receives its ordinary meaning to one of skill in this art as a "circuit constructed on a single monolithic substrate, commonly called a 'chip.'" Rambus, Inc. v. Infineon Techs. AG, 2001 U.S. Dist. LEXIS 10990, No. 3:00cv524, slip op. at 70 (E.D. Va. March 15, 2001) (Rambus argues for this construction.); cf. The New IEEE Standard Dictionary of Electrical and Electronic Terms 662 (5th ed. 1993); IBM Dictionary of Computing 347 (10th ed. 1994); see also Texas Digital Sys., Inc. v. Telegenix, Inc., 308 F.3d 1193, 1202, 64 USPQ2d 1812, 1818 (Fed. Cir. 2002).

Lastly, the parties contest the meaning of "integrated circuit device" as that term is found in claim 26 of the '804 patent. Rambus contends that the term means a "circuit constructed on a single monolithic substrate, commonly called a 'chip.'" Infineon, however, argues that representations made in the prosecution of the '804 patent limit this term to "a device composed of integrated circuits that include at least an ID register and related interface and comparison circuitry." 40

40 The parties have agreed that "integrated circuit device" is only disputed as it occurs in claim 26 of the '804 patent and not as it appears in the other patents. This is because the relevant file history limits the representations made to the PTO to only the '804 patent.
1. The Claim Language And The Specification

Neither the claim language nor the specification inform the present inquiry. Indeed, the specification mentions an integrated circuit only once.

2. The File History

The file history of this claim is the only relevant category of intrinsic evidence. During the prosecution of Claim 26 in the '804 patent, (which was at that time, U.S. Patent App. 08/798,525 or the '525 application) Rambus expressly limited its claims by adding certain restrictions in order to overcome the PTO's prior art rejections. In response to the rejections, Rambus submitted new claims -- including the claim that ultimately issued as claim 26 of the '804 patent. Rambus argued to the PTO that the newly submitted claims were different from prior art because they all contained a device ID register and relevant interface and comparison circuitry limitations:

The new claims submitted in this Supplemental Preliminary Amendment have been added to more definitely and fully protect Applicants' invention. These newly submitted claims are directed to a memory device (or an integrated circuit having memory) having (1) an internal register for storing an identification value, (2) interface circuitry to receive a request on an external bus, and (3) comparison circuitry to determine whether the identification information in the request corresponds to the identification value in the internal register - wherein when the identification information corresponds to the identification value, the memory device responds to the request.

Supplemental Preliminary Amendment, U.S. Patent App. 08/798,525, pp. 11-12. The '804 patent issued subsequently. Thus, it appears that Rambus believed that its claims did not cover devices without a device ID register and relevant interface and comparison circuitry. To allow Rambus to broaden its claim in the face of this restriction would defeat the public notice function of the patent history. In Hockerson-Halberstadt, Inc. v. Avia Group Intn'l, Inc., 222 F.3d 951 (Fed. Cir. 2000), the Federal Circuit explained:

[The inventor's] argument therefore reduces to a request for a mulligan that would erase from the prosecution history the inventor's disavowal of a particular aspect of a claim term's meaning. Such an argument is inimical to the public notice function provided by the prosecution history. The prosecution history constitutes a public record of the patentee's representations concerning the scope and meaning of the claims, and competitors are entitled to rely on those representations when ascertaining the degree of lawful conduct, such as designing around the claimed invention. . . . Were we to accept [the inventor's] position, we would undercut the public's reliance on a statement that was in the public record and upon which reasonable competitors formed their business strategies.

Id. at 957 (internal citations omitted).

"Absent qualifying language in the remarks, arguments made to obtain the allowance of one claim are relevant to interpreting other claims in the same patent." Digital Biometrics, 149 F.3d at 1347. Rambus claims to have presented such "qualifying language" in a footnote of the above-quoted representation to the PTO, which mentions two of the inventive technologies claimed in this suit:

The memory devices or integrated circuits having memory of the present invention may include additional and/or other inventive aspects, including, for example, delay lock loop circuitry and/or an internal register to store a value which is representative of a number of clock cycles to transpire before the memory device responds to a read request. This "latency" register may be employed to control the timing of the output data after receipt of, for example, a read request. However it is noted that, in light of the July 27, 1998 Office Action and the rejection based on Weymouth, these additional and/or other inventive aspects, although forming a basis of patentability in their own right, will not be the focus of these Remarks.
